Jaina temple at Lakkundi (*c.* 1050–1100) clearly demonstrate the transition. The superstructures, though basically of the South Indian type, have offsets and recesses that tend to emphasize a vertical, upward movement. The Lakkundi temple is also the first to be built of chloritic schist, which is the favoured material of the later period and which lends itself easily to elaborate sculptural ornamentation. With the Mahādevā temple at Ittagi (*c.* 1112) the transition is complete, the extremely rich and profuse decoration characteristic of this shrine being found in all work that follows. Dating from the reign of the Hoysaḷa dynasty (*c.* 1141) is a twin Hoysaḷeśvara temple at Halebīd, the capital city. The sanctums are stellate in form but lack their original superstructures. The pillars of the interior are lathe-turned in a variety of fanciful shapes. The exterior is almost totally covered with sculpture, the walls carrying the usual complement of images; the base, or socle, is decorated with several bands of ornamental motifs and a narrative relief. Among other temples that were constructed in this style, the most important are the Chenna Keśava temple at Belūr (1117), the Amṛteśvara temple at Amritpur (1196), and the Keśava temple at Somnāthpur (1268).

Strong traditions of cave architecture in Mahārāshtra

Medieval temple architecture: South Indian style of Mahārāshtra, Andhradeśa, and Kerala. The traditions of cave architecture are stronger in Mahārāshtra than in any other part of India; there, great shrines were cut out of rock right up to the 9th century AD and even later. Of those belonging to the early phase, the most remarkable is a temple at Elephanta (early 6th century); equally impressive are numerous temples at Ellora (6th–9th centuries). The Karnatic version of the South Indian style extended northward into Mahārāshtra, where the Kailāsa temple at Ellora, erected in the reign of the Rāṣṭrakūṭā Krishna I (8th century), is its most stupendous achievement. The entire temple is carved out of rock and is over 100 feet (30 metres) high. It is placed in a courtyard, the three sides of which are carved with cells filled with images; the front wall has an entrance *gopura.* The tall base, or plinth, is decorated with groups of large elephants and griffins, and the superstructure rises in four stories. Groups of important temples in the southern style are also found in the Andhra country, notably at Biccavolu, ranging in date from the 9th to the 11th centuries. The 13th-century temples at Palampet are the counterparts of the elaborate Karnatic style of the same period, but without its overpowering elaboration. The temples of Kerala represent an adaptation of the South Indian style to the great main fall of this region and are provided with heavy sloping roofs of stone that imitate timber originals required for draining away the water.

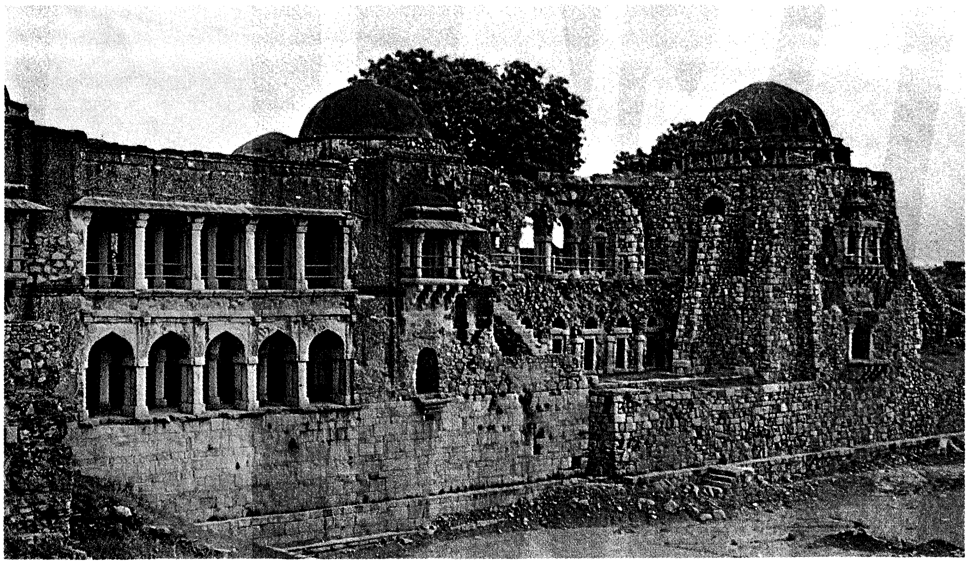
Islāmic architecture in India: period of the Delhi and provincial sultanates. Although the province of Sind was captured by the Arabs as early as 712, the earliest examples of Islāmic architecture to survive in the subcontinent date from the closing years of the 12th century; they are located at Delhi, the main seat of Muslim power throughout the centuries. The Qūwat-ul-Islām mosque (completed 1196), consisting of cloisters around a courtyard with the sanctuary to the west, was built from the remains of demolished temples. In 1198 an arched facade (*maqṣūrah*) was built in front to give the building an Islāmic aspect, but its rich floral decoration and corbelled (supported by brackets projecting from the wall) arches are Indian in character. The Quṭb Mīnār, a tall (288 feet high), fluted tower provided with balconies, stood outside this mosque. The Aṛhāi-dīn-

P. Chandra



Tomb and palace of Fīrūz Shāh (Hawz-e Khāss) at Delhi, *c.* 1380.

kā-jhomprā mosque (*c.* 1119), built at Ajmer, was similar to the Delhi mosque, the *maqṣūrah* consisting of engrailed (sides ornamented with several arcs) corbel arches decorated with greater restraint than the Quṭb example. The earliest Islāmic tomb to survive is the Sultān Gharī, built in 1231, but the finest is the tomb of Iltutmish, who ruled from 1211 to 1236. The interior, covered with Arabic inscriptions, in its richness displays a strong Indian quality. The first use of the true arch in India is found in the ruined tomb of Balban (died 1287). From 1296 to 1316 ʿAlāʾ-ud-Dīn Khaljī attempted to expand the Qūwat-ul-Islām mosque, which already had been enlarged in 1230, to three times its size; but he was unable to complete the work. All that has survived of it is the Alai Darwāzah, a beautiful entrance.

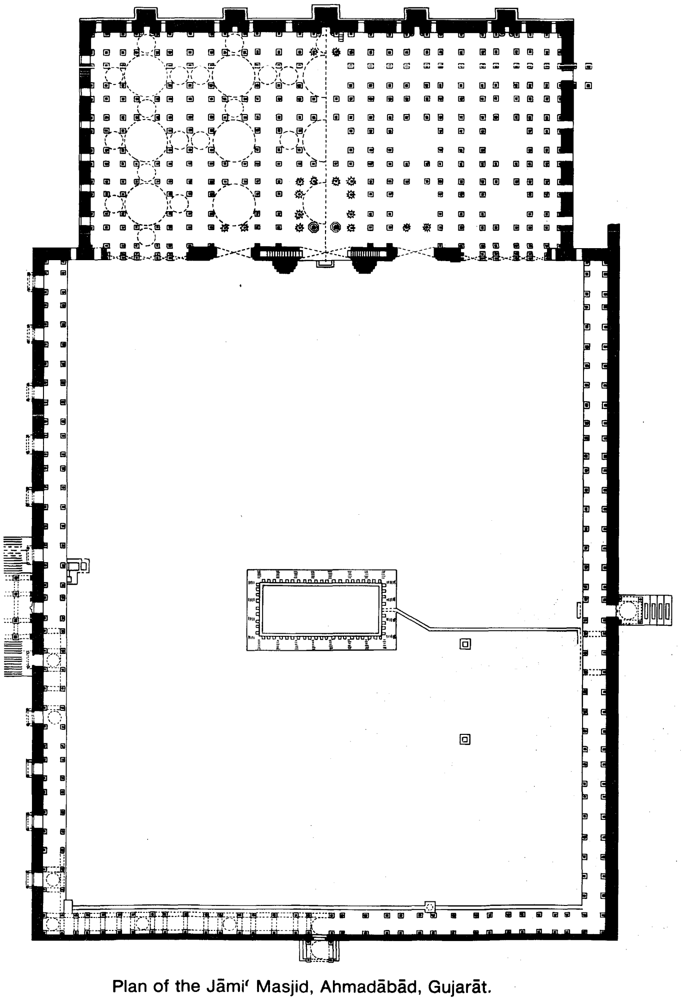
In contrast to this early phase, the style of the 14th century at Delhi, ushered in by the Tughluq dynasty, is impoverished and austere. The buildings, with a few exceptions, are made of coarse rubble masonry and overlaid with plaster. The tomb of Ghiyās-ud-Dīn Tughluq (*c.* 1320–25), placed in a little fortress, has sloping walls faced with panels of stone and marble. Also to be ascribed to his reign is the magnificent tomb of Shāh Rukn-e ʿĀlam at Multān in Pakistan, which is built of brick and faced with exquisite tile work. The Koṭla Fīrūz Shāh (1354–70), with its mosques, palaces, and tombs, is now in ruins but represents the major building activity of Fīrūz Shāh, who took a great interest in architecture. Many mosques and tombs of this period and of the 15th century are found in Delhi and its environs; the most notable of them are the Begampur and Khiṛkī mosques and an octagonal tomb of Khān-e Jahān Tilangānī. In the early 16th century, Shēr Shāh Sūr refined upon this style, the Qalʿah-e Kuhnah Masjid and his tomb at Sasarām (*c.* 1540) being the finest of a series of distinguished works that were created during his reign.



Plan of the Jāmiʿ Masjid, Ahmadābād, Gujarāt.

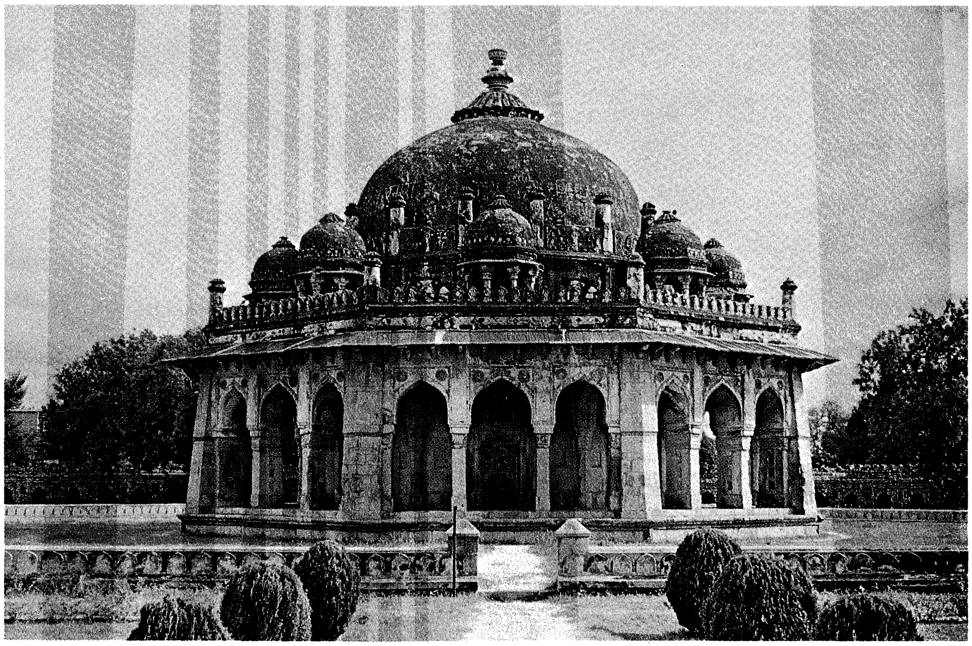
The provinces, which gradually became independent sultanates, did not lag behind in architectural activity. In West Bengal, at Pandua, is the immense Ādīna Masjid (1364–69), which utilized remains of Indian temples. In Jaunpur, Uttar Pradesh, are a group of elegant mosques, notably the Aṭalā Masjid (1377–1408) and the Jāmiʿ Masjid (*c.* 1458–79), characterized by *maqṣūrah*s that have the aspect of imposing gateways. The sultans of Mālwa built elegant structures at Māndu and at Chanderi in the middle of the 15th century. The sultanate of Gujarāt is notable for its great contribution to Islāmic architecture in India. The style, which is basically indigenous, reinterprets foreign influences with great resourcefulness and confidence, producing works notable for their integrity and unity. The city of Ahmadābād (Ahmedabad) is full of elegant buildings; the Jāmiʿ Masjid (*c.* 1424), for example, is a masterly exposition of the style. Fine examples dating from the second half of the 15th century are the small but exquisite mosques of Muḥāfiz Khān (1492) and Rānī Sabraʾi (1514) at Ahmadābād and the handsome Jāmiʿ Masjid at the city of Chāmpāner.

The Deccan was another great centre, but in contrast to Gujarāt it took little from the indigenous building traditions. Among the earliest works is the Jāmiʿ Masjid at Gulbarga (1367), with its extraordinary cloisters consisting of wide arches on low piers, producing a most solemn effect. The city of Bīdar possesses many remains, including a remarkable series of 12 tombs, the most elaborate of which is that of ʿAlā-ud-Dīn Aḥmad Bahmanī (died 1457), which has extremely fine decorations in coloured tile. Some of the finest examples of Islāmic architecture in the Deccan, however, are in Bijāpur. The most important buildings of this city are the great Jāmiʿ Masjid (begun in 1558) with its superb arched cloisters; the ornate Ibrāhīm Rawẓa; and the Gōl Gunbad (built by Muḥammad ʿĀdil Shāh), a tomb of exceptional size and grandeur, with one of the largest domes in existence.

The Hindu kingdoms that managed to retain varying degrees of independence during the period of Islāmic supremacy also produced important works. These structures naturally bore the imprint of what survived of traditional Indian architecture to a greater extent than did those monuments patronized by Muslims. Among the Hindu structures of this period are the extensive series of palaces, all in ruin, built by Rāṇā Kumbhā (*c.* 1430–69) at Chitor, and the superb Mān Mandir palace at Gwalior (1486–1516), a rich and magnificent work that exerted considerable influence on the development of Mughal architecture at Fatehpur Sīkrī.

Striking revival of Islāmic architecture

Islāmic architecture in India: Mughal style. The advent of the Mughal dynasty marks a striking revival of Islāmic architecture in northern India: Persian, Indian, and the various provincial styles were successfully fused to produce works of unusual refinement and quality. The tomb of Humāyūn, begun in 1564, inaugurates the new style. Built entirely of red sandstone and marble, it shows considerable Persian influence. The great fort at Āgra (1565–74) and the city of Fatehpur Sīkri (1569–74) represent the building activities of the emperor Akbar. The former has the massive so-called Delhi gate (1566) and lengthy and immense walls carefully designed and faced with dressed stone throughout. The most important achievements, however, are to be found at Fatehpur Sīkri; the Jāmiʿ Masjid (1571), with the colossal gateway known as the Buland Darwāza, for example, is one of the finest mosques of the Mughal period. Other notable buildings include the palace of Jodhā Bāī, which has a strongly indigenous aspect; the exquisitely carved Turkish Sultānā's house; the Pānch-Maḥal; the Dīvān-e ʿĀmm; and the so-called hall of private audience. Most of the buildings are of post and lintel construction, arches being used very sparingly. The tomb of the emperor, at Sikandarā, near Āgra, is of unique design, in the shape of a truncated square pyramid 340 feet (103 metres) on each side. It consists of five terraces, four of red sandstone and the uppermost of white marble. Begun about 1602, it was completed in 1613, during the reign of Akbar's son Jahāngīr. Architectural undertakings in this emperor's reign were not very ambitious, but there are fine buildings,

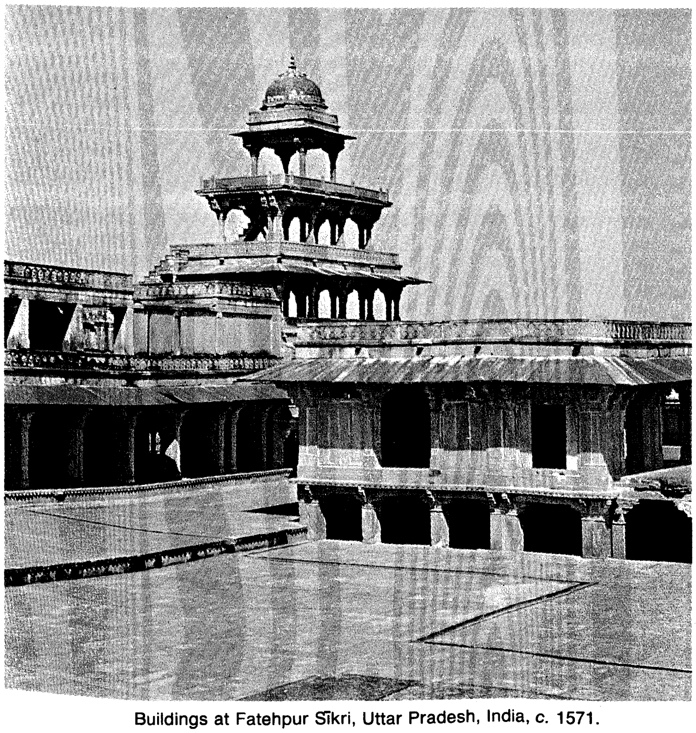


Tomb of 'Isā Khān at Delhi, 1547.

P. Chandra

chiefly at Lahore. The tomb of his father-in-law I'timād-ud-Dawla, at Āgra, is small but of exquisite workmanship, built entirely of delicately inlaid marble. The reign of Shāh Jahān (1628–58) is as remarkable for its architectural achievements as was that of Akbar. He built the great Red Fort at Delhi (1639–48), with its dazzling hall of public audience, the flat roof of which rests on rows of columns and pointed, or cusped, arches, and the Jāmi' Masjid (1650–56), which is among the finest mosques in India. But it is the Tāj Mahal (*c.* 1632–*c.* 1649), built as a tomb for Queen Mumtāz Maḥal, that is the greatest masterpiece of his reign. All the resources of the empire were put into its construction. In addition to the mausoleum proper, the complex included a wide variety of accessory buildings of great beauty. The marble mausoleum rises up from a tall terrace (at the four corners of which are elegant towers, or minārs) and is crowned by a graceful dome.

P. Chandra



Buildings at Fatehpur Sīkri, Uttar Pradesh, India, c. 1571.

Other notable buildings of the reign of Shāh Jahān include the Motī Masjid (*c.* 1648–55) and the Jāmi' Masjid at Āgra (1548–55).

Architectural monuments of the reign Aurangzel

Architectural monuments of the reign of Aurangzeb represent a distinct decline; the tomb of Rābī'ah Begam at Aurangābād, for example (1679), is a poor copy of the Tāj Mahal. The royal mosque at Lahore (1673–74) is of much better quality, retaining the grandeur and dignity of earlier work; and the Motī Masjid at Delhi (1659–60) possesses much of the early refinement and delicacy. The tomb of Ṣafdar Jang at Delhi (*c.* 1754) was among the last important works to be produced under the Mughal dynasty and had already lost the coherence and balance characteristic of mature Mughal architecture.

European traditions and the modern period. Buildings imitating contemporary styles of European architecture, often mixed with a strong provincial flavour, were known in India from at least the 16th century. Some of this work was of considerable merit, particularly the baroque architecture of the Portuguese colony of Goa, where splendid buildings were erected in the second half of the 16th century. Among the most famous of these structures to survive is the church of Bom Jesus, which was begun in 1594 and completed in 1605.

The 18th and 19th centuries witnessed the erection of several buildings deeply indebted to Neoclassic styles; these buildings were imitated by Indian patrons, particularly in areas under European rule or influence. Subsequently, attempts were made by the British, with varying degrees of success, to engraft the neo-Gothic and also the neo-Saracenic styles onto Indian architectural tradition. At the same time, buildings in the great Indian metropolises came under increasing European influence; the resulting hybrid styles gradually found their way into cities in the interior. In recent years an attempt has been made to grapple with the problems of climate and function, particularly in connection with urban development. The influence of the Swiss architect Le Corbusier, who worked on the great Chandīgarh project, involving the construction of a new capital for Punjab, in the early 1950s, and that of other American and European masters has brought about a modern architectural movement of great vitality, which is in the process of adapting itself to local requirements and traditions.

Sculpture. On the Indian subcontinent, sculpture seems to have been the favoured medium of artistic expression. Even architecture and the little painting that has survived from the early periods partake of the nature of sculpture. Particularly is this true of rock-cut architecture, which is

Church of Bom Jesus at Velha Goa, India, 1594–1605.
P. Chandra

often little more than sculpture on a colossal scale. Structural buildings are also profusely adorned with sculpture that is often inseparable from it. The close relationship between architecture and sculpture has to be taken into account when considering individual works that, even if complete in themselves, are also fragments belonging to a larger context. Indian sculpture, particularly from the 10th century onward, thus cannot be studied in isolation but must be considered as part of a larger entity to the total effect of which it contributes and from which it in turn gains meaning.

The subject matter of Indian sculpture is almost invariably religious. This does not mean that it cannot be understood as a work of art apart from its religious significance; but, at the same time, an understanding of its motivation and intent enriches one's appreciation. Much of what is represented is the recounting of legend and myth, particularly in the two centuries before Christ, when narrative relief was much in vogue. The work at this time, didactic and edificatory in intent, generally expresses itself in forms that are surprisingly earthy and sensuous. The anthropomorphic representation of the Buddha is avoided, and the subsidiary gods and goddesses are very much creatures of this earth. The Buddha image formulated around the 1st century AD is not what one would expect of the meditative, compassionate, Master of the Law; he is presented rather as an energetic, earthy being radiating strength and power.

ɹddhist
fluences

The foundations of traditional Hindu imagery were also laid about the same time that the Buddha image was first formulated: images with several arms, and sometimes heads, representing the Indian mind's attempt to define visually the infiniteness of divinity. In subsequent periods the image with many arms became a commonplace in Hindu, Buddhist, and Jaina iconography. Although the various pantheons expanded, they continued to share features of common derivation, expressing the belief that beyond the phenomenal multiplicity of forms lay the unity of the Godhead.

In addition to the major religions, there has always existed in India a substratum of folk beliefs and cults dedicated to the worship of powers that preside over the operation of the life processes of nature. These fertility cults, best expressed in the worship of the male and female divinities *yakṣas* and *yakṣīs*, played an important part in the development of Indian art. Among the perennial motifs that spring from the cults, those expressing life and

abundance—such as the lotus, the pot overflowing with vegetation, water, or the like, the tree, the amorous couple, and above all the *yakṣa*s and *yakṣī*s themselves—are most significant. The images of these divinities, in particular, are the source of a great deal of artistic imagery and played a leading part in the development of iconographic types such as the images of the Buddha, the goddess Śrī, and other divinities. The maternal as the ideal of female beauty, which is manifested artistically in the emphasis on full breasts and wide hips, can be traced to the same beliefs. The very richness and exuberance of much Indian art is an expression of the view of life that equates beauty with abundance.

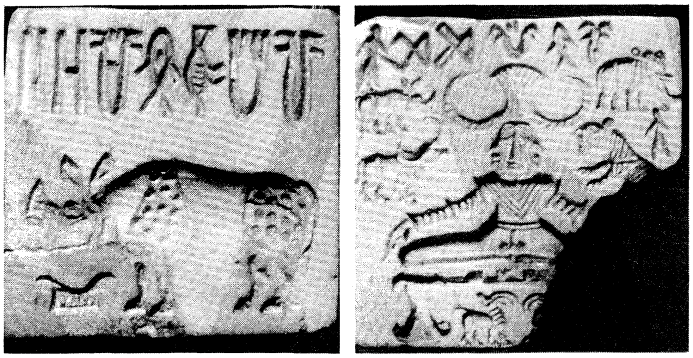
It is difficult to generalize about the style of a sculptural tradition that extended over a period of almost 5,000 years, but it is nevertheless clear that the distinguishing quality of Indian sculpture is its emphatic plasticity so obvious in Sānchi I and Mathurā sculpture from the 1st–3rd century AD. Forms are seen as swelling from within in response to the power of an inner life, the sculptor's function being to make these more manifest. At the same time a vision of form that is carved from without rather than modelled from within is also present, as for example at Bhārhut. The history of much of Indian sculpture, marked by periods of high achievement bursting with creativity followed by periods in which the potentialities so postulated are gradually worked out, is essentially the interaction of these two dominant tendencies.

Indus Valley civilization (c. 2500–1800 BC). Sculpture found in excavated cities consists of small pieces, generally terra-cotta objects, soapstone, or steatite, seals carved for the most part with animals, and a few statuettes of stone and bronze. The terra-cotta figurines are summarily modelled and provided with elaborate jewelry, which was fashioned separately and applied to the surface of the piece. Most of the work is simple, but a small group of human heads with horns are very sensitively modelled. Animal figures are common, particularly bulls, which are often carved with a sure understanding of their bulky, massive form. This plastic quality is also found in the humped bulls engraved on steatite seals, where the modelling is more refined and sensitive. A humpless beast, generally called a "unicorn," is another favourite animal, but it is frequently quite stylized. In addition to bisons, elephants, rhinoceroses, and tigers, seals are carved with images of apparent religious significance, often strongly pictographic.

Terra-cotta sculpture and seals

The terra-cotta sculpture and the seals both show two clear and distinct stylistic trends, one plastic and sensuous, the other linear and abstract. These appear during the same period and are also seen in the small group of stone and bronze sculptures that date from this period (National Museum, New Delhi). Of extraordinarily full and refined modelling is a fragmentary torso from Harappā, barely four inches (10 centimetres) high but of imposing monumentality; the same feeling for massive form is present in a lesser known bronze buffalo. A jaunty bronze dancing girl with head tilted upward (about 4½ inches [11 centimetres] high), from Mohenjo-daro, and a headless figure of a male dancer from Harappā, shoulders twisted in a circular movement, clearly demonstrate, in the attenuated and wiry tension of their forms, the second component of Indus Valley art. Of great interest is a famous bearded figure from Mohenjo-daro wearing a robe decorated with a pattern composed of trefoil motifs. The tight, compressed shape of the body and the expansive modelling of the head demonstrate that the two aspects of form revealed in Indus Valley art were not compartmentalized but interacted with each other. This can also be seen in the interplay of modelled form and textured surface frequently found in works produced by this civilization.

P. Chandra



Steatite seals of the Indus Valley civilization (*c.* 2300–*c.* 1750 BC). In the National Museum of India, New Delhi.

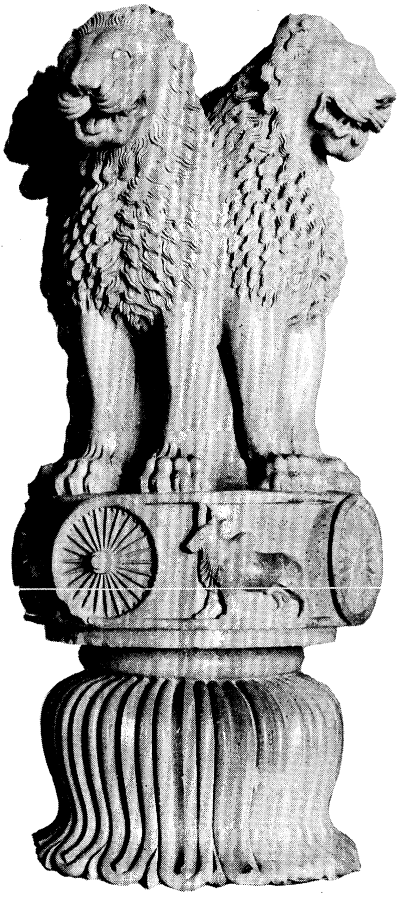
Maurya period (c. 3rd century BC). Little is known of Indian art in the period between the Indus Valley civilization and the reign of the Maurya emperor Aśoka. When sculpture again began to be found, it was remarkable for its maturity, seemingly fully formed at birth. The most famous examples are great circular stone pillars, products of Aśoka's imperial workshop, found over an area stretching from the neighbourhood of Delhi to Bihār. Made of fine-grained sandstone quarried at Chunār near Vārānasi (Benares), the monolithic shafts taper gently toward the top. They are without a base and, in the better preserved examples, are capped by campaniform lotus capitals supporting an animal emblem. The entire pillar was carefully burnished to a bright lustre commonly called the "Maurya polish." The most famous of these monuments is the lion capital at Sārnāth, consisting of the front half of four identical animals joined back to back. There is a naturalistic emphasis on build and musculature, and the modelling is hard, vigorous, and energetic, stressing physical strength and power. Very similar, if not at the same level of achievement, is the quadruple lion capital at Sānchi. Single lions are found at Vaiśālī (Bakhra), Rāmpurvā, and Lauriya Nandangarh. The Vaiśālī pillar is heavy and squat, and the animal lacks the verve of the other animals—features, according to some, designating it as an early work, executed before the Maurya style attained its maturity. By contrast, the Rāmpurvā lion, finished with painstaking and concise artistry, represents the style at its best. His smooth, muscled contours, wiry sinews, rippling, flamboyant mane, and alert stance reveal the work of a superior artist. An example at Lauriya Nandangarh is interesting because the pillar and the lion are both complete and in their original place, giving a clear idea of the column as it appeared to its contemporaries.

The Rāmpurv lion

The lion was the animal most often represented, but figures of elephants and bulls are also known. At Dhauli in Orissa, the fore part of an elephant is carved out of rock on a terrace above a boulder that carries several of Aśoka's edicts. The modelling here is soft and gentle, and the plump, fleshy qualities of the young animal's body, seen as emerging from the rock, are suffused with warmth and natural vitality. Since the contrast with the rather formal, heraldic lions could not be more complete, the sculpture clearly testifies to the simultaneous existence of a style different from that of the lion capitals. The style might very well represent the indigenous tradition of plastic form that appears consistently in later art and also in some of the animal capitals made in the imperial atelier, notably the damaged elephant that once crowned the pillar at Saṅkīsa and, above all, the splendid bull from Rāmpurvā. In this great work of art, the two opposing concepts of form merge in a work of harmonious power. The pronounced naturalism comes from the same source as do the lions, but the tense line and hard modelling yield to a form that wells from within and at the same time is given stability and strength by a vision imposed from without.

The sudden appearance of Maurya art with seemingly no tradition behind it has led to speculation that it was the creation of foreign artists, either Achaemenian or Hellenistic. Persian influence, particularly in the lotus capitals and the figures of lions can hardly be denied, but what is remarkable is the drastic reinterpretation of alien forms by Indian artists. This is a process that is repeatedly seen in the history of Indian art.

Besides the animal sculpture, some human figures, more or less life size, can also be assigned to the Maurya period, though scholarly opinion is by no means unanimous on the point. Among the most important are three images discovered at Patna (ancient Pāṭaliputra, the Maurya



Lion capital from Sārnāth, Uttar Pradesh, India, Chunār sandstone, mid-3rd century BC. Height 2.13 m.

P. Chandra

capital), two of which are representations of *yakṣa*s, the popular male divinities associated with cults of fertility, and the third, found at Dīdarganj (a section of Patna), a representation of a *yakṣī,* or female divinity. Stylistically the images are very similar. The standing *yakṣa*s (Indian Museum, Calcutta) are powerful creatures; the ponderous weight of their bodies, together with a certain refined appreciation of the soft flesh, is admirably rendered. The Dīdarganj *yakṣī* (Patna Museum), a masterpiece, displays the Indian ideal of female beauty, the heavy hips and full breasts strongly emphasizing the maternal aspect. In a nude torso discovered at Lopanipur, the sophisticated and sensitive treatment of the surfaces and the gentle blending planes that avoid all harsh accents produce a work of much refinement.

ıall
ıne
ıcs

Small stone discs (also called ring stones because several of them are perforated in the centre), found from Taxila to Patna, are clearly connected with the cult of a nude mother goddess. They represent Maurya sculpture on a smaller and more intimate scale but characterized by the same refined and exquisite workmanship. They are executed in bas-relief, which became the favourite form of sculpture in the subsequent period.

The terra-cotta art of the Maurya period is best represented by a substantial group of figurines, modelled for the most part, the clay sculptor performing work in his medium at the same level as the artist working in stone. Patna has yielded a large number of such works, but examples are found throughout the Gangetic Plain. The clothing and jewelry on the figurines are heavy and elaborate, the modelling, particularly of the head, is sensitive, and the expression is often one of great charm and refinement. There are also more archaic examples, distinguished by flat bodies, enormous hips, and modelled heads and breasts.

Indian sculpture in the 2nd and 1st centuries BC. The Maurya Empire collapsed in the early years of the 2nd century BC, and with it passed the art with which it was intimately related. The sculpture that is found throughout India from the middle of the 2nd century BC is startlingly different, but the process by which this change took place in a relatively short period of time is not fully understood. Several schools, sharing common features but nevertheless possessing distinct individual characteristics, are known to have existed. The history of the schools of northern India is somewhat obscure, largely due to the great destruction wrought in the Gangetic heartland; but there appears to have flourished there and in adjacent areas a school of great importance represented by the remains discovered at Bhārhut, Sānchi, Mathurā, and Buddh Gaya. Western India had its own school, as revealed in the sculptures decorating the cave temples, notably those of Bhājā, Pītalkhorā, and Kārli. In the southeast, the important school of Andhradeśa flourished in the Krishna River Valley at Amāravatī, Jaggayyapeta, and associated sites; and in eastern India, what is now the modern state of Orissa, made its contribution in the rock-cut sculptures at Udayagiri-Khandagiri. The distinctive schools, though spread over a subcontinent, were not isolated from each other. The contacts fostered by a flourishing trade and by the constant movement of pilgrims were always very close, and it was never long before developments in one part of India were echoed in another.

Judging from extant remains, artists of the earlier period (*c.* 3rd century BC) preferred figures carved in the round, relief sculpture being quantitatively quite insignificant. By contrast, it was sculpture in low relief that was favoured in the first two centuries before Christ; the earlier tradition was not quite forgotten, but figures carved in the round are relatively few. Although there is no stylistic difference, relief sculpture is here considered first according to the various regional schools, and sculpture in the round is treated separately.

Indian sculpture in the 2nd and 1st centuries BC: relief sculpture of northern and central India. Among the most important, and perhaps the earliest, remains in northern India are reliefs from the great *stūpa* at Bhārhut, dating approximately to the middle of the 2nd century BC. The work, suggesting a style imitating wooden sculpture, is characterized by essentially cubical forms, flat planes that meet at sharp angles, and very elaborate and precisely detailed ornamentation of surfaces. Most of the sculpture was confined to the railing of the *stūpa.* Some of the supporting posts bear large image of *yakṣa*s and *yakṣī*s of popular religion, now clearly pressed into the service of Buddhism, while most of the others are decorated with medallions in the centre and crescent-shaped motifs, or lunates, at the top and bottom, all filled with

Reliefs from the *stūpa* at Bhārhut

P. Chandra

lotus motifs. Some medallions contain amorous couples, the overflowing pot, the goddess Śrī standing on lotuses while being ceremonially bathed by elephants and other symbols of abundance; still others contain the earliest illustrations of events in the Buddha's life and of narratives of his former incarnations as related in the *Jātaka* tales (a collection of tales about the Buddha). Although compositions are crowded, great economy of expression is evident because the artist confines himself to the representation of essentials. Figures are often carved in horizontal rows, sometimes asymmetrically, adapting themselves awkwardly to the circular space of the medallion. Continuous narrative, in which events succeeding in time are shown in the same space, is often resorted to—the first occurrence of what was to become a favourite narrative technique. There is no attempt at establishing any interrelationship, psychological or compositional, between the various figures, each of which is strictly confined within its own space. The faces are masklike, without trace of emotion, lending a solemn and hieratic quality to their expression. Trapped between the background and a frontal plane beyond which they are not allowed to project, the figures are in a sense strictly two-dimensional, more so than in any other style of Indian sculpture. Often, however—particularly in the treatment of animals—the artist is more relaxed, giving glimpses of intimate observation and a natural rendering that anticipates the direction of future development. Like the posts, the top part, or coping, of the stone rail is also carved on both faces; on one of them is a continuous creeper bearing lotus flowers, leaves, and buds; on the other, again the winding stem of a creeper, but bearing other good things of life—such as clothes, jewelry, and fruits—and also scenes illustrating *Jātaka* stories.

Bhārhut is an extremely important monument inasmuch as it seems to mark a new beginning after the refined and naturalistic art of the Maurya Empire. The sophistication, in spite of the archaic, hieratic manner, would indicate that a considerable body of sculptural tradition, particularly in wood, preceded it; but of this no traces have survived. Be that as it may, Bhārhut states for the first time, and at some length, themes and motifs that would henceforth remain a part of Indian sculpture.

Stray finds of sculpture at Mathurā and other sites in modern Uttar Pradesh indicate that the Bhārhut style was spread over a large part of northern India, particularly the region roughly between that city and Vārānasi and Buddh Gaya in the east. A closely related style is also found at Sānchi in eastern Mālava, where a representative example is the sculpture of the railing of Stūpa II. Although the themes and motifs found at Bhārhut occur here, narrative representations are all but absent. The style is almost identical; the stiff and rigid contours are a little softer, but both the scale and richness of Bhārhut are missing.

Principal glory of Sānchi

It is the sculpture of the four gateways (*toraṇas*) of the Great Stūpa (Stūpa I) at Sānchi, however, that is the principal glory of that site, carrying the promise of the Bhārhut style to its fulfillment. The *toraṇas,* four in number, were attached to the plain railing around the middle of the 1st century BC. They consist of square posts with capitals supporting a triple architrave, or molded band, with voluted (turned in the shape of a spiral, scroll-shaped ornament) ends and a top crowned with Buddhist symbols. Bracket figures, in the form of *yakṣīs*, serve as additional supports. All parts of these gates, strongly reminiscent of wooden construction, are covered from top to bottom with the most exquisite sculpture. Subjects and motifs found at Bhārhut are also found here, the same profusely flowering lotus stem and associated motifs, the same compositions with figures basically arranged in horizontal rows, the same love for clear detail; but to all of these are added a truly voluminous sense of form, a smoother and more energetic movement, and a keen appreciation for the forms of nature, all of which endow the sculpture with a naïve and sensuous beauty unparalleled in Indian art.

Departures from the Bhārhut style are particularly striking in the narrative reliefs. Their greater depth, taken together with their crowded composition, results in the background, visible at Bhārhut, being submerged in shadow. The figures, in all their richness and abundance, flow out from the dark ground, secured in place by the frame of the panels. The Bhārhut angular silhouette and the rigid, severe outline of the body yields at Sānchi to a gently swelling plasticity, animated by a soft, breathing quality that molds the contours without strain or tension. There is a pronounced concern with the organization of composition, and the narration is often leisurely and discursive; the artist does not just tell the basic story but also lingers over the details, amplifying them to give a vivid picture of everyday life. The emotional monotone of Bhārhut survives in some Sānchi sculptures, but in others it is superseded by joyous faces and the emotional impact of vivid gesture and movement. Dejection is written large on the faces of the soldiers of Māra's army, who had tried to disturb the Buddha's meditation, as they stagger away from the scene of defeat, and the sensuousness of the amorous scenes is successfully evoked by the tender and intimate gestures of the couples. No longer transfixed in their own space, they turn to look at each other lovingly, responding to each other with a deeply felt understanding.

Long and elaborate bas-reliefs carved on the architraves of the *toraṇas* are the summit of the Sānchi sculptor's art. Among the finest are representations of the wars for the relics, the defeat of Māra, the *Viśvāntara Jātaka,* and the *Ṣaḍḍanta Jātaka.* The compositions are rich and crowded with figures, and are arranged with great skill. Particularly striking is the masterly handling of animals, notably the elephant, whose fleshy body and graceful movement are captured unerringly. Deer, water buffaloes, bulls, monkeys—all of the beasts and birds of the forests—are rendered with a sense of intimacy indicating the artist's sense of the fellowship of man and animal in the world of nature. The lush Indian landscape is often carved with ornamental trees, waterfalls, pools, mountains, and rivers. The Sānchi sculptor also shows a marked preference for architectural settings, filling his compositions with numerous buildings that often provide the spatial context for the action. Entire cities, with surrounding walls, elaborate gate houses, and palatial mansions, are depicted. Depth is achieved by rendering side views, and multiple perspective continues to be the rule.

Images of *yakṣīs*

The several large images of *yakṣīs* serving as brackets supporting the lowermost architraves of the *toraṇas* are unique achievements. Like the same goddesses at Bhārhut, they are shown in association with a tree to which they cling, but the style is remarkably different. The modelling shows a concern for the charms of the body, stressing the tactile nature of its flesh. The heavy jewelry and clothing that conceal the body are drastically reduced, revealing its nudity. The soft, melting sensuousness of the female form is so greatly emphasized that the belly and the folds of flesh at the waist are almost flabby, redeemed only by the smooth, firm breasts and the tender arms and limbs.

By comparison, reliefs adorning the railing around the Mahābodhi temple at Buddh Gaya (of about the same date or a little earlier) are in a somewhat impoverished idiom, lacking the rich proliferation both of Bhārhut and Sānchi. The posts have the usual medallions, lunates filled with lotuses, and reliefs depicting the familiar scenes of Buddhist myth and legend. The artistry of Buddh Gaya, however, is of a lower level of achievement than that at either Bhārhut or Sānchi: the relief is deeper than that at Bhārhut but shallower than that at the Great Stūpa of Sānchi; and crowded compositions are lacking, as are the clear and precise ornament and the rich floral motifs. The Buddh Gaya sculptor, however, though abbreviating even further the iconography of Bhārhut, breaks up, as does the Sānchi sculptor, the spatial isolation that so uncompromisingly separated each individual figure at that site.

The great school of Mathurā, also, seems to have come into existence about the 2nd century BC, though its period of greatest activity falls in the first two centuries after Christ. The city was repeatedly sacked in the course of the centuries, which may account for the paucity of materials, but enough has been discovered to reveal that the style, in its early stages, was very similar to that of Bhārhut, characterized by flat two-dimensional sculpture decorated with abundant and precise ornament. Several fragments discovered at the site show the gradual stages by which this style evolved, leading to the sculpture of the Great Stūpa at Sānchi on the one hand and to Buddh Gaya on the other.

Indian sculpture in the 2nd and 1st centuries BC: relief sculpture of Andhradeśa. Besides the schools of northern India, a very accomplished style also existed in southeast India; the most important sites are Jaggayyapeta and Amarāvatī, activity at the latter site extending well into the 2nd century AD. The early remains are strikingly similar to those at Bhārhut, the relief generally even shallower and the modelling comparatively flat. In contrast to those found in northern India, the proportions of the human body are elongated; but in its flat, cubical modelling, angular, halting contours, and precise, detailed ornamentation, the style is essentially similar to contemporary work elsewhere, right down to the same conventional clothing and jewelry. The nervous, fluid treatment of surfaces, so characteristic of subsequent Andhra sculpture, is already present here. The preferred material is marble rather than the sandstone invariably used in the north.

The style of the Andhradeśa school developed in a manner consistent with other regions of India, becoming more voluminous and shedding the early rigidity fairly rapidly. A group of sculptures at Amarāvatī are characterized by the same qualities that distinguish the work at the Great Stūpa of Sānchi: full and lissome forms, modelling that emphasizes mass and weight, and sensuously rendered surfaces.

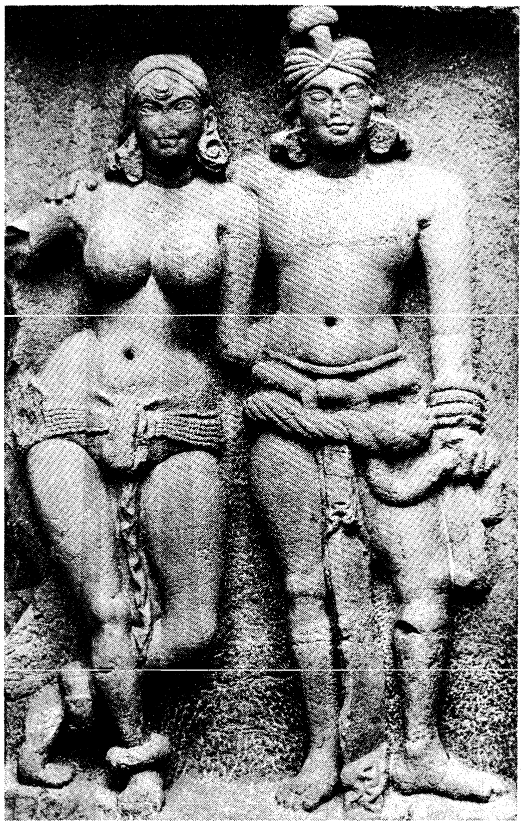
Indian sculpture in the 2nd and 1st centuries BC: relief sculpture of western India. The numerous rock-cut cave temples in the Western Ghāts are, comparatively speaking, much less profusely adorned with sculpture than remains from other parts of India. The earliest works are undoubtedly the bas-reliefs on a side wall of the porch of a small monastery at Bhājā. They are commonly interpreted as depicting the god Indra on his elephant and the sun god Sūrya on his chariot but are more probably illustrations of the adventures of the mythical universal emperor Māndhātā. What is immediately evident is that these sculptures are not imitations of wooden prototypes, like those at Bhārhut, but, rather, reflect a tradition of terra-cotta sculpture, abundant examples of which are found in northern India and Bengal, where this medium was very popular because of the easy availability of fine clay. The terra-cotta tradition is reflected in the amorphous, spreading forms of Bhājā and in the fine striations used in depicting ornaments and pleated cloth, techniques natural and appropriate to the fashioning of wet clay. The fact that there are some similarities to the Bhārhut style—the stilted postures of the figures and the flat contours of the body, for example—indicates that the beginnings of the western Indian school would also have to be placed about the middle of the 2nd century BC.

The next major group of sculptures in western India have been found at Pītalkhorā. The colossal plinth of a monastery decorated with a row of elephants, the large figures of the door guardians, and several fragments recovered during the course of excavations are among the more important remains. A great proportion of the work represents an advance over the style of Bhājā, though features derived from terra-cotta sculpture continue to be found: the figures are carved in greater depth and volume, but the texture of the drapery, the soft contours of the body, and the high relief of the jewelry, which sometimes gives the impression of having been fashioned separately and then applied, testify to the continuing strength of the terra-cotta tradition. Although the hard line and sharp cutting of some sculpture is reminiscent of the earlier, wood-carving tradition as seen at Bhārhut, the forms are more appropriate to the stone medium. Moreover, the expression is more explicit; and for the first time, both gently smiling and boldly laughing figures of *yakṣa*s appear, as well as the figure of a lover blissfully drunk on wine offered to him by his beloved. These features are also found in the later sculpture of the Great Stūpa at Sānchi and, to a more pronounced extent, in the sculpture of the Mathurā school of the 1st centuries AD—for example, in the happily smiling *yakṣī*s from Bhutesar.

The cave temple at Kondane has, above the entrance hall, four beautiful panels depicting pairs of dancers. The forms retain the robust and full modelling of the more developed sculpture at Pītalkhorā, but to this is added an ease of movement and considerable rhythmic grace. Traces of the terra-cotta tradition are now totally absent; nor do they occur in the next phase, best represented by a group of sculptures found in the rock-cut temples and monasteries at Beḍsā and Nāsik and in the *caitya,* or temple proper, at Kārli. Sculpture at all these sites shows many affinities to the Great Stūpa at Sānchi and should be approximately contemporary or a little earlier. Easily the most outstanding achievements of this region and period, and for that matter one of the greatest achievements of the Indian sculptor, are the large panels, depicting amorous couples, located in the entrance porch of the Kārli *caitya.* Here the promise of early work achieves its fulfillment, the full weighty forms imbued with a warm, joyous life and a free, assured movement. The resemblance to work at the Great Stūpa of Sānchi is obvious, though these figures at Kārli are on a much larger scale and possess a massiveness and monumentality that is a characteristic of the distinct western Indian idiom.

P. Chandra



Amorous couple, detail of the *caitya* at Kārli, Mahārāshtra, India.

Indian sculpture in the 2nd and 1st centuries BC: relief sculpture of Orissa. Sculpture decorating the monasteries cut into the twin hills of Udayagiri and Khandagiri in Orissa represents yet another early Indian local idiom. The work is not of one period but extends over the first two centuries before Christ; the stages of development roughly parallel the styles observed at Sānchi Stūpa No. II, Buddh Gaya, and the Great Stūpa at Sānchi, but they possess, like other regional schools, fairly distinct and individual features. The earliest sculptures are the few simple reliefs found in the Alakāpurī cave, humble works that recall the bas-reliefs of Sānchi Stūpa II. The Mañcapurī, Tatowā Gumphā, and Anantā cave sculptures—particularly the image of Sūrya riding a chariot—are more advanced and resemble work at Buddh Gaya. The forms are heavy and solid and lack the accomplished movement of the later cave sculpture adorning the Rānī Gumphā monastery.

Sculpture decorating rock-cut monasteries

These, like other sculptures here, are in a poor state of preservation, but they represent the finest achievements at the site. Most remarkable is a long frieze, stretching between the arched doorways of the top story, representing a series of incidents that have not yet been identified. The work parallels that of the Great Stūpa at Sānchi, with the same supple modelling and crowded compositions. At the same time there is a nervous agitation, a fluid, agile movement together with a decided preference for tall, slender human figures. The reliefs on the guard rooms of Rānī Gumphā are also quite remarkable, depicting forested landscapes filled with rocks from which waterfalls flow into lakes that are the sporting grounds of wild elephants. The fine work of this cave strikes a romantic and lyrical note seldom found in Indian art.

Indian sculpture in the 2nd and 1st centuries BC: sculpture in the round and terra-cotta. The most important sculpture in the round are the life-size or colossal images of *yakṣa*s and *yakṣī*s, which reinterpret forms established by the two Patna *yakṣa*s and the Dīdarganj *yakṣī* of the Maurya period—very much as a few animal capitals, particularly the *makaras* (a crocodile-like creature) from Kauśāmbī and Vidiśā (Besnagar), echo the tradition of the superb Maurya animal capitals. It is the *yakṣa* figures, however, that deserve special attention, for they played a significant part in the iconographic developments of the 1st century AD and later and contributed substantially to the imagery of the anthropomorphic Buddha icon.

The most famous of the *yakṣa* images is a colossal figure recovered from the village of Pārkham, near Mathurā (Archaeological Museum). It is about 8⅔ feet (2.6 metres) in height, and, though the two hands are broken and the head is considerably damaged, it is an image of great strength. Its squat neck, its head set close to the body, which tends toward corpulence, its swelling belly restrained by a flat band, and a broad chest adorned with necklaces—all of these features contribute to an image turgid with earthy power. The back is flat and cursively finished, so that the figure has the appearance more of a bifacial relief than of an image carved in the round. Although the forms retain some of the cubical modelling of Bhārhut, the swelling limbs and torso have a massive weightiness that makes the image an appropriate representation of a divinity that presides over the productive processes of nature and endows plenty and abundance on his worshippers.

Mathurā *yakṣa* images

The Mathurā region seems to have been an important centre of *yakṣa* worship, for several images, most of them fragmentary, have been discovered there. Some images have also been found from the ancient city of Vidiśā (Vidisha Museum), one of which is even larger than the Pārkham example and is in a better state of preservation. The god holds a bag in one hand (the other was held below the chest), and the hair is tied in a large top knot over the forehead. The image is accompanied by a female consort (*yakṣī*), wide-hipped and full-breasted, who also emphasizes and personifies the powers of fertility.

The widespread nature of the cult is evidenced by the occurrence of *yakṣa* images throughout India. Fragments in the round (not to speak of the relief representations in a Buddhist context) of the 2nd to 1st centuries BC have been found from Madhyadeśa, Orissa, Rājasthān, Andhradeśa, and Mahārāshtra. At Pītalkhorā there is an exceptionally fine image of a *yakṣa* conceived as a potbellied dwarf carrying a shallow bowl on his head; the features, with a gently laughing mouth, are suffused with good humour. Similar *yakṣa*s, employed as atlantes (male figures used as supporting elements), are also found on the western gateway of the Great Stūpa at Sānchi and at other sites, notably Sārnāth.

The latest in the series of cult images is the image of the Yakṣa Maṇibhadra, from Pawāyā (Gwalior Museum). The sculpture is at present headless, but the rest of the body is well preserved. The right hand holds a fly whisk that flares over the shoulder; the modelling of the legs and torso is sensitive, and the folds of the garment wrapped around the body are full and voluminous, recalling the style of sculpture at Sānchi.

The terra-cotta sculpture of the period consists mainly of relief plaques made from molds found at numerous sites in northern India. These generally depict popular divinities; a richly dressed female figure loaded with profuse jewelry, obviously a mother goddess, is the favoured subject. Scenes from daily life also abound—as well as what appear to be illustrations of current myths and stories. Superb examples have been found from Mathurā, Ahichhatrā, Kauśāmbī, Tāmlūk, and Chandraketugarh. The workmanship is often of the most exquisite clarity and delicacy, the style paralleling that of contemporary stone sculpture.

Indian sculpture from the 1st to 4th centuries AD. This period is characterized by the dominance in northern India of the ancient school of Mathurā. Other schools, such as those that flourished at Sārnāth and Sānchi in the first two centuries before Christ, for example, were markedly restricted in their artistic output. Much of their sculpture was imported from Mathurā, and the few images they produced locally were strongly influenced by Mathurā work. The narrative bas-relief tradition, consisting of elaborate compositions of edificatory character, was on the wane, and the emphasis was on carving individual figures, either in high relief or in the round. For the first time, images appear of the Buddha, *bodhisattva*s, and various other divinities including specifically Hindu images representing the gods Vishnu, Śiva, Varāha, and Devī slaying the buffalo demon; some of these figures begin to feature several arms, a characteristic of later iconography. There are also many images of *yakṣī*s, often in most alluring attitudes and gestures. Their enticing bodies are now presented as unified organic entities, lacking all traces of the stiff, puppetlike aspect that had not been entirely overcome even at the Great Stūpa of Sānchi. During this period, also, a

fresh incursion of foreign influence by way of western Asia was received, quickly assimilated, and transformed in the characteristic manner of Indian art.

e
ıool of
ındhāra

The school of Gandhāra, with Taxila in Pakistan as its centre and stretching into eastern Afghanistan, flourished alongside the Kushān school of Mathurā. It is of a startlingly different aspect, stressing a relatively naturalistic rendering of form, ultimately of Greco-Roman origin. The school evolved a distinct type of Buddha image and was also rich in relief sculptures depicting Buddhist myth and legend. Drawing largely on Indian traditions of composition, it nevertheless reinterpreted them in its own manner. The schools of Mathurā and Gandhāra were in close proximity and undoubtedly influenced each other, but essentially each adheres to its own concept of style.

The ancient Indian relief style found its fullest expression and development at neither Mathurā nor Gandhāra but in Andhradeśa, notably at the great sites of Amarāvatī and Nāgārjunikoṇḍa. Railing pillars and other parts of *stūpa*s decorated with *Jātaka* tales and scenes from the Buddha's life are found in great number and are of the most exquisite quality. Free-standing images of the Buddha, on the other hand, are relatively rare, being found only toward the close of the period.

Indian sculpture from the 1st to 4th centuries AD: Mathurā. One of the most important contributions of the school of Mathurā was the development of the cult image of the Buddha, who had been previously represented by aniconic (not made as a likeness) symbols. There is a certain amount of controversy about whether Mathurā or Gandhāra originated the Buddha image, which appears to be insoluble in view of the circumstantial nature of the evidence. It is possible that the two schools independently developed their own separate types of images; but, at least as far as the Mathurā image is concerned, it is clear that it is a natural development from the tradition of large *yakṣa* sculptures found in this region. The development can easily be seen in a famous image (discovered at Sārnāth and now in the Sārnāth Museum) of Mathurā manufactured and dedicated by the monk Bala. Carved in the round, the image is shown in a pose of strict frontality, the left hand held at the waist and the right arm, now damaged, originally raised to the shoulder—a posture immediately recalling that of the *yakṣa* images. The jewelry, however, is appropriately omitted, and the body is clothed in simple monastic garments. The modelling throughout is strong and sensuous, and the radiant energy of the body, its affirmative, outgoing movement, is more appropriate to the personality of a *yakṣa* than to that of the Buddha. This standing Buddha image, as seen in the Bala statue, is the standard Mathurā type, several examples of which are known. Along with this one, a similar, seated type developed, of which the best example is the splendid image known as the Kaṭra Buddha (Archaeological Museum). The modelling of the body is refined, the breasts characteristically heavy and prominent, and the flesh of the torso, with its subtle modulations, as convincingly rendered as the Bala image.

ɔne
ɔlets

The new trends formulated early by the Mathurā school do not indicate a sharp break from the traditions of the earlier schools. This is clear in a series of magnificent *āyāgapaṭas,* or stone tablets originally set up outside *stūpa*s to receive worship and offerings. They are usually square or rectangular and richly decorated with auspicious and religious symbols as well as angelic and mythical beings. The extremely decorative, lavish surface treatment gives the immediate impression of a great profusion of multiple forms, akin in feeling to the sculpture of the Great Stūpa of Sānchi. The organization of these forms, however, has none of the easy freedom of Sānchi. The figures, for example, are often cast in a regular, winding shape imitating the movement of the undulating lotus creeper. The same movement is seen in rows of animals depicted with haunches raised and chests touching the ground, features seen in earlier art but now much more emphatically stylized. The bodies of the animals also begin to be overpowered by vegetal forms, the tails, for example, terminating in foliate tips; in a later age, this tendency results in the almost total disintegration of animal shapes under the pressure of the floral.

It is not to these bas-reliefs, however, that one turns for the most delightful creations of the Mathurā school (for they are in fact the last vestiges of a style rapidly passing out of favour) but to the large number of railing pillars usually carved with representation of *yakṣī*s engaged in playful and enticing activities such as plucking blossoms from trees or leaning on its branches, dancing, bathing under a waterfall, and adorning themselves. Among the most beautiful of these is a group that was recovered from Kaṅkālī Ṭīlā and now in the State Museum at Lucknow. The modelling of the figures is generally heavy, the soft, plump bodies suffused with a slow, languorous movement. What is important, however, is the emotion, which is no longer expressed in the face alone but in the whole attitude of the body. The pensive mood of a woman holding a lamp, for instance, is evoked not only by the serene features of the face but by the gentle sway of the relaxed body. Present throughout is a fresh movement of life, a marked striving for diverse and varied effects of posture, movement, expression, and even dress and ornament that brings about vital changes in the nature of Indian sculpture. A remarkable group of railing posts decorated with *yakṣī* images, which were recovered from Bhūtēsar near Mathurā (Archaeological Museum), represent an even more refined achievement than the Kaṅkālī Ṭīlā figures. The heavy proportions, in spite of the full breasts and the wide hips, have been overcome; the happy faces express carefree joy, and the postures of the body are so alive with rhythm as to give the impression of a dancing figure.

Mathurā, during this period, was ruled by the Kushān (Kuṣāṇa) dynasty. A group of portrait sculptures of these rulers (Archaeological Museum), recovered from a village called Māt in the environs of Mathurā, gives an interesting glimpse of the foreign influences entering India at the time. One of them (unfortunately lacking the head) represents the emperor Kaniṣka wearing heavy boots, a tunic, and a coat, and leaning on a mace. The image is quite

P. Chandra

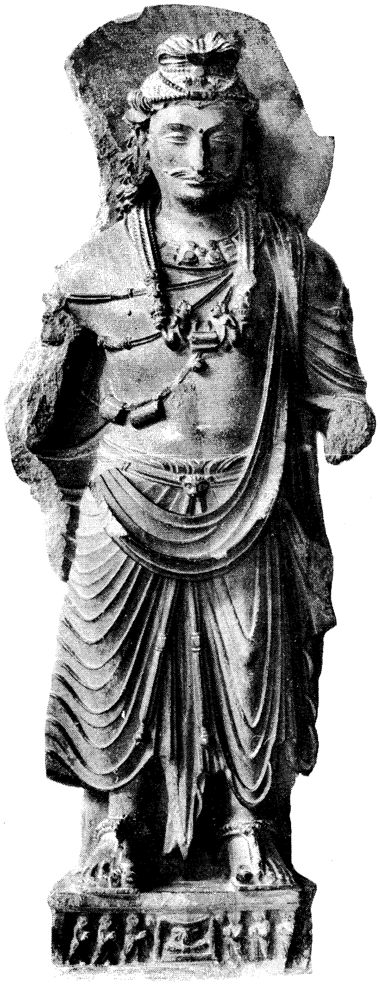
different not only in dress but also in style from other contemporary works, being essentially linear, with the forms entirely set into the surface. The surfaces have little ornamentation and are marked by extreme simplicity; they are also uncompromisingly stiff and rigid. It is possible that these images represent attempts by a Mathurā artist to imitate a style preferred by his imperial masters; but it was not long before the foreign elements were assimilated into the Mathurā style proper, for later images of Kushān chiefs have the same expanding and voluminous form that characterizes other sculptures of this school. A large number of ornamental motifs that now appear in India for the first time undergo a similar process of transformation.

The extent of Mathurā influence on Indian art of this period can be gauged by the sculpture of the school found at several sites in different parts of northern India, notably Ahichhatrā, Kauśāmbī, Sārnāth, and Sānchi. Most of these sites had been flourishing centres earlier, but only a very limited amount of sculpture was produced during the ascendancy of the Mathurā school; and whatever local sculpture was produced at this time was heavily influenced by the Mathurā style. At Sārnāth, for example, both the Bala Buddha imported from Mathurā and its local imitations have been found.

Ivory plaques of Bagrām

Ivory plaques discovered at Bagrām (Begrām) in Afghanistan are closely related to the school of Mathurā. These are of great importance; for, though ivory must have been a favourite medium of sculpture, little has been preserved of the early work. Most of it is in very low engraved relief, with fluent, sweeping outlines. The figures are depicted in easy and elegant postures, and the workmanship often attains considerable virtuosity.

P. Chandra



Bodhisattva of the Gandhāra school, schist sculpture, *c.* 2nd century AD. In the Municipal Museum, Allāhābād, Uttar Pradesh, India.

Indian sculpture from the 1st to 4th centuries AD: Gandhāra. Contemporary with the school of Mathurā, and extending almost into the 6th century, is the Gandhāra school, whose style is unlike anything else in Indian art. It flourished in a region known in ancient times as Gandhāra, with its capital at Taxila in the Punjab, and in adjacent areas including the Swāt Valley and eastern Afghanistan. The output of the school was very large; numerous images, mostly of Buddhas and *bodhisattvas*, and narrative reliefs illustrating scenes from the Buddha's life and legends have been found. The favoured material is gray slate or blue schist and, particularly during the later phases, stucco. Except for objects excavated at a few well-known sites (such as Taxila, Peshāwar, and the Swāt Valley, in Pakistan, and Jalālābād, Haḍḍā, and Bāmiān, in Afghanistan), most of the finds have been the result of casual discovery or clandestine treasure hunts and plunder, so that their correct provenance is not known. If to this are added the large variety of idioms that appear to have existed simultaneously and the total absence of securely dated images, the wide divergence of scholarly opinion with regard to the schools' evolution can be understood. In the present day, there is general agreement, however, that its most flourishing period probably coincided with Kushān rule, particularly the reigns of the emperor Kaniṣka and his successors, and that the school did not long outlast the growth of the Gupta school in the 5th century.

The origins of the Gandhāra style are ultimately Greco-Roman, though, recently, emphasis has been placed on Roman art as the more immediate source. It has also been suggested that the school was created by foreign craftsmen imported into India and by their Indian pupils.

The Gandhāra school is also credited by some scholars with the invention of the anthropomorphic Buddha image. Whether this is correct or not, the Gandhāra image is quite different from that of Mathurā and illustrates the difference between the two schools. Instead of the powerful images directly descended from *yakṣa* prototypes, the Gandhāra version is an adaptation of an Apollo figure, with rather sweet and sentimental features. The definite volume and substance given to the pleated folds of the monastic robes make this image more naturalistic than anything found in Indian art. At the same time, the iconographical features are of Indian origin. Large numbers of *bodhisattva* images conceived in the image of royalty, some with strongly individualized facial features, have also been found.

Narrative relief sculpture

In contrast to Mathurā, narrative relief sculpture was very popular in Gandhāra art. Again, in composition and iconography these reliefs are largely dependent on the earlier Indian schools, but the style is quite distinct. Instead of continuous narrative, incidents separated in time are separately represented, though often arranged in sequence. Violent emotions are realistically rendered. The compositions range from simple horizontal placement of figures to rich and complex arrangements, which often attempt to render space illusionistically.

In the course of time, Indian influence was increasingly felt in the art of Gandhāra, and an abstract vision began to obscure the Greco-Roman naturalism of the earlier forms. In spite of the new influence (and the many graceful but cloying stucco sculptures that are representative of this late phase) the style shows no signs of vital change. This conservatism, together with the large artistic production, gives an overall impression of considerable monotony. Without any real roots in India and with marked foreign features, the avenues of natural development seem to have been closed to the school, which thus finally disappeared. Nevertheless it made vital contributions to the art of Central and eastern Asia, and several features, drastically transformed, were incorporated in Gupta art.

Indian sculpture from the 1st to 4th centuries AD: Andhradeśa. Besides the schools of Mathurā and Gandhāra, a most accomplished school of sculpture flourished in Andhradeśa during the three centuries after Christ, the most important centres being Amarāvatī and Nāgārjunakoṇḍa. The remains consist mainly of carved railings and rectangular slabs that decorated the great Buddhist *stūpas*, which have largely disappeared. The finds are thus fragmentary and belong to several phases of construction or to separate monuments spanning the 1st, 2nd, and 3rd centuries AD.

Unlike the school of Mathurā, which concentrates on the carving of single figures, the Amarāvatī school carried to the fullest limit of its development the ancient tradition of relief sculpture, which flourished in the two centuries before Christ at sites such as Bhārhut, Sānchi, and Amarāvatī itself. The marble railing posts are decorated with central medallions and lunates at the top and bottom, all filled with lotus flowers of a very rich design. Often the medallions also contain reliefs illustrating scenes from the Buddha's life and from the *Jātaka* stories, and these are the principal glory of the site.

Two broad phases in the development of narrative relief can be distinguished. In the first, the artist builds on the achievements of early relief sculpture as seen on the Great Stūpa of Sānchi. The forms are still comparatively heavy, the figures increasingly soft and fleshy, the movement freer but still pervaded by a sense of calm repose. This type of work, represented by relatively few examples, is followed by a phase in which the compositions achieve an extraordinary elaboration and complexity. Most striking is the restless, energetic movement, often nervous and flurried, that possesses the participants in any given scene. Complex relationships and patterns are established between the figures; and space is so articulated that the eye participates in the swirling inner movement of the composition that effectually dissolves the ground on which the figures are carved, while the figures themselves flow out in an endless movement from the ground. The setting is dramatic in the extreme. The loving workmanship, reminiscent of ivory carving, and the superb technical proficiency mark the Amarāvatī reliefs as the culminating point of the entire relief style.

The figures, of both men and women, are of unprecedented suppleness and plasticity, the forms rendered in every variety of torsion and flexion. A fluent, gliding line, often more appropriate to painting than to sculpture, encloses the figures, and pervading the whole is a subtle voluptuousness. The reliefs are often only nominally religious, a pretext for the sculptor's pleasure in representing the leisured and sophisticated life of the time.

Nāgārjunakoṇḍa sculpture marks the last phase of the relief style. The figures become stiffer and puppet-like, the patterns of movement frozen and mechanical but still possessing the energy and richness that always characterize this style.

ddha
ages of
ıdhra-
ıa

The Buddha is represented in Andhradeśa by both symbolic and anthropomorphic forms. The iconographic formula developed shows him clad in a rather thick garment with stylized folds, and the postures are not as formal and hieratic as the Mathurā. This type of Buddha exercised considerable influence in the development of the Buddha image in Ceylon. In several other features as well, the Andhra style also contributed to the development of early sculpture in Southeast Asia.

Indian sculpture from the 1st to 4th centuries AD: terracotta. The quality of terra-cotta figurines of this period is generally inferior to work produced in the first two centuries BC. Many heads of crude workmanship, with protruding eyes, apparently representing foreigners, were found at sites such as Mathurā, Ahichhatrā, and Kauśāmbī. At the same time, there are some well-modelled heads that imitate the style of stone sculpture and are equally expressive.

Gupta period (c. 4th–6th centuries AD). During the 4th and the 5th centuries, when much of northern India was ruled by the Gupta dynasty, Indian sculpture entered what has been called its classic phase. The promise of the earlier schools was now fully realized, and at the same time new forms and artistic ideals were formulated that served as the source for development in succeeding centuries. The more or less sensuous and earthy rendering of form was drastically transformed, so that artistic expression closely conformed to the religious vision. The forms are refined and treated with sure and unsurpassed elegance. The volumes, impelled by an inner life, still swell from within but are restrained and controlled, made to flow in smooth and abstract rhythms in an organic and unified concept in which the sensual and the spiritual are inextricably blended. The edificatory, didactic intent of early relief sculpture is abandoned; instead, the works produced are pronouncedly meditative; and the repose and calm that settles on the images of the Buddha, the master of the inner contemplative life, is also seen on images of other divinities. Decorative ornament is in perfect harmony with the volumes it adorns, each emphasizing the other, so that in every respect this classic style of the Gupta period is one of great composure and perfect balance.

Gupta period: Mathurā. The impetus for the new schools seems to have come from Mathurā, which is hardly surprising in view of the preponderant role played by the city in the preceding period. The transformation into the new idiom is best illustrated by a splendid image of the Buddha which is dated AD 384 (Indian Museum, Calcutta). Memories of the rather massive and ponderous weight of the earlier style are present, but the calm face no longer looks out at the world; rather, the vision is turned within, the mood being one of serene contemplation. The style, which consistently uses the local red sandstone, undergoes further refinement, seen in a series of magnificent life-size Buddha images of the 5th century (now scattered in museums throughout the world). The more delicate face radiates a feeling of calm inner bliss, and the body is most subtly modelled by smoothly flowing planes that both suggest the swelling force of life and subordinate it to

the spiritual vision of the whole. Mathurā images generally show the Buddha wearing a diaphanous robe, the folds of which are rendered by stringlike ridges in a reinterpretation of a Gandhāra convention. The gestures of the hand are delicate and varied. The hair is usually rendered by rows of small curls that conceal the conical protuberance. These Mathurā images established an iconographical type that became the norm for the Buddha image.

Mathurā Hindu images

In addition to the Buddha figure, Mathurā has yielded large numbers of images of the various Hindu divinities, particularly Vishnu-Krishna. This is in keeping with the increasing strength of the various Hindu cults and the intimate association of Mathurā with the god Krishna. The famous image of Vishnu from Kaṭrā Keśavadeva in Mathurā is one of the finest (National Museum, New Delhi). The god is conceived as a royal figure, wearing a crown and appropriate jewelry, his features imbued with a dignified calm that is suitable to his function as the preserver and is also characteristic of most Gupta art.

Gupta period: Sārnāth. This famous centre of Indian art developed a sweeter and more elegant version of the Buddha image than Mathurā's. Instead of the rather strict frontal posture, the weight of the body is thrown more on one leg, resulting in a very subtle contrapposto position, in which the hips, shoulders, and head are turned in different directions. This lends a certain movement to the figure, so that it does not quite possess the static, steadfast quality of Mathurā. The robes are no longer ridged with folds but are plain, and the surface of the stone is even more abstractly handled than is the Mathurā. The faces are heart-shaped, the transitions from one part of the body to another smoother, so that the images have great refinement even if they do not possess the strength of Mathurā. The characteristic Sārnāth style, the preferred material of which is the local buff Chunār sandstone, seems to have developed in the late 5th century, the few earlier works being closer to the Mathurā school. The most famous image from the site and one of the masterpieces of Indian art is that of the seated Buddha preaching (Sārnāth Museum). It is exceptionally well preserved and delicately carved. The face, with serene features and a gentle smile playing on the lips, suggests the joy of supreme spiritual achievement. The halo behind the Buddha is also very beautifully carved, with exquisite floral patterns. Large numbers of Buddha and *bodhisattva* images have been excavated at Sārnāth and are to be found in the museum at the site and in major collections throughout the world.

Gupta period: central India. In addition to the major schools of Sārnāth and Mathurā, important sculpture of the 5th and 6th centuries is found at several sites in central India. The sculptures here are often in their original locations, surviving not as isolated images torn from their architectural context but in association with the temples of which they formed a part. At Udayagiri, near Vidiśā, are a series of simple rock-cut caves of the opening years of the 5th century. The sculpture, made of soft stone, has suffered greatly, but whatever has survived reveals a style that stresses strength and power. Perhaps the most magnificent work is a great relief panel depicting the boar incarnation of Vishnu lifting the earth goddess from the watery deeps into which she had been dragged by a demon. The massive figure of the god, with the body of a man and the head of a boar, is carved in a surging movement across the face of the rock, the goddess resting easily on his shoulder, while a host of beings, human and divine, celebrate this great triumph.

The Śiva temple at Bhumarā has also yielded some sculpture of fine quality. The stone is carved with great precision and skill, nowhere more evident than in the handling of exuberant floral ornament. Little in Indian decorative sculpture can match the brilliance of the large panels filled with lotus stems and floriated scrolls discovered at this site and at Nāchnā Kutharā.

Some of the finest Gupta sculpture adorns the walls of the Vishnu temple at Deogarh. Particularly striking are three large relief panels depicting Vishnu lying on the serpent Śeṣa, the elephant's rescue, and the penance of Nara-Nārāyaṇa. The compositions tend to be dramatic; the carving and decoration, sumptuous, the sturdy forms recalling Mathurā rather than the attenuated grace of Sārnāth. The doorframe of the sanctum of this temple is an especially fine example of architectural decoration popular in this period. Bands of floral scrolls, amorous couples, and flying angels of great elegance are carved around the entrance. Particularly impressive are groups of worshippers at the base, their swaying bodies related to each other with an easy rhythm.

Gupta period: Mahārāshtra. A great revival of artistic activity seems to have taken place in this region during the reign of the Vākāṭaka dynasty and its successors, best expressed in the splendid sculpture decorating the cave temples of Ajantā and Elephanta. The idioms established in the North were adapted here to the needs of a style that conceived figures on a massive scale, as determined by the demands of the great expanses of rock out of which they were carved. Although the sculpture at Ajantā (mostly of the late 5th century) combines the old weightiness with the new restraint and elegance, the style finds its supreme expression in the magnificent cave temple at Elephanta. The central image of this great temple is of immense size and in deep relief. It represents Śiva in his cosmic aspect, the central head clam, introspective, self-sufficient, and transcending time, the heads to the sides, in their sensuous beauty and awesome terror, reflecting the creative and the destructive aspects of the supreme divinity.

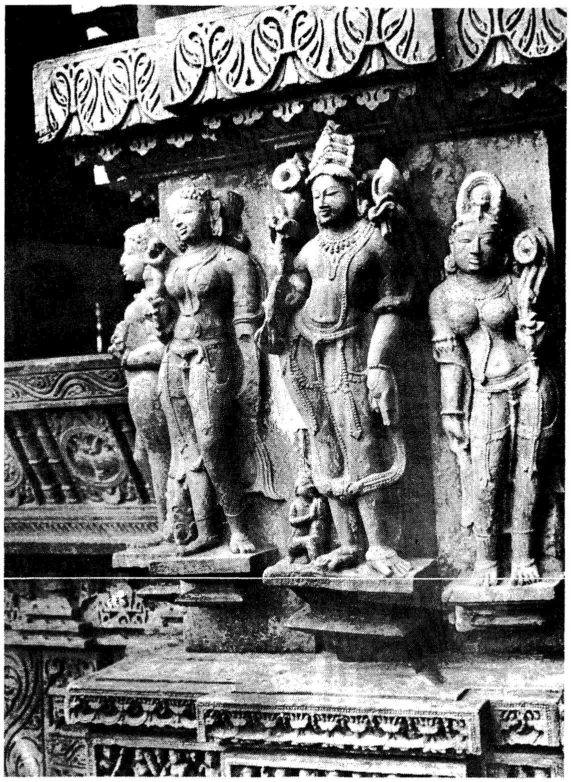
Gupta period: other regions. The impact of the Gupta style of the 5th and 6th centuries was felt in many parts of India, though actual remains thus far discovered are more abundant in some parts than in others. There appears to have been, in Bihār, a distinct school characterized by rather heavy, compact forms; and Gujarāt and southern Rājasthān developed an individual style of considerable voluptuousness and plasticity. Among the notable sculpture of the Idar region are groups of mother goddesses whose massive forms are rendered with an easy grace and intimacy. In the Karnataka country, to the south, the cave temples of Bādāmi reveal yet another distinct idiom, somewhat direct and elemental but nevertheless belonging to the same general style, with local variations, that prevailed over the greater part of India.

Gupta period: terra-cotta. Terra-cotta sculpture, like art in other mediums, was greatly developed. Fairly large and elaborate plaques were used to adorn brick *stūpa*s and Hindu temples from Sind to Bengal. The polychrome relief images of the Buddha from Mīrpur Khās are delicate and slender, with traces of Gandhāra feeling. Representations of divinities and mythological scenes from temples in Bīkaner, Ahichhatrā, Bhītargaon, and Śrāvastī are works on a more popular level, possessing an earthy ponderousness. A large number of figurines, particularly fragments of heads with elaborate coiffures and delicate, smiling features, have been found at Rājghāt in Vārānasi (Benares) and at other sites.

Medieval Indian sculpture. Indian sculpture from the 7th century onward developed, broadly speaking, into two styles that flourished in northern and southern India, respectively. In each of these regions there also developed additional local idioms, so that there was a wide variety of schools. All, however, evolved in a consistent manner, the earlier phase marked by relatively plastic forms, the later phase by a style that emphasizes a more linear rendering. The sculpture was used mainly as a part of the architectural decor, and the quantity required was vast. This often entailed a mechanical production, with the result that works of quality are few in proportion to the numbers.



Detail of a wall of the Lakṣmaṇa temple at Khajurāho, Madhya Pradesh, India, sandstone, *c.* AD 941.

P. Chandra

Besides the two main idioms, the local schools of Mahārāshtra and Karnataka are of particular interest because they possess considerable individuality and often show both northern and southern features.

Sculpture in bronze was also produced in fairly large quantities in this period. Again, several local schools can be distinguished, the most important of which are those of eastern and southern India.

Medieval Indian sculpture: North India. The history of North Indian sculpture from the 7th to the 9th centuries is one of the more obscure periods in Indian art. Two trends, however, are clear: one exhibits the decline and disintegration of classical forms established during the 5th and 6th centuries; and the other, the evolution of new styles that began to possess overall unity and stability only in the 10th century.

A breakdown of the Gupta formula is observable from at least the 7th century onward, if not a little earlier: harmonious proportion, graceful movement, and supple modelling begin to yield to squat proportions, a halting movement, and a more congealed form. Toward the 8th century, signs of a new movement become evident in a group of sculptures that departs from the progressively lifeless working out of the Gupta idiom. The modelling emphasizes breadth but with a pronounced feeling for rhythm, and the delineation of decorative detail is fairly restrained. In the 9th century, particularly during the second half, a distinct change came over the styles of all of northern India. A new elegance, a richer decorativeness, and a staccato rhythm so characteristic of the medieval styles of the 10th and 11th centuries begin to be clearly seen and felt. Sculpture of this period reaches a standard of elegance never surpassed in the medieval period: the grace and voluminousness of earlier work are modified

Signs of
a new
movement

but not lost; the harsh angularity of later work, avoided. An idea of the style can be formed from an important group of sculptures at Ābānerī, the Śiva temple at Indore, and the Telī-kā-Mandir temple at Gwalior, as well as from individual works in various North Indian museums.

With the 10th century, the conventions of North Indian sculpture became fairly well established. The style is represented by examples from such monuments as the Lakṣmaṇa temple at Khajurāho (dated 941), the Harasnāth temple at Mt. Harsha (*c.* mid-10th century), in Rājasthān, and numerous other sites scattered all over northern India. These works are executed in a style that has become harder and more angular, the figures covered with a profusion of jewelry that tends to obscure the forms it decorates. These features are further accentuated in the 11th century, when many temples of great size, adorned with prodigious amounts of sculpture, were erected all over northern India. There is a decline in the general level of workmanship: the carving is often entirely conventional and lifeless, the features rigid and masklike, and the contours stiff and unyielding. The ornamentation, consisting of a profusion of beaded jewelry, is for the most part as dull, repetitive, and lifeless as the rest of the sculpture. This phase of artistic activity is represented at important centres from Gujarāt to Orissa; one of them is Khajurāho, with a vast amount of sculpture, all in a good state of preservation but conceived and executed as perfunctory architectural ornamentation. Not all sculpture, however, is of inferior quality; the hard, metallic carving and angular, stylized line sometimes result in works possessing a cold brilliance.

The 12th century marks the end of traditional sculpture all over northern India, except for a few pockets not yet penetrated by the Islāmic invasions. A rigid line imposed itself on the forms, which in turn became desiccated and hard, so that whatever unity of surface may have existed was entirely shattered. A brief revival took place in parts of Gujarāt and Rājasthān in the 15th century, but the sculpture merely imitated the work of the late medieval phase. The pure geometry of their forms, however, sometimes results in works possessing a curious archaistic power.

Sculpture in eastern India

Sculpture in eastern India (consisting of Bangladesh and the modern Indian states of Bihār, West Bengal, and Orissa), though sharing in the broad pattern of development of the rest of northern India, nevertheless represents a distinct idiom. The flatness of planes and angularity of contours are less pronounced, the figures retaining a sense of mass and weight for a greater period of time and to a greater degree. This can be clearly seen in sculpture from Konārak, in Orissa. Dating to the 13th century, the style retains a considerable semblance of plasticity at a period when sculpture in other parts of northern India had assumed a very wooden appearance. In Bihār and Bengal a flourishing school of bronze sculpture also developed, as evidenced by the large number of finds, notably from the sites of Nālandā and Kurkihār. The style generally parallels works in stone, emphasizing plastic values to a great degree. The most flourishing period was the 9th century, when a series of magnificent images representing the gods and goddesses of the Buddhist pantheon were made at Kurkihār and Nālandā. The work of the 10th and 11th centuries is more decorative and often very skillfully and elaborately cast. Of relatively small size and therefore easily transportable, bronze sculpture from this area played an important part in the diffusion of Indian influence in Southeast Asia.

Kashmir sculpture tends to be weightier and more massive than works in other parts of India. Some Gandhāra memories surivive, particularly in the fleshy rendering of the body and the drapery, but the sculpture is very much a part of the stylistic developments in northern India. Representative examples of the style, dating to around the mid-9th century, have been found from Avantipura. A flourishing school of bronze sculpture also existed, numerous examples having come to light in recent years. One of the finest, discovered at Devsar (Sir Pratap Singh Museum, Srinagar), is a large 9th-century ornamental frame, 6½ feet (two metres) high, decorated with various incarnations of Vishnu, all filled with great energy and movement. A good number of ivory images of Kashmir workmanship have also been preserved. These are generally of miniature size, polychromed, and of extremely fine and delicate workmanship. Influences of the Kashmir style of sculpture were strongly felt in the neighbouring Himalayan region, including both Tibet and Nepal.

century sculptures at Mahābalipuram, by far the most impressive of which is a large relief depicting the penance of Arjuna (previously identified as an illustration of the mythical descent of the Ganges). It is carved on the face of a granite boulder with a deep cleft in the centre, representing a river, down which water actually flowed from a reservoir situated above. On both sides are carved numerous figures of divinities, human beings, and animals that crowd the hermitage where Arjuna, practicing penance, is visited by Śiva. The tall, slender figures, with supple tubular limbs, remotely recall the proportions of Amarāvatī, now greatly transformed; and the numerous animals, including the elephant herd with its young, show the same intimate feeling for animal life that characterizes all Indian sculture, but in a manner that has seldom been surpassed.

The light, aerial forms gained stability and strength in subsequent centuries, culminating in superb sculptures adorning small, elegant shrines built during the late 9th century when the Cōḻa dynasty was consolidating its power. The temples at Tiruvalīśvaram, Kodumbālūr, Kilaiyur, Śrīnivāsanālūr, Kumbakonam, and a host of other sites of this period are only sparingly adorned with sculpture, but it is of superb quality. With the 10th and 11th centuries, South Indian sculpture, like its counterpart in the north though to a lesser degree, was carved in flatter planes and more angular forms, and the fresh, blooming life of earlier work is gradually lost. This can be seen, for example, in the sculpture of the numerous temples of Thanjāvūr and Gaṅgaikoṇḍacōḻapuram. The subsequent phase, extending up to the 13th century, is represented by work at Dārāsuram and Tribhuvanam; although the forms become increasingly congealed, brittle works of fine quality—often capturing outer movement with great skill—continue to be produced. Sculpture in southern India continued when artistic activity was interrupted in the north by the Islāmic invasions but, in spite of technical virtuosity, became progressively lifeless. Artistic activity continued in the south into the 17th century, the elaborately sculptured halls at Madurā and the masses of stucco sculpture adorning the immense entrances, or *gopuras*, testifying to the prodigious output and the undistinguished quality of the work produced.

South Indian bronze sculpture

South Indian bronze sculpture has a special place in the history of Indian art. A large number of images were made (some of them still in worship in the mid-20th century and others unearthed from the ground by chance), but examples before the 8th century are quite rare. In bronze, as in stone, the 9th and 10th centuries were periods of high achievement, and many images of excellent quality have survived. They are all cast by the lost-wax, or cire perdue, process (in which a wax model is used) and technically are very accomplished. In the early stages the forms were smooth and flowing, with a fine balance maintained between the body and the complex jewelry, the lines of which follow and reinforce every movement of the plastic surface. The bronzes of the later period lose this cohesiveness, the ornament, by virtue of its hardness, tending to divide and fragment the body it covers. The modelling also became flatter and sharper, though not quite as rapidly in bronze sculpture as in stone. Ancient traditions of workmanship survive to the present day, and a few guilds of craftsmen continue to make competent if somewhat lifeless images.

Most South Indian bronze images are representations of Hindu divinities, notably Vishnu and Śiva. One particular form deserves special notice as a striking southern contribution to Indian iconography. It is that of a four-armed Śiva as Lord of the Dance (Naṭarāja), shown within a flaming halo, or aureole, one hand holding the doubleheaded drum symbolizing sound, or creation, and the other holding the fire that puts an end to all that is created. The palm of the third hand faces the devotee, assuring him of freedom from fear, while the fourth hand points to the raised foot, the place of refuge from ignorance and delusion, which are symbolized by the dwarf demon crushed beneath the other foot. Several splendid images are known, the finest being, perhaps, the great image still worshipped in the Bṛhadīśvara temple at Thanjāvūr.

Medieval Indian sculpture: Mahārāshtra and Karnataka. The Karnataka country possessed a flourishing school of sculpture in the 7th and 8th centuries, as seen in examples from Aihole, Pattadkal, and Ālampur. As in architecture, influences from the north are discernible, but the style is basically southern, emphasizing rugged strength and power compared to the more elegant and delicate forms of the Tamil country. In Mahārāshtra, cave temples at

Ellora carry the most important examples of this phase of sculpture. Here the tradition is continued of images of great size that, in their primitive strength, partake of the nature of the rock out of which they are carved. A series of large, splendid panels (6th century AD) depicting incidents from Hindu mythology in high relief are to be found in the Rameśvara cave; notable among them is a fearsome representation of the dancing Kālī, goddess of death. The Kailāsa temple (*c.* 757–783) has a remarkable group of elephants struggling with lions all around the plinth. Of the several large reliefs, also at Kailāsa, the depiction of Rāvana shaking Kailāsa is a composition of considerable grace and charm.

Distinctive style of Karnataka

Toward the 13th and 14th centuries, a very distinctive style developed in the Karnataka country, which was then largely ruled by kings of the Hoysaḷa dynasty. The materials employed are varieties of stone that are soft when freshly quarried but harden on exposure, which may account partially for the extreme richness of the work. The sculpture is in very high relief, often undercut and literally covered with the most elaborate ornaments and jewelry from top to toe. This unrestrained extravaganza is unique even for Indian art, which shows a preference for intricate and elaborate ornament at all stages of its history.

Painting. Literary works testify to the eminence of painting as an art form in India, particularly in the decoration of walls, but climate has taken a devastating toll, leaving behind only a few tantalizing examples. By far the bulk of the preserved material consists of miniature painting, initially done on palm leaf but later on paper. The subject matter is generally religious (illustrating divinities, myths, and legends) and literary (illustrating poetry and romances, for example), though the Mughal school was also concerned with historical and secular themes. The styles were rich and varied, often closely connected with one another and sometimes developing and changing rapidly, particularly from the 16th century onward. The work also shows a surprising vitality under strained circumstances, surviving up to the very eve of the modern period when the other arts had deteriorated greatly.

Prehistoric and protohistoric periods. Painting in India should have a history stretching as far back as any of the other arts but, because of its perishable nature, little has survived. None of the examples found in rock shelters over almost all of India, and chiefly representing scenes of hunting and war, appears to be earlier than the 8th century BC, and all may be as late as the 10th century AD. A faint idea of the painter's art in the Indus Valley civilization can be had from the pottery, elaborately decorated with leaf designs and geometrical patterns.

Paintings at Ajantā

Ancient wall painting. The earliest substantial remains are those found in rock-cut cave temples at Ajantā, in western India. They belong to the 2nd or 1st century BC and are in a style reminiscent of the relief sculpture at Sānchi. Also found at Ajantā are the most substantial remains of Indian painting of about the 5th century AD and a little later, when ancient Indian civilization was in full flower. The paintings, the work of several ateliers, decorate the walls and ceilings of the numerous cave temples and monasteries at the site. They are executed in the tempera technique on smooth surfaces, prepared by application of plaster. The themes, nominally Buddhist, illustrate the major events of the Buddha's life, the *Jātaka* tales, and the various divinities of the expanding Buddhist pantheon. The ceilings are covered with rich motifs, based generally upon the lotus stem and the world of animals and birds. The style is unlike anything seen in later Indian art, expansive, free, and dynamic. The graceful figures are painted by a sweeping and accomplished brush; and they are given body and substance by modelling in colour and by a schematic distribution of light and shade that has little to do with scientific chiaroscuro. The narrative compositions, handled with utmost dexterity, are a natural outgrowth of the long traditions of relief sculpture and reflect the splendour and maturity of contemporary sculpture. The large images of the *bodhisattvas* in Cave 1, combining rich elegance with spiritual serenity, reflect a vision that sees the shifting world of matter and the transcendental calm of Nirvāṇa as essentially one.

Except for a large and magnificent painting of a dance scene found at the rock-cut cave at Bāgh—a painting executed in a style closely resembling Ajantā—hardly any other work of this great period survives. Cave temples at Bādāmi, in the Karnataka country, and Sittānavāsal, in Tamil Nadu, probably of the late 6th and 7th centuries AD are already but echoes of the style of the 5th century, which appears to have died out around this time.

Eastern Indian style. Small illustrations on palm leaf, chiefly painted at the great Buddhist establishments of eastern India, appear to have conserved some elements of this ancient style; but they have lost its dramatic impact, which is replaced by a studied preciosity and an inhibited meticulousness. The surviving paintings date from the 11th and 12th centuries and are conventional icons of the numerous Buddhist gods and goddesses, narrative representations having largely disappeared. With the destruction of these Buddhist centres by the Islāmic invader, the east Indian style seems to have come to an end.

Western Indian style. The style of Ajantā is succeeded in western India by what has been appropriately named the western Indian style. Among the earliest examples are a few surviving wall paintings of the Kailāsa temple (mid-8th century) at Ellora and the Jaina temples, built at the same site a hundred years later. The plastic sense of form, so evident at Ajantā, is emphatically replaced by a style that even at this early stage is heavily dependent on line. The contours of the figures are sharp and angular, the forms dry and abstract; and the fluent, stately rhythms of Ajantā have become laboured and halting.

Jaina manuscripts

The most copious examples of this style, however, have survived not on the walls of temples but in the large number of illustrated manuscripts commissioned by members of the Jaina community. The earliest of these are contemporary with eastern Indian manuscripts and are also painted on palm leaf; but the style, instead of attempting to cling to ancient traditions, moves steadily in the direction already established at Ellora. It is a perfect counterpart of contemporary sculpture in western India, relying for its effect on line, which progressively becomes more angular and wiry until all naturalism has been deliberately erased. The figures are almost always shown in profile, the full-face view generally reserved for representations of the *tīrthaṅkaras*, or the Jaina saviours. A convention that appears unfailingly for the duration of the western Indian style is the eye projecting beyond the face shown in profile, meant to represent the second eye, which would not be visible in this posture. The colours are few and pure: yellow, green, blue, black, and red, which was preferred for the background. In the beginning, the illustrations are simple icons in small panels; but gradually they become more elaborate, with scenes from the lives of the various Jaina saviours as told in the *Kalpa-sūtra* and from the adventures of the monk Kālaka as related in the *Kālakācāryakathā* the most favoured.

Even greater elaboration was possible with the increasing availability of paper from the late 14th century; with larger surfaces to paint on, by the middle of the 15th century artists were producing opulent manuscripts, such as the *Kalpa-sūtra* in the Devasanopaḍā library, Ahmadābād. The text is written in gold on coloured ground, the margins gorgeously illuminated with richest decorative and figural patterns, and the main paintings often occupying the entire page. Blue and gold, in addition to red, are used with increasing lavishness, testifying to the prosperity of the patron. The use of such costly materials, however, did not necessarily produce works of quality, and one is often left with the impression of cursive and hasty workmanship. With some variations—but hardly any substantial departures from the bounds that it had set for itself—the style endured throughout the 16th century and even extended into the 17th. The political subjugation of the country by the forces of Islām may have contributed to the conservatism of the style but did not result in its total elimination, as seems to have been the case in eastern India. Indeed, in the course of its long life, the western Indian school became a national style, painting at other centres in India interpreting and elaborating its forms in their own individual manner. In the province of Orissa, painting on palm leaf and in a manner entirely dependent on the western Indian style has continued up to the present day.

Transition to the Mughal and Rajasthani styles. The belief held earlier by scholars that the new Islāmic rulers of India did not patronize any painting until the rise of the Mughal dynasty in the 16th century is being abandoned in the face of the literary testimony and the discovery or recognition of illustrated manuscripts that were painted at Indian courts. Nor should this be surprising, as the Muslim kings of India had before them the example of other rulers of the Islāmic world who were great patrons of painting in spite of the injunctions of orthodox Islām against the portrayal of living beings. The taste of these Indian rulers, however, did not turn to the western Indian style but to the flourishing traditions of Islāmic painting abroad, notably neighbouring Iran. As many painters as architects had in all probability been invited from foreign countries; and illustrated manuscripts, handily transported, must have been easily available. As a result there appears to have developed what can only be called an Indo-Persian style, based essentially on the schools of Iran but affected to a greater or lesser extent by the individual tastes of the Indian rulers and by the local styles. The earliest known examples are paintings dating from the 15th century onward. The most important are the *Khamseh* ("Quintet") of Amīr Khosrow of Delhi (Freer Gallery of Art, Washington, D.C.), a *Bostān* painted in Mandu (National Museum, New Delhi), and, most interesting of all, a manuscript of the *Neʿmat-nāmeh* (India Office Library, London) painted for a sultan of Mālwa in the opening years of the 16th century. Its illustrations are derived from the Turkmen style of Shīrāz but show clear Indian features adapted from the local version of the western Indian style.

Fifteenth-century changes in western Indian style

Though the western Indian style was essentially conservative, it was not unfailingly so. It began to show signs of an inner change most notably in two manuscripts from Mandu, a *Kalpa-sūtra* and a *Kālakācāryakathā* of about 1439, and a *Kalpa-sūtra* painted at Jaunpur in 1465. These works were done in the opulent manner of the 15th century, but for the first time the quality of the line is different, and the uncompromisingly abstract expression begins to make way for a more human and emotional mood. By the opening years of the 16th century, a new and vigorous style had come into being. Although derived from the western Indian style, it is clearly independent, full of the most vital energy, deeply felt, and profoundly moving. The earliest dated example is an *Āraṇyaka Parva* of the *Mahābhārata* (1516; The Asiatic Society of Bombay), and among the finest are series illustrating the *Bhāgavata-Purāṇa* and the *Caurapañcāśikā* of Bilhaṇa, scattered in collections all over the world. A technically more refined variant of this style, preferring the pale, cool colours of Persian derivation, a fine line, and meticulous ornamentation, exists contemporaneously and is best illustrated by a manuscript of the ballad *Candāmyana* by Mullā Dāūd (*c.* first half of the 16th century; Prince of Wales Museum of Western India, Bombay). The early 16th century thus appears to have been a period of inventiveness and set the stage for the development of the Mughal and Rājput schools, which thrived from the 16th to the 19th century.

Mughal style: Akbar period (1556–1605). Although the Mughal dynasty came to power in India with the great victory won by Bābar at the Battle of Pānīpat in 1526, the Mughal style was almost exclusively the creation of Akbar. Trained in painting at an early age by a Persian master, Khwāja ʿAbd-uṣ-Ṣamad, who was employed by his father, Humāyūn, Akbar created a large atelier, which he staffed with artists recruited from all parts of India. The atelier, at least in the initial stages, was under the superintendence of Akbar's teacher and another great Persian master, Mīr Sayyid ʿAlī; but the distinctive style that evolved here owed not a little to the highly individual tastes of Akbar himself, who took an interest in the work, inspecting the atelier frequently and rewarding painters whose work was pleasing.

The technique of Mughal painting

The work of the Mughal atelier in this early formative stage was largely confined to the illustration of books on a wide variety of subjects: histories, romances, poetic works, myths, legends, and fables, of both Indian and Persian origin. The manuscripts were first written by calligraphers, with blank spaces left for the illustrations. These were executed largely by groups of painters, including a colourist, who did most of the actual painting, and specialists in portraiture and in the mixing of colours. Chief of the group was the designer, generally an artist of top quality, who formulated the composition and sketched in the rough outline. A thin wash of white, through which the initial drawing was visible, was then applied and the colours filled in. The colourist's work proceeded slowly, the colour being applied in several thin layers and frequently rubbed down with an agate burnisher, a process that resulted in the glowing, enamel-like finish. The colours used were mostly mineral but sometimes consisted of vegetable dyes; and the brushes, many of them exceedingly fine, were made from squirrel's tail or camel hair.

The earliest paintings (*c.* 1560–70) of the school of Akbar are illustrations of *Ṭūṭī-nāmeh* ("Parrot Book; Cleveland Museum of Art) and the stupendous illustrations of the *Dāstān-e Amīr Ḥamzeh* ("Stories of Amīr Ḥamzeh"; Österreichisches Museum für Angewandte Kunst, Vienna), which originally consisted of 1,400 paintings of an unusually large size (approximately 25 inches by 16 inches [65 by 40 centimetres]), of which only about 200 have survived. The *Ṭūṭī-nāmeh* shows the Mughal style in the process of formation: the hand of artists belonging to the various non-Mughal traditions is clearly recognizable, but the style also reveals an intense effort to cope with the demands of a new patron. The transition is achieved in the *Dāstān-e Amīr Ḥamzeh,* in which the uncertainties are overcome in a homogeneous style, quite unlike Persian work in its leaning toward naturalism and filled with swift, vigorous movement and bold colour. The forms are individually modelled, except for the geometrical ornament used as architectural decor; the figures are superbly interrelated in closely unified compositions, in which depth is indicated by a preference for diagonals; and much attention is paid to the expression of emotion. One of the last manifestations of this bold and vigorous early manner is the *Dārāb-nameh (c.* 1580) in the British Museum.

Immediately following were some very important historical manuscripts, including the *Tārīkh-e Khāndān-e Tīmūrīyeh* ("History of the House of Timūr," *c.* 1580–85; Khuda Baksh Library, Patna) and other works concerned with the affairs of the Tīmūrid dynasty, to which the Mughals belonged. Each of these manuscripts contains several hundred illustrations, the prolific output of the atelier made possible by the division of labour that was in effect. Historical events are recreated with remarkable inventiveness, though the explosive and almost frantic energy of the *Dāstān-e Amīr-Ḥamzeh* has begun to subside. The scale was smaller and the work began to acquire a studied richness. The narrative method employed by these Mughal paintings, like that of traditional literature, is infinitely discursive; and the painter did not hesitate to provide a fairly detailed picture of contemporary life—both of the people and of the court—and of the rich fauna and flora of India. Like Indian artists of all periods, the Mughal painter showed a remarkable empathy for animals, for through them flows the same life that flows through human beings. This sense of kinship allowed him to achieve unqualified success in the illustration of animal fables such as the *Anwār-e Suhaylī* ("Lights of Caropus"), of which several copies were painted, the earliest dated 1570 (School of Oriental and African Studies, London). It was in the illustrations to Persian translations of the Hindu epics, the *Mahābhārata* and the *Rāmāyaṇa,* that the Mughal painter revealed to the full the richness of his imagination and his unending resourcefulness. With little precedent to rely on, he was nevertheless seldom dismayed by the subject and created a whole series of convincing compositions. Because most of the painters of the atelier were Hindus, the subjects must have been close to their hearts; and, given the opportunity by a tolerant and sympathetic patron, they rose to great heights. It is no wonder, therefore, that the *Razm-nāmeh* (City Palace Museum, Jaipur), as the *Mahābhārata* is known in Persian, is one of the outstanding masterpieces of the age.

Illustrations for Persian translations of Hindu epics

In addition to large books containing numerous illustrations, which were the products of the combined efforts of many artists, the imperial atelier also cultivated a more intimate manner that specialized in the illustration of books, generally poetic works, with a smaller number of illustrations. The paintings were done by a single master artist who, working alone, had ample scope to display his virtuosity. In style the works tend to be finely detailed and exquisitely coloured. A *Dīvān* ("Anthology") of Anwarī (Fogg Art Museum, Cambridge, Massachusetts), dated 1589, is a relatively early example of this manner. The paintings are very small, none larger than five inches by $2^1/_2$ inches (12 by 6 centimetres) and most delicately executed. Very similar in size and quality are the miniatures illustrating the *Dīvān* of Ḥāfeẓ (Reza Library, Rāmpur). On a larger scale but in the same mood are the manuscripts that represent the most delicate and refined works of the reign of Akbar: the *Bahāristān* of Jāmī (1595; Bodleian Library, Oxford), a *Khamseh* of Neẓāmī (1593; British Museum, London), a *Khamseh* of Amīr Khosrow (1598; Walters Art Gallery, Baltimore and Metropolitan Museum of Art, New York), and an *Anwār-e Suhaylī* (1595–96; Bharat Kala Bhavan, Vārānasī).

Also prepared in the late 1590s were magnificent copies

of the *Akbar-nāmeh* ("History of Akbar"; Victoria and Albert Museum, London) and the *Kitāb-e Changīz-nāmeh* ("History of Genghis Khan"; Gulistan Library, Tehrān). These copiously illustrated volumes were produced by artists working jointly, but the quality of refinement is similar to that of the poetic manuscripts.

Of the large number of painters who worked in the imperial atelier, the most outstanding were Dasvant and Basāvan. The former played the leading part in the illustration of the *Razm-nāmeh.* Basāvan, who is preferred by some to Dasvant, painted in a very distinctive style, which delighted in the tactile and the plastic, and with an unerring grasp of psychological relationships.

Mughal style: Jahāngīr period (1605–27). The emperor Jahāngīr, even as a prince, showed a keen interest in painting and maintained an atelier of his own. His tastes, however, were not the same as those of his father, and this is reflected in the painting, which underwent a significant change. The tradition of illustrating books began to die out, though a few manuscripts, in continuation of the old style, were produced. For Jahāngīr much preferred portraiture; and this tradition, also initiated in the reign of his father, was greatly developed. Among the most elaborate works of his reign are the great court scenes, several of which have survived, showing Jahāngīr surrounded by his numerous courtiers. These are essentially large-scale exercises in portraiture, the artist taking great pains to reproduce the likeness of every figure.

ortraiture

The compositions of these paintings have lost entirely the bustle and movement so evident in the works of Akbar's reign. The figures are more formally ordered, their comportment in keeping with the strict rules of etiquette enforced in the Mughal court. The colours are subdued and harmonious, the bright glowing palette of the Akbarī artist having been quickly abandoned. The brushwork is exceedingly fine. Technical virtuosity, however, is not all that was attained, for beneath the surface of the great portraits of the reign there is a deep and often spiritual understanding of the character of the person and the drama of human life.

Many of the paintings produced at the imperial atelier are preserved in the albums assembled for Jahāngīr and his son Shāh Jahān. The Muraqqah-e Gulshan is the most spectacular. (Most surviving folios from this album are in the Gulistan Library in Tehrān and the Staatliche Museen Preussischer Kulturbesitz, Berlin; a section is temporarily housed in Tübingen.) There are assembled masterpieces from Iran, curiosities from Europe, works produced in the reign of Akbar, and many of the finest paintings of Jahāngīr's master painters, all surrounded by the most magnificent borders decorated with a wide variety of floral and geometrical designs. The album gives a fairly complete idea of Jahāngīr as a patron, collector, and connoisseur of the arts, revealing a person with a wide range of taste and a curious, enquiring mind.

Jahāngīr esteemed the art of painting and honoured his painters. His favourite was Abū al-Hasan, who was designated Nādir-uz-Zamān ("Wonder of the Age"). Several pictures by the master are known, among them a perceptive study of Jahāngīr looking at a portrait of his father. Also much admired was Ustād Manṣūr, designated Nādir-ul-ʿAṣr ("Wonder of the Time"), whose studies of birds and animals are unparalleled. Bishandās was singled out by the emperor as unique in the art of portraiture. Manohar, the son of Basāvan, Govardhan, and Daulat are other important painters of this reign.

Mughal style: Shāh Jahān period (1628–58). Under Shāh Jahān, attention seems to have shifted to architecture, but painting in the tradition of Jahāngīr continued. The style, however, becomes noticeably rigid. The portraits resemble hieratic effigies, lacking the breath of life so evident in the work of Jahāngīr's time. The colouring is jewel-like in its brilliance, and the outward splendour quite dazzling. The best work is found in the *Shāhjahānnāmeh* ("History of Shāh Jahān") of the Windsor Castle Library and in several albums assembled for the emperor. Govardhan and Bichitra, who had begun their careers in the reign of Jahāngīr, were among the outstanding painters; several

works by them are quite above the general level produced in this reign.

Genre scenes

Mughal style: Aurangzeb and the later Mughals (1659–1806). From the reign of Aurangzeb (1659–1707), a few pictures have survived that essentially continue the cold style of Shāh Jahān; but the rest of the work is nondescript, consisting chiefly of an array of lifeless portraits, most of them the output of workshops other than the imperial atelier. Genre scenes, showing gatherings of ascetics and holy men, lovers in a garden or on a terrace, musical parties, carousals, and the like, which had grown in number from the reign of Shāh Jahān, became quite abundant. They sometimes show touches of genuine quality, particularly in the reign of Muḥammad Shāh (1719–48), who was passionately devoted to the arts. This brief revival, however, was momentary, and Mughal painting essentially came to an end during the reign of Shāh ʿĀlam II (1759–1806). The artists of this disintegrated court were chiefly occupied in reveries of the past, the best work, for whatever it is worth, being confined to copies of old masterpieces still in the imperial library. This great library was dispersed and destroyed during the uprising of 1857 against the British.

Company school. Rising British power, which assumed political supremacy in the 19th century, resulted in a radical change of taste brought about by the Westernization of important segments of the population. Heavily influenced by Western ideas, a style emerged that represented the adjustment of traditional artists to new fashions and demands. Rooted at Delhi and the erstwhile provincial Mughal capitals of Murshidābād, Lucknow, and Patna, it ultimately spread all over India. Most of the works produced were singularly impoverished, but occasionally there were some fine studies of natural life.

Deccani style. In mood and manner, Deccani painting, which flourished over much of the Deccan Plateau from at least the last quarter of the 16th century, is reminiscent of the contemporary Mughal school. Again, a homogeneous style evolved from a combination of foreign (Persian and Turkish) and Indian elements, but with a distinct local flavour. Of the early schools, the style patronized by the sultans of Bijāpur—notably the tolerant and art-loving Ibrāhīm ʿĀdil Shāh II of Bijāpur, famous for his love of music—is particularly distinguished. Some splendid portraits of him, more lyrical and poetic in concept than contemporary Mughal portraits, are to be found. A wonderful series depicting symbolically the musical modes (*rāgamālā*) also survives. Of illustrated manuscripts, the most important are the *Nujūm-ul-ʿulūm* ("The Stars of the Sciences," 1590; Chester Beatty Library, Dublin) and the *Tārīf-e Ḥuseyn-Shāhī* (Bharata Itihasa Samshodhaka Mandala, Pune), painted around 1565 in the neighbouring state of Ahmadnagar. The sultanate of Golconda also produced work of high quality—for example, a manuscript of the *Dīvān* of Muḥammad Qulī Quṭb Shāh in the Salar Jang Library, Hyderābād, and a series of distinguished portraits up to the end of the 17th century (dispersed in various collections). The state of Hyderābād, founded in the early 18th century and headed by a grandee of the Mughal Empire, was a great centre of painting. The work that was produced there reflects both Golconda traditions and increasing Mughal and Rajasthani influences.

The Hindu basis of Rajasthani style

Rajasthani style. This style appears to have come into being in the 16th century, about the same time the Mughal school was evolving under the patronage of Akbar; but, rather than a sharp break from the indigenous traditions, it represented a direct and natural evolution. Throughout the early phase, almost up to the end of the 17th century, it retained its essentially hieratic and abstract character, as opposed to the naturalistic tendencies cultivated by the Mughal atelier. The subject matter of this style is essentially Hindu, devoted mainly to the illustration of myths and legends, the epics, and above all the life of Krishna; particularly favoured were depictions of his early life as the cowherd of Vraja, and the mystical love of Vraja's maidens for him, as celebrated in the *Bhāgavata-Purāṇa,* the *Gītagovinda* of Jayadeva, and the Braj Bhasa verses written by Sūrdās and other poets. The style of the painting, no less than the literature, is a product of the new religious movements, all of which stressed personal devotion to Krishna as the way to salvation. Related popular themes were pictorial representations of the musical modes (*rāgamālā*) and illustrations of poetical works such as the *Rasikapriyā* of Keśavadāsa, which dealt with the sentiment of love, analyzing its varieties and endlessly classifying the types of lovers and beloveds and their emotions. Portraits, seldom found in the early phase, became increasingly common in the 18th century—as did court scenes, scenes of sporting and hunting events, and other scenes concerned with the courtly life of the great chiefs and feudal lords of Rājasthān.

The Rajasthani style developed various distinct schools, most of them centring in the several states of Rājasthān, namely Mewār, Būndi, Kotah, Mārwār, Bīkaner, Kishangarh, and Jaipur (Amber). It also had centres outside the geographical limits of present-day Rājasthān, notably Gujarāt, Mālwa, and Bundel Khand. The study of Rajasthani painting is still in its infancy, for most of the material has been available for study only since the mid-1940s.

The Mughal and Rajasthani styles were always in contact with each other, but in general the Rajasthani schools were not essentially affected by the work produced at the Mughal court during the greater part of the 17th century. This became less true in the 18th century, when the sharp distinction between the two became progressively obscured, though each retained its distinctive features right up to the end.

Rajasthani style: Mewār. The Mewār school is among the most important. The earliest dated examples are represented by a *rāgamālā* series painted at Chawand in 1605 (Gopi Krishna Kanoria Collection, Patna). These simple paintings, filled with bright colour, are only a step removed from the pre-Rajasthani phase. The style became more elaborate in the first quarter of the 17th century when another *rāgamālā,* painted at Udaipur in 1628 (formerly in the Khajanchi Collection, Bīkaner; now dispersed in various collections), showed some superficial acquaintance with the Mughal manner. This phase, lasting until around 1660, was one of the most important for the development of painting all over Rājasthān. Ambitious and extensive illustrations of the *Bhāgavata,* the *Rāmāyaṇa,* the poems of Sūrdās, and the *Gītagovinda* were completed, all full of strength and vitality. The name of Sāhabadī is intimately connected with this phase; another well-known painter is Manohar. The intensity and richness associated with their

atelier began to fade toward the close of the 17th century, and a wave of Mughal influence began to affect the school in the opening years of the 18th century. Portraits, court scenes, and events in the everyday world of the ruling classes are increasingly found. Although the emotional fervour of the 17th century was never again attained, this work is often of considerable charm. The 19th century continued to create work in the tradition of the 18th, one of the most important centres being Nāthdwāra (Rājasthān), the seat of the Vallabha sect. Large numbers of pictures, produced here for the pilgrim trade, were spread over all parts of Rājasthān, northern India, Gujarāt, and the Deccan.

arliest xamples f Būndi hool

Rajasthani style: Būndi and Kotah. A school as important as that of Mewār developed at Būndi and later at Kotah, which was formed by a partition of the parent state and ruled by a junior branch of the Būndi family. The earliest examples are represented by a *rāgamālā* series of extraordinarily rich quality, probably dating from the end of the 16th century. From the very beginning the Būndi style seemed to have found Mughal painting an inspiring source, but its workmanship was as distinctively Rajasthani as the work of Mewār. The artists of this school always displayed a pronounced preference for vivid movement, which is unique in all of Rājasthān. Toward the second half of the 17th century, work at Būndi came unmistakably under the influence of Mewār; many miniatures, including several series illustrating the *Rasikapriyā,* indicate that this was a period of prolific activity. The sister state of Kotah also appears to have become an important centre of painting at this time, developing a great fondness for hunting and sport scenes, all filled with great vigour and surging strength. This kind of work continued well into the 19th century, and if the workmanship is not always of the highest quality, the style maintained its integrity against the rapidly increasing Western influence right up to the end.

Rajasthani style: Mālwa. It has been suggested but not definitely determined that the school itself does not belong to Mālwa but to some other area, probably Bundelkhand. In contrast to the Būndi school, miniatures generally thought to have been painted in Mālwa are quite archaistic, with mannerisms inherited from the 16th century retained until the end of the 17th. The earliest work is an illustrated version of the *Rasikapriyā* (1634), followed by a series illustrating a Sanskrit poem called the *Amaru Śataka* (1652). There are also illustrations of the musical modes (*rāgamālā*), the *Bhāgavata-Purāṇa,* and other Hindu devotional and literary works. The compositions of all of these pictures is uncompromisingly flat, the space divided into registers and panels, each filled with a patch of colour and occupied by figures that convey the action. This conservative style disappeared after the close of the 17th century. The course of Mālwa painting in the 18th century and later is not known.

Rajasthani style: Mārwār. A *rāgamālā* series dated 1623 reveals that painting in this state shared features common to other schools of Rājasthān. Miniatures of the second half of the 17th century are distinguished by some splendid portraits that owe much to the Mughal school. A very large amount of work was done in the 19th century, all of which is highly stylized but strong in colour and often of great charm.

Rajasthani style: Bīkaner. Of all Rajasthani schools, the Bīkaner style, from its very inception in the mid-17th century, shows the greatest indebtedness to the Mughal style. This is due to the presence in the Bīkaner atelier of artists who had previously worked in the Mughal manner at Delhi. They and their descendants continued to paint in a style that could only be classed as a provincial Mughal manner had it not been for the quick absorption of influences from the Rajasthani environment and a sympathy for the religious and literary themes favoured by the royal Hindu patrons. Delicacy of line and colour are consistent characteristics of Bīkaner painting even when, toward the end of the 18th century, it assumed stylistic features associated with the more orthodox Rajasthani schools.

Characteristics of the Bīkaner style

Rajasthani style: Kishangarh. The Kishangarh school, which came into being toward the mid-18th century, was also indebted to the contemporary Mughal style but combined a rich and refined technique with deeply moving religious fervour. Its inspiring patron in the formative phase was Sāvant Singh, more of a devotee and a poet than a king. The style established by him, characterized by pronounced mystical leanings and a distinctive facial type, continued to the middle of the 19th century, though at a clearly lower level of achievement.

were closely allied to the Mughal dynasty, but paintings of the late 16th and early 17th centuries possessed all of the elements of the Rajasthani style. Little is known about the school until the opening years of the 18th century, when stiff, formal examples appear in the reign of Savāī Jai Singh. The finest works, dating from the reign of Pratāp Singh, are sumptuous in effect and include some splendid portraits and some large paintings of the sports of Krishna. Although the entire 19th century was extremely productive, the work was rather undistinguished and increasingly affected by Western influences. Of the Rajasthani styles of this period, the Jaipur school was the most popular, examples having been found all over northern India.

Pahari style. Closely allied to the Rajasthani schools both in subject matter and technique is the Pahari style, so-named because of its prevalence in the erstwhile hill states of the Himalayas, stretching roughly from Jammu to Gaṛhwāl. It can be divided into two main schools, the Basohlī and the Kāngra, but it must be understood that these schools were not confined to the centres after which they are named but extended all over the area. Unlike Rājasthān, the area covered by the Pahari style is small, and the probability of artists travelling from one area to another in search of livelihood was much greater. Thus, attempts to distinguish regional schools are fraught with controversy, and it has been suggested that a classification based upon ateliers and families is likely to be more tenable than those presently current among scholars. Because the Basohlī and the Kāngra schools show considerable divergences, scholars have postulated the existence of a transitional phase, named the pre-Kāngra style.

Pahari style: Basohlī school. The origins of this remarkable style are not yet understood, but it is clear that the style was flourishing toward the close of the 17th century. The earliest dated paintings are illustrations to the *Rasamañjarī* of Bhānudatta (a Sanskrit work on poetics), executed for a ruler of Basohlī (1690; Boston Museum of Fine Arts). Bold colour, vigorous drawing, and primitive intensity of feeling are outstanding qualities in these paintings, quite surpassing the work of the plains. In addition to other Hindu works such as the *Gītagovinda* and the *Bhāgavata-Purāṇa,* a fairly large number of idealized portraits have also been discovered.

Pahari style: Kāngra school. The Basohlī style began to fade by the mid-18th century, being gradually replaced by the Kāngra style, named after the state of Kāngra but, like the Basohlī style, of much wider prevalence. A curvilinear line, easy flowing rhythms, calmer colours, and a mood of sweet lyricism easily distinguish the work from that of the Basohlī style. The reasons for this change are to be sought in strong influences from the plains, notably the Mughal styles of Delhi and Lucknow. These influences account for the more refined technique; but whatever was borrowed was transmuted and given a fresh and tender aspect. Among the greatest works are large series illustrating the *Bhāgavata-Purāṇa* (National Museum, New Delhi), the *Gītagovinda,* and the *Satsaī* of Bihārī (both in the collection of the maharaja of Tehrī-Garhwāl), all painted in 1775–80. The corpus of work produced is very large and, although it seldom fails to please, works of high achievement are rare. The school flourished from about 1770 to almost the end of the 19th century, but the finest work was produced largely around 1775–1820.

Modern period. Toward the late 19th century traditional Indian painting was rapidly dying out, being replaced by feeble works in a variety of idioms, all strongly influenced by the West. A reaction set in during the early 20th century, symbolized by what is called the Bengal school. The glories of Indian art were rediscovered, and the school consciously tried to produce what it considered a truly Indian art inspired by the creations of the past. Its leading artist was Rabindranath Tagore and its theoretician was E.B. Havell, the principal of the Calcutta School of Art. Nostalgic in mood, the work was mainly sentimental though often of considerable charm. The Bengal school did a great deal to reshape contemporary taste and to make Indian artists aware of their own heritage. Amrita Sher-Gil, who was inspired by the Postimpressionists, made Indian painters aware of new directions. Mid-20th-century Indian painting is very much a part of the international scene, the artists painting in a variety of idioms, often attempting to come to terms with their heritage and with the emergence of India as a modern culture.

The Beng
school

Decorative arts. Fragmentary ivory furniture (*c.* 1st century AD) excavated at Begrām is one of the few indications of the existence in ancient India of a secular art concerned with the production of luxurious and richly decorated objects meant for daily use. Objects that can be clearly designated as works of decorative art become much more extensive for the later periods, during which Islāmic traditions were having a profound effect on Indian artistic traditions. The reign of the Mughal emperors, in particular, produced works of the most elaborate and exquisite craftsmanship; the decorative tradition is clearly preserved in architectural ornament, though surviving decorative objects themselves, particularly before the 17th century, are far fewer than might be expected. Economic conditions, including competition with machine-made goods imported from English factories, and a change in taste from increasing European influence had disastrous consequences for traditional craftsmanship, especially in the late 19th and 20th centuries.

Pre-Islāmic period. Of the very few objects surviving from the pre-Islāmic period, the most important are fragments of ivory caskets, chairs, and footstools found at Begrām, in eastern Afghanistan, but obviously of Indian origin and strongly reminiscent of the school of Mathurā in the 1st century AD. The work is profusely decorated with carved panels and confirms the wide reputation for superb ivories that India had in ancient times. Nothing as spectacular has come down from the succeeding periods, but stray examples such as the so-called Charlemagne chessman (*c.* 8th century; Cabinet des Medailles, Paris) and two magnificent throne legs, of Orissan workmanship, carved in the shape of griffins with elephant heads (13th century; Freer Gallery of Art, Washington D.C., and Philadelphia Museum of Art), indicate that ivory craftsmanship was always vital. Ancient traditions, relatively unaffected by Islāmic influence, continued in southern India up to modern times. An exquisitely carved box from Vijayanagar (16th century; Prince of Wales Museum of Western India, Bombay) is representative; many other exquisite objects of this period and later are among the treasures of South Indian temples.

P. Chandra

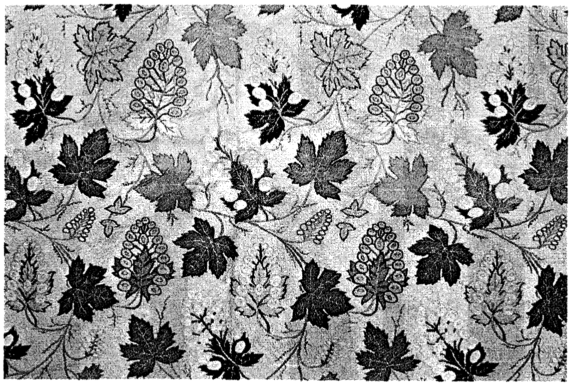
There is even less evidence of what the decorative work in metal was like. The practice of re-using the metal by melting unserviceable items may account for the paucity of objects, for there is little doubt that the craft was always flourishing. A hoard found at Kolhāpur, consisting of plates, various kinds of vessels, lamps and *objets d'art,* including a superb bronze elephant with riders, constitutes the most important surviving group of metal objects and is datable to about the 2nd century AD. Some fine examples of ritual utensils, notably elaborate incense burners, of the 8th–9th century have been excavated at Nālandā; and a large number of 14th-century ceremonial vessels of complex design and excellent workmanship, and apparently belonging to the local temple, were discovered at Kollur, in Mysore state.

Gold played an extremely important role in the manufacture of jewelry, but once again the finds are hardly commensurate with tradition. Small amounts of gold jewelry have been excavated at Mohenjo-daro and Harappā (3rd millennium BC); and, in the historical period, a very important group, of delicate workmanship, has been excavated at Taxila (*c.* 2nd century AD).

From earliest times, India has been famous for the variety and magnificence of its textiles. In this case, however, the Indian climate has been particularly destructive; virtually nothing has survived the heat and moisture. Besides the testimony of literature and the evidence of figural sculpture, only a few fragments of printed textiles are preserved—at Fusṭāṭ in Egypt, where they had been exported. These date approximately to the 14th century.

Islāmic period. Traditions of craftsmanship established during the Islāmic period came to full flower during the reign of the Mughal dynasty. Surviving works of decorative art are more abundant, though once again there are hardly as many examples as might be expected, particularly from the 16th and 17th centuries. According to literary testimony and the few available examples, the finest objects were undoubtedly made in the imperial workshops set up in large number at the capital and in the great cities of the empire, where they were nourished by local traditions. Well-organized, these shops specialized in particular items, such as textiles, carpets, jewelry, ornamental arms and armour, metalware, and jade. Textile manufacture must have been enormous, considering the demands of court and social etiquette and ritual. Contributing to the popularity of tapestries, curtains, draperies, canopies, and carpets in contemporary architecture were the nomadic tenting traditions of the Mughal rulers.

P. Chandra



Detail of a Kashmir shawl, wool embroidery, 19th century. In the Prince of Wales Museum of Western India, Bombay.

Popularity of textiles

The variety of techniques employed in the manufacture of textiles was infinite, ranging from printed and painted patterns to the exquisite embroidery decoration of woolen shawls and the costly figured brocading of silk. An important contribution to carpet weaving was the landscape carpet that reproduced pictorial themes inspired by miniature painting. Much of the surviving textile work dates from the 18th century or later, though the 16th and 17th centuries produced works of the most outstanding quality.

In response to growing European trade, a considerable amount of furniture (chairs, cabinets, chests of drawers, and the like) was produced, mostly wood inlaid with ivory. Many of these pieces have been preserved in the kinder European climate. Although the furniture made for export gives some idea of the craft in India, it must be emphasized that only the ornamental and figural work was Indian, while the form was European. Also in a hybrid Indō-European style were the Christian objects produced by a local school of ivory carvers at Goa.

Metal objects of sumptuous quality were also made, a unique example of which is a splendid, elaborately chiselled 16th-century cup in the Prince of Wales Museum of Western India in Bombay. This tradition was continued in the 17th and particularly the 18th century, when vessels made of a variety of metals and adorned with engraved, chiselled, inlaid, and enamelled designs were very popular. Arms and armour, in particular, were decorated with the skill of a jeweler. Particularly striking are the carved hilts, often done in animal shapes.

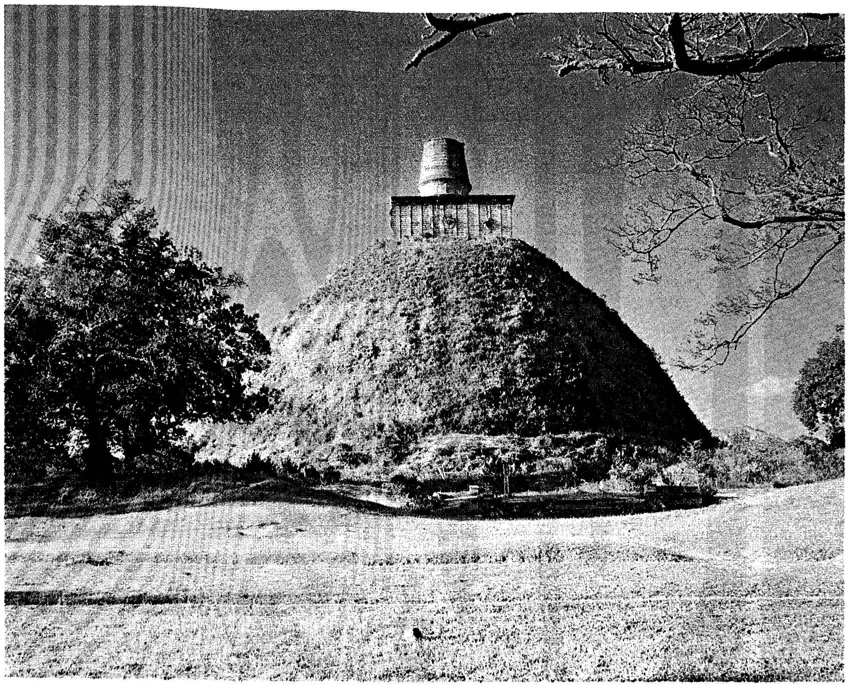
Jade or jadeite was much fancied by the rich and was used together with crystal to make precious vessels as well as sword and dagger hilts. A rather large number of 18th- and 19th-century objects have survived, but they are often of nondescript quality. The greatest period for jade carving seems to have been the 17th century; a few outstanding examples associated with the emperors Jahāngīr and Shāh Jahān are of singular delicacy and perfection. The practice of inlaying jade, and also stone, with precious or semiprecious stones became more popular with the reign of Shāh Jahān and increasingly characteristic of Indian jade craftsmanship from that time on.

Architectural decoration provides a clear idea of the range of ornamental patterns used by the Mughal artist. They consisted mainly of arabesques (intricate interlaced patterns made up of flower, foliage, fruit, and sometimes animal and figural outlines) and infinitely varied geometric patterns—motifs shared with the rest of the Muslim world—together with floral scrolls and other designs adapted from Indian traditions. As a whole, the Mughal decorative style tends to endow ornamental patterns with a distinctive plasticity not seen in the more truly two-dimensional Iranian and Arab work. From the 17th century, a type of floral spray became the most favoured motif and was found on almost every decorated object. The motif, symmetrical but relatively naturalistic at the beginning, became progressively stiff and stylized, but never lost its importance in the ornamental vocabulary.

VISUAL ARTS OF SRI LANKA (CEYLON)

Distinction between art of Sri Lanka and that of India

The art of Sri Lanka is closely allied to that of India but presents several distinctive features that make a separate treatment convenient. There is, first, the considerable transformation of Indian influences, resulting in an idiom of great power and individuality. Sri Lanka also often served as a geographical pocket in which styles that had disappeared in India were preserved, which accounts for the anachronistic features of some phases of Sinhalese art. It also appears that although predominant influences were from neighbouring southern India, this was not exclusively

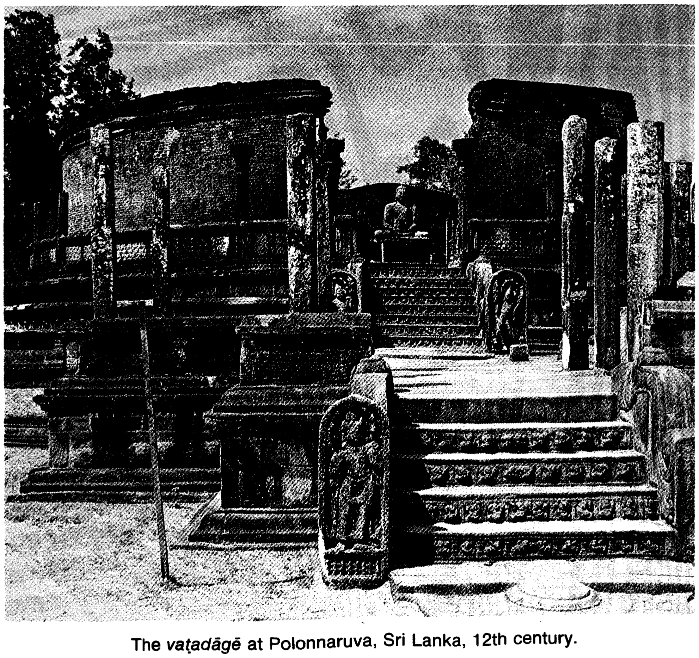


Abhayagiri *dagāba* in the Jetavana at Anurādhapura, Sri Lanka, *c.* 4th century.
ZEFA

so, and styles flourishing in western and northern India, too, contributed to the formulation of Sinhalese art. The difficulties in the study of the art are considerable: the long, unbroken Buddhist traditions and the piety of the rulers and the people have led to the successive renovation of monuments; and in the absence of firmly dated monuments, one of the few relatively reliable tools of study is comparison with Indian art, an approach full of pitfalls and shortcomings.

Architecture. The most impressive monuments are the great *stūpa*s, some of gigantic size and considerable antiquity but often reconstructed in the course of the centuries. They generally have a triple circular base, and as in early Indian *stūpa*s, a hemispherical dome with a miniature railing on top, and a multiple parasol that tends to solidify into a conical structure in the course of time. The material is brick, sometimes covered with plaster and white paint. An important feature are the platforms (*vāhalakaḍa*s) at the cardinal points, often adorned with sculpture. There are many *stūpa*s at the ancient capital of Anurādhapura, at Polonnaruva, and at other sites; of these the Jetavana at Anurādhapura is the largest, though now largely ruined.

ZEFA



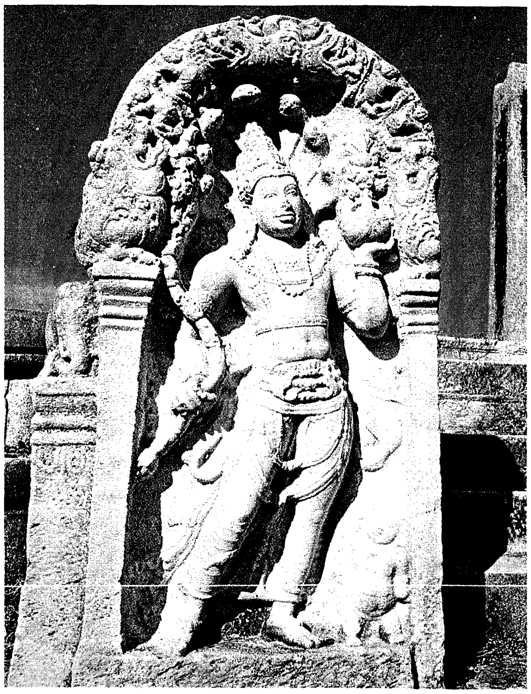
The *vaṭadāgē* at Polonnaruva, Sri Lanka, 12th century.

Small *stūpa*s were often placed in a circular building with a domical metal and timber roof supported by concentric rows of stone pillars. This type of building, known in ancient India as the *caityagṛha,* was very popular in Sri Lanka, though it had disappeared at a fairly early period in the country of its origin. A famous example is the *vaṭadāgē* at Polonnaruva, a structure of great elegance. The dome itself, being of perishable material, has not survived. The *geḍigē,* or large rectangular hall with a corbelled brick vault, housing a Buddha image, is first found in Sri Lanka from the 8th century AD; the most impressive example is the Laṅkātilaka at Polonnaruva built by Parākramabāhu I in the 12th century.

Literature testifies to the existence of elaborate royal and priestly residences of wood, which have largely disappeared. The Lohapāsāda at Anurādhapura, traditionally ascribed to Duṭṭhagāmaṇi (101–77), was originally a nine-story building, now destroyed except for the large number of stone pillars that supported the upper floors. Sigiriya, a 6th-century fortress city with extensive remains, is another notable example of secular architecture.

Sculpture. The earliest sculpture, perhaps, is from the platforms, or *vāhalakaḍa*s, of the Kanṭaka Cetiya, at Mihintalē, and reveals an archaistic style indebted to 1st-century-BC Indian sculpture of Sānchi and Amarāvatī regions. A certain simplicity and restraint characteristic of most Sinhalese work is present even at this early stage. The first Buddha images show a pronounced relationship to examples from Andhradeśa of the 2nd–3rd century AD but often possess considerable vigour, revealing the contribution of the local sculptor. Several fine images are known, one of the best of which is at Ruanveli, Anurādhapura, now very badly restored.

Dated monuments are absent from the 5th to the 12th centuries, but an approximate idea of stylistic development can be obtained by a comparative study of Indian examples. An outstanding image, rather hideously repaired in recent years, is a great seated Buddha in Anurādhapura, the smooth and abstract modelling of which recalls the school of Sārnāth of the 5th–6th century. At Isurumuni, near Anurādhapura, are some marvellous reliefs carved on rocks. One of these depicts elephants at play, and another, a seated man with the head of a horse carved in the background. These fine sculptures recall the South Indian style of the 7th century. A radiant amorous couple carved



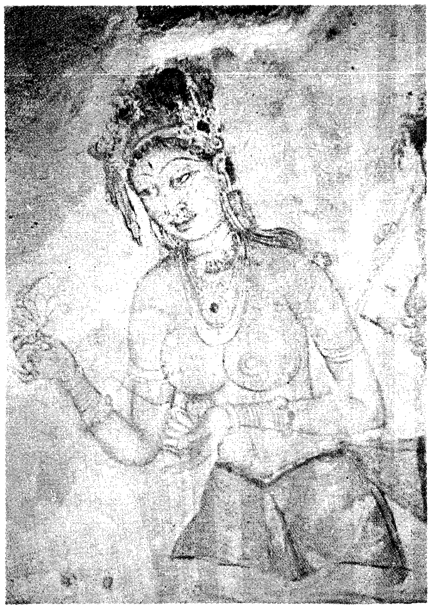
Nāga stele from Anurādhapura, Sri Lanka, 10th century.
George Holton—Photo Researchers

in relief on a stone slab, also at Isurumuni, represents Sinhalese sculpture at its most joyous.

culptured
:aircases

Of about the same period or a little later, are exquisitely sculptured staircases decorated with moonstones, and stelae, or commemorative pillars, carved with a guardian *nāga*, a spirit with combined superhuman and serpent qualities. The latter are among the finest examples of Sinhalese sculpture, the full and weighty modelling relieved by the skillful movement of clearly chiselled ornament. The Ratnapāsāda at Anurādhapura and the eastern staircase of the *vaṭadāgē* at Polonnaruva possess particularly superb specimens. Moonstones—decorated with bands of floral motifs, geese, and a row of animals consisting of a lion, bull, elephant, and horse—placed at the bottom of the staircase, testify to the great taste and elegance that mark Sinhalese decorative carving. At Anurādhapura and related sites a certain freedom characterizes the work, while the slightly later examples at Polonnaruva are stiffer but technically brilliant.

P. Chandra



Painted figure of an *apsaras* from Sigiriya, Sri Lanka, 6th century.

A colossal Buddha, 42 feet (13 metres) high, at Avukana, testifies to the increasing hardness of the Sinhalese style, which, even so, never ceases to be moving. Large images of the Buddha at the Gal Vihāra and a figure supposedly representing Parākramabāhu at Potgal Vihāra, both at Polonnaruva, are of the 12th century. They are figures of great majesty and surpass contemporary work in southern India. After the 13th century, Sinhalese sculpture began to decline, though work of some decorative value was produced up to the 19th century.

Painting. The rock at Sigiriya is adorned with a series of exquisitely painted *apsaras*es (nymphs) showering flowers, their torsos emerging from clouds. The paintings are dated to the 6th century AD; in their plastic resiliency they are reminiscent of contemporary work in India. The next important group of wall paintings come from Tivaṁkapatimā-ghara at Polonnaruva. Although dated to the 12th or 13th century, the figures continue to be modelled, relatively unaffected by the linear distortions of the western Indian style that was flourishing in India. Eighteenth-century paintings, with their flat figures arranged in horizontal rows, reflect contemporary styles of southern India. (P.Ch.)

BIBLIOGRAPHY

Literature: (Sanskrit, Pāli, and Prākrit): The old literature of Southeast Asia has been more extensively described than any of the modern literatures. Though antiquated, MORIZ WINTERNITZ, *Geschichte der indischen litteratur,* 3 vol. (1908–22; Eng. trans., *A History of Indian Literature,* 2nd ed. 1959–67), is still very useful. So is ARTHUR B. KEITH, *A History of Sanskrit Literature* (1928, reprinted 1956), which, however, does not include the Sanskrit theatre. For the old literature of the Veda, ARTHUR A. MACDONNELL, *A History of Sanskrit Literature* (1900), remains very helpful as a survey. A full inventory of the literature is given by S.N. DAS GUPTA and S.K. DE, *A History of Sanskrit Literature, Classical Period,* 2nd ed. (1962). The epochal material is best treated by EDWARD W. HOPKINS, *The Great Epic of India* (1901). On the Sanskrit play specifically, the study by the French scholar SYLVAIN LEVI, *Le Théâtre indien* (1890), remains an important contribution. The best introduction to the narrative literature is to be found in CHARLES H. TAWNEY (trans.), *The Ocean of Story,* ed. by NORMAN M. PENZER, 10 vol. (1923–28, reprinted 1968). GEORGE L. HART, *The Relation Between Tamil and Classical Sanskrit Literature* (1976), is an argument that the two literatures stem from a common source.

Modern Indian literatures: The literatures in the modern Indian languages are bibliographically underrepresented in English. For some of them the best sources are to be found written in those languages themselves. The following bibliography must confine itself to works written in more accessible languages. (*Hindi*): A good though incomplete inventory of the older literature in Hindi and Hindustani is found in JOSEPH GARCIN DE TASSY, *Histoire de la littérature hindouie et hindoustanie,* 2nd ed., 3 vol. (1870–71, reprinted 1968). A useful guide up to its date is EDWIN GREAVES, *A Sketch of Hindi Literature* (1918). A survey of the more modern literature in Hindi is R.A. DWIVELDI, *A Critical Survey of Hindi Literature* (1966). (*Assamese*): Among the few works available is B.K. BARUA, *Assamesè Literature* (1941) and *A History of Assamese Literature* (1965). (*Bengali*): The best extensive introduction to the literature in Bengali is that of SUKUMAR SEN, *History of Bengali Literature* (1960). Another useful source is J.C. GHOSH, *Bengali Literature* (1948). (*Marathi*): Many works on Marathi literature are written in Marathi itself. A good guide is G.C. BHATE, *History of Modern Marathi Literature, 1800–1938* (1939). (*Gujarati*): Little is written in English on Gujarati literature. To be recommended is K.M. MUNSHI, *Gujarāt and Its Literature from Early Times to 1852,* 3rd ed. (1967). A useful older study is K.M. JHAVERI, *Milestones in Gujarati Literature* (1914). (*Punjabi*): A good survey of Punjabi is given by MOHAN SINGH, *An Introduction to Panjabi Literature* (1951). For information about literature in the smaller Indo-Aryan languages, see the symposium of the All-India Writers' Conference, *Writers in Free India* (1950). (*Muslim contributions*): The best short introduction to the cultural and intellectual life of the Moslems of the subcontinent is AZIZ AHMAD, *An Intellectual History of Islam in India* (1969). A comprehensive survey of the literature in Urdu produced in South India, especially in the medieval kingdoms of Bijāpur and Golconda and in the later state Hyderābād is the Urdu work *Dekan men Urdu* by NASIRRUDDIN HASHMI (1963). A study of the convention of classical Urdu poetry in the light of the writings of three Urdu poets of 18th-century Delhi is RALPH RUSSELL and KHURSHIDUL ISLAM, *Three Mughal Poets: Mir, Sauda, Mir Ḥasan* (1968). The latest and most comprehensive survey of literature produced in Persian in various countries, including India and Pakistan, is JAN RYPKA, *History of Iranian Literature* (1968). A useful introduction is MUHAMMAD SADIQ, *A History of Urdu Literature* (1964). (*Tamil*): KAMIL V. ZVELEBIL, *Tamil Literature* (1974), is an introduction to and critical study of the literature. Much useful information is found in XAVIER S. THANI NAYAGAM, *A Reference Guide to Tamil Studies* (1966). Fuller treatment is given in C. and H. JESUDASAN, *A History of Tamil Literature* (1961). Especially recommended are also T.P. MEENAKSHISUNDARAM, *A History of Tamil Literature* (1965); and J.M. SOMASUNDARAM PILLAI, *A History of Tamil Literature with Texts and Translations from the Earliest Times to 600 A.D.* (1968). A good account of Telugu literature is P. CHENCHAYYA and R.M. BHUJANGA RAO BHADUR, *A History of Telugu Literature* (1928). More recent is P.T. RAJU, *Telugu Literature* (1944); and GIDUGU VENKAJA SITAPATI, *History of Telugu Literature* (1968). Very little has been written on Kannada literature. Mention can be made of the older EDWARD P. RICE, *A History of Kanarese Literature*, 2nd ed. rev. and enl. (1921); and of H. THIPPERUDA SWAMY, *The Vīraśaiva Saints* (1968). The literature in Malayalam is sketched in K.M. GEORGE, *A Survey of Malayalam Literature* (1968). Further mention can be made of K.K. NAIR, *A History of Malayalam Literature* (1971); and of P.K. PARAMESWARAN NAIR, *History of Malayalam Literature* (Eng. trans. 1967). Finally, among the very few books in English on the literature of Ceylon (Sri Lanka), prominent mention can be made of CHARLES EDMUND GODAKUMBURA, *The Literature of Ceylon* (1963).

Music: ARNOLD A. BAKE, "The Music of India," in *The New Oxford History of Music*, vol. 1 (1957), a general chapter on Indian music dealing with the philosophical background, Vedic chant, the ancient musical system, the modern classical system, and musical instruments; ELISE B. BARNETT, "Special Bibliography: The Art Music of India," *Ethnomusicology*, 14:278–312 (1970), a listing of books and articles on Indian music, published since 1959, which includes some publications on folk and religious music, dance, and drama; SUDHIBHUSHAN BHATTACHARYA, *Ethnomusicology and India* (1968), a synchronic approach attempting to relate folk, tribal, religious, and classical music in terms of the cultural background—includes outline notations in Indian *sargam;* ALAIN DANIELOU, *The Rāga-s of Northern Indian Music* (1968), an individualistic interpretation of modern North Indian *ragas,* based partly on ancient theory; B.C. DEVA, *Psychoacoustics of Music and Speech* (1967), a collection of articles on various aspects of music and speech, with emphasis on acoustics and the scientific study of Indian music; ARTHUR H. FOX-STRANGWAYS, *The Music of Hindostan* (1914, reprinted 1965), a work of wide scope including discussion of Vedic chant, folk music, and modern Indian classical music (includes notations in Western staff and analogies with Western music); O.C. GANGOLY, *Rāgas and Rāginīs*, 2 vol. (1934–35, reprinted 1948), a historical study that traces the systems of classifying *ragas* in Indian musical treatises, including a discussion of the time-theory of *ragas* as well as their iconography; NAZIR A. JAIRAZBHOY, *The Rāgas of North Indian Music* (1971), a technical work dealing with the structure and evolution of North Indian *ragas* (includes a 45 r.p.m. record of *raga* demonstrations performed on the *sitar* by VILAYAT KHAN, and extensive notations in Western staff and Indian *sargam*); BABURAO JOSHI and A. LOBO, *Introducing Indian Music* (n.d.), a series of four long-playing records, including musical examples and commentary, illustrating the main features of North Indian classical music, with accompanying booklet; WALTER KAUFMANN, *The Rāgas of North India* (1968), description and notations, in Western staff, of about 230 *ragas* of modern North Indian music; ALLEN KEESE, *The Sitar Book* (1968), an elementary guide to the *sitar,* with some description of playing techniques, musical exercises, and *gats* in ten *ragas;* HERBERT A. POPLEY, *The Music of India,* 3rd ed. (1970), a general work including discussion of historical background, scale, *raga, tala,* musical form, and instruments, with notations in Western staff and Indian *sargam;* HAROLD S. POWERS, "Indian Music and the English Language: A Review Essay," *Ethnomusicology,* 9:1–12 (1965), a survey of the most important literature on Indian music written in the English language; and "An Historical and Comparative Approach to the Classification of Rāgas (with an Appendix on Ancient Indian Tunings)," in *Selected Reports* of the Instiute of Ethnomusicology, UCLA, 1:1–78 (1970), a scholarly monograph that attempts to show the relationship between North and South Indian *ragas* that bear the same name but now differ in scale—includes material on ancient Indian music and gives many musical examples in Western staff; SWAMI PRAJNANANDA, *A History of Indian Music,* vol. 1 (1963), a technical work dealing with the origins and the music of the ancient period; P. SAMBAMOORTHY, *South Indian Music,* 5 vol. (1958–69), a comprehensive work covering many aspects of South Indian musical theory, both synchronically and diachronically; RAVI SHANKAR, *My Music, My Life* (1969), a general book combining autobiographical and biographical material with a discussion of Indian music history, theory, and instruments, including a manual for the *sitar.* BONNIE C. WADE, *Music in India: The Classical Traditions* (1979), a discussion of performance, theory, and basic instruments of both the North and South; M.R. GUATAM, *The Musical Heritage of India* (1981), a history with emphasis on classical traditions of both the North and South; WIM VAN DER MEER, *Hindustan: Music in the Twentieth Century* (1980), an introduction with emphasis on vocal music; DANIEL M. NEUMAN, *The Life of Music in North India* (1980), an analysis of the place in society of the musician.

Dance and theatre: The main source book of Indian classical dance and theatre is the *Nātya-śāstra,* ascribed to BHARATA MUNI, trans. by MANMOHAN GHOSH, 2 vol. (1950–61), which deals with ceremonies, gesture language, architecture, production styles, makeup, and costumes. A.K. COOMARASWAMY, *The Dance of Shiva,* rev. ed. (1957), brings alive the philosophy and aesthetics of Hindu dance. For general understanding of classical dance forms and techniques, see RINA SINGHA and REGINALD MASSEY, *Indian Dances* (1967), which includes semiclassical styles, modern ballet, and biographical notes on dancers and gurus. FAUBION BOWERS, *The Dance in India* (1953), is a fascinating description of the four major classical dances. K. BHARATHA IYER, *Kathakali* (1955), is perhaps the best work on this dance-drama, with detailed descriptions of characters, historical background, and interpretation of dramatic symbols, with photographs and line drawings. KAPILA VATSYAYAN, *Classical Indian Dance in Literature and the Arts* (1968), surveys dance as found in temple sculpture, the plastic arts, and literature—a scholarly work with photos. For tribal dances and ceremonies of Central India, see VERRIER ELWIN, *The Muria and Their Ghotul* (1947; abridged ed., *The Kingdom of the Young,* 1968). For dramatic forms, production techniques, and classical rules the best source book is also the *Nātya-śāstra,* ascribed to BHARATA MUNI, *op. cit.* ARTHUR B. KEITH, *Sanskrit Drama in Its Origin, Development, Theory and Practice* (1924, reprinted 1959), remains a standard scholarly critical work for comparative analysis of Sanskrit plays. P. LAL, *Great Sanskrit Plays* (1964) are actable transcreations in crisp modern English. A delightfully-written survey is FAUBION BOWERS, *Theatre in the East* (1956), which puts Indian dance and theatre in the larger perspective of South Asia with vivid and perceptive descriptions. For a general survey of classical, folk, and modern drama with sidelights on opera and ballet, illustrated by photographs and sketches, see BALWANT GARGI, *Theatre in India* (1962). HEMENDRA NATH DAS GUPTA, *The Indian Stage,* 4 vol. (1934–44), deals mainly with the growth of Bengali theatres, actors, and productions in exhaustive detail with reproductions of period notebooks and papers. BALWANT GARGI, *Folk Theatre in India* (1966), is an eyewitness account of religious, secular, and masked dramas in villages, with over 100 photographs and line sketches. See also J.C. MATHUR, *Drama in Rural India* (1964). BERYL DE ZOETE, *Dance and Magic Drama in Ceylon* (1957), is a vivid account of rituals and magical masked dances in a diary form of day-to-day performances. E.R. SARACHCHANDRA, *The Folk Drama of Ceylon,* 2nd ed. (1966), is a scholarly work on the development and background of Sinhalese folk dramas and cults of exorcism. For puppets and masks, see two small pamphlets: J. TILAKASIR, "Puppetry in Ceylon" and SIRI GUNASINGHE, "Masks of Ceylon" (both published by the Department of Cultural Affairs, Ceylon, 1962). For the history of Kolam and description of various characters see O. PERTOLD, "The Ceremonial Dances of the Sinhalese," *Archiv Orientální,* vol. 2 (1930). For Devil Dances and their interpretation in the light of witchcraft rituals, see DANDRIS DE SILVA GUNARATNA, "Demonology and Witchcraft in Ceylon," *J. Ceylon Brch. R. Asiat. Soc.,* vol. 4, no. 13 (1861); PAUL WIRZ, *Exorzismus und Heilkunde auf Ceylon* (1941); RACHEL VAN M. BAUMER and JAMES R. BRANDON (eds.), *Sanskrit Drama in Performance* (1981), essays on Ancient Indian theatrical performance.

Visual arts (General works): VINCENT A. SMITH, *A History of Fine Art in India and Ceylon,* 3rd ed. rev. and enl. (1962); A.K. COOMARASWAMY, *History of Indian and Indonesian Art* (1927, reprinted 1965); and BENJAMIN ROWLAND, *Art and Architecture of India,* 3rd ed. rev. (1967), are general introductions with good bibliographies. A.K. COOMARASWAMY, *Figures of Speech or Figures of Thought* (1946), and *Tranformation of Nature in Art* (1934, reprinted 1956), contain important essays which discuss Indian aesthetic theories from the traditional point of view. A clear classification of Hindu images with particular reference to south India has been made in T.A. GOPINATHA RAO, *Elements of Hindu Iconography,* 2 vol. in 4 (1914–16, reprinted 1968); and J.N. BANERJEA, *The Development of Hindu Iconography,* 2nd ed. rev. and enl. (1956), is an analytical introduction to the subject. N.K. BHATTASALI, *Iconography of Buddhist and Brahmanical Sculptures* *in the Dacca Museum* (1929); BENOYTOSH BHATTACHARYYA, *The Indian Buddhist Iconography,* 2nd ed. (1958); and ALFRED FOUCHER, *Étude sur l'iconographie bouddhique de l'Inde,* 2 vol. (1900–05), are important studies of Buddhist iconography. A.K. COOMARASWAMY, *Yaksas,* 2 vol. (1928–31), is a masterly study of early iconography. HEINRICH ZIMMER, *Myths and Symbols in Indian Art and Civilization* (1946, reprinted 1963), discusses some important symbols of Indian art. Good collections of photographs are in JAMES BURGESS, *The Ancient Monuments, Temples and Sculptures of India,* 2 vol. (1897–1911); A.K. COOMARASWAMY, *Viśvakarma* (1912); STELLA KRAMRISCH, *The Art of India* (1954); and HEINRICH ZIMMER, *The Art of Indian Asia,* 2 vol. (1955).

Architecture: JAMES FERGUSSON, *History of Indian and Eastern Architecture,* rev. ed., 2 vol. (1910, reprinted 1967); PERCY BROWN, *Indian Architecture,* 2 vol., 5th ed. (1965); and S.K. SARASWATI, "Architecture," in R.C. MASUMDAR (ed.), *History and Culture of the Indian People,* vol. 3 and 5 (1954–57), are standard works that survey the entire history of Indian architecture. JAMES FERGUSSON and JAMES BURGESS, *The Cave Temples of India* (1880, reprinted 1969), is a comprehensive account of rock-cut architecture. STELLA KRAMRISCH, *The Hindu Temple,* 2 vol. (1946), is concerned with principles and symbolism, and KRISHNA DEVA, *Temples of North India* (1969), presents a synoptic view of the various north Indian styles. G. JOUVEAU-DUBREUIL, *Archéologie du sud de l'Inde,* 2 vol. (1914), analyses the south Indian style. K.R. SRINVASAN, *Cave Temples of the Pallavas* (1964); and ARTHUR H. LONGHURST, *Pallava Architecture,* 3 vol. (1924–30), are important studies of early south Indian architecture. SIR JOHN MARSHALL, "The Monuments of Muslim India," in *The Cambridge History of India,* vol. 3, pp. 568–640 (1928, reprinted 1965); and PERCY BROWN, "Monuments of the Mughal Period," *ibid.,* vol. 4, pp. 523–576 (1937, reprinted 1963), are important essays on Islamic architecture in India. See also ELIZABETH S. MERKLINGER, *Indian Islamic Architecture: The Deccan 1347–1686* (1981).

Sculpture: S.K. SARASVATI, *A Survey of Indian Sculpture* (1957); and STELLA KRAMRISCH, *Indian Sculpture* (1933), discuss the broad historical and stylistic trends. LUDWIG BACHHOFER, *Early Indian Sculpture* (1929), is a fine stylistic analysis of sculptures from the third century B.C. to the third century A.D. The classic work on Gandhāra art is ALFRED FOUCHER, *L'Art gréco-bouddhique du Gandhâra,* 2 vol. (1905–41), though several of its conclusions are no longer tenable. SIR JOHN MARSHALL, *Taxila,* 3 vol. (1951), discusses works recovered from that site; and HAROLD INGHOLT, *Gandharan Art in Pakistan* (1957, reprinted 1971), provides excellent photographic documentation. R.D. BANERJI, *The Age of the Imperial Guptas* (1933), has a general discussion of the Gupta style; D.R. SAHNI, *Catalogue of the Museum of Archaeology at Sārnāth* (1914), contains information of interest on the school of Sārnāth. ELIKY ZANNAS, *Khajurāho* (1960); K.C. PANIGRAHI, *Archaeological Remains at Bhubaneswar* (1961); and R.D. BANERJI, *Eastern Indian School of Medieval Sculpture* (1933), are monographs on schools of north Indian medieval sculpture. A.H. LONGHURST, *op. cit.;* and K.A. NILAKANTA SASTRI, *The Cōlas,* 2nd ed. rev. (1955), contain information on the south Indian medieval styles. C. SIVARAMAMURTI, *South Indian Bronzes* (1963); P.R. SRINIVASAN, *Bronzes of South India* (1963); DOUGLAS E. BARRETT, *Early Cōla Bronzes* (1965), are important studies of south Indian bronzes; FREDERICK M. ASHER, *The Art of Eastern India: 300–800* (1980), a study of the pre-Pala period.

Painting: In considering the published literature it is important to remember that the study of Indian painting, confined to a limited number of scholars, is of comparatively recent growth, and is therefore full of controversies and uncertainties which keep shifting with the discovery of fresh materials. The standard work on Ajanta is GHULAM YAZDANI, *Ajanta,* 4 vol. (1930–55); and on the western Indian style, MOTI CHANDRA, *Jain Miniature Paintings from Western India* (1949). Much interesting information on the period of transition to the Rajasthani and Mughal styles has been brought together in KARL J. KHANDALAVALA and MOTI CHANDRA, *New Documents of Indian Painting* (1969). The Mughal school has been ably presented in PERCY BROWN, *Indian Painting under the Mughals, A.D. 1550 to A.D. 1750* (1924); and STUART C. WELCH, *The Art of Mughal India* (1964). DOUGLAS E. BARRETT, *Painting of the Deccan, XVI–XVII Century* (1958), is a brief introduction to the subject. The main publication on the Company style is MILDRED and WILLIAM G. ARCHER, *Indian Painting for the British, 1770–1880* (1955). The classic work on Pahari and Rajasthani painting is A.K. COOMARASWAMY's pioneering *Rajput Painting,* 2 vol. (1916). Fresh discoveries which have considerably changed the understanding of its history are summarized in KARL KHANDALAVALA, MOTI CHANDRA, and PRAMOD CHANDRA, *Miniature Painting: A Catalogue of the Exhibition of the Sri Motichand Khajanchi Collection* (1960). MOTI CHANDRA, *Mewar Painting in the Seventeenth Century* (1957); WILLIAM G. ARCHER, *Indian Painting in Bundi and Kotah* (1959); PRAMOD CHANDRA, *Bundi Painting* (1959); ERIC DICKINSON and KARL KHANDALAVALA, *Kishangarh Painting* (1959); WILLIAM G. ARCHER, *Central Indian Painting* (1958); and ANAND KRISHNA, *Malwa Painting* (1963), are informative summaries of the growing knowledge of the various schools of Rājasthān. The standard work, illustrated copiously, on the Pahari style is KARL KHANDALAVALA, *Pahāṛī Miniature Painting* (1958), and different in its account from WILLIAM G. ARCHER, *Indian Painting in the Punjab Hills* (1952). Books which cover most of the schools and are profusely illustrated include N.C. MEHTA, *Studies in Indian Painting* (1926); WILLIAM G. ARCHER, *Indian Miniatures* (1960); ROBERT SKELTON, *Indian Miniatures from the XVth to the XIXth Centuries* (1961); DOUGLAS E. BARRETT and BASIL GRAY, *Painting of India* (1963); and STUART C. WELCH and MILO C. BEACH, *Gods, Thrones and Peacocks: Northern Indian Painting from Two Traditions, Fifteenth to Nineteenth Centuries* (1965). (*Ceylon*): Standard works on Sinhalese art are SENERAT PARANAVITANA, *The Stūpa in Ceylon* (1946), *Art and Architecture of Ceylon: Polonnaruva Period* (1954), and *Ceylon: Paintings from Temple, Shrine and Rock* (1957). MOTI CHANDRA, *Studies in Early Indian Painting* (1975), covers the 5th through 16th centuries; CALAMBUR SIVARAMAMURTI, *The Art of India* (1977), covering all types of art with 1175 illustrations; STUART C. WELCH, *Room for Wonder: Indian Painting During the British Period, 1760–1880* (1978), an exhibition catolog with detailed comments on 125 illustrations.

Decorative arts: Scholarly literature on the decorative arts in India is scanty and mainly in learned journals. The *Journal of Indian Art and Industries* (1886–1916) is the most important and contains numerous pioneering studies. SIR GEORGE WATT, *Indian Art at Delhi* (1903); and SIR GEORGE BIRDWOOD, *The Industrial Arts of India,* 2 vol. (1880), are for the most part descriptive texts emphasizing the technical aspects of the decorative arts as they had survived up to the closing years of the 19th century. JOHN IRWIN, "Textiles and the Minor Arts," in LEIGH ASHTON (ed.), *The Art of India and Pakistan,* pp. 201–237 (1950), is a brief historical survey of the subject. MOTI CHANDRA, "Ancient Indian Ivories," *Bulletin of the Prince of Wales Museum of Western India,* no. 6, pp. 4–63 (1957–59), is a monograph on the history of Indian ivory carving. THOMAS H. HENDLEY, *Asian Carpets* (1905), treats Indian examples in the important collections of the Maharaja of Jaipur. GEORGE P. BAKER, *Calico Painting and Printing in the East Indies in the XVIIth and XVIIIth Centuries* (1921), is the most important work on the subject; WILBRAHAM EGERTON, *An Illustrated Handbook of Indian Arms* (1880), catalogs and describes the wide range and achievement of the armourer's craft.

Mainland Southeast Asia

The mainland of Southeast Asia comprises the Indochinese Peninsula, which is divided into the following countries: Kampuchea (Cambodia), Laos, Malaysia, Myanmar (Burma), Singapore, Thailand, and Vietnam. The peninsula consists principally of a series of north–south-trending ranges and valleys associated with some of Asia's largest rivers, including the Mekong and the Irrawaddy. The climate is predominantly tropical, and the natural vegetation is forest.

The area is highly diversified culturally. Rice and corn (maize) are the principal dietary staples. Southeast Asia is an important source of rubber, rice, coconut oil, sugar, teak, hemp, tea, coffee, tobacco, and pepper and of tin, petroleum, bauxite, and other minerals.

Before the 16th century, Southeast Asia had contacts with India and China, and in several places, such as Kampuchea and Thailand, high civilizations had developed. The region was colonized by Western powers from the 16th to the 20th century. In the latter half of the 20th century, all the colonial states achieved independence. Only Thailand had avoided colonization, but it has been heavily influenced by the West. After World War II, Southeast Asia became enmeshed in power struggles between East and West and between the Soviet Union and China. (Ed.)

For a discussion of the artistic expressions of the peoples of Southeast Asia, see SOUTHEAST ASIAN ARTS.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* sections 937, 969, and 976, and the *Index*.

This article is divided into the following sections:

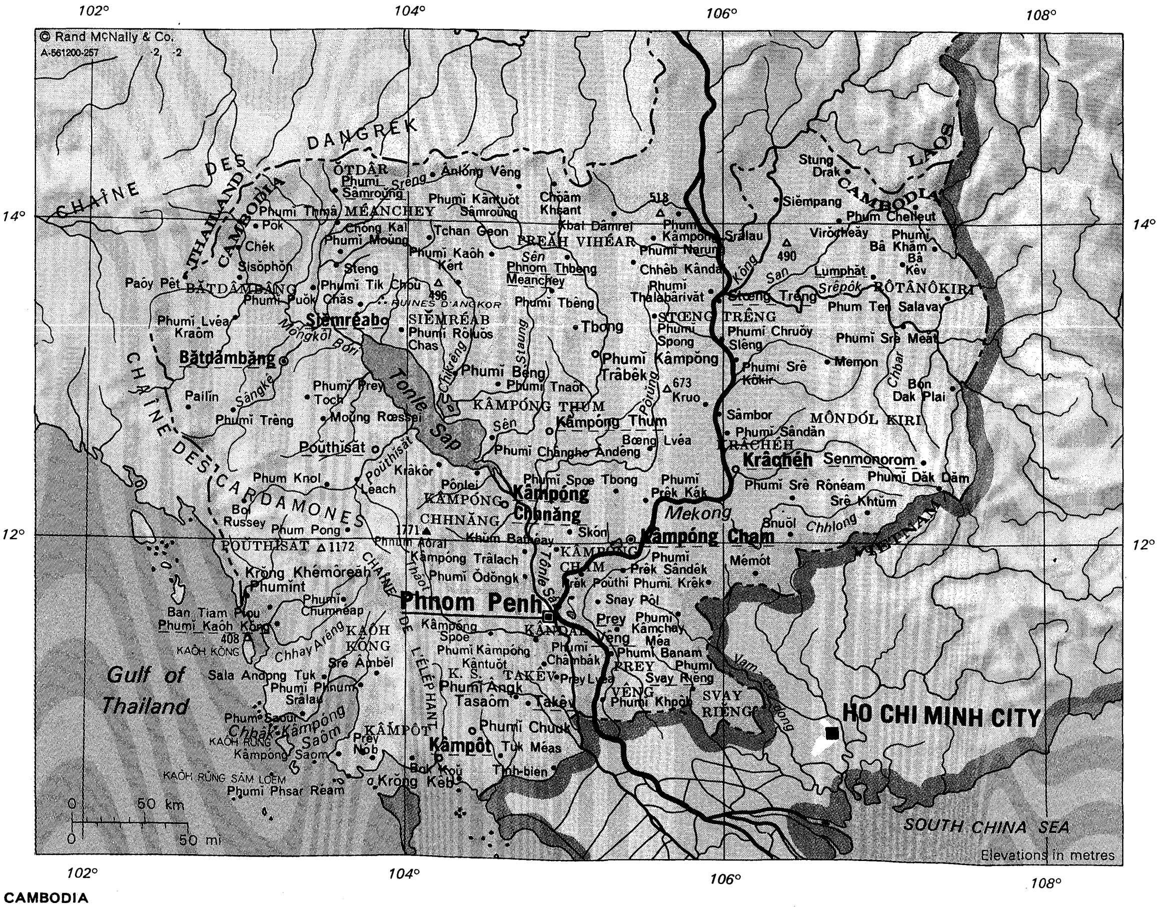
KAMPUCHEA

Kampuchea is a country located in Southeast Asia in the southwest part of the Indochinese Peninsula. Together with Laos and Vietnam, Kampuchea is part of what was formerly known as Indochina. Covering a land area of 69,898 square miles (181,035 square kilometres), it is bordered on the west and northwest by Thailand, on the northeast by Laos, on the east and southeast by Vietnam, and on the southwest by the Gulf of Thailand (Gulf of Siam).

The names Cambodia and Kampuchea are transliterations of the country's traditional name in the Khmer language. Cambodia was adopted as the Western conventional spelling for the French transliteration Cambodge. Under the Khmer Republic, established in 1970, official use of the transliteration Cambodia, with its colonial connotation, was abolished. The transliteration Kampuchea, however, was allowed. In this article Cambodia is used as a general historical term and Kampuchea is used for the country after 1975.

Jpheavals
f the
970s

Throughout the 1970s, Kampuchea was devastated by the enlarged Second Indochinese War, civil war, and social upheavals that damaged, destroyed, or redirected much of its economy and killed hundreds of thousands of its people. In April 1975, the government of the Khmer Republic collapsed under attacks by Communist guerrilla forces that had been fighting the regime, at first with Vietnamese help, since 1970. From 1975 to 1978, Kampuchea was known as Democratic Kampuchea and was governed by a pro-Chinese faction of the Kampuchean Communist Party. This regime's years in power were characterized by a dramatic attempt to increase Kampuchea's agricultural production by collectivizing its villages and regimenting its people. Under the regime, millions of people were moved from urban centres into rural areas, currency was abolished, and the postal system did not operate. Violent clashes along the border with Vietnam began in 1976 and developed into warfare in 1978. In January 1979 a pro-Vietnamese Communist movement, aided by Vietnamese armed forces, captured the national capital of Phnom Penh and began to administer the surrounding area as the People's Republic of Kampuchea. Remnants of the army of Democratic Kampuchea and thousands of Cambodians loyal to that government continued resistance in the northwestern region of the country.



CAMBODIA

Physical and human geography

THE LAND

Relief. Kampuchea's maximum extent is about 280 miles (450 kilometres) from north to south and 360 miles (580 kilometres) from east to west. The central region is a low-lying alluvial plain surrounding the Tonle Sap (Great Lake) and the beginnings of the Mekong River Delta. Extending outward from this region are transitional plains, thinly forested and with prevailing elevations no higher than several hundred feet above sea level. On the north, along the border with Thailand, the Cambodian plain abuts a sandstone escarpment that marks the southern limit of a mountain range, the Chuŏr Phnum Dângrêk. A southward-facing cliff, stretching for more than 200 miles in a west to east direction, rises abruptly from the plain to heights ranging from 600 to 1,800 feet (180 to 550 metres), forming a natural frontier boundary. East of the Mekong the transitional plains gradually merge with the eastern highlands, a region of densely forested mountains and high plateaus that extend northward and eastward into Laos and Vietnam. In southwestern Kampuchea two distinct upland blocks, comprising the Chuŏr Phnum Krâvanh (Cardamom Mountains) and the Chuŏr Phnum Dâmrei (Elephant Mountains), form another highland region that covers much of the land area between the Tonle Sap and the Gulf of Thailand. In this remote and largely uninhabited area is found Phnum Aôral (5,949 feet; 1,813 metres), Kampuchea's highest peak. The southern coastal region adjoining the Gulf of Thailand is a narrow lowland strip, heavily wooded and moderately populated. It is effectively isolated from the central plain by the southwestern highlands.

Drainage. The two most dominant topographical features of Kampuchea are the Mekong River and Tonle Sap. Rising in Tibet and emptying into the South China Sea, the Mekong enters Kampuchea from Laos and flows broadly southward to the border with Vietnam, covering a distance inside Kampuchea of approximately 315 miles. Its annual flooding during the rainy season deposits a rich alluvial sediment that accounts for the fertility of the central plain.

Tonle Sap (the Great Lake)

The Tonle Sap, joined to the Mekong by a river called the Tônlé Sab, serves as a reservoir for the Mekong. During the rainy season, from mid-May to early October, the Mekong's enormous volume of water backs up the connecting river for a distance of 65 miles and flows into the Tonle Sap lake, expanding its surface area from the dry season minimum of 1,200 square miles to a rainy season maximum of more than 3,000 square miles and increasing its maximum depth from seven feet to 35 feet. As the water level of the Mekong falls during the dry season, the process is reversed. Water drains from the Tonle Sap lake back into the Mekong, reversing its directional flow. As a result of this annual phenomenon, the Tonle Sap lake is one of the richest sources in the world of freshwater fish.

Climate. Kampuchea has a climate governed by rain-bearing winds (monsoons) and characterized by two major seasons. From mid-May to early October, strong prevailing winds blow out of the southwest, bringing heavy rains and high humidity. From early November to mid-March, winds are from the northeast and are light in velocity.

Cloudiness is variable, precipitation is infrequent, and humidity is low. Between these seasons the weather is transitional. Maximum temperatures are high throughout the year, ranging from the mid-90s (° F, about 35° C) in April, the warmest month, to the low 80s in January, the coldest month. Daily minimums are usually 15° to 20° F lower than maximums. Annual rainfall varies considerably throughout the country, from more than 200 inches (5,000 millimetres) on the seaward slopes of the southwestern highlands to 55 inches in the central lowland region. Between 70 and 80 percent of the annual rainfall occurs during the months of the southwest monsoon.

Plant and animal life. About three-fourths of Kampuchea's land area is forested. The central lowland region is covered with rice paddies, fields of dry crops (such as corn [maize] or tobacco), tracts of tall grass and reeds, and thinly wooded areas. Savanna (grassy parkland) is the prevailing vegetation of the transitional plains, with grass growing to a height of five feet. In the eastern highlands the high plateaus are covered with deciduous forest and grassland. Broadleaf evergreen forests grow in the mountainous areas to the north, with trees 100 feet high emerging from thick undergrowths of vines, rattans, palms, bamboos, and assorted woody and herbaceous ground plants. In the southwestern highlands open forests of pines are found at the higher elevations, while the rain-drenched seaward slopes are blanketed with virgin rain forest growing to heights of 150 feet or more. Vegetation along the coastal strip ranges from evergreen forests to nearly impenetrable mangrove forests.

Fruit, growing wild or cultivated, includes breadfruit, jackfruit, durian, mango, mangosteen, papaya, rambutan, and bananas.

Animal life includes elephant, wild oxen, tiger, panther and other leopard, bear, and innumerable small game. Among the more common birds are heron, crane, grouse, pheasant, peacock, pelican, cormorant, egret, and wild duck. Four varieties of snakes are especially dangerous: the cobra, the king cobra, the banded krait, and Russell's viper.

Settlement patterns. Until the upheavals of the 1970s, Kampuchea was a country of villages. Only a small fraction of the total population lived in urban areas of 10,000 or more inhabitants; the major part of the urban population was concentrated in Phnom Penh, which is situated at the confluence of the Mekong, Basăk (Bassac), and Tônlé Sab rivers.

illage life

Until the mid-1970s the vast majority of Cambodia's people inhabited the central lowland region, where the rural village was second only to the family as the basic social unit. The typical Kampuchean village, in those days, was to a large extent autonomous and self-sufficient, made up of ethnically homogeneous people and having a population of fewer than 300 persons. The village (*phum*) was part of a hamlet or community (*khum*) with which it shared one or more Buddhist temples (*wat*), an elementary school, and several small shops. Cambodian villages usually developed in a linear pattern along waterways and roads; more isolated villages were rectangular or, more rarely, circular in the arrangement of their houses. Houses were also dispersed through the countryside on largely self-contained paddy farms. Houses in Kampuchea were generally built on high wooden pilings and had thatched roofs, walls of palm matting, and floors of woven bamboo strips resting on bamboo joists. More prosperous houses, while still on pilings, were built of wood, and had tile or metal roofs.

Until they were forced off their holdings in 1975 and made to work as ordinary peasants, there were a few large landowners in Kampuchea. Before collectivization the typical villager owned and worked enough land to provide for his family, with a small surplus to be converted into cash for additional goods or the payment of taxes. Landholdings tended to be small in the crowded south-central regions of the country, where the least fertile soils occur. During the 1960s, the government of Prince Norodom Sihanouk was successful in colonizing frontier regions, especially in the northwest, with army veterans or needy farmers from more crowded parts of the country. These programs did not significantly alter Kampuchean settlement patterns, however.

Throughout rural Kampuchea, life-style was closely geared to the agricultural cycle, which was based, in large part, on family-oriented subsistence farming. Family members were awake before dawn, and the major portion of the day's work was accomplished before noon, although minor tasks were performed in the cool of the early evening. Electricity has always been rare in village areas, and country people were generally asleep soon after sunset. During the rice-growing season, all family members worked together in the fields, because the work of planting, transplanting, and harvesting must be done quickly. Without mechanical assistance, the work of more than one or two people is needed to grow enough rice to feed a family for a year. Because of the intensive labour requirements of paddy farming, reciprocal extra-family obligations would build up within a village during the agricultural season. Festivals and marriages, celebrated by a whole village, were usually held in the off-season, after the rice had been harvested.

Urban areas

The urban areas of Kampuchea, most of which were abandoned as an official policy in 1975, had developed, for the most part, during the first half of the 20th century as commercial and administrative centres serving their surrounding rural regions. Most of them were located at the intersections of land or river routes and were relatively accessible to the areas they served. Phnom Penh (*phnom* means "hill"; Penh is a woman's name) was Kampuchea's single metropolis before it was abandoned in 1975. Its population fluctuations reflect Kampuchea's recent history. Before the outbreak of war in 1970, it held some 500,000 persons; its population by 1975, then swollen with refugees, numbered some 2,000,000. Several thousand people moved back into the city in 1979, after its official depopulation. In 1970, Bătdâmbâng in the northwest was Kampuchea's second largest city, with about 40,000 people. No other city at that time held more than 20,000.

THE PEOPLE

Kampuchea's first national census as an independent nation was taken in 1962. The results showed that the population totalled about 5,700,000. Overall population density is difficult to determine, because of the enormous losses and movements of people in the years after 1970. Because so much of the country is poorly watered and without inhabitants, the actual density in populated areas is quite high.

Population distribution

The war and social revolution in the 1970s seriously affected the distribution of Kampuchea's population. Between 1975 and 1978, thousands of urban people were forcibly moved into the northwest to cultivate rice and to dig and maintain extensive networks of irrigation canals. During the war with Vietnam in 1978–79, the populated districts adjacent to Vietnam were devastated and deserted. Cities throughout the country were emptied and thousands of smaller population centres were destroyed by U.S. bombing in 1973, fought over in the civil war of 1970–75, or abandoned in 1975–78.

Ethnic distribution. Khmer (Cambodian) stock accounts for the vast majority of the total population. This has produced a homogeneity that is unique in Southeast Asia and has encouraged a strong sense of national identity. Before 1975, other major ethnic groups included the Chinese (350,000), Vietnamese (200,000), Cham-Malays (90,000), various tribal peoples (90,000), and Europeans, mainly French (5,000). All of these minorities, except for the ethnic Chinese and tribal peoples, were expelled from Democratic Kampuchea; many of the Chinese, in turn, sought refuge in Vietnam.

The Khmer are concentrated principally in the lowland regions surrounding the Mekong and Tonle Sap, on the transitional plains, and in the coastal area. They belong to the Mon-Khmer ethnolinguistic group. An end product of centuries of intricate cultural and racial blending, the Khmer descended before 200 BC into the fertile Mekong Delta from the Khorat Plateau of what is now Thailand. They were Indianized by successive waves of Indian influence and in the 8th century AD were exposed to Indo-

Malayan influences and perhaps immigration from Java. This was followed by Tai migrations from the 10th to 15th centuries, by a Vietnamese migration beginning in the 17th century, and by Chinese migrations in the 18th and 19th centuries. As a result of this racial admixture, the Khmer are generally classified as Austroasiatics linked to the Veddoid, Indo-Australoid, and Mongoloid peoples. Their physical characteristics reflect their mixed background. Despite wide variations, they tend to be of short stature (the average height of a male is about five feet, three inches), robust, and muscular. Skin colour is light to brown, and hair is black. About half show the epicanthic fold (a fold of skin extending from the eyelid over the inner corner of the eye; it is sometimes called the Mongolian fold). The typical Khmer family before 1975 consisted of a married couple and their unmarried children. Both sons and daughters usually left the parental home after marriage to establish their own households.

The ethnic minorities

Among the ethnic minorities in Kampuchea before 1975, the Chinese were clearly the most important, for they controlled the country's economic life and retained a high degree of cultural distinctiveness, even though many assimilated into Khmer society through intermarriage. The Vietnamese minority occupied a somewhat lower status, and most of them fled or were repatriated to Vietnam after 1970. Centuries of mutual dislike and distrust have clouded Vietnamese–Khmer relations, and intermarriage is infrequent. The next most important minority, the Cham-Malay group known in Cambodia as Khmer Islām, also maintained a high degree of ethnic homogeneity and was discriminated against in 1975–78. By contrast, scattered evidence suggests that the tribal people of Cambodia, living originally in the forested northeast of the country, received favoured treatment during that period perhaps because the Communists of Democratic Kampuchea had used tribal areas as guerrilla bases during the 1960s. This favouritism may also have reflected that regime's revolutionary concern for the downtrodden or forgotten inhabitants of Cambodia, for in the years before 1970, and indeed for centuries, the tribal minorities (known collectively as *phnong,* or "savages") had been mistreated by the ethnic Khmer.

Religion. The Khmer were almost universally Theravāda (Hīnāyana) Buddhists (*i.e.,* belonging to the earlier of the two great schools of Buddhism, the latter school being represented by the Mahāyāna), and Buddhism was officially recognized as the state religion. Between 1975 and 1978, Buddhist monks were made to work in the fields, like everyone else; images of Buddha from monasteries were destroyed; and temples were used as granaries and barracks. Although the social and psychological characteristics often ascribed to the Khmer—individualism, conservatism, patience, gentleness, and unconcern for material wealth—were often in the eyes of the beholder, they did represent Buddhist ideals toward which many Kampucheans aspired, and Buddhist precepts permeated Kampuchean education and ideology. These precepts were systematically attacked during the years of Democratic Kampuchea, which placed "superstition" in opposition to self-reliance.

Minority populations were not Theravāda Buddhists. Tribal people were animists and the ethnic Vietnamese and Chinese were eclectic, following Mahāyāna Buddhism, Taoism, and such syncretic Vietnamese religious movements as the Cao Dai. The Cham were strict Muslims, and a sizable number of Vietnamese were members of the Roman Catholic Church.

THE ECONOMY

Even before 1975, Kampuchea's economy was one of the least developed of the Southeast Asia region. It was heavily dependent upon two major products—rice and rubber—and consequently was vulnerable to profound annual fluctuations caused by vagaries in rainfall and world market prices. Agriculture dominated the economy. Most rural families were engaged in rice cultivation. Although the tradition of landownership was strong, family landholdings were relatively small. But even with small family farms, the rural population was largely self-sufficient. One hectare of rice paddy provides for the needs of a family of five persons, and supplementary requirements were traditionally satisfied by fishing, cultivating fruit and vegetables, and raising livestock. Famine was rare in Kampuchea, but the self-sufficiency of the rural family produced a conservatism that proved resistant to government efforts before 1975 to modernize the country's primitive agricultural methods.

Resources. Kampuchea has few known mineral resources. Some limestone and phosphate deposits are found in Kâmpôt province, and precious stones in limited quantities are mined in Bătdâmbâng. Iron and coal traces have not justified commercial exploitation. Electrical power sources are mainly dependent upon imported oil.

Rice production

Agriculture and fisheries. Rice is Kampuchea's principal food, its major crop, and, in times of peace, its most important export commodity. Rice is grown on most of the country's total cultivated land area. The principal rice regions surround the Mekong and the Tonle Sap, with cultivation particularly intensive in Bătdâmbâng, Kâmpóng Cham, Takêv, and Prey Vêng provinces. Lacking sufficient irrigation systems, Kampuchea has traditionally produced only one rice crop per year.

Under the government of Democratic Kampuchea, great strides were taken to build irrigation systems throughout the country, using mass labour and abolishing private ownership of land. According to scattered information, the results were often impressive, and in parts of the country peasants were able to grow two, and more rarely three, crops of rice per year. These irrigation works broke down or were abandoned in the war with Vietnam in 1978 and in the civil war that followed. In 1979–80 famine was widespread, and hundreds of thousands of Kampucheans fled into Thailand or became dependent, inside Cambodia, on food provided by international aid.

Under the traditional patterns of agriculture, planting normally begins in July or August, and the harvest period extends from November to January. The amount of rainfall, when there is little irrigation, determines the size and quality of the crop. Other food products include corn (maize), beans, soybeans, and sweet potatoes. The principal fruit crops, all of which are consumed locally, include oranges, bananas, and pineapple.

Fisheries and livestock are important components of the domestic economy. Fish in its various forms—fresh, dried, smoked, and salted—constitutes the single most important source of protein in the Kampuchean diet, and subsistence fishing is part of every farmer's activity. The annual freshwater catch includes perch, carp, lungfish, and smelts. Cattle, particularly water buffalo, are used principally as draft animals in the rice paddies and fields. Hog production has also played a large role in agriculture. The efforts of the government of Democratic Kampuchea to increase the number of livestock—seriously depleted by years of war—broke down in 1978, when war and counterinsurgency again occupied the government's attention.

Industry. Although industrial development remains at a low level, successive governments made strong efforts to build a modest industrial base suitable to the needs of the country.

Finance and trade. Foreign trade has been at a standstill in the years of warfare, and imports have taken the form of foreign aid. Traditionally, the bulk of Kampuchea's exports, consisting almost entirely of rice, rubber, corn (maize), and other agricultural products, went to other Asian nations, while imports came mainly from Japan, the United States, and western Europe.

The civil war in Kampuchea of 1970–75 devastated the countryside, sharply reduced foreign trade, and destroyed the nation's fragile economic infrastructure. After the Communist victory in 1975, large-scale economic policies involving the depopulation of urban areas, the construction of giant irrigation works, and the pursuit of industrial self-sufficiency met with mixed results and certainly left the people with few resources with which to fight a full-scale war against Vietnam. The port of Kâmpóng Saôm (formerly Sihanoukville) was used by both Democratic Kampuchea and the People's Republic of Kampuchea, largely to receive foreign aid. During the war of 1978–79, most of the earlier progress made in the countryside was erased.

Changing development policies

Administration of the economy. In seeking rapid economic development, the government in 1963 adopted a socialistic policy characterized by nationalization of the private banking system, establishment of a government monopoly over imports and exports, and extensive state participation in building and managing industrial enterprises. This policy proved to be unsuccessful, mainly because of defective economic planning, insufficient labour and managerial skills, and rigidly fixed agricultural prices that discouraged production incentive.

The government of the Khmer Republic, in turn, supported the idea of industrialization, but was unable to accomplish much because Cambodia's cities were under siege for most of 1972–75. The regime of Democratic Kampuchea pursued a policy of self-reliance modelled on that of the People's Republic of China. This meant that existing factories were expanded and new ones were built to meet local needs for cloth, cigarettes, sheet rubber, farm machinery, fertilizer, and cement. Smaller factories were installed inside the agricultural communes.

Transportation. Kampuchea's inland waterways and road systems constitute the main transportation routes. Each is invariably affected by the floods of the rainy season, which result in heavy silting and washouts (flash floods). Railroads rank third in significance. Domestic shipping and civil air facilities are limited. Maritime commerce is carried out almost exclusively by foreign vessels.

The road system

The road system eventually surpassed the country's inland waterways as the principal means for moving cargo and passengers. The network was originally designed by the French during the protectorate period to link the agricultural hinterland with the port of Saigon, now Ho Chi Minh City, Vietnam. Consequently, the system did not serve Kampuchea as a whole. Extensive land tracts in the northern, northeastern, and southwestern parts of the country were roadless. Of the total road network, only a fraction has been paved; other roads have been surfaced with crushed stone, gravel, or laterite or have been simply graded without being paved. The country's longest bridge—a ten-span structure more than 2,300 feet in length, traversing the Tônlé Sab at Phnom Penh—was destroyed in 1975.

The inland waterways have a collective extent of 1,200 miles, of which more than 90 percent are part of the Mekong and Tonle Sap systems. Phnom Penh, located about 200 miles from the mouth of the Mekong, can be reached by oceangoing vessels of less than 13-foot draft. North of Phnom Penh, the Mekong is navigable to Krâchéh for rivercraft, but rapids and winding channels in the 117-mile section between Krâchéh and the Laos border generally preclude commercial navigation.

Port at Kâmpóng Saôm

Kampuchea's single maritime port is located at Kâmpóng Saôm on the Gulf of Thailand. Completed in 1960, Kâmpóng Saôm can provide unlimited anchorage for oceangoing ships. The port is of strategic importance to Kampuchea, and considerable industrial development has taken place in the area. A modern four-lane highway links Kâmpóng Saôm with Phnom Penh.

The railroad system is owned and operated by the Kampuchean government. One line, completed prior to World War II, connects Phnom Penh with Paôy Pêt on the Thai frontier—a distance of 239 miles—and facilitates the movement of milled rice from the western provinces of Bătdâmbâng, Poŭthĭsăt, and Kâmpóng Chhnăng. Another line, completed in 1969, connects Phnom Penh with Kâmpóng Saôm, covering a distance of 168 miles through the provinces of Kândal, Takêv, and Kâmpôt.

ADMINISTRATIVE AND SOCIAL CONDITIONS

Government. The structure of government under the People's Republic of Kampuchea was not made clear to the international community. Local government, as it was known under more Western-style regimes, had probably disappeared under the pressures of civil war and contending Communist ideologies. Nothing was known of the judicial system then in effect; it appeared that no judicial system functioned under Democratic Kampuchea. One peculiarity of all the regimes that followed the Kingdom of Cambodia was that each condemned to death the leaders of the preceding regime.

Armed forces. The armed forces of Democratic Kampuchea include a number of ethnic Kampuchean forces loyal to the People's Republic of Kampuchea. There are considerable numbers of Vietnamese troops garrisoned throughout most of the country.

Education. Kampuchea's educational system, as it had developed in the first 70 years of the 20th century, was another casualty of warfare and ideology. Under Democratic Kampuchea, only primary schools were open; older students attended irregularly scheduled political and technical courses, often held in the communes. The People's Republic stated its eagerness to reopen the schools, but it was hampered by a shortage of funds, teachers, books, and students, as well as the continuing civil war.

Literacy rates

Literacy levels in Kampuchea have always been relatively low. Although Democratic Kampuchea claimed to have eliminated illiteracy in 1975–76, such an achievement seemed unlikely, given the conditions in the countryside, the absence of schools, and the government's discrimination against educated members of the "old society." Indeed, according to reports of refugees, illiterate peasants often rose to positions of power under that government.

Health and welfare. Throughout Kampuchea's history, an acute shortage of medical personnel has been a major obstacle to the implementation of an effective public health program. Even before the civil war, Kampuchea had few doctors, hospitals, or medical facilities. The civil war of 1970–75 strained and eroded this fragile structure. Democratic Kampuchea moved medical personnel onto collective farms and, as part of its policy of self-reliance, encouraged non-Western medical practices based on the use of local herbs. Because of unsettled conditions, a lack of sanitation, and a shortage of medicine, epidemics of cholera and malaria were reported and instances of other diseases, especially those related to malnutrition, were frequent.

CULTURAL LIFE

Khmer architecture

Before 1970, Cambodian culture and artistic expression were overshadowed by the greatness of the past. Although owing much to Indian influence, the achievements of the Khmer Empire represented original contributions to Asian civilization. The magnificent architecture and sculpture of the Angkorean period (802–1432), as seen in the temple complexes at Angkor Wat and Angkor Thom, marked the apex of Khmer creativity. Following the capture of Angkor by the Thai (15th century) and the crumbling of the empire, the region underwent four centuries of foreign invasions, civil war, and widespread depopulation. It was not until the establishment of the French protectorate in 1863 that internal security was restored, the country's borders stabilized, and efforts undertaken to revive traditional Khmer art forms. After gaining independence from France in 1953, the government placed particular emphasis upon accelerating that revival by establishing a national school of music, a national school of ballet and theatre, and a fine arts university. This coincided with the rapid expansion of elementary and secondary school facilities, and the emergence of education as the most important factor of social mobility.

Music occupied a dominant place in Kampuchean culture. It was sung and played everywhere—by children at play, adults at work, by young men and women while courting—and invariably was part of the many celebrations and festivals that took place throughout the year at Buddhist temples in the rural countryside. Instruments used in full orchestras included xylophones with wooden or metal bars, one- and two-stringed violins, wooden flutes, oboes, and drums of different sizes. The Kampuchean musical scale had five tones, compared with seven in the Western scale. Orchestral music had no harmony, in the technical musical sense. The players followed the lead of one instrument, usually the xylophone, and improvised as they wished.

Dancing and drama

Dancing and drama were also popular forms of artistic expression. The Royal Ballet in Phnom Penh exemplified the classic, highly stylized dance form adapted by the Kampucheans and Thai from the ancient dances of Angkor. Accompanied by an orchestra and choral narration, the dancers acted out stories and legends taken principally from Hindu epics such as the *Rāmāyaṇa.* In the countryside, folk drama and folk dances were performed at festivals and weddings by wandering troupes. The actors invariably depicted stereotyped characterizations familiar to all: the country yokel, the clumsy lover, the beautiful princess, the cruel father, and the greedy merchant. The visual arts revealed the essential conservatism of the Kampucheans. Ancient themes were preferred and rarely was there an effort to improve or adapt. The principal crafts were weaving, working silver and gold, making jewelry, and the sculpture of wood and stone. (L.C.O./D.P.Ch.)

For statistical data on the land and people of Kampuchea, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL.

History

The importance of Cambodia's cultural and historical contributions to the development of mainland Southeast Asia is out of proportion to its present reduced territory and limited political power. At the height of its power (11th–13th centuries), the Khmer (Cambodian) state stretched across a vast area of the Indochinese Peninsula and incorporated much of southern Vietnam, Laos, and Thailand, and the cultural influence of Cambodia on the other peoples of Southeast Asia has been enormous.

CAMBODIA BEFORE THE 9TH CENTURY AD

Knowledge of Cambodian prehistory is extremely limited. Excavations at three prehistoric sites—Samrong Sen and Longprao, in central Cambodia, and Melouprei, in northeastern Cambodia—have yielded remains from the Neolithic Age sufficient to permit only the barest reconstruction of life in the region more than 2,000 years ago. Nor is it possible to link the makers of the various artifacts that have been discovered with the succession of ethnic groups that moved through the Indochinese region as a whole in the prehistoric period, peopling both that region and the maritime areas of Southeast Asia as well.

Early inhabitants

Moving by both land and sea routes from areas to the north of Indochina, successive waves of migrants passed through the area. The original Australoid inhabitants were succeeded by Melanesians and then by Indonesians probably moving southward in two distinct phases, one by land and the other by sea. The languages spoken by these various migratory groups are increasingly seen by linguists as having had a distant common origin, whatever the later differentiations established among them. In the area of modern Kampuchea, a language of the Mon-Khmer eventually became the dominant tongue after the Khmers, relative latecomers to the scene, had asserted themselves as political leaders, first in the state of Funan—centred in present southern Kampuchea and the southernmost part of Vietnam—and later in the north-central kingdom of Chenla.

The story of human activity in the area before the establishment of Funan, which Cambodian tradition ascribes to the 1st century AD, is not known in any detail. Settlements were close to lakes and rivers; the inhabitants engaged in agriculture and maintained cattle and pigs as domestic animals. They hunted with weapons that included the bow and arrow, for which arrowheads of polished stone, bone, and iron have been found. Metal cultures reached the Cambodian region well before the 1st century AD, and a site at Melouprei (now Phumĭ Mlu Prey) has revealed traces of iron and bronze casting. Close to the modern capital of Phnom Penh, the discovery of a bronze urn having close links with the Dong Son style of northern Vietnam (5th to 1st centuries BC) suggests that highly developed metalworking may have been taking place in pockets of Cambodian territory as early as the 4th century BC. Despite this evidence of growing technical capabilities, excavations at Oc Eo, Funan's major port on the southern coast of modern Vietnam along the Gulf of Thailand (Gulf of Siam), suggest that the Neolithic culture characterized by polished stone implements survived alongside the more advanced metal culture.

Funan. While future archaeological work may lead to a better understanding of Cambodian prehistory, true historical knowledge begins with the rise of Funan. From its claimed mythical beginnings in the 1st century AD until its incorporation into the successor state of Chenla in the 6th century, Funan was vitally important as a recipient of Indian culture, which shaped the political institutions, art, and general culture of later Khmer states. Always regarded by later Khmer dynasties as the state from which they sprang, Funan owed its prosperity to its position on the great east–west trade route between India and China. The name of the state is generally believed to come from a Chinese transliteration of a Khmer word *bnam* (*phnom* in modern Cambodian), meaning "hill." If correct, such a derivation is important as evidence of substantial Khmer influence over a state in which there was also a strong Indonesian ethnic and cultural presence.

Legendary origins

The national birth legend of the Funanese state tells of the arrival of a foreign Brahmin, Kaundinya, who overcame and subsequently married a local woman named Willow Leaf and set Funan upon its path to greatness. The legend is suggestive of the early influence of Indian thought and culture in the Indochinese area. Rejecting an earlier belief that large colonies of Indians settled in Southeast Asia, modern scholarship increasingly holds to a view that a relatively limited number of Indians, sometimes Buddhist traders, at other times Brahmins (high-caste Hindus), established themselves in positions of influence and propagated their more advanced knowledge of statecraft, religion, and art. A part of this view is the assumption that the existing populations of such areas as Funan were far from primitive savages and may have mastered the intricacies of wet rice cultivation.

The extent of implanted Indian influence in Funan before the middle of the 3rd century is uncertain, but a clearer picture of that period emerges from records left by two Chinese ambassadors who visited the country, *c.* AD 245. By that time Funan had extended its political power over the lower reaches of the Mekong and Tônlé Sab rivers and as far west as a section of the Malay Peninsula where trade passed from the Indian Ocean into the Gulf of Siam. This advance had taken place under the direction of King Fan Shih-man (*c.* 205–*c.* 225) and his nephew, Fan Chan (*c.* 225–*c.* 240), who took the throne as a usurper. Their successor, Fan Hsun (*c.* 240–*c.* 287), another usurper, was ruling at the time of the Chinese ambassadors' visit. The account of one of these ambassadors, K'ang T'ai, speaks of Funan as a land of walled cities whose inhabitants went unclothed through the streets but whose rulers gathered taxes in the form of precious metals, jewels, and perfumes. An Indian-based script was in use, and there were libraries and archives. The reference to the use of an Indian script is a clear indication of Indian influence, but it was not until the end of the 4th century that the full impact of Indian culture was felt in Funan.

This second "Indianization" of Funan came after a period about which there is little if any knowledge of developments within the state. Fan Chan's and Fan Hsun's reigns had seen the growth of official relationships between Funan and China and India. Relatively little is known, however, of the extent to which these official contacts were matched by a significant spread of Indian culture among the population at large. The appearance of a foreigner, Chandan, on the throne of Funan in 357 has been seen by some historians as a reinforcement of Indian influence and by others as reflecting a link with the Iranian world. Whatever may be the case, under Chandan's successors in the latter part of the 4th century and particularly in the 5th, there is a sense of Indian influence at a much wider level. Sanskrit inscriptions provide a more precise chronology of the reign of Funanese rulers and reveal that Hinduism and Mahāyāna Buddhism coexisted within the state.

Chandan's successor, according to the Chinese *History of the Liang,* was another Brahmin called Kaundinya, whose arrival in Funan was received with popular rejoicing and who instituted many reforms based on Indian models of law and administration. However mythical this Kaundinya may have been, the account of his arrival appears to capture correctly the importance of a new infusion of Indian culture. This cultural influence is abundantly apparent in the records that have survived describing the reigns of Funanese rulers during the 6th century. Funan was at the height of its power under the rule of King Kaundinya Jayavarman (d. 514).

'unan's reatest eriod

Excavations at the port city of Oc Eo have indicated the extent to which Funan prospered as a trading kingdom with links, indirectly, even with countries of the Mediterranean. Aerial photography has revealed a complex series of irrigation and communication canals that were established in the hinterland away from the coast. While Oc Eo may have been the most important port city, the royal capital was inland from the sea, at one time near the modern Cambodian town of Banam in Prêy Veng province and bearing the name Vyādhapura (Sanskrit: "City of the Hunters").

From passages preserved in Chinese dynastic histories there is considerable information on the material culture of Funan in its heyday as well as insights into the state's religious life. It was a slave-owning society in which the rich decked themselves with gold and silver jewelry and wore rich brocades. The king lived in a richly constructed palace and travelled on the back of an elephant. The common people amused themselves with cock fights and contests between fighting pigs. Justice was administered through trial by ordeal. Since most buildings were constructed of wood, little is known of the style of Funanese building. A few architectural remnants at Oc Eo reinforce the evidence of Indian influence. The same initial source of inspiration was present in Funanese statuary. Sculpture from the 4th century has very obvious links with Gupta art in India. In the 6th century a distinctively Funanese art emerged in which Indian iconography was given a Cambodian form.

Hinduism was the religion of the rulers of Funan in the 5th and 6th centuries, but Buddhism was widely diffused in the kingdom also. There is evidence that Buddhism also enjoyed a measure of royal patronage. The importance of Buddhism in Funan in the 6th century was so great that a Chinese embassy visited the country between 535 and 545 to ask the ruler, Rudravarman (514–539), for Buddhist texts and teachers who could give Buddhist instruction in China.

Rudravarman was the last king of Funan to reign over an independent state. The subjugation of Funan by the rulers of the emerging state of Chenla marks a major division in Cambodian history. Although there are gaps in the history of Funan, the importance of the state is clearly apparent. It was through Funan that the initial process of Indianization took place, and it was this state which was always regarded by later Cambodians as the origin of their dynasties. Though this view was propounded in part to enhance legitimacy, it also reflected an awareness of the vital links that Funan had with its Angkorian successor state (9th-15th centuries). While the details are unclear, Funan before its absorption into Chenla already had links with the Khmers, whose base area was well to the north in the middle Mekong or Champassak area of modern Laos. There is clear evidence that Khmer princes were already associated with the Funanese ruling house and that some areas under the control of the Funanese state in the north of the kingdom were settled by Khmers.

henla– ınan lation- ıip

Chenla. The first ruler claiming sovereignty over both Chenla and Funan was Bhavavarman (reigning 598), the grandson of Rudravarman of Funan, a fact which, along with his claim to power over both kingdoms, has led some authorities to suggest that the Chenla and Funan kings originally belonged to two branches of the same dynasty. Since Funan continued to send embassies to China until the beginning of the 7th century, the southern state apparently retained a degree of autonomy under Bhavavarman, whose capital was probably on the northern shore of the Cambodian Great Lake (Tonle Sap). Bhavavarman's brother, who succeeded him as Mahendravarman (*c.* 600–*c.* 611), left inscriptions that reveal considerable activity in the northeastern region of modern Cambodia around Krâchéh and Stœng Trêng. With Mahendravarman's son, Iśanavarman (*c.* 611–635), the power of the Chenla rulers over the declining state of Funan became absolute. Under Iśanavarman the power of Chenla was extended to the west as well as to the south, and good relations with the state of Champa (in modern Vietnam) were sealed by Iśanavarman's marriage to a Cham princess. Iśanavarman's capital, Iśanapura, at the modern site of Sambor Prei Kuk, about 12 miles north of Kâmpóng Thum, is the most impressive group of pre-9th-century remains so far discovered in Cambodia. A series of brick towers prefigure a number of later developments in Khmer art, and the site remained important as a centre of scholarship during the Angkorian period.

Under Iśanavarman's successors, Bhavavarman II (whose reign dates are unknown) and Jayavarman I (who reigned through most of the latter half of the 7th century), Khmer power extended throughout the Indochinese region. Yet, despite the description of Jayavarman as "glorious lion of kings" on one of his many inscriptions, the later division of the Chenla dominions into two separate regions probably began during his reign. Having expanded their power rapidly, the Chenla rulers were unable to maintain strict control over the various territories that they claimed the right to rule. Nevertheless, whatever political difficulties later sprang from the period, the 7th century was a time of continuing artistic development. Chinese accounts of court life under Iśanavarman give a picture of a rich material culture probably little different from that which had existed in Funan. Indian influence continued to be important in the art of the 7th century, and the two great Indian religions of Hinduism and Buddhism continued their coexistence. Of great significance for the future was the fact that the Khmers, when they established their settlements in lowland Cambodia, used hydraulic techniques for agriculture that they had developed in lands further to the north. Their "captive water" technique, which dammed water to be distributed by canals to less elevated regions, was later to be exploited to its full in the complex systems of Angkor.

Chenla's decline

Following Jayavarman I's death, the state of Chenla split into rival petty principalities. The history of the 8th century is obscure, but certain broad trends may be recorded. Land Chenla, the name given by the Chinese to the northern of the two divisions, apparently enjoyed a fairly stable existence with the centre of the state probably to the north of Angkor. By contrast, Water Chenla, the southern division, was an unsettled state beset by dynastic rivalries. As heir to Funan's position as an entrepot on the great east–west trade route, Water Chenla was grievously affected in the 6th and 7th centuries when traders began to bypass the Malay Peninsula, travelling to China by way of the Indonesian state of Śrivijaya in southern Sumatra. Along with the interruption of the trading link with the West, there was a sharp decline in direct cultural contact with India during the 7th century. Despite the diminution, and even elimination, of direct Indian influence, Khmer artistic achievements remained impressive until the latter half of the 8th century. And even this period of relative decline was rapidly followed by a dramatic efflorescence of Khmer artistic output, inspired by local genius rather than foreign models. This resurgence was the cultural accompaniment to the emergence of the Angkorian dynasty under the great Khmer ruler Jayavarman II (reigned *c.* 802–850), a man only distantly related to the ruling dynasties of pre-9th-century Cambodia.

THE ANGKOR PERIOD

Jayavarman II and his successors. In the latter part of the 8th century the Śailendra rulers of Java appear to have created a sphere of influence in Cambodia, and it was from Java that Jayavarman II returned to establish his kingdom about the year 800. Not the least remarkable aspect of his reign is the fact that since he left no inscriptions his achievements must be reconstructed from 11th-century inscriptions that give a clear picture of the vital importance of Jayavarman's reign. The concept of a unified Cambodian state was established, never to be forgotten by his successors, and a new state religion that established the Khmer ruler as a *devarāja* (god-king) was introduced during his reign.

On his return to Cambodia from Java, Jayavarman first established a capital at Indrapura, in modern Kâmpóng Cham province. But his subsequent three capitals were all in the region farther north, close to but not actually in the area of the later Angkor complex. Strategically, the area on the east of the Great Lake was distant from the threat of external attack. The lake was a source of fish, and the plains about it were, with the application of hydraulic engineering, a great source for rice. Once Jayavarman had chosen this region as the centre for Khmer power, it remained so for most of the Angkorian era.

Khmer kingship

At his last capital of Mahendraparvata, in the Kulén hills to the east of Angkor, he took part in a Śaivite Hindu ceremony consecrating him as a *devarāja* and establishing both him and his kingdom as independent of any other power, especially that which the Javanese had claimed to exert over Cambodia. In this ceremony—perpetuated by Jayavarman's Angkorian successors—the king's sacred personality, the very essence of the kingdom, was enshrined in a sacred *liṅga* (a ritual phallic symbol) that was housed in a pyramidal structure called a temple mountain. This temple mountain was both the centre of the earthly kingdom over which the king ruled and the symbolic centre of the universe within which the kingdom existed. The details of this highly complex concept are possibly less important than the recognition that through participation in it Jayavarman and his successors saw themselves as universal rulers, subservient to no other state. The same symbolic purpose led to the establishment of the great Angkor temples, which were prefigured by those of Jayavarman's reign. In sculpture and the plastic arts, generally, the 9th century witnessed a revival and development of styles and techniques that blended Khmer traditions with those of Java and Champa.

After Jayavarman's death in 850 he was succeeded by a son, Jayavarman III (reigned 850–877), who left no significant mark upon Khmer history. The next ruler, Indravarman I, a cousin of Jayavarman III and possibly a usurper, played an important role in the development of the Angkorian state. Although his capital was not yet located on the site of the later Angkorian kings, it was at Roluos, not far distant, where Jayavarman II had founded one of his four capitals. At Roluos, Indravarman built two great stone temple mountains, Bakong and Preah Ko, which mark the beginning of Khmer classical art, the form from which the later temples developed. Even more important, however, was Indravarman's construction of a vast irrigation system that, by means of an artificial reservoir, permitted the assured exploitation of rice lands that otherwise would have remained unproductive. The later elaboration of artificial irrigation systems allowed the Khmers at Angkor to maintain a densely populated and highly centralized state in a relatively limited area. Only with such an irrigation system was it possible to feed the immense labour force necessary for the construction of the Angkor temples.

The 8th-century empire

Indravarman's successor, Yaśovarman I (reigned 889–900), inherited a kingdom from his father that was at peace, and he proceeded to build solidly upon Indravarman's achievements. His new capital of Yaśodharapura, the first Khmer city in the Angkor area proper, centred on the hill Phnom Bakheng, which Yaśovarman crowned with a temple. The city complex occupied some 16 square miles; the irrigation of this area depended upon a new system, fed from a great reservoir east of the city, the so-called *baray oriental,* or eastern *baray* of modern times, which was fed from the Siĕmréab River. The power which Yaśovarman accumulated at Angkor enabled him to extend Cambodian domination over a territory as large as Funan's at that empire's height. It is uncertain whether this extension of power was the result of armed conquest or the readiness of other states to acknowledge the suzerainty of the leading power in the region. Some authorities believe that achievements attributed to Yaśovarman rightly belong to later reigns, but he was certainly a figure of great importance. He built monasteries throughout his kingdom for both Śaivites and Buddhists, and the remains of his temples, particularly that of Phnom Bakheng, show a continuing development of the Khmer genius of blending architectural construction with religious symbolism.

The century following Yaśovarman's presumed death in 900 was one for which political records are now at a minimum. External commentary from Chinese sources vanished with the internal division of China after the fall of the T'ang dynasty. Within Cambodia itself the progress of the state must be charted through inscriptions, which provide a highly selective view of developments, and through the material evidence of temples, both royal and nonroyal in foundation. Nevertheless, close study of the extant inscriptions does permit some insight into the life of Cambodian rulers, the narrow oligarchy of priests and advisers who supervised the complex bureaucracy that presided over the daily business of the state, and even, occasionally, the activities of less elevated members of the population. Six Khmer kings ruled during the 10th century. Probably the most significant political developments of their reigns were the temporary abandonment of the Angkor capital under the usurper Jayavarman IV (reigned 928–942) and its subsequent re-establishment by Rajendravarman II (reigned 944–968). Rajendravarman's successor, Jayavarman V (968–1001), is known chiefly for his continuation of Rajendravarman's efforts to control Champa and for his promotion of scholarship and learning. In religious matters the 10th century continues to provide a record of Hindu cults coexisting with Buddhism. Although Saivism (worship of the Hindu god Śiva) was the principal royal cult, Buddhism also received its share of patronage.

Angkorian government and society. Though the Khmer monarchs were absolute rulers in theory, their power was often limited by the complex bureaucracy of the Angkorian state. The king was the final arbiter in legal matters and sometimes led his troops in battle, but much of his time was taken up with ceremonial and religious functions deemed necessary to insure the well-being of the state. If he was not a forceful personality, he might be reduced to a figurehead.

The bureaucracy

The bureaucracy was composed of learned Brahmins (members of hereditary priestly families) and military leaders who were sometimes members of the royal family. These men formed a class separate from the population at large; there is considerable evidence that their separate identity was reinforced through intermarriage. They were particularly influential in regions more distant from the capital. Although the construction of a temple mountain was the prerogative of the king alone, the great officials founded their own shrines, each supported by surrounding villages, which met the high cost of maintaining the temple and its priests. None of these shrines rivals the great royal foundations in size, but the temple of Banteay Srei, a little to the northeast of the Angkor complex, is considered by many to be the most perfect of all Khmer temples. It was built in 967 by a Brahmin, Yajñavarāha, a man of royal descent who had supervised the education of both Rajendravarman II and Jayavarman V.

Between the great officials, on the one hand, and the peasants and slaves (about whom little is known), on the other hand, there was another group, whose existence is recorded in inscriptions but whose role in the Khmer state has yet to be studied in any detail. This was a group of land-owning men who held no official position and who, unlike the priestly officials of the great foundations in provincial regions, appear to have had little contact with the capital. Their existence, and the existence of "castes" of teachers and priests who were recruited from provincial areas but who were clearly not of the elevated status of the great officials, provided some qualification to the narrow classifications into which Khmer society has frequently been divided in modern historical accounts. While the size of these intermediate groups is unknown, their existence suggests a more complex society than that which envisages a single, sharp division between the king and his officials, and the peasantry and slaves.

The 11th century. At the beginning of the 11th century one of the most energetic of the Khmer monarchs, Suryavarman I (reigned *c.* 1002–50), challenged the position of Jayavarman's legitimate successor, Udayadityavarman I, to hold the throne. A Cambodian prince, but with scant direct claim to the throne, Suryavarman had defeated Udayadityavarman by 1002, but a long civil war dragged on until he finally gained control over the whole kingdom about 1011. Although the evidence comes from chronicles of a considerably later period, Suryavarman appears to be correctly credited with the extension of Khmer power over much of modern southern Thailand and over Mekong valley regions as far north as Luang Prabang. In contrast to this activity in the west, his relations with Champa and Vietnam, to the east, seem to have been calm and stable. His long reign enabled the restoration of many of his predecessors' foundations both at Angkor itself and in other parts of the country, and the completion, notably, of the Phimeanakas and Ta Keo temples begun by Jayavarman V.

ynasty

Suryavarman's son, Udayadityavarman II (reigned 1050–66), carried on his father's expansionist policies. While some historians judge that this led to the Khmer state reaching its furthest limits, these policies also provide part of the explanation for the record of revolts that marked Udayadityavarman II's reign. Cham encouragement appears to have been behind a revolt in the southeast of the kingdom. And in the west the Khmers found themselves in confrontation with the newly victorious Burmese, who had conquered the Mon capital of Thaton. Other revolts within Cambodia itself are believed by some historians to have reflected resentment at the favour which the ruler showed toward Buddhism, a religion that his father had done much to promote. Despite the record of warfare and revolt during his reign, Udayadityavarman II found time to build another great *baray,* or reservoir, the western *baray,* which greatly increased the cultivable area of the region around Angkor. Udayadityavarman's successor was his brother, Harshavarman III (reigned 1066–80), who was unable to prevent a major incursion into Cambodia by a Cham army that marched to Sambhupura, a city on the Mekong near the modern town of Krâchéh, and sacked it. Harshavarman was overthrown by a usurper, who reigned as Jayavarman VI (1080–1107), but possibly never occupied the capital at Angkor. He and his successor, Dharanindravarman I (1107–13), had to contend with the opposition of members of Harshavarman's family.

From Suryavarman II to Jayavarman VII. *Suryavarman II.* This opposition was finally and forcefully crushed by Suryavarman II, one of the greatest figures in Cambodian history, who came to the throne in 1113. Reducing the kingdom of Champa to vassal status, he annexed it completely when the Cham king would not cooperate in his campaigns against the Vietnamese state farther north. Suryavarman's expeditions against the Vietnamese took his armies as far north as Thanh Hoa in modern North Vietnam. The extent of his success in the Mae Nam Chao Phraya Valley is open to some doubt, but the substantial Khmer influence found in the architecture of the Thai state of Lopburi suggests an important impact on that region (present Thailand). Khmer influence also reached well down into the Malay Peninsula.

Suryavarman's military and political conquests are matched by the magnificence of his achievements in building the great temple complex of Angkor Wat. Completed at about the time of his death in 1150, Angkor Wat was only one of the outstanding architectural achievements of his reign. Beng Mealea, some 25 miles to the east of Angkor, and Banteay Samre on its outskirts are other magnificent examples of Khmer art and architecture.

Suryavarman blended Śaivism and Vaiṣṇavism (the cult of Vishnu, or Viṣṇu) in his state religion. Within the inner sanctuary of Angkor Wat was a gold statue of Vishnu mounted on the fabled winged Garuḍa, representing the deified Suryavarman as Vishnu. Yet once again, there was no religious exclusiveness within the Khmer state. Buddhism, even if overshadowed by the Hindu cults, continued nonetheless to have its adherents.

The first period of decline. Suryavarman's successes rested on uncertain foundations, and by the end of his reign the combined effects of an overambitious external policy and the demands that his building program placed upon the resources of the state entailed heavy costs. His repeated expeditions against the Vietnamese failed to achieve his goal of subjugating that energetic neighbouring state. A year before his death (*c.* 1150), the Chams freed themselves from Khmer domination and their strength in the immediately succeeding decades was directed toward wiping out the stigma of Khmer overlordship by attacking the Cambodian heartland. Indeed, between 1050 and the accession of Jayavarman VII in 1181, the fragility of the Khmer state after a period of greatness was demonstrated time and again. Internal rebellion was added to the challenge of the Chams to further weaken the power of the ruler. Suryavarman's immediate successor, Dharanindravarman II (1150–60), had an apparently uneventful reign, notable largely for the fact that the new king was a devotee of Buddhism rather than of Hinduism. But at his death the rightful successor, Jayavarman, was passed over and the throne was occupied by his younger brother Yaśovarman II (reigned 1160–*c.* 1166). In the space of six years Yaśovarman faced a peasant or slave revolt, which was successfully subdued, and the rebellion of an ambitious official, Tribhuvanadityavarman, which caused the king's dethronement and death. Although Jayavarman came out of exile in Champa to defend the king, he arrived after the usurpation had taken place and again retired from the scene. During Tribhuvanadityavarman's reign the resurgent Chams began their long campaign of attrition against the Khmers. Border skirmishes begun in 1167 finally culminated in the humiliating and highly successful Cham attack against the capital at Angkor in 1177. The capture of the capital and the death of the ruler left Cambodia in chaos.

Cham
attacks

Khmer Empire, *c.* 1200.

Jayavarman VII. The accession of Jayavarman VII brought a change. This ruler ranks with Suryavarman II among the greatest of all Angkorian rulers. His energy was phenomenal: in both the success of his campaigns against the Chams and his devotion to temple construction he revivified the Khmer empire. As was the case with Suryavarman II, however, this massive outpouring of energy exacted a heavy cost. Jayavarman's policies so exhausted the state that, once his leadership had gone, no other ruler was able to maintain it in the same manner. The most active builder of all the Angkorian monarchs, he left a large number of inscriptions. To his reign belongs the great complex of Angkor Thom, which rivals Angkor Wat in magnificence.

Jayavarman was nearly 60 when, following a period of almost constant campaigning, he achieved sufficient control to assume the kingship in 1181. He repaid in full the injuries his country had suffered at the hands of the Chams. The Khmer armies laid waste to their kingdom and sacked the Cham capital of Vijaya. Through skillful use of Cham allies opposed to their own ruling family, Jayavarman prepared a campaign that finally led to the annexation of Champa, which remained under Khmer control from 1203 to 1220. Within Cambodia itself Jayavarman was unchallenged after the first year of his reign. To the west and south of Cambodia, the Chao Phraya Valley and parts of the Malay Peninsula recognized Cambodian suzerainty. An inscription near modern Vientiane, Laos, records his domination of that area.

Though Jayavarman's Buddhist adherence was to the Mahāyāna school, which had long been dominant in Cambodia, during his reign Theravāda Buddhism was introduced into Burma by the Mon monk Chapata. Among Chapata's companions was a Khmer prince who has been identified as one of Jayavarman's sons. This link with the Theravāda school foreshadowed its later patronage by the Khmer kings, which led to its supplanting the Mahāyāna school and so to a major change in the state's religion. Although modern scholarship rejects the view that the conversion of the Cambodian state to Theravāda Buddhism provides a single convincing explanation for the decline of Angkorian power, the change when it came was a profound one, not least because the Theravāda cult did not call for the construction of great temples as did both Hinduism and Mahāyāna Buddhism.

Jayavarman VII's greatest energies during his reign, as far as external policies were concerned, had been directed toward the conquest and subjugation of the Chams. Before the end of his life, however, the most formidable threat to Khmer power was developing to the west.

The Thai threat

The Thais had been filtering into the Chao Phraya Valley from well before the beginning of the 12th century. In a famous section of the Angkor Wat bas-relief, Thai mercenaries are depicted as ill-disciplined and strangely dressed men of little civilization. Thai chieftains living under Khmer rule in what was the northwestern extension of the Cambodian empire were, however, growing in power and absorbing much of the civilization of their overlords. Only 20 years after Jayavarman's death the Thais of the state of Sukhothai were powerful enough to break the shackles of foreign rule. That this should have been so emphasizes the rapid reversals that followed the end of Jayavarman's rule (*c.* 1215, possibly as late as 1219). He was the last of the great kings. Yet even if the 13th and 14th centuries were centuries of decline, they were by no means a period of eclipse, despite the repeated incursions of the Thais, which forced a temporary abandonment of Angkor before the end of the 14th century.

The final decline. After Jayavarman's death, no significant building took place at Angkor, and the Khmer empire began to contract. Control over Champa ended in 1220. In 1238 a Thai chieftain—son-in-law of Jayavarman VII—mounted a successful coup d'etat against the Khmer governor of the upper Chao Phraya region and founded the Thai state of Sukhothai. Khmer overlordship in the Malay Peninsula also disappeared after Jayavarman's death. For the greater part of the 13th century, however, Angkor remained a glittering and wealthy city, one which inspired wonder in the eyes of the Chinese traveller Chou Ta-kuan when he visited the city in 1296. The account that Chou Ta-kuan provides of Angkor at this time is both the longest and most detailed description of the Khmer capital, and despite its inaccuracies and reliance on legend it gives a remarkably vivid picture of the rich court society that continued to exist, even though the Chinese writer records the fact that Cambodia had been under attack from the Thais shortly before. Chou Ta-kuan left a picture of a bustling city in which the king still went forth in great pomp and ceremony. Whatever weakness now characterized the Khmers, Chou Ta-kuan still judged Cambodia to be the strongest of the states to the south of China. Notable among his observations was the presence in the Khmer capital of Buddhist monks of the Theravāda school. Thus, by the end of the 13th century the Cambodian state had abandoned its adherence to Hinduism and, at the court and in the capital at least, adopted Theravāda Buddhism.

Theravāda Buddhism

This change took place during the long reign of Jayavarman VIII (reigned 1243–95), probably about the middle of the century. Its causes remain a matter for some debate. The view of some of the earliest scholars of Cambodian history, that Theravāda Buddhism was a "democratic" religion that appealed to the Cambodian masses bowed down before the overwhelming exactions of their kings, has been severely qualified. The adoption and propagation of a particular religion within Angkorian society is much more likely to have been a matter for royal patronage. One intriguing suggestion is that the rulers and their advisers at Angkor were aware of the political success of the increasingly powerful Thai states to the west and attributed this to the form of Buddhism, the Theravāda school, which the Thai rulers followed. Adherence to Theravāda Buddhism was never incompatible with the pursuit of power for the Thai rulers and would not have been viewed so by those in power at Angkor. Moreover, placing importance on the population's acceptance of Buddhism seems illogical in view of the fact that their most fundamental religious adherence was to animistic cults. Viewed from a slightly different perspective, however, there may be value in considering the permeation of Theravāda Buddhism into the ranks of the general population as reflecting some readiness on the part of the people to accept a new religion that made few demands upon them—in contrast to Hinduism and Mahāyāna Buddhism, which had sapped their material and physical resources. Not only did the introduction of the new religion mean the end of temple building on the old scale, it also led to the disappearance of the use of Sanskrit; the latest Cambodian Sanskrit inscription dates from 1327. Henceforth Pāli was the sacred language.

For a short period at the beginning of the 14th century the Khmers enjoyed a respite from external threat. The great Thai ruler of Sukhothai, Ramkhamhaeng, died *c.* 1317 and his death removed the motive force that had brought Sukhothai to a position of considerable power, posing a threat to Angkor. The respite, however, was a brief one. Whereas the selection of the Angkorian region as a site for the Khmer capital in the 9th century had ensured its isolation from external threats, the ever-growing presence of the Thais in the Chao Phraya Valley meant that Angkor was in an increasingly exposed position. The king at Angkor when Chou Ta-kuan visited the city in 1296 was Indravarman III (1296–1308). His successors, the last to leave inscriptions, were Indrajayavarman (1308–27) and Jayavarman Paramesvara, who acceded to the throne in 1327 but for whom no date of death is recorded. With an absence of inscriptions and the unreliability of other records, there has been a measure of historical disagreement over developments during the 14th and 15th centuries. Recent research has challenged the previous assumption that the Thais captured Angkor in 1431, from which date the Khmers abandoned their capital. According to this new view, based on both Cambodian and Chinese sources, Angkor fell to Thai attacks in 1369 and 1389 and was on each occasion occupied by Thai forces. It was not, however, until 1444 that the final (third) great attack against Angkor took place that did, indeed, lead to its ultimate abandonment.

The fall of Angkor

The proposed new chronology, which is accompanied by evidence of considerable Thai involvement in the family rivalries of the Khmer royal house, is helpful for an assessment of why it was that Angkor was finally abandoned in such a dramatic fashion. Emphasis on the political significance of the change to Theravāda Buddhism remains important, with its overtones of a sense of crisis in Khmer national confidence. But other, more obvious, material factors were clearly involved. The record of Thai attacks against Angkor highlights the extreme fragility of the Angkorian economic system. Under pressure from the Thais, and on occasion from the Chams also, the Khmer rulers at Angkor had the greatest difficulty in maintaining the intricate hydraulic system upon which Angkor's survival depended. The reservoirs and canals needed constant attention, which was impossible under conditions of war. Damage to the system during actual attacks on the city, and the shipping off of thousands of prisoners of war, further weakened the economic base of the state. Recent analysis now discounts the view that malaria, spreading from the shattered hydraulic system, played a part in Angkor's decline. When, in a manner that became so characteristic in the years of decline after the fall of Angkor, squabbles between members of the royal family further weakened the Khmers, the stage was set for the collapse of the Angkorian empire. After the abandonment of the former imperial city in 1444, the Khmer court moved south to a site near modern Phnom Penh, and thence to Phnom Penh itself. For the remainder of Cambodian history to the present, this region was to be the centre of a contracting Khmer world.

The artistic traditions of Angkor did not immediately disappear. The expression of these traditions was no longer the mighty temples in stone but rather the more intimate art of the religious statue, and even this art form declined as political power waned more rapidly during the 17th and 18th centuries before the ever greater power of the Thais and the Vietnamese. When a French colonial presence was established in Cambodia shortly after the middle of the 19th century, it was common for the European newcomers to speak of Cambodia as having "fallen from its antique splendour." This comment accurately assessed the manner in which the once singularly powerful Khmer empire had, in the years after the fall of Angkor, gradually ceased to play any major role in the Indochina region.

THAI AND VIETNAMESE HEGEMONY

In the century and a half following the abandonment of Angkor, much of Khmer history is a confusing mixture of uncertain dates and complex dynastic rivalries within the Khmer royal family. Dominating the years up to the Thai conquest of Lovek (a later Khmer capital a little to the north of Phnom Penh) in 1594 is the record of almost incessant warfare between the Khmers and the Thais, now based in their capital of Ayutthaya. The contest was not entirely uneven. During the reign of Ang Chan (1516–66) the Khmers carried their campaign deep into Thai territory on one occasion, in 1564, but reached the city of Ayutthaya only to find it occupied by Burmese invaders. Yet despite the temporary success of his son Barom Reachea I (1566–76), which enabled the Cambodian court to reoccupy the city at Angkor temporarily, the tide was flowing against the Khmers. Once the Thais had successfully resisted the challenge posed by repeated Burmese invasions, they were able under the leadership of King Naresuan to plan and deliver a crushing blow against the Cambodian state. This was the capture of the capital at Lovek in 1594.

The "Spanish interlude." Before Lovek fell to the Thais the Cambodian king Satha (1576–*c.* 1594) had sought to gain assistance from the Portuguese and Spaniards, who were now established in Southeast Asia. Satha's efforts to enlist their support and the ambitions of both missionaries and soldiers of fortune led to one of the more curious episodes in Cambodian history. For a brief period, after the fall of Lovek, Spanish soldiers became arbiters of power within the Khmer state. A Spanish expedition arrived in Cambodia in 1596 with the intention of giving aid to King Satha. By then, however, Satha had been deposed and a usurper, Chung Prei, occupied the throne. After a series of disagreements and the sacking of the Chinese quarter of Phnom Penh by the Spanish forces, the Spaniards attacked the king in his palace at Srei Sânthôr, killing him and his son. Deciding to return to Manila after this affair, the Spaniards later changed their minds while sailing along the Vietnamese coast and marched overland to Laos, where they found one of Satha's sons and successfully installed him upon the Cambodian throne in 1597 as Barom Reachea II (1597–99). The great officials within the Cambodian court were by this time deeply resentful of the power wielded by the foreigners and were anxious to depose Barom Reachea in favour of Satha's brother, Soryopor. An incident involving one of the Spanish leaders in Phnom Penh led to a massacre of the Spanish garrison in mid-1599 and, after a period in which three princes occupied the throne, Soryopor returned to gain the throne as Barom Reachea IV (1603–18), with the assistance of a Thai army. The Spanish interlude was the last significant contact the Cambodian court had with Europeans until the onset of French colonialism in the mid-19th century. It was an exotic interregnum that had no lasting political effect but did, however, provide later historians with one of the few accounts of the Angkorian irrigation system, written by an observer who visited Angkor at a time when it had been reoccupied toward the end of the 16th century.

Cambodia as a vassal state. Cambodian history from the accession of Barom Reachea IV until the establishment of the French Protectorate in 1863 is a sorry record of weak kings, almost always under challenge from dissident members of the royal family and forced to seek the protection of either of their stronger neighbours, Siam (Thailand) and Vietnam. Between 1603 and 1848, the date of the last Cambodian ruler to assume the throne free from French political control, no fewer than 22 monarchs uneasily occupied the throne. Several of these rulers had more than one reign, as they gave up their position either through choice or under duress, only to return when their successors either proved incapable or were themselves deposed. The details of this unstable period are less important than the record that is available of the manner in which Cambodia slowly slipped under the dual suzerainty of Siam and Vietnam. Early in the 17th century, Chey Chetta II (1618–28) successfully, if rather temporarily, declared his country's independence from Siam. In order to strengthen his position, the king sought assistance from the Nguyen lords of southern Vietnam. This fatal decision, which had involved Chey Chetta's marrying a Vietnamese princess, brought a Vietnamese demand for the right to settle Vietnamese colonists in areas of modern southern Vietnam, near Saigon, which until this time had been Cambodian territory. From this point onward, rival claimants for the Khmer throne sought to advance their interests through the respective support of either the Thais or the Vietnamese, at the ever-increasing cost of loss of territory or loss of power. For the Vietnamese, assistance given to Cambodian princes was followed by the extension of Vietnamese settlement into former Cambodian territories. For the Thais, the provision of aid was joined to an insistence upon Cambodia's assuming a vassal status, but it did not involve the colonization of Cambodian lands.

Vietnamese
expansion

That Cambodia survived at all during this bitter period was attributable in large part to the other preoccupations that weighed upon the Thais and the Vietnamese. In the middle years of the 18th century, Thai energies were largely taken up with wars against the Burmese, which led, in 1767, to the Burmese capture of Ayutthaya. Later in the same century, the Nguyen rulers of southern Vietnam were engaged in a prolonged campaign to regain power from the usurping Tay Son rebels. Yet if these facts had slowed the pace of Cambodia's decline, the situation by the end of the 18th century was nonetheless grim. Over the course of the century, all of what was to become the French colony of Cochinchina had fallen under Vietnamese control. In the west, Thai suzerainty had been firmly established over the great provinces of Bătdâmbâng and Siĕmréab. As the century drew to a close, and as the Vietnamese leader Nguyen Anh, later to reign as Gia Long, still fought to unify his country, the Thai court at Bangkok was firmly in control of the Cambodian royal family. King Ang Eng (reigned 1779–96) was actually crowned in Bangkok and was placed on the throne at the Khmer capital, Oudong, north of Phnom Penh, through the support of a Thai army. Following Ang Eng's death, Ang Chan, a minor, succeeded to the throne. He was crowned in 1806 and ruled uncertainly until 1835.

Ang
Chan's
reign

The reign of Ang Chan II confirmed Cambodia's dual vassalage to Siam and Vietnam. Faced with his rebellious brothers, Ang Chan gained assistance from Vietnam, while the Thais supported his brothers. The uneasy calm that was finally established, as Cambodia acknowledged both Thai and Vietnamese suzerainty, ended with Ang Chan's death. Vietnamese pressure was strong enough to ensure that a weak and powerless princess was then placed on the throne while almost total Vietnamese control was exercised over the country. Not until 1841, when Ang Duong (reigned 1848–60) returned from exile in Bangkok supported by Thai troops, were the Cambodians able to exercise even a minimal degree of independence. Because Thai support had helped him to the throne, Siam exercised a preponderant influence over Ang Duong, but he remained in tributary relations with Vietnam. As the last king to rule free from French control, Ang Duong has often been idealized in modern Cambodia. He was devoted to revitalizing the state, but his resources were desperately limited. Cambodia survived essentially because of the restraint of its neighbours, and before the end of his reign, Ang Duong's rule was troubled by internal rebellions.

FRENCH RULE

The protectorate. French control over Cambodia developed as an adjunct to French colonial involvement in Vietnam. Before his death, Ang Duong, on the urging of a French missionary, had sought to gain French assistance to regain former Cambodian lands held by the Vietnamese. He did not seek a French protectorate over his country, as many French accounts have suggested. There was no response to Ang Duong's call for help, and the French decision to advance into Cambodia came only when, with a colony implanted in Cochinchina, the French began to fear that British and Thai expansion might lead to hostile control of the Mekong River. In an almost classic use of gunboat diplomacy, the French in 1863 intimidated the Cambodian king Norodom (acceded 1860) into signing a protectorate treaty that gave France control of Cambodia's foreign affairs. When Norodom was crowned at Oudong in 1864, the French stood by as new suzerains of the weak Cambodian state.

Reign of Norodom

In the early years of the French protectorate, the European newcomers interfered little in the affairs of the Cambodian state. Indeed, French protection had distinct similarities to the part played by Cambodia's Asian suzerains in the past. At odds with his half brothers and faced with rebellion, Norodom gained rather than lost as the result of the French presence. Although he bitterly resented the French recognition of Thai control over Bătdâmbâng and Siĕmréab provinces, he might well have lost the throne if it had not been for French support. By the mid-1870s, however, French officials in Cambodia were pressing for greater control over internal affairs. Shocked by what they regarded as the profligacy and barbarity of Norodom's court and methods of government, they sought to introduce reforms. In pursuing their goals they acted with the knowledge that Norodom's half brother Prince Sisowath was ready to cooperate with them and was most ambitious to replace Norodom on the throne. Yet, despite the power that the French could exercise, their repeated efforts to change the methods of Cambodian administration foundered on the rock of Norodom's stubborn opposition to change. Exasperated by the king's intransigence, Gov. Charles Thomson of Cochinchina, who also held responsibility for the French position in Cambodia, forced Norodom in June 1884 to sign a convention virtually transforming Cambodia into a colony. The result of this action was a Cambodian rising that broke out in January 1885 and lasted for two years.

Anti-French rebellion

This rebellion was the only major anti-French movement to occur in Cambodia until after World War II. It gravely threatened the French position in the country and was finally put down only when French officials were able to persuade the King to call upon his countrymen to lay down their arms in return for some French concessions to the King's position. This was, basically, a hollow victory for Norodom. What the French had been unable to achieve in a single sweep by the convention of 1884 they proceeded to gain through piecemeal action. As Norodom's health declined and as senior Cambodian officials began to see their interests linked as much with French power as with their monarch, the way was opened for greater and greater French control over the actual business of government. In 1897 the French representative in Phnom Penh assumed the chairmanship of the Cambodian Council of Ministers, and the King's influence in government was reduced to a bare minimum. Norodom died a bitter man in 1904.

Yet Norodom's reign was not entirely one of constant loss for the Cambodian monarchy. Although the French gained political ascendancy, they ensured the survival of the Cambodian state, and, by maintaining the king in a splendour that had probably not been equalled since Angkorian times, they greatly enhanced his symbolic position within the kingdom. This fact was to be of considerable importance in the post-independence period following World War II.

King Norodom's ambitious half brother Sisowath finally did succeed to the Cambodian throne in 1904. Already in his 60s, he nonetheless continued to reign until 1927. While Sisowath held the throne, no difficulties arose between the Cambodian king and the French, nor was there any growth of nationalist activity comparable to that in Vietnam. By preserving the Cambodian monarchy, the French administration successfully prevented the development of any alternative focus for national identification. The one significant event that occurred during Sisowath's reign involved a mass peasant protest against tax and corvée (forced labour) requirements in 1916. Yet even this peasant protest was essentially peaceful and the protesters disbanded once the King had given his assurance that royal consideration would be given to ameliorating conditions. During Sisowath's reign, and that of his son and successor, Monivong (1927–41), the first notable economic developments derived from French rule took place. Red-earth lands in the east were brought under rubber cultivation, and, for the first time, there was a realization that Cambodia's economic opportunities went beyond the export of rice.

Rubber cultivatio

World War II and the First Indochina War. When Monivong died in 1941, the Japanese had occupied Indochina while leaving the French administration in nominal control. In these difficult circumstances, the French governor general of Indochina, Adm. Jean Decoux, placed Prince Norodom Sihanouk on the Cambodian throne. Although some uncertainties remain about the reasons for Sihanouk's elevation, Decoux seems to have been guided by the expectation that, as a young man of 18, Sihanouk, unlike the late King Monivong's son, Prince Monireth, would be readily controlled by the French. The error of the French estimation of Sihanouk's pliability became apparent in the years after the end of the war.

The effect of the Japanese occupation on Cambodia was less profound than it was in many other Southeast Asian countries. The overthrow of the French administration throughout Indochina in March 1945 brought the opportunity for political development to Cambodia. Although Sihanouk declared his country's independence from France, he and his advisers looked forward to cooperation with the former protecting power. Others, led by Son Ngoc Thanh, who had urged opposition to the French in the 1930s and been forced into exile in 1942, urged a sharp break with France.

The end of World War II brought the re-establishment of French control over Cambodia. Despite abolition of Cambodia's protectorate relationship, as it became an "autonomous state within the French Union," real power remained in French hands. Yet between 1945 and Cambodia's final achievement of independence in 1953, important political developments occurred. There were more demands for full independence, and a contest developed between the King and his supporters, who wished to uphold the supremacy of the crown, and those who sought to make Parliament the predominant power.

Re-establishment of French control

Cambodia was ill prepared for parliamentary democracy, and the years between 1945 and 1953 were marked by factional strife. The dominant Democratic Party was frequently at odds with the King and suffered from internal dissension. The death in 1947 of its able leader, Prince Youtevong, was a blow to the party and to those who hoped for a constitutional monarchy. Outside Parliament, Son Ngoc Thanh, now a bitter opponent of Sihanouk's policies, led the dissident Khmer Issarak (Independent Cambodians), who opposed both the King and the French. With this internal disunity and with the

French fighting the Vietnamese revolutionaries, the Viet Minh, throughout Indochina, Sihanouk acted. In January 1953 he dissolved Parliament, declared martial law, and left Cambodia to seek the support of world opinion for his country's independence.

INDEPENDENCE

Sihanouk finally succeeded in his personal campaign, known as the Royal Crusade, when the French granted independence on November 9, 1953. At the Geneva Conference in May of the following year, Sihanouk's representatives achieved a further triumph when his government was recognized as the sole legitimate authority within the country. This decision prevented the Viet Minh forces and the limited number of left-wing Khmers who were their allies from gaining any regional authority within the country, as happened in Laos. The King's achievements left him in a momentarily unchallengeable position; even Son Ngoc Thanh appeared ready to cooperate with Sihanouk.

Independence and the end of the First Indochina War did not, however, bring an end to political factionalism. Finding himself once again in conflict with his domestic opponents, Sihanouk took a dramatic new step. In March 1955 he abdicated in favour of his father, Norodom Suramarit, and formed a new mass political movement, the Sangkum Reastr Niyum (People's Socialist Community). Loyalty to Sihanouk and the country were the guiding principles of the Sangkum. In the elections of September 1955 it won every seat in the National Assembly. From then until his fall in March 1970, Sihanouk was the central figure in Cambodian politics, sometimes as prime minister and, after his father's death in 1960, when no new monarch was named, as chief of state. Overt political life was carefully controlled by the Prince and his advisers.

ounding

ingkum

Before the mid-1960s, external crises posed the greatest threat to Cambodia's stability. Conscious of historical precedent, Sihanouk saw South Vietnam and Thailand as the greatest threats to Cambodia's survival, particularly as these two neighbouring states were allied with the United States, which Sihanouk distrusted. At the same time Sihanouk feared the eventual success of the Vietnamese Communists and the danger he saw in a unified Vietnam. In these circumstances he proclaimed a policy of neutrality in international affairs. Convinced, however, of U.S. involvement in plots against his state and his family in 1959 and 1960, Sihanouk finally broke relations with Washington in May 1965 and aligned Cambodia more closely with China, North Vietnam, and the National Liberation Front in South Vietnam. From 1965, in an attempt to anticipate the future, he agreed clandestinely to the use of Cambodian territory by the Vietnamese Communists.

This decision further alienated right-wing elements in Cambodian society, particularly the army officer corps. The conservative urban elite already resented the economic policies introduced in 1963 and 1964, and they saw the closer alignment with the Vietnamese Communists as potentially ruinous to their interests.

From 1966 Cambodia's internal politics developed in a complex fashion. Although Prince Sihanouk remained a revered, even semi-divine figure for most of the peasantry, he was increasingly seen as a threat by both the right and the left. Young left-wing Cambodians, many of them educated abroad, resented Sihanouk's internal policies, which did not tolerate radical dissent. The outbreak of a rural rebellion in 1967 convinced Sihanouk that the greatest danger to his regime came from the left. He increasingly bowed to pressure from the army and other conservatives to follow a policy of harsh repression against left-wing elements.

By 1969 Sihanouk's personal position had deteriorated, and conflict between the army and left-wing opponents of the Prince's regime had increased. Right-wing politicians, most notably Gen. Lon Nol and Prince Sisowath Sirik Matak, plotted to depose Sihanouk, whom they saw as the root cause of their country's problems. They enlisted the support of Sihanouk's long-time enemy Son Ngoc Thanh, who had remained a dissident throughout the 1960s at the head of the Khmer Serei (Free Cambodians), a group receiving clandestine assistance from the United States. The extent of U.S. involvement in this plotting against Sihanouk is a matter of controversy. There seems little doubt, however, that U.S. intelligence services were aware of developments.

Matters came to a head in March 1970 when, with Sihanouk absent in France, Lon Nol and Sirik Matak called for the evacuation of all Vietnamese Communist forces from Cambodian soil and instigated demonstrations against the North Vietnamese and National Liberation Front embassies in Phnom Penh. At the same time, Sihanouk's conservative opponents called on him to renounce his international and domestic policies. Within a week it was clear that neither the Vietnamese Communists nor Sihanouk would negotiate under threat, and on March 18, Lon Nol's faction deposed the Prince. Sihanouk took up residence in Peking. From there he became the head of both a government in exile and a National United Front of Cambodia (NUFC), which was dedicated to overthrowing the Lon Nol regime.

Deposition of Sihanouk

Sihanouk's overthrow brought Cambodia's full involvement in the Second Indochina War, particularly after the U.S. and South Vietnamese invasion of the country in May 1970. At first the Lon Nol regime confronted a largely Vietnamese military threat, but a Khmer revolutionary force slowly emerged as the principal opponent. The leaders of this newly important group included men such as Khieu Samphan, Hou Yuon, and Hu Nim, who had opposed Sihanouk's policies in the past and who had fled into the countryside before his overthrow to escape the summary justice of the Prince's security forces.

As these and other left-wing leaders emerged into prominence, Sihanouk's importance declined. Although he remained a symbol of the legitimacy of those who opposed the Lon Nol regime, Sihanouk was clearly not in charge of either the daily tactics or the long-term strategy of those fighting against the Phnom Penh forces. By 1973 he spoke publicly of his difficulties with the Cambodian revolutionaries.

Despite proclaimed policies of reform and United States military and economic aid, the Lon Nol regime never succeeded in gaining the initiative against its opponents. Gestures such as declaring Cambodia the Khmer Republic in 1970 were of little account, as the revolutionary forces pursued a strategy of attrition, choking off provincial capitals from the countryside. Following the end of the U.S. bombing of Cambodia in August 1973, the balance tilted toward the eventual success of the NUFC forces despite continuing strong U.S. aid to the Lon Nol regime. This success was finally achieved when Phnom Penh fell to the revolutionary forces on April 17, 1975.

Great secrecy surrounded developments after April 1975. Sihanouk returned to Phnom Penh in September 1975 as titular chief of state but resigned three months after a new constitution of Democratic Kampuchea was instituted on January 5, 1976. Amid reports by refugees of mass executions and death from disease, major political and social changes took place. Phnom Penh was forcibly evacuated and programs were instituted to reorient the country toward agricultural self-sufficiency and to remove the economic and social patterns of the prerevolutionary period. Elections for the People's Representative Assembly were held in March 1976, and in April Khieu Samphan was named head of state and Pol Pot was named premier. In 1977 the Communist Party of Kampuchea was first officially recognized as the country's governing body.

Pol Pot as premier

(M.E.O.)

The regime of Pol Pot and Khieu Samphan gained a reputation of being one of the cruelest in modern history, with reports of arrests and mass executions common. In the meantime, the border clashes between Kampuchea and Vietnam escalated throughout 1977, culminating in Cambodia breaking relations with Vietnam on December 31. The differences between Cambodia and Vietnam were ideological as well as territorial. Vietnam, always suspicious of its northern neighbour, China, was antagonized by Cambodia's pro-Chinese policies. Pol Pot's strengthening of ties with China led to an escalation of successful Vietnamese attacks. Not only was the Cambodian government weakened by warfare with its neighbour but the internal disruption of the economy and agricultural system led to massive famines. It was estimated that at least 1,000,000 people died in 1975–78 from starvation or disease or in government purges.

In January 1979 guerrillas backed by Vietnam seized Phnom Penh and set up a government headed by Heng Samrin. Vietnam's occupation of Cambodia did nothing to promote stability or stop the bloodshed. Both Khieu Samphan and Pol Pot managed to escape to China, where they organized resistance to the new government. Sihanouk, who had been under house arrest during the Pol Pot regime, also went to Peking as well as to North Korea to ask for aid against the Vietnamese.

There ensued a protracted civil war resulting in many casualties and a large number of refugees, many of whom fled to an already beleaguered Thailand. Resistance to the Vietnamese-backed government consisted of three groups: the Khmer Rouge, headed by Pol Pot and Khieu Samphan; the staunchly anti-Communist Khmer People's National Liberation Front (KPNLF) headed by Son Sann, a former Kampuchean premier; and the supporters of Sihanouk, later called the Armée Nationale Sihanoukist.

Although the guerrillas under Pol Pot met with only limited military success, they fared better on the diplomatic front, with the UN refusing to recognize any Kampuchean government but Democratic Kampuchea. The Khmer Rouge won strong support from China, but most nations, even those ideologically sympathetic, were repelled by the Pol Pot regime's reputation for butchery during its years in power, and many chose to support the KPNLF or the more moderate resistance group headed by Sihanouk. Despite some success at unified action, these groups continued to fight each other as well as the Vietnamese occupiers. (Ed.)

For later developments in the history of Kampuchea, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL.

LAOS

Laos (in full Lao People's Democratic Republic; Lao: Sathalanalat Paxathipatai Paxaxôn Lao) is a small, landlocked, underdeveloped country on the Indochinese Peninsula. It is bounded on the north by China, on the northeast and east by Vietnam, on the south by Kampuchea, and on the west by Thailand and Myanmar. Following the contour of the Indochinese Peninsula, Laos extends more than 600 miles (966 kilometres) from northwest to southeast, and it has a total area of approximately 91,400 square miles (236,800 square kilometres). The capital is Vientiane.

In the 1950s Laos became a focus of struggle among the major powers of the world. Despite international agreements to neutralize and isolate the country from external threat and to support its unity and development, Laos continued until 1975 to be the scene of others' battles, and then became the object of political competition between Vietnam and the Soviet Union, on one hand, and the People's Republic of China, on the other, while its own people remained divided and in conflict.

Located in an area of strategic importance among contending powerful neighbours, Laos possesses neither the natural barriers nor a population large enough to withstand foreign encroachment. The majority of its population live in the lowlands and in the valley of the Mekong River in the western and central part of the country. The remainder live in small groups in the eastern hill areas. The Laotian people are divided by differences of religion, language, and custom. Another source of disunity is the fact that, until the 19th century, Thailand, Myanmar, and Vietnam either held territory that at present is a part of Laos or exercised suzerainty and indirect rule over parts of the land and its people. Although the peoples of Laos can look back to a golden age when the country was strong and united under its own kings, since the 18th century it has been divided and weak.

Rise of Pathet Lao

Laos gained legal unity and the formal status of a nation on October 22, 1953, when France recognized the Kingdom of Laos as fully independent and sovereign; in December 1955 it was admitted to the United Nations. In reality, however, it was at best a divided state. In 1953 the Communist Pathet Lao, a dissident group supported by the Viet Minh military forces of Vietnam, established itself in the northeast and claimed to be the legal government. The Geneva Conference of 1954, while recognizing the unity of Laos and the legality of the kingdom, permitted the Pathet Lao forces to occupy the provinces of Phôngsali and Houaphan (Sam Neua), "pending a political settlement." No real settlement occurred, despite efforts by the leaders of Laos to integrate the dissidents, and internal warfare continued until 1975 as foreign forces supported rival Laotian factions and used Laos as a battlefield in the Vietnam war. Intra-Laotian strife became intertwined with the larger conflict. In 1975 the Pathet Lao gained control of the country, and the monarchy was ended and the Lao People's Democratic Republic inaugurated in December.

Physical and human geography

THE LAND

Relief. Dominating the landscape of Laos are its inhospitable, forest-covered mountains, which in the north rise to a maximum of 9,248 feet (2,819 metres) above sea level. The principal range lies along a northwest–southeast axis, but in the north there are lower, secondary ranges along a northeast–southwest axis. The ranges are broken by narrow, deep valleys through which rivers flow. A vital area strategically and politically is the Plain of Jars (a name derived from large prehistoric stone jars discovered there; Laotian Thông Haihin), a part of the Plateau de Xiangkhoang that often changed hands during the Vietnam war. In the central and northern parts of the country, the mountains form part of the Chaîne Annamitique. The only lowlands lie alongside the eastern bank of the Mekong. The general slope of the land is upward to the east.

Drainage. The rivers on the eastern mountain slopes flow toward Vietnam and the South China Sea; the rivers on the western side drain into the Mekong, which flows in a southerly direction from the province of Yunnan in China to the South China Sea, forming Laos' boundaries with Myanmar and (for the most part) with Thailand. The floodplains of the lowlands are formed from the alluvial soils carried by the river and its tributaries. The only other important fertile area is the Plateau des Bolovens, at an elevation of about 3,500 feet. The hills and mountainsides can be cultivated temporarily by the slash-and-burn method, but they quickly lose their fertility and the cultivators must move to other areas.

Climate. The climate in Laos reflects its location between the latitudes of 14° and 22° N. During the rainy season, May to October, the winds blow from the southwest and deposit an average rainfall of between 50 and 90 inches (1,300 and 2,300 millimetres). In the Plateau des Bolovens precipitation reaches 160 inches (4,100 millimetres) per year. The dry season, from November to April, is dominated by northeast winds. Temperatures average between 60° and 70° F (16° and 21° C) in the cool months of December through February, increasing to more than 90° F (32° C) in March and April, just before the rains. In the wet season, the average temperature is 80° F (27° C).

Plant life. Laos has tropical rain forests of broadleaf evergreens in the north and monsoon forests of mixed evergreens and deciduous trees in the south. In the monsoon forest areas the ground is covered with tall, coarse grass called *tranh;* the trees are mostly second growth, with an abundance of bamboo, scrub, and wild banana.

Settlement patterns. More than half the population is concentrated in the lowlands, where most are engaged in wet-rice farming. The isolated valley communities preserve different traditions and different dialects. Village populations range between 50 and 2,000, usually located close to rivers and roads that give the people access to itinerant

traders as well as to each other. Most villages are laid out around a main street or open area, farmlands being adjacent to the residential areas. Every village, if it can, has a pagoda and supports at least one Buddhist monk. The pagoda compound usually includes a public building that serves as a school and a meeting hall. Village leadership is usually divided, the headman having authority in secular matters and the monk in religious.

The hill peoples

The hill peoples are usually organized on tribal lines and live in smaller groupings. They are hunters and gatherers of forest products as well as farmers; their techniques of shifting cultivation prevent them from establishing permanent villages. Their political and social structures are varied. The tribal Tai have a stratified social structure and a political hierarchy, while the Mon-Khmer tend to have a simple political organization with a single headman. The Meo (Miao) tribesmen have a tradition of a king and chiefs; in theory their villages are tribal, but in fact they usually have a headman. Hill peoples living close to the Lao and Tai tend to acquire the languages and cultures of their neighbours and to engage in limited trade with them; those living at higher elevations remain unacculturated.

Urban life in Laos is limited to the capital, Vientiane, the former royal capital, Louangphrabang, and four or five large towns. With the exception of Louangphrabang, all are located near the Mekong in the floodplain area. Their populations are predominantly Lao, with many Chinese, Vietnamese, and Europeans. The Lao elite tends to be Westernized in its life-style and dress. By comparison with the cities of Thailand, Malaysia, or Vietnam, those of Laos are small and provincial.

THE PEOPLE

The peoples of Laos are divided by language, culture, and location. Lao officials distinguish four basic linguistic-political groups: Lao-Lu, or valley Lao; Lao-Tai, or tribal Tai; Lao-Theng, or Mon-Khmer; and Lao-Soung, or Meo and Man. Mountain people sometimes are called Kha ("Slave"), a pejorative term.

The Lao-Lu live in the lowlands, on the banks of the Mekong and its tributaries, and in the cities. They speak Laotian Tai, which is closer to the language spoken by Thais in Thailand than it is to the language of the local Tai-speaking tribes. It is the language that the minorities living near Lao areas are gradually adopting.

The Lao-Tai include such local groups as the Black Tai and Red Tai, both names referring to the dress of the women; the Tai Neua, or Tai of the north; the Tai Phuan; and the Phon Tai. The Lao-Tai live in all parts of the country, chiefly in upland areas. The various dialects of the Lao-Tai are mutually intelligible.

Mon-Khmer

The Lao-Theng, better known as Mon and Khmer, or Mon-Khmer, include many groups of people scattered throughout Laos, northeastern Myanmar, northern Thailand, and southern China and are thought to be descendants of the earliest populations in the region. These people do not form a single coherent group but rather include between 25 and 30 distinct groups, some closely related, others only tenuously identified as part of this linguistic group.

The Lao-Soung, which include the Meo (Miao) and the Man (Yao), are believed to have come from southern China since the late 18th century. They are divided into subgroups, and neither constitutes a large proportion of the population of Laos.

The other distinct linguistic groups are few. Tibeto-Burman-speakers, who came from southern China, live in the north and northwest. Chinese and Vietnamese live primarily in the urban areas. Initially, French was the language of the Lao elite and of the cities, but by the 1970s English had begun to displace it. Under the leadership of the Lao People's Revolutionary Party, Vietnamese has become the third language of the elite.

Prior to the emergence of the Lao People's Democratic Republic in 1975, it was accurate to say that the Lao peoples had a distinct pattern of culture and dress. They also had a well-defined social structure, differentiating between royalty and commoners. The members of the elite were said to number about 2,000, which included only a few outsiders who were not descendants of nobility. Most of the elite lived in the cities, drawing their incomes from rural land rents or from urban occupations. After 1975 a new elite emerged representing the victorious leftist forces. Many of this group were of aristocratic origin.

Traditionally the Lao-Tai, or tribal Tai, were organized in groups larger than villages, called *muong.* Each was ruled by a hereditary ruler called the *chao muong.* Within this broad grouping, however, there were ethnic variations. Among the Black Tai, the nobility consisted of two descent groups, the Lo and the Cam, who provided the rulers of the *muong.* The religious leaders came from two other descent groups, the Luong and the Ka. The Black Tai tribal organization had three levels: the village; the commune, which was composed of a number of villages; and the overall *muong.* The latter two were ruled by nobles, while the village headman was selected from among the commoners by the heads of households. The Red Tai had a similar social structure, with the addition of a council of five to aid the *chao muong.* The nobility owned the land and had the right of service from the commoners. Not all of them were Buddhists; those living in the higher and more isolated areas retained their traditional culture.

The Lao-Theng, or Mon-Khmer, have no political or social structure beyond the village. They are led by a village headman, who is their link to the central government; but his role in the village is not clear. The people traditionally have been spirit worshippers; one subgroup, the Lamets, practices ancestor worship. Some have adopted Buddhism.

Among the Lao-Soung, the Meo (also known as the Hmong) have a tradition of a king and subchiefs and a large-scale organization, although in practice this is usually limited to the village. The village consists of several extended families. In some villages, all the heads of households are members of a single clan, and the head of the clan is the headman of the village. Where several clans reside together in a large village there are several headmen, one being the nominal head and the link to the government. The headman has real authority in the village and is aided by a council. The Meo have extended their organization beyond the village for military purposes. They are spirit and ancestor worshippers.

The religion of most of the people of Laos is Theravāda Buddhism, professed by most Lao and by a small number of other ethnic groups. The rest of the people are animists or spirit worshippers. Many see no contradiction in being both, since Buddhism shows the way to Nirvāṇa while spirit worship helps a person to cope with daily and local problems. Among the hill peoples, especially those who have migrated from southern China, there are groups that mix Confucian ideas with Buddhism and animism. There were Catholic and Protestant missionaries in the country before 1975, but it is estimated that no more than 2 or 3 percent of the population is Christian. The Vietnamese, who live both in the cities and in the northeastern rural areas, practice a mixture of Mahāyāna Buddhism and Confucianism.

Laos remains an underpopulated country, with considerable migration taking place in and out of China, Vietnam, and Thailand.

THE ECONOMY

Resources. The natural resources of Laos include coal, iron, copper, lead, gold, tin, and precious stones. Only tin has been extracted on a commercial scale, though the others have been mined in primitive and unsystematic ways. Most of the tin ore is produced from the mines at Phôntiou and Nong Sun.

ce

Agriculture. The chief occupation of the people is agriculture, with an estimated 90 percent engaged in rice farming. Since the creation of the Lao People's Democratic Republic in 1975, natural calamities, including both drought and excessive rainfall, have prevented the people from achieving self-sufficiency in rice production, causing the nation to look to imports and gifts to make up for inadequate production. Modest amounts of corn (maize), sugarcane, tobacco, and cotton are produced. The forests provide teak and other woods, gum benzoin, cardamom, and stick lac. A major agricultural commodity that does not find its way into the statistics is opium, grown mainly by the Meo and traded illegally.

Nearly every household raises livestock—including cattle and buffalo—and poultry. Leather and hides are traded.

Under the revolutionary government, a serious effort is being made to relocate hill peoples onto the plains and to get them to adopt wet rice farming practices in place of their traditional slash and burn. It has been reported that some of the Meo have been forced to resettle in agricultural cooperatives in the region of the Plain of Jars. The majority of hill dwellers are resisting change, however, despite pressure and persuasion to alter their agricultural practices, social customs, and traditions. If the government persists in this policy it may provoke outright opposition to, and revolt against, the most serious challenge to Meo traditional life.

Industry. The tiny industrial sector manufactures bricks and ceramics, matches, cigarettes, soft drinks and beer, rubber sandals, cloth, pottery, and plastic bags. A major hydroelectric plant produces surplus electricity that is sold to Thailand.

Finance and trade. The chief exports are timber, tin, coffee, leather and hides, cardamom, gum benzoin, and stick lac. The major buyers formerly were Singapore, Malaysia, Thailand, the United States, and Hong Kong. The major suppliers of imports were Thailand, Japan, the United States, France, and the United Kingdom. New trading relationships are beginning to develop with Thailand and Vietnam and with Communist European states. Imports always vastly exceed exports in value.

River
traffic

Transportation. A major obstacle to the economic and social development of Laos is its transportation system. Rivers and roads are the major avenues of communication, supplemented by air transport. The Mekong River is the major north–south commercial artery; all but two sections of it—Chutes de Khone (Khone Falls) and the rapids of Khemmarat (Khemarat)—are navigable either all or part of the year. Large barges operated by Chinese ply the deeper sections of the rivers between towns, but most of the water traffic is carried in Lao-operated sampans and pirogues. The latter average 25 to 35 feet in length and can carry up to seven passengers and half a ton of cargo. Some of the mountain people build bamboo rafts and float their goods to market, selling the raft along with the goods.

During French rule, a primitive network of roads was created. The main artery joined Saigon with Louangphrabang, and several lesser roads led eastward through the four mountain passes to Vietnam and to the main towns and population centres. During the 1960s, with U.S. assistance, an all-weather road was added between Vientiane and Pakse; another was to be built between Vientiane and Louangphrabang. In addition, the North Vietnamese developed a complex of roads and trails across eastern Laos for their own use during the war. Laos itself has no railways, but a railroad from Bangkok, Thailand, to the Lao border serves as a major artery.

The newest means of transport is the airplane. The Wattay international airport at Vientiane connects with Bangkok, Phnom Penh and Hong Kong.

ADMINISTRATIVE AND SOCIAL CONDITIONS

Government. Before December 2, 1975, Laos was a constitutional monarchy. Real power rested with the prime minister and the legislature. There had been nominal political parties since 1947, when the constitution was promulgated, but they were loose coalitions of leaders with little popular following. In 1953 there were two main parties, the National Progressive and the Independent, and two splinter parties, the National Union and the Democratic. In 1958 the Lao Patriotic Front, backed by the Communist Pathet Lao, participated in the elections, as did the Peace Party; together they won several seats. In the late 1950s two new parties emerged, the Rally of the Lao People and the Committee for the Defense of the National Interest.

Beginning in 1973, when a cease-fire agreement was reached, a series of coalition governments sought to exercise power. The traditional elite continued to rule in urban areas, while the bulk of the people in the countryside remained outside the national political process. The coalition government gave way in December 1975 to a new body, the National Congress of People's Representatives, which, under the guidance of the Pathet Lao, met and passed several resolutions that ended the monarchy and replaced it with the Lao People's Democratic Republic. The King abdicated.

Supreme People's Council

The government is headed by a president, who is also chairman of the Supreme People's Council, an interim (pending elections) legislative body. The secretary general of the Lao People's Revolutionary Party (the only political party) serves as prime minister. The party, which replaced the Pathet Lao as leader of the Socialist revolution, was formerly called the People's Party of Laos and is the Communist core of the Lao Patriotic Front. It is organized much like other Communist parties, with a Central Committee headed by a Politburo.

The country is divided into 20 provinces, each subdivided into districts, which, in turn, are subdivided into towns and villages. At each level of local government there are "people's revolutionary committees," which receive directions from the Central Committee of the Lao People's Revolutionary Party.

Armed forces. Between independence, in 1953, and the cease-fire, in 1973, the military forces grew to become a major institution. In addition to the Royal Laotian Army, Royal Lao Air Force, Laotian River Flotilla, and Lao National Police Corps, there were the separate armies of the Pathet Lao and the neutralists. The government forces received aid from the United States. The Pathet Lao army was supported by North Vietnam and China.

After the victory of the Pathet Lao (officially Lao People's Liberation Army from 1965), the Royal Laotian Army was in part integrated with it and the rest was disbanded. There is a small navy and an air force.

Education. Education has been reorganized. The government has set up a number of agricultural schools, sent teachers to give literacy classes in provincial villages, and opened new primary, secondary, and teacher-training schools.

Health and welfare. The country has around 40 hospitals, supplemented by infirmaries and rural dispensaries. With the departure of the majority of medical doctors after 1975, the government began building village infirmaries in most of the provinces and training medical workers. Using medicinal herbs, these village medical workers provide most of the primary health care. Malaria and gastroenteritis are the major health problems.

CULTURAL LIFE

The basis of Laotian culture is religion and tradition. Art, literature, music, and drama draw mainly from these sources, and there appears to be little Western influence outside Vientiane.

Religious basis of cultural life

Theravāda Buddhism entered the country in the 14th century and along with Hinduism has been a major influence on cultural and intellectual life. The story of the Buddha and Hindu myths are the subjects of the carvings and sculptures found in all religious places. In the south, Khmer influences on the peoples of Laos are strong; in the north, Myanmar and Thai influences are readily apparent. As elsewhere in Southeast Asia, religious symbols, stories, and themes have been modified and localized. The snake, for example, representations of which adorn religious and royal buildings, represents the benevolent spirit of the water and the protector of the king.

The Laotians have a variety of folk arts, including weaving, basketmaking, wood and ivory carving, and silverwork and goldwork. There are a number of Laotian musical instruments, of which the *khene,* a bamboo wind instrument, is most widely known. Music is not written down but is played from memory.

Dancing is a profession rather than a form of recreation; the professional dance troupes travel throughout the country performing for religious celebrations or on important holidays. Their main themes are drawn from the Indian epics. All professional dancers are male, the female roles being performed by young men and boys.

Laotian literature is predominantly religious and linked to the Buddhist tradition. There is also a secular literary stream based on themes of the Hindu epic poems, which have been transmuted into popular language, as in the Laotian epic the *Sin Xay.* The popular poems and songs are often satirical. (J.Si.)

For statistical data on the land and people of Laos, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL.

History

The Lao people, the predominant ethnic group in present-day Laos, are a branch of the Tai peoples who by the 8th century AD established a powerful kingdom, Nanchao, in southwestern China. From Nanchao the Tai gradually penetrated southward into the Indochinese Peninsula; their migration was accelerated in the 13th century by the Mongol invasions of southern China by Kublai Khan. The Lao, together with other Tai peoples, gradually supplanted various primitive tribes (collectively known as Kha, or "Slaves") that from the 5th century on had lived in what is now Laos under the suzerainty of the Indianized Khmer Empire of Cambodia. During the 12th and 13th centuries they established the principality of Muong Swa (later Luang Prabang, now Louangphrabang), which was ruled by various Tai leaders and the history of which survives in Laotian legend and myth.

LAN XANG

The first Laotian state

Recorded Laotian history begins with Fa Ngum, who founded the first Laotian state, Lan Xang (Kingdom of the Million Elephants), with the help of the Khmer sovereign at Angkor. Fa Ngum was a great warrior, and between 1353 and 1371 he conquered territories that included all of present-day Laos and much of what is today northern and eastern Thailand. He extended the Indo-Khmer civilization to the upper Mekong River and introduced Theravāda Buddhism, preached by Khmer missionaries from Angkor.

In 1373 Fa Ngum was succeeded by his son Phya Sam Sene Thai, who did much to organize the pattern of administration and defense for the kingdom. After his death in 1416, a long period of calm, broken only by a Vietnamese invasion in 1478, allowed his successors to complete the work of organizing Lan Xang. This period of peace and tranquillity ended with Photisarath (reigned 1520–47), who involved Lan Xang in a struggle against Myanmar and Siam that lasted two centuries. Photisarath waged three wars against Siam and succeeded in placing his son Sethathirath on the throne of the Tai state of Chiang Mai (Chiengmai), marking Lan Xang's maximum territorial expansion. On Photisarath's death, Sethathirath returned to occupy his father's throne. His reign was marked by the loss of Chiang Mai to the Myanmar, by the transfer of the capital from Luang Prabang to Vientiane, and by the repulsion of two Myanmar invasions that took place *c.* 1565 and 1570.

When he died (1571) the Myanmar seized Vientiane (1574) and ravaged the country, which lapsed into anarchy until Souligna-Vongsa ascended the throne in 1637 and restored order. He fixed the frontiers with Vietnam and Siam by means of treaties and led two victorious expeditions against the principality of Chieng Khouang in the south. A defender of Buddhism and a patron of the arts, he embellished Vientiane and made it a centre of intellectual brilliance. His reign is considered by Laotians to be a Golden Age.

Vietnames rule

When Souligna-Vongsa died in 1694, one of his nephews seized the throne with the help of a Vietnamese army, thus placing Lan Xang under Vietnamese rule and initiating a period of chaos that ended in the partition of the kingdom of Lan Xang. Other members of the royal family refused to accept Vietnamese vassalage. With the northern provinces under their control, they declared themselves independent (1707) and established the separate kingdoms of Luang Prabang and Vientiane. The south seceded in turn and set itself up as the kingdom of Champassak (1713). Split into three rival kingdoms, Lan Xang ceased to exist.

UNDER FOREIGN RULE

During the 18th century the three Laotian states, continually at loggerheads, tried to maintain their independence from the Myanmar and the Siamese, who were contending for the control of western Indochina. Their weakness, resulting from their disunity, inevitably caused them to fall prey to the Siamese.

Vientiane, which had sided with the Myanmar, was invaded (1778), annexed, and made a state subject to Siam (1782). Luang Prabang, which had supported the Siamese, was invaded by the Myanmar (1752), who imposed their rule upon it until the Siamese supplanted them (1778). In the south, Champassak, which had supported Myanmar revolt against the Siamese, was also invaded (1778) and transformed into a dependency of Siam. Each of these kingdoms was placed under the control of a Siamese commissioner. The kings of Champassak, Vientiane, and Luang Prabang were allowed to rule in their respective kingdoms but had to pay tribute to Bangkok. Their appointments to the throne were made in Bangkok.

Chao Anou (king of Vientiane 1805–28) attempted to shake off this yoke. First, he strengthened the bonds of allegiance uniting Vientiane to Vietnam (1806), whose influence in Indochina had grown to rival that of Siam. Next, he persuaded Bangkok to give his son the governorship of Champassak, thus extending his frontiers as far as the old southern boundaries of Lan Xang. Thinking that the British, who had just defeated Myanmar, were going to attack Siam, he led three armies against Bangkok (*c.* 1826). But the Siamese regrouped their forces, marched on Vientiane, and defeated Anou, who fled to Vietnam. Vientiane was pillaged and destroyed. In 1819 Anou attempted another attack but was again defeated. Vientiane was made a Siamese province.

For the Siamese the annexation of Vientiane was the first step toward the creation of a great empire. They next extended their colonization of the left bank of the Mekong to protect themselves from an eventual Vietnamese expansion westward. They therefore garrisoned Champassak (1846) and Luang Prabang (1885) and stationed troops as far as the Chaîne Annamitique. Siamese expansion toward the northeast—where the mountain states were placed under the cosuzerainty of Vietnam and Luang Prabang—provoked the protests of the French, who had established a protectorate over Vietnam. France entered into negotiations with Bangkok (1886) to define the Siamese-Vietnamese frontier and won the right to install a vice consul in Luang Prabang. The office was entrusted to Auguste Pavie, who, owing partly to his popularity with the Laotians, succeeded in winning Luang Prabang over to France. After a number of Franco-Siamese incidents in the Mekong Valley, French ships made a show of strength off Bangkok. On the advice of the British, Siam withdrew from the left bank of the Mekong and gave official recognition to the French protectorate in the evacuated territory (1893). French annexation was completed by treaties with Siam (Thailand) in 1904 and 1907.

ench
otec-
rate

The French organized this territory as the Protectorate of Laos and allowed it autonomy in local matters. The kingdom of Luang Prabang survived, but the other provinces were placed under the direct authority of a French official. France paid little attention to Laos until 1941, when, under Japanese pressure, the Vichy government restored to Thailand the territories acquired in 1904. In March 1945 the Japanese drove the French from Indochina and proclaimed the independence of Laos.

Two movements sprang up at this time. The first was anti-Japanese and was represented by the court of Luang Prabang and Prince Boun Oum of Champassak; the second was anti-French (the Free Laos movement, or Lao Issara), was located in Vientiane, the former French colonial administrative centre, and was led by Prince Petsarath. These two movements remained in conflict until the return of French troops, which compelled the supporters of the Lao Issara to flee to Thailand. In 1946 France, in a temporary agreement, recognized the internal autonomy of Laos under the king of Luang Prabang, Sisavang Vong. Finally, after the promulgation of a constitution and general elections, a Franco-Laotian convention was signed on July 19, 1949, by which Laos was granted limited self-government within the French Union. All important power, however, remained in French hands.

Although many of the Lao Issara leaders were prepared to work with the French under this new arrangement, their decision was opposed by a more radical group led by Prince Souphanouvong. Under Souphanouvong's presidency a new political movement, the Pathet Lao (Lao Country), was created (1950) that joined forces with the Viet Minh of Vietnam in opposing the French. The Pathet Lao remained unreconciled when the French took further steps toward granting independence to Laos in October 1953, while still retaining control of all military matters in the kingdom. Between 1950 and early 1954 the Pathet Lao gained strength in northeastern Laos and had a firm grip on two of the country's provinces when the Geneva Conference brought the First Indochina War to an end.

INDEPENDENT LAOS

Geneva
Conference

At the Geneva Conference the 14 participating nations (including France, Great Britain, the U.S., China, and the Soviet Union) agreed on the establishment of Laos as a unified, independent buffer state between Thailand and North Vietnam, which were allied, respectively, to the West and to the Communist bloc. But this compromise agreement concerned only the international aspects of Laos' neutral status; the Laotians were left with the problem of making it work on the local level. The deep political divisions within Laos made it impossible for the country to function effectively as a neutral buffer state.

Relative calm prevailed during 1955–58 as a government of national union, including Pathet Lao representatives, sought to implement the Geneva accords. When elections held in 1958 showed there was significant support for the Pathet Lao, the right reacted by forcing the neutralist prime minister, Prince Souvanna Phouma, out of office and installing their own candidate, Phoui Sananikone. Then in July 1959 the right-wing forces in control of Vientiane imprisoned Prince Souphanouvong (he escaped a year later). In further violation of the Geneva agreement, the rightists accepted military aid from the U.S. and the Philippines. The Pathet Lao retaliated by seizing control of Phôngsali and Houaphan (Sam Neua) provinces, and a period of inconclusive hostilities followed. When Phoui showed some readiness to move toward a neutralist position, he was deposed by rightist army officers and his place was taken by Gen. Phoumi Nosavan. A period of great confusion followed as Phoumi Nosavan and his supporters were themselves deposed in a coup led by a parachute battalion commander, Kong Le, in August 1960, only to succeed in recapturing Vientiane, with considerable U.S. and Thai support, in the following December. By this stage the situation in Laos was a cause for growing tension between the U.S. and the Soviet Union.

Souvanna
Phouma
coalition

A change in U.S. policy under the new administration of Pres. John F. Kennedy brought acceptance of the concept of a neutral Laos, and in May 1961 the Geneva Conference was reconvened to seek a formula that would allow Laos to occupy a neutral position as a buffer zone. In June 1962 Prince Souvanna Phouma formed a new coalition government that included Pathet Lao, neutralist, and rightist representatives. Despite international support for such a solution, Laos could not disentangle its affairs from the war being fought in neighbouring Vietnam. Nor were the major political groupings within the country ready to give up control over those areas they dominated by means of their armed forces.

Increasingly from 1963, developments in Laos were linked with those in Vietnam. Sections of eastern Laos were a vital part of the Vietnamese Communist supply lines to the south (the Ho Chi Minh Trail), and, as the Vietnamese Communists gave their aid to the Pathet Lao, the U.S. joined in military support of the forces of the government in Vientiane. Despite the external assistance received by both sides, neither the government in Vientiane nor the Pathet Lao was able to break the pattern by which the territory of Laos was divided between them, with little apparent possibility of either gaining a decisive victory. In these circumstances, and with the U.S. and

North Vietnam negotiating for a cease-fire in Paris, the Vientiane government and the Pathet Lao began negotiations in 1972 and signed a cease-fire in February 1973. (P.-B.L./M.E.O.)

Beginning in that year, yet another effort was made to find a way to rule Laos through a coalition of rightists, neutralists, and the Pathet Lao. After further protracted negotiations, a Provisional Government of National Unity was inaugurated in April 1974 that had an equal number of members drawn from those who had been associated with the Vientiane government and from the Pathet Lao. Once associated with this provisional government, the Pathet Lao demonstrated an organizational ability that contrasted with the disunity of their rightist opponents. When Saigon and Phnom Penh fell to Communist forces in April 1975, morale dropped sharply among rightists in Laos; and from May onward, as many of the most important rightist politicians and soldiers fled to Thailand, the Pathet Lao moved swiftly and firmly to establish control over the whole of the country.

Lao People's Revolutionary Party

After the Pathet Lao gained control over Laos, the existence of a Laotian Communist Party (the Lao People's Revolutionary Party, founded in 1955 as the People's Party of Laos) was revealed. This party controls the Lao People's Democratic Republic, which was inaugurated in December 1975. The Communist regime has developed close military and economic ties with Vietnam, and it has supported Vietnam's involvement in Kampuchea. Despite considerable economic aid from Vietnam, the Soviet Union, and other countries, Laos has remained one of the world's poorest nations. (P.-B.L./M.E.O./Ed.)

For later developments in the history of Laos, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL.

MALAYSIA

Malaysia, a country in Southeast Asia, is composed of two regions—West Malaysia, on the Malay Peninsula, and East Malaysia, consisting of the territories of Sarawak and Sabah on the island of Borneo. It has a total land area of 127,316 square miles (329,747 square kilometres).

West and East Malaysia

West Malaysia has an area of about 50,800 square miles and occupies most of the Malay Peninsula south of latitude 6°40′ N. To the north it is bordered by Thailand, with which it shares a land boundary of 300 miles (480 kilometres). To the south, its nearest neighbour is the island republic of Singapore, with which it is connected by a causeway; to the southwest, across the Strait of Malacca, is the Indonesian island of Sumatra. East Malaysia, consisting of Sarawak and Sabah (formerly North Borneo), is separated from West Malaysia by some 400 miles of the South China Sea. Sarawak, with an area of 48,050 square miles, and Sabah, 28,460 square miles, occupy most of the northwestern coastal part of the large island of Borneo. Both these territories share land boundaries with each other and with the Indonesian provinces of Borneo (Kalimantan). Within Sarawak is the small enclave of Brunei, a sultanate under British protection, politically separate from Malaysia.

Malaysia, a member of the Commonwealth, represents the political marriage of territories that were formerly under British rule. When it was established on September 16, 1963, Malaysia was composed of Malaya (now West Malaysia), Singapore, Sarawak, and Sabah. In August 1965 Singapore left the federation and became an independent republic.

While not large by Asian standards, Malaysia is nevertheless one of the richest countries in the region. It occupies a central position in Southeast Asia, commanding one of the major sea lanes of the world, the Strait of Malacca. Malaysia is unique in that it is the only country that has territory on both the mainland and insular regions of Southeast Asia. The physical separation between mainland Malaysia and insular Malaysia (Sarawak and Sabah), however, inevitably poses problems of communication. The division between West and East Malaysia is not only physical. There are wide disparities and differences as well in the degree of development and in the living standards of the population.

Malaysia inherited many problems from its colonial past. The country was faced with the tasks of instilling a polyglot society with a sense of common identity and national purpose and of resolving the tensions arising from inequalities of political and economic conditions. Economically, difficulties have included a high rate of population growth (which poses the related problems of finding productive employment for an expanding labour force and of at least maintaining, if not raising, living standards); an initial inordinate dependence on rubber and tin production, which has been eased somewhat by the export of palm oil and timber; disparities in income between rural and urban peoples and between ethnic groups; and a shortage of skilled manpower.

Physical and human geography

THE LAND (WEST MALAYSIA)

Relief. The Malay Peninsula is a long, narrow strip of mountainous land extending southward from Myanmar and Thailand. West Malaysia occupies the southern half of the peninsula and is about 500 miles long and—at its widest east–west axis—about 200 miles wide. About half of Malaysia is covered by granite and other igneous rocks, a third more is covered by stratified rocks older than the granite, and the remainder is covered by alluvium. At least half of the land area is more than 500 feet (150 metres) above sea level.

Mountain ranges

Topographically, the country is dominated by its mountainous core, which consists of a number of roughly parallel mountain ranges aligned north–south. The most prominent of these is the Main Range, which has peaks rising more than 7,000 feet above sea level and is about 300 miles long. Limestone hills, with characteristically steep, whitish-gray sides, stunted vegetation, caves created by the dissolving action of water, and subterranean passages, are distinctive landmarks in central and northern West Malaysia. Bordering the mountainous core are the coastal lowlands, 10 to 50 miles wide along the west coast of the peninsula but narrower and discontinuous along the east coast. Settlement and development have taken place primarily along the west coast.

Drainage. The peninsula is drained by an intricate system of rivers and streams. The longest river—the Sungai Pahang—is only 270 miles long. The year-round rainfall results in perennial streamflow, but the volume of water transported fluctuates because of the localized and torrential nature of the rainfall. In the western part of the peninsula such heavy falls may occur at any time of year, but in the eastern part they are more likely to occur during the northeast monsoon that occurs from about November to March. Prolonged rains often cause floods, especially in those areas where the natural regimes of the rivers have been disrupted by uncontrolled mining or agricultural activities.

Soils. The soils of the peninsula have been exposed for an extremely long period of time to intense tropical weathering, with the result that most of their plant nutrients have been leached out. The soils are typically strongly acid and coarse textured; they are deficient in nitrogen, phosphorus, potassium, and magnesium and have low amounts of organic matter. Only a small proportion of the soils of West Malaysia are fertile; regular applications of fertilizers are therefore necessary in order to sustain crop yields. On sloping ground, such additional measures as the building of contour embankments or the planting of protective cover crops are also needed in order to minimize soil erosion.

Climate. The Malay Peninsula has an equatorial climate, but its narrowness and topographical configuration—a central mountainous core with flat, flanking coastal plains—facilitate the inland penetration of mar-

Effects of monsoons

itime climatic influences. In addition, monsoonal effects further modify the climate. The country is influenced by eight or nine major airstreams, flowing from the northeast, the south, and the west; the advance and retreat of these airstreams are responsible for the division of the climatic year into four seasons. These are the northeast monsoon (from November or December until March), the first intermonsoon period (from March to April or May), the southwest monsoon (from June to October), and the second intermonsoon period (from October to November). The onset and termination of the monsoons are not sharply defined.

The mean annual rainfall is approximately 100 inches (2,540 millimetres). The driest location, in Kuala Kelawang (formerly Jelebu), about 30 miles southeast of Kuala Lumpur, receives about 65 inches of rain a year; while the wettest, Maxwell's Hill, about 25 miles northwest of Ipoh, receives 200 inches annually. Temperatures are uniformly high throughout the year, averaging 78° to 82° F (25° to 28° C) for the majority of lowland areas. Relative humidities are also persistently high, averaging from 82 to 86 percent. The climate, in consequence, tends to be hot and humid.

Plant and animal life. The characteristic vegetation of the peninsula is the dense, evergreen rain forest—the climax vegetation of the hot, wet tropics. Rain forest still covers about half of the total land area; another fraction is under swamp forest. The flora of the Malayan rain forest is among the richest in the world. There are about 8,000 species of flowering plants, of which at least 2,500 are trees. An acre (0.4 hectares) of forest may have as many as 100 different species of trees, as well as shrubs, herbs, lianas (creepers), and epiphytes (plants that grow nonparasitically upon others, deriving nourishment from the atmosphere). The forest canopy is so dense that little sunlight can penetrate it. As a result, the undergrowth is usually poorly developed and—contrary to popular belief—is not impenetrable. Much of the original rain forest has been destroyed by severe wind and lightning storms, by aborigines clearing it for temporary agricultural exploitation, or by clearances made for agricultural or commercial purposes. When such cleared land is subsequently abandoned, coarse grassland, scrub, and secondary forest develop. These types of vegetation constitute a smaller fraction of the total land area.

The forests and scrubland are inhabited by a large variety of animal life. Mammals include the elephant, the tiger, the magnificent seladang (or Malayan gaur, a massive wild ox), the Sumatran rhinoceros, the tapir (a hoofed and snouted quadruped), the wild pig, and many species of deer, including the *pelandok*, or mouse deer (a small, deerlike ruminant). Crocodiles, monitor lizards, cobras, and king cobras also are indigenous to the country, while the green sea turtle and the giant leathery turtle nest regularly on the beaches of the east coast.

Settlement patterns. West Malaysian settlements range from the rudimentary settlements of the Orang Asli (aborigines) to modern cities. This complexity and variety reflect in part the range of economic activities, in part the cultural diversity of the residents, and in part the long history of settlement in the peninsula. The first settlers were small groups of Orang Asli, who were later followed by peoples of Malay stock and by immigrants from China and India.

The Malay are predominantly a rural people. Their settlements are similar in appearance and pattern to those of their rural counterparts elsewhere in Southeast Asia. The basic unit is the kampong (village, or community of houses), composed of dwellings on stilts, which are commonly erected beside rivers, canals, beaches, roads, and footpaths. The houses are usually built of wood and a thatched roofing called atap, woven from the leaves of the nipa palm, a species also used for basketry. Each house is surrounded by trees bearing coconuts, bananas, papayas, and other fruits. The four main types of Malay settlements—fishing villages, paddy (rice-field) villages, cash-crop villages, and mixed-crop villages—despite their variations, all conform to the same basic pattern.

Types of rural settlement

Most other rural settlements are associated with peoples who have settled in the country since the early 19th century. The earliest of these were the mining camps, which sprang up in the tin fields on the western peninsula. Some have since grown into large towns, but others—especially in the Kinta Valley—still remain small. The British introduced the plantation system of agriculture, and the subsequent cultivation of rubber and of the oil palm has changed the face of rural West Malaysia, bringing to the landscape the plantation, or estate, settlement. This is usually a group of buildings composed of the processing factory and storehouse, the labourers' quarters, and the manager's house.

A modern type of settlement is the New Village, which originally was simply a group of buildings occupying a defensive site enclosed with barbed wire near a road. A total of about 550 New Villages were established between 1948 and 1960, during the Emergency, the formal name for the period when the administration was engaged in suppressing the Communist guerrilla uprising. They were part of a plan to resettle rural dwellers in easily defended positions, so as to prevent contact between them and the armed Communists. With the end of the Emergency in 1960, some of the New Villages were abandoned and have since disappeared. Most of them, however, took root and now have become permanent settlements. With their barbed-wire fences dismantled, they differ little from other small towns.

The cities and large towns were built up during the colonial and postcolonial periods and are distributed mainly along the tin and rubber belt in the western peninsula. The towns are associated with mining, purchasing, processing, distributing, exporting, and administrative functions; each town usually performs several of these functions. Some towns are located at coastal or riverine sites, emphasizing the early importance of water transport; more modern towns have been built in inland areas served by road, rail, and air transport. Slightly more than half the population of the urban centres is Chinese, and about one-third is Malayan. Indians and Pakistanis make up most of the remainder.

Jrban
opulation

Except for satellite towns such as Petaling Jaya (outside Kuala Lumpur), the towns of West Malaysia are unplanned, having grown up around pre-urban nuclei. Urban land use is generally mixed, and buildings are put to multiple uses. Streets, built for a more leisurely era, are narrow and often congested. In the larger centres, such as Kuala Lumpur, Ipoh, and George Town (Pinang), distinct central business districts, similar to those in Western cities, have emerged. These are characterized by heavy population and traffic densities, high land values, and a concentration of shopping, banking, insurance, entertainment, and other facilities.

THE LAND (EAST MALAYSIA)

Relief. East Malaysia is an elongated strip of land approximately 670 miles long, with a maximum width of about 160 miles. The coastline of 1,400 miles is paralleled inland by a 900-mile land boundary with Kalimantan (Indonesian Borneo). For most of its length the relief is composed of three topographic features. First, there is the flat coastal plain, which in Sarawak, where the coastline is regular, averages 20 to 40 miles in width. In Sabah, where the coastline is rugged and deeply indented, it is only 10 to 20 miles in width. Inland from the coastal plain is the second topographic feature—the hill and valley region. This is generally less than 1,000 feet in altitude, but isolated groups of hills reach heights of 2,500 feet or more. The terrain in this region is usually very irregular, with steep-sided hills and narrow valleys. The mountainous backbone that forms the divide between East Malaysia and Kalimantan is the third topographic feature. This backbone is both higher and nearer the coast in Sabah than it is in Sarawak. It is composed of an ill-defined complex of plateaus, ravines, gorges, and mountain ranges, all of which have been cut by erosion. The summits of the ranges are between 4,000 and 7,000 feet. Mt. Kinabalu (13,455 feet), the highest peak in the Malay Archipelago, towers above this mountain complex; no other peak in the country reaches 8,000 feet in height.

Drainage. As in West Malaysia, the drainage pattern is set by the interior highlands, which also form the watershed between East Malaysia and Kalimantan. The rivers are perennial because of the year-round rainfall. They form a dense network of drainage lines covering all parts of the country. The longest river in Sarawak—the Rajang—is 350 miles long and is navigable by shallow-draft boats for about 150 miles from its mouth; its counterpart in Sabah—the Kinabatangan—is of comparable length but is only navigable to about 120 miles from its mouth. The rivers are of importance as they provide a means of communication between the coast and the interior. Settlement also has taken place along the rivers, as it did on the peninsula in an earlier period.

ommuni-
ıtion by
ver

Soils. The soils of East Malaysia, like those of the peninsula, developed under intensive tropical weathering conditions over a long period. They are heavily leached and are generally poor in plant nutrients. When exposed, the organic matter in such soils is rapidly oxidized, and the soils consequently become even poorer. Soil erosion is always a danger on sloping land. In such an environment, agricultural development poses considerable problems. Generally, soil conditions in Sarawak and Sabah do not differ greatly from those in West Malaysia. Of these three territories, only Sabah has appreciable areas of fertile soils. These are found in particular on the Semporna peninsula, where the parent material from which the soil is formed is composed of basic volcanic rocks.

Climate. Both continental and insular Malaysia are in the same latitudes and are influenced by similar airstreams. They consequently have similarly high temperatures and humidities, heavy rainfall, and a climatic year patterned around the northeast and southwest monsoons. In coastal areas in East Malaysia minimum temperatures range from 72° to 76° F (22° to 24° C), and maximum temperatures from 88° to 92° F (31° to 33° C); temperatures are lower in the interior because of higher altitudes. As on the peninsula, rainfall variations are pronounced. Mean annual rainfall in Sabah varies from 60 to 120 inches, while most parts of Sarawak receive between 100 and 160 inches. The northeast monsoon brings heavy rain and rough seas to the exposed coasts of southwestern Sarawak and northern and northeastern Sabah. The southwest monsoon, however, affects mainly the southwest coastal belt of Sabah. Floods are common, especially along the west coast of Sabah. Neither mainland nor insular Malaysia is in the typhoon belt, but their coasts are occasionally subject to the heavy rainstorms associated with squalls.

Plant and animal life. Large expanses of East Malaysia—some three-fourths of Sarawak and Sabah—are still covered by dense evergreen rain forest. Soil type, location, and altitude produce distinctive vegetation zones, varying from tidal swamp forest on the coast, to freshwater and peat swamp forest on the ill-drained parts of the coastal plains, to lowland rain forest on the well-drained parts of the coastal plains and foothills up to an altitude of about 2,000 feet, to submontane and montane (lower mountain-type) forest above that altitude. The highly leached and sandy soils of parts of central Sarawak and the coast support an open, heathlike forest, known locally as *kerangas* forest. Large expanses of the forested land, especially in the upland areas, have been cleared for shifting cultivation, and the original forests have given way to scrub and savanna.

Animal life in East Malaysia is even more varied than it is on the peninsula. In addition to the peninsula species, East Malaysia is also the home of the fast-disappearing orangutan ape, the rhinoceros, the honey bear, and the unique proboscis monkey—a reddish tree-living species. There are also vast numbers of cave swifts, whose nests are regularly collected and sold as the main ingredient of bird's-nest soup.

Settlement patterns. About three-fourths of the population of East Malaysia is still rural, and it is in the rural areas that the greatest variety of settlement types is encountered. This variety is a direct reflection of the almost bewildering ethnic complexity of the population and of the fact that indigenous as well as immigrant groups are settled in the rural areas. The indigenous ethnic groups, such as the Iban (Sea Dayak), Land Dayak, Kenyah, Kayan, and Murut, are thinly scattered in the foothill country and, to some extent, in the coastal lowlands as well. They are primarily shifting cultivators and live in locations on or near the banks of rivers. Their characteristic dwelling is the longhouse, more commonly found in Sarawak than in Sabah. Each longhouse is raised on stilts and is composed of a number of rooms, known as *bileks;* each *bilek* houses a family. A longhouse can grow by accretions of related families, and an Iban longhouse may in time reach a length of 50 *bileks.* Some groups, such as the Melanau of Sarawak and the Kadazan (Dusun) of Sabah, have abandoned the longhouse settlement form, adopting instead the individual dwelling of the Malay.

The Malay and Melanau of East Malaysia share many common characteristics with their rural counterparts on the peninsula. They tend to be a riverine and coastal people, with an economy based on agriculture and fishing. Many live in kampongs set in the midst of coconut, mangrove, or other swamp trees. Their houses are generally built on stilts. The Melanau specialize in sago production; their kampongs are built in the large delta swamp region between Bintulu and Rajang. The rural Chinese in Sarawak have settled in the region between the coast and the uplands, usually in homesteads strung along both sides of the roads. They grow cash crops such as rubber, pepper, fruits, and vegetables in small holdings. Their houses are commonly built at ground level and are thus easily distinguishable from the stilt-raised dwellings of the Dayak and Malay.

Principal towns

Urbanization in East Malaysia has proceeded slowly. Only a small percentage of people live in towns. The largest towns in East Malaysia are Kuching, Sibu, and Miri in Sarawak, and Sandakan, Kota Kinabalu, and Tawau in Sabah. As on the peninsula, the urban population is predominantly Chinese. The large towns are invariably located on coastal or riverine sites. The layout and appearance of these towns are markedly similar: a wharf area; rows of Chinese shop-houses in the central business districts; more substantial buildings in the governmental administrative area; and one or more timber and atap kampongs built on the river banks.

THE PEOPLE

The population of Malaysia is unevenly divided between the peninsula and East Malaysia, with the vast majority living in West Malaysia. The population shows great ethnic, linguistic, cultural, and religious diversity. There are important differences between the indigenous and immigrant peoples, as well as among the indigenous peoples themselves, and between the Muslims, Buddhists, Christians, and tribes adhering to traditional religions.

West Malaysia. The Malay Peninsula, situated at one of the great maritime crossroads of the world, has been the meeting place of peoples from other parts of Asia. As a result, the population shows the ethnographic complexity typical of Southeast Asia as a whole. In essence there are four groups of people—the Orang Asli, the Malay, the Chinese, and the Indians and Pakistanis.

The Orang Asli constitute the smallest group and can be divided ethnically into the Jakun, who speak an archaic Malay, and the Semang and Senoi, who speak languages of the Mon-Khmer language family. They are primarily adherents of traditional religions, but a number have been converted to Islām.

The Malay originated from different parts of the peninsula and the Malay Archipelago. They comprise slightly more than half of the population and are politically the most important group. They share with each other a common culture, speak a common Austronesian language, Bahasa Malaysia, which is the national language, and are firm adherents of the Muslim religion. Adherence to Islām is regarded as one of the most important factors distinguishing a Malay from a non-Malay; the number of Malays who are not Muslim is negligible. Minor differences in dialect, culture, and physical characteristics are noticeable among the Malay living in the south in Johor state, on the east coast in the states of Kelantan and Terengganu, and on the west coast in the states of Negeri Sembilan, Perak, Kedah, and Perlis.

The Chinese, who make up about one-third of the peninsular population, were originally from the provinces of southeastern China and are ethnically homogeneous. They are, however, less homogeneous than the Malay in language and religion. These peoples from southeastern China comprise several different dialect groups, each with its own spoken language. Oral communication between two Chinese may thus sometimes depend on Mandarin Chinese, English, or Malay. A minority, the Baba Chinese, speak a Malay patois, although otherwise they remain Chinese in customs, manners, and habit. The most important cultural and linguistic Chinese groups are the Hokkien, from Fukien Province; the Cantonese, from the Canton region of Kwangtung Province; the Hakka, from the area between Canton and Swatow; the Tiechiu, from the Swatow region of Kwangtung Province; the Hainanese, from the island of Hainan; the Kwongsai, or Kwangsi, from Kwangsi Province; and the Hokchiu, from the hinterlands of Fukien Province. The Chinese do not have a dominant religion; most of them, while subscribing to the Confucian code of moral behaviour, are either Buddhists or Taoists. A small minority is Christian.

Origins of the Chinese populatioı

The peoples from the Indian subcontinent—the Indians, Pakistanis, and Tamil from Sri Lanka—constitute about 10 percent of the population of West Malaysia. Linguistically, they can be subdivided into speakers of Dravidian languages (Tamil, Telugu, Malayalam, and others) and speakers of Indo-European languages (Punjabi, Bengali, Pashto, and Sinhalese). Numerically, the Tamil speakers are the largest group. Most of the Indians and Sri Lankans are Hindus, while the Pakistanis are predominantly Muslim. Some Indians have been converted to Christianity. The Sikh, from the Punjab, speak their own language and also adhere to their own religion, Sikhism.

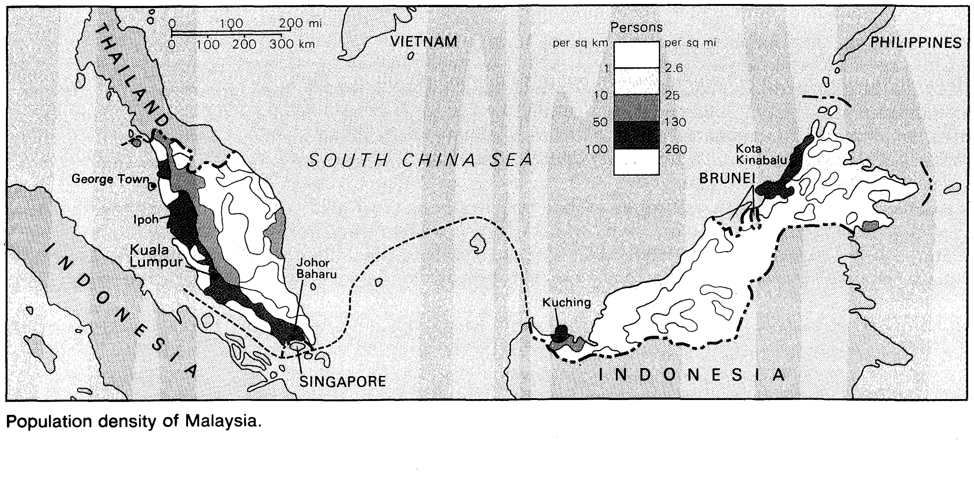
The population of West Malaysia also includes small numbers of Europeans, Americans, Eurasians, Arabs, and Thai.

Ethnic diversity

East Malaysia. The population of East Malaysia is ethnographically even more complex than that of West Malaysia. The government has tended to oversimplify the situation, listing seven main ethnic groupings in Sarawak and seven in Sabah, while there are, in fact, 25 ethnic groups in Sarawak and in Sabah, not counting minor tribal groups. The main ethnic groups in Sarawak are the Chinese, almost one-third of the total population; various speakers of mutually unintelligible Austronesian languages including the Iban (less than one-third); the Malay (less than one-fifth); the Land Dayak (about 9 percent); the Melanau (about 5 percent); and other minor groups, who make up the rest of the population.

The Chinese of Sarawak, drawn from the southeastern provinces of China, share common regional origins with the Chinese of West Malaysia, but the relative importance of each dialect group varies. Thus the Hakka and Foochow (Hokchiu) groups, who are less numerous than the Cantonese and Hokkien in West Malaysia, are the dominant linguistic groups, and together they comprise two-thirds of the Chinese population in Sarawak. The other important dialect groups are the Hokkien, the Cantonese, the Tiechiu, the Henghua, and the Hainanese. As in West Malaysia, the Chinese of Sarawak practice Buddhism, Taoism, and Confucianism. Only a few of the Chinese are Christians.

The Iban are the largest and most important indigenous



Population density of Malaysia.

group in Sarawak. Their origins are obscure, but they were originally headhunters. They are a homogeneous people speaking a language described as a type of pre-Islāmic Sumatran Malay. Most of them are longhouse dwellers, practicing shifting cultivation in the interior uplands. They have a distinctive culture, in which religion plays an important part; nearly every activity is influenced or governed by animist beliefs.

The Malay of Sarawak are a heterogeneous group of people, among whom only a few are of immigrant West Malaysian origin. Most are the descendants of indigenous peoples who were converted to Islām and adopted the Malay way of life some time since the mid-15th century. Although ethnically diverse, they are culturally homogeneous, speaking a common language and observing the Muslim faith.

he and ayak

The Land Dayak live in hill country; most of them are found in the First Division (one of Sarawak's seven administrative units that were created at different stages in its historical growth as a political entity). Although all are of the same ethnic group, they speak five different but related dialects that are to some extent mutually intelligible. The majority of the Land Dayak are adherents of traditional religions, but Christian missionaries have made some converts among them.

The Melanau differ ethnically from the Sarawak Malay, being shorter, broader shouldered, and of a lighter complexion. Their dialects, which are distinct from Malay, do not differ sufficiently to constitute a barrier to communication. Three-fourths of the Melanau population are Muslims; the rest, except for a small number of Christians, follow traditional religions. Other indigenous peoples—the Kenyah, Kayan, Kedayan, Murut, Kelabit, Bisaya, Punan, and others—contribute much to the ethnic and cultural diversity of East Malaysia.

Sabah also has a kaleidoscopic mixture of peoples. Of the total population, almost one-fourth are Kadazan; about one-fifth Chinese; about one-tenth Bajau; almost 5 percent Murut; while about one-fifth are composed of such indigenous peoples as the Brunei Malay, Kedayan, Orang Sungei, Bisaya, Sulu, Tidong, and Sino-native. Europeans, Eurasians, Malay, Indonesians, Filipinos, and Indians and Pakistanis comprise the remainder.

The Kadazan are composed of a number of tribes, each speaking a dialect that the others can understand. About a fourth of the Kadazan population are Christians, a small percentage are Muslims, and the remainder are animists. More than half of the Chinese are Hakka-speaking; the other important Chinese dialect groups are Cantonese, Hokkien, Tiechiu, and Hainanese. The Bajaus are not a cohesive community, being split into two main groups—the sedentary agriculturists, who have settled on the north coast, and those who live by the sea on the east coast. Most are Muslims, but not all of them can communicate with each other. The Murut of Sabah are ethnically different from the Murut of Sarawak, being descended from the same stock as the Kadazan. They are shifting cultivators. Although they are divided into subtribes, their languages are mutually intelligible. Although most follow traditional religions, approximately one-fourth are Christians.

THE ECONOMY

Malaysia's economy is one of the strongest in Southeast Asia. The monetary unit is the Malaysian dollar (*ringgit*). The country is the world's largest producer of rubber, tin, and palm oil. Its economy, compared with those of most developing countries, is relatively advanced in its infrastructure (*i.e.,* roads, water supplies, and electricity), diversification, institutional patterns, commercial and financial patterns, and management, professional, and administrative skills.

Resources. There are many mineral resources in Malaysia. West Malaysia's resources include tin, iron ore, bauxite (from which aluminum is made), coal, gold, china clay (kaolin), monazite (the principal ore of thorium, a malleable, radioactive metallic element), ilmenite (a titanium mineral), columbite (the principal ore of niobium, used in making steel alloys), manganese, tantalite (a mineral containing tantalum, a metallic element resistant to corrosion), wolframite (an important ore of tungsten, a metallic element with a high melting point), and zircon (the chief ore of zirconium, a metallic element, used in steel metallurgy). Antimony (a brittle, lustrous, white metallic element, used in alloys), mercury, gold, coal, petroleum, bauxite, phosphate, and glass sand are found in Sarawak; and gold, coal, manganese, and copper in Sabah. Except for petroleum, tin, iron ore, bauxite, and copper, most of the minerals are of minor economic importance. In Sabah the only mineral of great importance is copper.

Tin

Other than crude petroleum, tin is the most important mineral in Malaysia. It is found in most of the West Malaysian states and is distributed in two belts—western and eastern. The western tin belt runs along the flanks of the Main Range and along either side of the subsidiary granite ranges to the west of the Main Range. The less continuous, and also less rich, eastern tin belt runs from southern Terengganu to eastern Johor. Investigations indicate that there are large deposits of tin in the Malay Reservations (lands set aside by law for the use of Malays and which cannot be sold to others). The search for new fields has been extended to the offshore areas of the western peninsula. Iron ore deposits along the eastern and western peninsula have been largely depleted.

The production of crude petroleum is increasingly important. Malaysia is one of the largest producers of crude petroleum in the Far East.

Hydroelectric potential

The power resources of Malaysia include coal, peat, wood, petroleum, and hydroelectricity. Although there are proved reserves of coal and peat, they are not economical to mine and therefore remain only of potential use. Wood and charcoal were the traditional domestic fuels, but in the urban areas they have largely been displaced by bottled gas. Very little hydroelectric power is generated in East Malaysia, but, as on the peninsula, the abundant rainfall and steep gradients of the rivers in the interior highlands offer good hydroelectric resources. The nation's petroleum resources constitute a major source of fuel oil. For power generation, therefore, Malaysia continues to depend primarily on fuel oil.

Agriculture, forestry, and fisheries. Agriculture, mining, forestry, and fishing combined constitute the most important sector of the Malaysian economy. More than four-fifths of the work force of West Malaysia and almost two-fifths of the work force in Sarawak and one-fourth in Sabah are engaged in these pursuits. Nearly half of the economically active population continues to depend upon agriculture for a livelihood. The most important cash crops are rubber (the country's second largest foreign exchange earner), oil palm, and forest products. The main food crop raised in Malaysia is rice (called *padi* in Malay), which ranks second only to rubber in terms of the amount of land and labour devoted to its production. Cultivation systems range from the traditional shifting cultivation, still commonly practiced in East Malaysia, to the most modern forms of plantation agriculture.

The main biological resources of Malaysia are its forests and its fisheries. The extensive areas still under rain forest in both West and East Malaysia are a source of various forest products used by the indigenous peoples, as well as of timber, charcoal, firewood, poles, resins, gums, and rattans, which are produced both for local consumption and for export.

Most of the land area in Malaysia is still covered by forest. The timber industry has expanded, and the sustained export demand for tropical timber has stimulated the opening up of additional forest areas. The output of timber also has increased as a result of the clearance of large areas of forest for land development. Timber has become Malaysia's third largest foreign exchange earner, after crude petroleum and rubber.

The shallow seas off the coasts of Malaysia are the principal fishing grounds. In general the nutrient level, and hence the productivity of these seas, is low, the richer portions being those fertilized by drainage waters from the land. The annual output of the fishermen who use traditional techniques and who fish in inshore waters is low. Progress in the Malaysian fishing industry has been impressive. The long coastlines provide the Malaysian fishermen with easy access to the surrounding seas, although most of them still confine their fishing to the over-exploited shallow inshore waters. The greater use of trawlers and mechanized fishing boats has allowed the fish resources of the offshore grounds to be tapped, however.

Mining and petroleum exports

Industry. The mining and extractive industry contributes about one-third of the total export receipts. The main minerals produced are petroleum, tin, iron ore, and bauxite. West Malaysia is the world's largest producer of tin, but intensive exploitation has led to a steady depletion of known deposits, and the tin industry is consequently searching for new deposits off the coast of the western peninsula, as well as in Malay Reservations. The output of iron ore also has dropped due to the gradual depletion of high-grade deposits. Bauxite production declined after the closure of the Sarawak mine in 1965, but this was partially offset by increased output from the mines in southeastern Johor. West Malaysia and Sarawak produce most of the oil, while Sabah produces smaller amounts. The first offshore well began production in Sarawak in 1968. Malaysia's only copper mine is located in Mamut, Sabah; its output of copper concentrates has increased greatly.

Most of Malaysia's manufacturing plants are located on the peninsula. The contribution of the manufacturing sector of the economy has increased. Malaysia has attempted to broaden its economic base by industrialization. Efforts have been directed mainly at the production of hitherto imported consumer goods, and the range of manufacturing also has been widened to include production for export. Governmental efforts to promote industrialization include the granting of favoured treatment, including tax holidays, for selected industries; the establishment of tariff barriers for the protection of the home market; and the establishment of institutions to promote industrial development. The government has fostered industrial estates in the less developed states in an effort to industrialize those regions and to balance overall industrial growth.

Trade. Most of Malaysia's exports are made up of raw materials. Five commodities—crude petroleum, rubber, timber, palm oil, and tin—account for about three-fourths of the total value of all exports. The most important imports are transport equipment and machinery, manufactured goods, and food, which together constitute about two-thirds of the total value of all imports.

Economic development

Administration of the economy. The free enterprise system introduced during the British colonial era has been modified since independence. The government has embarked upon a program of planned economic development that aims at raising living standards of the population in general and of the economically weaker communities in particular. The program, however, encourages the continued participation of the private sector. Direct governmental participation is limited to the development of such infrastructural facilities as transportation, public utilities, drainage and irrigation works, agricultural settlement schemes, and industrial estates, as well as of social and administrative services. Malaysia is a member of the Association of South East Asian Nations (ASEAN), which works to integrate the economic and social development of the Philippines, Thailand, Indonesia, Singapore, and Malaysia.

Malaysia's systems of public finance—auditing and organization of accounts, parliamentary control, and revenue collection—are generally based on British principles. The country's fiscal system—rather than being employed to manipulate the pace of economic activity, the level of employment, or the level of prices—is basically a mechanism for raising revenue for governmental expenditure. Increasing dependence is being placed by the government on income and other direct taxes for revenue collection, while customs and excise duties provide a slightly smaller proportion of the total yield. The government is attempting, meanwhile, to distribute the tax burden equitably, by using such means as sliding income tax scales, higher duties on luxury goods, and lower duties on essential commodities.

More than half the total labour force of Malaysia is engaged in primary production. There is continued dependence on imports for many manufactured goods, and the industrial sector remains relatively small, though it has become the fastest growing sector of the economy. By the standards of other developing countries in Asia, Malaysia's economy is nevertheless relatively advanced, varied, and complex. The component states of Malaysia are, however, in widely different stages of economic development. West Malaysia, contributing almost 90 percent of the total GNP, is clearly the dominant area, with Sarawak and Sabah lagging far behind.

Economically, Malaysia needs to maintain a steady rate of economic growth despite a relatively rapid population increase. Underemployment, while its extent has not been accurately assessed, is widespread, especially in the subsistence agricultural sector. In Sarawak, population pressure already has led to land exhaustion and to soil erosion in many areas of shifting cultivation. Higher income agricultural industries, by contrast, have increased their employment.

In order to reduce its vulnerability to world market fluctuations, Malaysia has to diversify its economy and at the same time raise standards of living, especially in its depressed areas—in the eastern side of the peninsula and in the interior parts of Sarawak and Sabah.

Transportation. Although Malaysia's transportation system has expanded rapidly, it has failed to keep pace with the country's economic growth. The transport network in West Malaysia is well developed, especially in the tin and rubber belt. Both Sarawak and Sabah, however, have poor transport facilities, relying primarily on river transport for movement between the coast and the interior.

Peninsula roads

The road network in West Malaysia is considered the best in Southeast Asia. Most of the roads are hard-surfaced. There are highways running from Kuala Lumpur to Seremban, Kuala Lumpur to Karak, and Jerangau to Jabor. The road networks in Sarawak and Sabah are still inferior. Some of the roads in East Malaysia are bitumen-surfaced; the rest of the system, however, is generally of poor quality.

The rail transport system is only well developed on the peninsula. Sarawak has no railway, and Sabah has only a short line linking Kota Kinabalu to Tenom. Growth is notable in rail traffic, especially in bulk cargo and long-distance passenger traffic.

Traditionally, transport in both East and West Malaysia has been by water. River transport, however, is no longer important in West Malaysia except on parts of the east coast, but in East Malaysia it continues to play a major role. On the rivers of Sarawak and Sabah, which link the interior and the coast, almost all settlements are riverine, and many are frequently accessible only by water. Due to the long coastlines, the coastal and sea transport systems of Malaysia are of great importance. A number of coastal and river ports have been established at strategic locations—George Town and Port Kelang in West Malaysia; and Kuching, Sibu, Labuan, Kota Kinabalu, Sandakan, and Tawau in East Malaysia. Traffic at these ports has steadily increased.

Air transport has grown even more rapidly, with passenger traffic increasing mostly in West Malaysia. The rate of increase has been lower in East Malaysia. Regular internal services fly between Kuala Lumpur, Kuching, and Kota Kinabalu and also link the states of Malaysia. The Malaysian Airlines System was formed in 1971 and operates international services in the Pacific region in addition to its internal operations.

ADMINISTRATIVE AND SOCIAL CONDITIONS

The *yang di-pertuan agong*

Government. Malaysia is a federal constitutional monarchy with a nonpolitical head of state, or *yang di-pertuan agong* ("the supreme ruler"), who is elected from among nine state hereditary rulers for a five-year term. The legislature is composed of the Dewan Negara, or Senate, and the Dewan Rakyat, or House of Representatives. Malaysia also has a prime minister and cabinet, an independent judiciary, and a neutral civil service. The federal parliament is the supreme legislative body of the country. It also controls the finances of the government. A bill passed by both houses and sanctioned by the *yang di-pertuan agong* becomes a federal law.

The House of Representatives functions in a similar manner to the British House of Commons. It has a membership of 154, of which 114 are from West Malaysia, 24 from Sarawak, and 16 from Sabah. Members are elected to office from single-member constituencies on the basis of a simple majority. The term of office of a member is five years. The Senate has a membership of 58, of which 32 are appointed by the *yang di-pertuan agong* on the recommendation of the prime minister. The 26 elected members are made up of representatives from each of the state legislative assemblies. Voting in either house is by a simple majority, but amendments to the constitution require a two-thirds majority.

The *yang di-pertuan agong* appoints the prime minister, who must be a citizen in law as well as a member of the House of Representatives. On the advice of the prime minister, the *yang di-pertuan agong* then appoints the other ministers who make up the cabinet. The number of ministers is not fixed, but all must be members of the federal parliament.

The powers of the federal parliament are relatively wide and include the authority to legislate in matters concerned with defense, external affairs, internal security, the administration of justice, and citizenship. The state legislatures, however, retain responsibility for matters pertaining to Islāmic law and for matters pertaining to personal and family laws affecting those of the Islāmic faith, as well as for land laws. The constitution also provides that some items may be dealt with either by the federal or by the state legislature.

Each state of Malaysia has its own written constitution and its own legislative assembly. Each state also has an executive council collectively responsible to the legislative assembly and headed by a chief minister. Several Malay states—Johor, Kedah, Kelantan, Pahang, Perak, Selangor, and Terengganu—have hereditary rulers, who are entitled sultans. The raja (king) is the ruler in Perlis, and the *yang di-pertuan besar* ("the chief ruler") in Negeri Sembilan. The heads of the other states are appointed to office. They are known as governors in Melaka, Pinang, and Sarawak, while in Sabah the head of state is known as the *yang di-pertuan negara.* The ruler or governor of a state acts on the advice of the state government. The constitution provides for parliamentary elections and for elections to state legislatures, to be held at least every five years.

lections

Justice. The constitution of Malaysia, which is the supreme law of the country, provides that the judicial power of the federation shall be vested in the High Court of West Malaysia and the High Court in East Malaysia and also in subordinate courts. Above the High Courts is the Federal Court, with jurisdiction to hear and determine appeals from decisions by any High Court. The supreme head of the judiciary is the lord president of the Federal Court.

Each High Court consists of a chief justice and a number of other judges—12 in West Malaysia and four in East Malaysia. The High Court has unlimited criminal and civil jurisdiction and may pass any sentence allowed by law. Below the High Court are the subordinate courts, which consist of the Sessions Courts and the Magistrates' Courts. Both these lower courts have criminal and civil jurisdiction—criminal cases coming before one or the other court depending upon the seriousness of the offense and civil cases depending upon the sum involved. In addition, there are religious courts in those Malay states that are established under Islāmic law. These courts are governed by state and not federal legislation.

Armed forces. The Malaysian armed forces have increased in strength and capability since the formation of Malaysia in 1963. After the withdrawal of British military forces from Malaysia and Singapore at the end of 1971, a five-power agreement between Malaysia, Singapore, New Zealand, Australia, and Great Britain was concluded to ensure defense against external aggression. The ASEAN also provides additional regional security. In the early 1970s Malaysia was engaged in internal security operations against guerrilla forces of the Malaysian Communist Party on the West Malaysia–Thai border, as well as against the clandestine Communist organization in Sarawak.

:curity
range-
ents

The armed forces consist of the army, the navy, and the air force. The army, which is the most experienced and the largest of the three, includes infantry brigades, reconnaissance regiments, scout cars, artillery regiments, and various supporting arms. The Royal Malaysian Navy includes a complement of frigates, coastal minesweepers, and a number of patrol boats. The emphasis is on speed and manoeuvrability for the purpose of defending the long, indented coastlines and narrow waters of Malaysia against intruders. The Royal Malaysian Air Force has combat aircraft, as well as many transport aircraft and helicopters.

The states of Malaysia inherited from their common colonial past an internal security system based on the British model. The police force is well trained and combats not only crime but also subversive activities, including armed Communist insurrection.

Education. Governmental policy is to provide nine years of education to each child. Enrollment in primary schools has increased. Considerable progress also has been achieved at the secondary level. Institutions of higher learning include the Universiti Malaya (University of Malaya), the Universiti Sains Malaysia (University of Science, Malaysia, formerly the University of Pinang), the Universiti Kebangsaan Malaysia (National University of Malaysia), the Universiti Pertanian Malaysia (University of Agriculture), and the Universiti Teknologi Malaysia (Technological University of Malaysia). The Mara Institute of Technology and a number of teacher-training colleges and vocational training centres are other important facilities. Enrollment in higher education has also increased.

Health and welfare. The general level of health has improved. The country is free from many of the diseases that plague tropical countries, but diseases borne by carriers, such as malaria, are still a problem in rural areas. Health conditions and health facilities vary among the component states, being better in West Malaysia than in the states of Borneo. Within each state, health services are better in the towns and cities than in the rural areas. Segments of the rural population continue to rely on traditional rather than modern medicine for treatment. Most of the modern health services are provided by the government. Welfare services are, however, provided by both government and voluntary agencies and include relief programs for the needy, the aged, and the handicapped.

The multicultural character of the population of Malaysia is visibly reflected in the wide variety of houses, which range from the longhouses and stilt houses of the rural peoples to examples of modern architecture in the cities. There is an abundance of forest-derived building material in the rural areas, so that no statistically measurable housing problem is evident, even though some of the dwellings in the more remote areas are often only temporary shelters. In the larger towns and cities of Malaysia, however, slums are common. A governmental housing authority has been established to assist in developing low-cost housing.

Many people, especially in Sarawak and Sabah, live by hunting, gathering, fishing, and simple farming; wage earners form only part of the total economically active population. Because of the increasing pressure of population on the land, however, there is a growing tendency for the male labour force to seek employment in manufacturing. Persons with an upper secondary or post-secondary education have entered the labour force at a fast rate, resulting in a higher unemployment rate among skilled workers than among the unskilled. Wages in the manufacturing sector, nevertheless, continue to be higher than wages in the agricultural sector, and underemployment continues to characterize the rural economy. Increasing industrialization is expected to draw increasing numbers of workers from the countryside to the cities and to create a greater demand for skilled workers.

CULTURAL LIFE

Malaysia, with its complexity of peoples and cultures, is a melting pot of several important cultural traditions, stemming from the Malay Archipelago as well as from China, the Indian subcontinent, the Middle East, and the West. Malay culture and Bornean culture are indigenous to the area. In the first one and a half millennia AD, indigenous Malay culture in the Malay Peninsula and in other parts of Southeast Asia was strongly marked by pre-Islāmic Indian and early Islāmic influences. Indian contact with the Malay Peninsula extended over a period from about the 4th century AD to the late 14th century, exerting a profound influence upon religion (through Hinduism and Buddhism), art, and literature. Islām, introduced to Malacca (now Melaka) in the 15th century, soon became the dominant religion of the Malay. The introduction of Western cultural influences in the 19th century affected many aspects of Malay life, especially in technology, law, social organization, and economics.

Contemporary Malay culture is thus multifaceted, consisting of many strands—animistic, early Hindu, early and modern Islāmic, and, especially in the cities, Western. The collective pattern thus established is distinct from other cultures and recognizably Malay.

Unlike the early Chinese traders who settled in Malacca and George Town and were partially assimilated (at least to the extent of adopting the Malay language), the Chinese who emigrated to the Malay Peninsula in the late 19th and early 20th centuries in large numbers were usually transients who established self-contained communities. Chinese cultural influence has consequently been minimal. The Chinese immigrants themselves, moreover, did not form a homogeneous group. Their culture in Malaysia has its roots in the culture and civilization of prerevolutionary China, with modifications brought about by local circumstances and environment.

Most of the Indians and Pakistanis originally came as labourers to work in the coffee and rubber plantations. Like the Chinese, they too, until World War II, were mainly transients, living in closed communities and remaining virtually unassimilated.

The communities of Malaysia have been affected by British colonial rule and Western modernizing influences. Western cultural influence has been greatest in education and institutional forms. Traditions and cultural institutions have been least affected in the rural areas—in eastern West Malaysia and in the interior of East Malaysia—while the cities have been the focus of the most rapid cultural changes.

Art forms

External cultural influences have made the least impact in music, dancing, literature, and the decorative arts. In East Malaysia the indigenous cultural background includes no written history or literature. Architecture is little developed, and the principal art forms are dancing and handicrafts, represented notably by the textiles handwoven by the Punan tribe, cloth made by the Bajau people, patterned rattan mats and basketwork, and wood carvings. Particularly on the peninsula, the artistic manifestations of Malay culture are mainly in literature, music, dancing, and the decorative arts. Painting and sculpture are poorly developed, primarily because Islām does not encourage the representation of the human form. Examples of the Malay decorative arts include batik cloth (cloth hand dyed by using a special technique), silverware, the handmade kris (a short sword or heavy dagger with a wavy blade), wood carving, and basketwork. Malaysian Chinese culture is derived from Chinese civilization and is represented by literature, drama, music, painting, and architecture. Some Malaysian artists, of Malay, Chinese, and Indian origin, also have begun to produce new art forms, especially in painting and architecture, that represent a synthesis that is distinctively Malaysian in character.

The newspapers are all privately owned and vary greatly in circulation, quality of reporting, and news coverage. Among the educated groups, the press is the principal source of information. In remote rural areas the radio is relied upon. Television is, however, the most popular medium among all language groups. (O.J.B.)

For statistical data on the land and people of Malaysia, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL.

History

WEST MALAYSIA

Malaya has been inhabited for at least 6,000 years. Archaeologists have unearthed evidence of several Stone Age cultures as well as an Early Bronze Age civilization. These probably existed contemporaneously with more advanced settlements stimulated by the arrival of adventurers from India beginning in the 2nd century BC.

Rise of Indianized states. The Malay Peninsula, and indeed most of Southeast Asia, experienced more than 1,000 years of Indian or Indianized influence. Indian blood and Indian culture blended with indigenous elements to produce an amalgam, which found political expression in the creation of a number of states and several great empires. Lacking the fertile plains of Java or Cambodia, the peninsula was unable to support a great empire. Although knowledge is scanty and is based largely on Chinese written sources, it does appear that at least 30 small states, nearly all along the east coast, flourished during this millenium. These included Tun Sun, in the northeastern part of the peninsula, where in the 3rd century AD there were more than 500 Indian merchants and priests. Ch'ih-t'u ("Red Land," Tanah Merah in Malay) may have been established in the 6th century on either the Kelantan or Trengganu River. The most important of the Indianized states was Lankasuka, whose control extended at times across the whole northern part of the peninsula. The most significant complex of Indianized temple ruins in Malaya, on the slopes of Kedah Peak opposite Pulau Pinang (former Penang Island), was at one time part of this state. Kedah, the name of a modern Malay state, was once thought to be Kalah, described by Arab sailors of the 9th through the 14th centuries. This state, it is now thought, was north of the peninsula, in present-day Thailand.

Indian influence

These small states, now long forgotten, have left a living legacy, traces of which are to be found even in the political structure of modern Malaysia. In religion, too, traces of Hinduism and Buddhism persist in the ritual, language, and practice of the Malay Muslims. A similar influence is seen in many of the arts and crafts still flourishing on the peninsula.

Much of the influence was imposed indirectly from India by the great Indianized empires of Southeast Asia. The small states of the peninsula, it would appear, were usually under the hegemony of one or the other of these empires, either in Siam or Cambodia to the north or Sumatra and Java to the south. On Singapore Island, for example, Tumasik, an Indianized settlement, owed allegiance in the 14th century first to Sumatra-West Malaya, under Śrivijaya; then to Majapahit, the great Javanese empire; and finally to Ayutthaya (Siam). Paramesvara, Tumasik's Sumatran ruler near the end of the 14th century, unsuccessfully attempted to win independence for Tumasik from Ayutthaya. Tumasik was sacked, but Paramesvara found refuge at the small fishing village of Malacca (now Melaka), where he established himself as ruler in about 1400.

Advent of Islām. From this precarious beginning, Malacca rose during the 15th century to become a political power of the first rank, the most important commercial mart in Southeast Asia, and the main centre for the diffusion of Islām. A fortunate set of circumstances combined to permit this. Soon after he won control of Malacca, Paramesvara secured the support of China. Chinese settlers at that time were beginning to move into the Nanyang ("South Seas"), or general Southeast Asian region. The Chinese admiral Cheng Ho called at Malacca in 1409 and again in 1414. In return for annual tribute, once taken to Peking by Paramesvara himself, the Chinese emperor promised his protection to Malacca. For three decades, China's guardianship deterred other Southeast Asian states, notably Siam, from crushing Paramesvara's settlement and permitted it to develop. Its location, in addition, was attractive to traders from India, Arabia, China, and the Indonesian islands as a central, independent meeting place not for the purchase of Malaccan goods, of which there were few, but for barter and exchange. A good government and a sensible nonrestrictive policy encouraged the traders to frequent the peaceful bay in increasing numbers. The fishing village thus grew into a bustling and famous city where many of the commodities of Asia were traded.

Emergence of Malacca

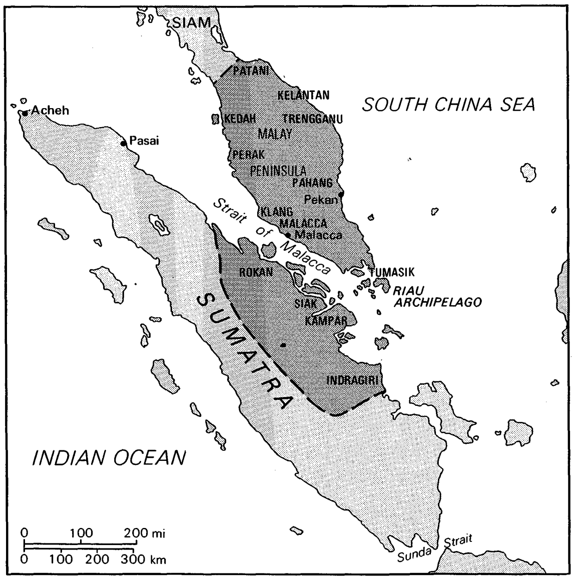
Malacca's most important role, however, was not commercial but religious. It replaced Sumatran ports as the main centre for the transmission of Islām throughout Southeast Asia. Originally disseminated by peddlers and traders from east Bengal and other areas of the Indian subcontinent, Islām had secured a toehold in north Sumatra and east Malaya during the 14th century or earlier. With the growth of Malacca in the 15th century, however, the new faith was conveyed most effectively along Malaccan trade routes by missionaries and merchants. The ancient Hindu beliefs survived only on Bali; elsewhere, the courts and the peoples accepted the new faith and helped it to spread, mainly as a major movement for peace, to the coastal areas of West Irian and the Philippines.

On the Malay Peninsula itself, the spread of Islām was linked closely to the territorial expansion of the Malacca sultanate, which began during the reign of Muzaffar Shah (1446–59), Paramesvara's great-grandson. In 1456 Muzaffar Shah appointed an outstanding man, Tun Perak, as *bendahara* ("prime minister"). In that year, also, Tun Perak became the saviour of Malacca, defeating the Siamese in a fierce naval battle off South Johore. For some 40 years (1456–1498), although he never became sultan, he was the effective ruler of Malacca and promoted its expansion. The state of Perak already had become Muslim and in 1460 became a part of Malacca; Pahang, a tributary of Siam, was conquered. Islām followed and moved north to Trengganu. South Malaya also was made part of the growing sultanate. The river states in Sumatra that had been commercially linked to Malacca were acquired in 1477. In 1474 Kedah, Malaya's one granary of importance, also received a Muslim sultan.

Early European intrusions. Long before the end of the 15th century the fame of Malacca had reached Europe, attracting those interested in the spice trade. The Portuguese, who for a century had been dedicated to the national endeavour of reaching the Orient by sea, arrived at Malacca in 1509. It was the beginning, as one Asian historian has called it, of "the Vasco da Gama Era," the period of European dominance in Asia. Although the Portuguese and subsequently the Dutch did not exert the dominance exercised by the British in the 19th century, the European intrusion of the 16th century was, nevertheless, the beginning of a political movement that grew in strength for over 400 years and has only just ended.

In 1511 Malacca was captured by a Portuguese fleet led by Afonso de Albuquerque. Along with the Moluccas (Maluku) and Goa (in India), it became one of Portugal's major trading outposts in Asia. The Portuguese were, however, few in number, and although they retained defensive possession of Malacca until 1641, Malaya was more deeply influenced in the 16th century by Acheh, an aggressive state in Sumatra.

When the Achinese first attacked Malacca in 1537, the city was saved by its new stone fort. Subsequent assaults came in 1539, 1547, 1568, 1570, and 1573. Acheh's target was not merely Malacca but all the Malay states as well. The story is complex and confused, for the allies of one decade were often enemies in the next. The Malay states and the Portuguese sometimes fought one another, sometimes joined together. Acheh remained the aggressor until well into the 17th century. By that time the few hundred Portuguese at Malacca were a spent force. They had to face a new opponent, the Dutch, who had secured a base in 1596 on Java. In 1607 the Dutch allied themselves with Acheh, while the Portuguese in Malacca joined with Johore. The Achinese sacked Johore, 1613–1615; Pahang in 1617; Kedah in 1619; and Perak in 1620. Acheh thus secured suzerainty over the Malay states for 20 years.



Malacca Empire in 1500.

The Dutch

In Java the Dutch, in the meantime, had grown steadily in strength. They began actively meddling in the affairs of the Malay states in 1633, when they laid siege to Malacca. Year after year the few Portuguese waited in vain for relief, surrendering finally in 1641. Malacca had become a moribund town, its bustle and importance long vanished. Despite all efforts by the Dutch to revive the port and to channel the trade in tin from the west Malay states to it, Malacca never recovered its earlier glory.

The Minangkabau and the Buginese. The last 50 years of the 17th century witnessed the migration of many Minangkabau people from Sumatra. These sturdy agriculturalists settled in south Malaya, which until then had been virtually unpopulated. They brought with them an almost uniquely matrilineal outlook by which property and authority descended through the female. Their leader was freely elected (their method of election has served as the basic model for selecting the ruler of modern Malaysia), and in the late 18th century, they formed a confederation of small states, which came to be known as Negri Sembilan, or "Nine States."

During the 18th century the Dutch found that profits from dealings with Malacca could not compare with the benefits to be derived from trade with Java and the Spice Islands. Malacca was therefore neglected, a situation that permitted large-scale penetration of Malaya by the "Norseman of the East," the Buginese rovers from the Celebes (or Sulawesi). Just as the well-governed state of Normandy arose as the Norseman's contribution to Atlantic civilization, so are Selangor and Johore perhaps the best examples of Buginese occupation and organization in Southeast Asia. Hardly a member of the Johore civil service today does not have Buginese blood in his veins, and Johore's independent progress in the 19th and 20th centuries is attributable largely to the migrations of the 18th century. Although the Buginese had traded for many centuries on the Java Sea, they did not begin to settle in the relatively weak Malay Peninsula until the late 17th century. In Selangor they established their ruler as sultan as early as 1700. The Buginese leader, Raja Haji, seized Perak and sacked Alor Star, capital of Kedah, in 1770. By that time the Buginese had developed a new trading centre south of Singapore, in the Rhio (Riau) archipelago, where a policy of free trade and peaceful government attracted Asian and European merchants. Malacca was nearly captured by the Buginese in 1784.

The Buginese

Dutch influence in the Malay Peninsula was weakened not only by the Buginese invasions but also by the arrival of the British. Seeking a source for goods to be sold in China, the East India Company acquired Penang Island in 1786. In 1795 the British captured Malacca, and in 1819 Sir Thomas Stamford Raffles established a settlement on Singapore Island. Britain's entrenched position was clarified beyond dispute by the Anglo-Dutch treaty of 1824. Malacca, Singapore, and Penang Island, the three "Straits Settlements," came under the direct control of the British Colonial Office in 1867. Singapore, a free port, grew rapidly.

With the opening of the Suez Canal in late 1869, the full effect of European technological superiority swept over Southeast Asia. The Malay states were little prepared. With the exception of Johore, which was effectively ruled by Abu Bakar, the states were generally poorly administered and failed to cope with their mounting problems, chief of which was the steady immigration of Chinese in search of tin. From the mid-19th century to the present, the Chinese and the Malays have been two elements of an inadequately integrated community, prone to racial clashes and communal disorder. The clashes, which included disputes between rival Chinese groups on the newly discovered tin fields of Perak, became sufficient in 1874 to provoke British intervention.

Chinese immigration

This intervention by a European power into the internal affairs of weak Asian states was at first crude. Malay reaction saw the murder of J.W.W. Birch, the first British resident (chief officer) in Perak (1875). Lack of understanding and incompetence also characterized the first British residents in Selangor and Sungei Ujong, one of the Negri (Negeri) Sembilan ("Nine States"). They were followed, however, by more talented men. Frederick Weld (1823–91) expanded the policy of intervention to encompass all the Negri Sembilan and Pahang on the east coast. He selected competent officers to work as residents in the various states. Among these was Frank Swettenham, resident in Selangor, whose service in the Malay Peninsula culminated in his appointment as first resident general, when the four states of Perak, Selangor, Negri Sembilan, and Pahang were brought together in a federation in 1896, with Kuala Lumpur as its capital. The other sultanates in the peninsula were also induced to accept British officers as residents or "advisers" but managed to avoid joining the federation. They saw too great a loss of individuality and control despite the British policy of preserving the sultanates, the Muslim faith, and the Malay way of life. Between 1902 and 1909 Trengganu (Terengganu), Kelantan, and Kedah were extricated from the Siamese sphere of influence. In the south, Johore (Johor) accepted a British adviser in 1914.

The genesis of the modern state of Malaya. British political control over the whole peninsula radically transformed Malaya economically and socially. As with the Romans in Britain, the British in Malaya devoted much attention to transport. Railways appeared, first from the coast to the tin fields, and then north to south down the peninsula until connections with Singapore were completed in 1924. A road network was constructed and paved to withstand the rains. Penang (Pinang), Singapore, Port Swettenham (Klang), and other ports were improved and given constant attention by the British.

Tin and rubber industries

Development of transport assisted in the rapid growth of the important tin and rubber industries. During the 19th century technological developments in the U.S. and Europe created an ever-increasing demand for tin. The Malays were indifferent to the opportunities created by this demand, and thousands of Chinese migrated to Malaya during the second half of the century to develop tin mining and manufacture. Vast new deposits were found, and the industry remained in Chinese hands through the 19th century. The Chinese, however, lacked capital and technology. Their open-cut, labour-intensive methods of mining were replaced by the mining dredge introduced by British-financed companies in the early 20th century. Two major tin smelters were established at Penang and Singapore, and "Straits tin" became known throughout the world. The tax on exported tin became one of the two main sources of revenue for Malaya; the other was a similar levy on rubber.

The first strain of rubber, introduced in the 1870s, had proved unsuccessful. The planters grew coffee until the development in the 1890s of a superior strain of rubber. From 1896 through the early 20th century, funds from British financiers provided for the clearing of thousands of acres of virgin jungle and the establishment of new rubber plantations. Rubber production was increased also with the allotment of acreage to individual Malay and Chinese smallholders.

Whereas Chinese immigrants had been attracted in great numbers by the tin industries of Perak and Selangor in central Malaya, between 1880 and 1920 thousands of south Indians moved to the west coast of Malaya to work on the rubber estates. A plural society was thus created and was maintained largely by the educational system. One school system taught the Malays in Malay. Missionary schools used English to teach the Christian Chinese, Indians, and Malays. Still other schools, financed by Chinese and supported by the Chinese Communist and Kuomintang parties, instructed Chinese residents in Chinese. The status quo of the plural society, preserved by Britain, was unchallenged until 1941. The few attempts toward self-government were discouraged.

In the field of public health, the British eliminated malaria, beriberi, and other previously incurable diseases.

Japanese invasion and occupation

By the close of 1941 the relations among East Asian nations had reached a critical stage. Japan, locked in a struggle with China since 1937, and increasingly desperate for raw materials such as oil, faced an embargo on raw materials from its major supplier, the U.S. To reach the oil and rubber of Java, Japan had to neutralize the great British naval base on Singapore Island. Attacks on Pearl Harbor on December 7, 1941, and on the Philippines on December 10 eliminated the U.S. from the Pacific, at least for several decisive months. On December 8 the Japanese had invaded Malaya and then headed south to Singapore.

The campaign was the greatest disaster the British had experienced since Cornwallis' surrender at Yorktown; the Japanese victory was complete. Singapore was captured within 70 days. Within three days Japanese aircraft had sunk the major British battleships "Prince of Wales" and "Repulse." Within a week they had swept the skies clear of the antiquated British aircraft. The troops of Gen. Yamashita Tomoyuki outfought and outmanoeuvred Gen. A.E. Percival and his British, Indian, Australian, and Malay troops. The Japanese scored further successes at Jitra in north Kedah, December 11–12, 1941, and at Slim River in Perak on January 7, 1942. Singapore fell on February 15. The Japanese lost 15,000 men. The total loss to the British Commonwealth was approximately 166,600 men.

Birth of Malayan nationalism

Following the expulsion of the Japanese and the return of British rule in late 1945, an attempt by London to organize Malaya into one state deeply offended the Malays, who prized their treaty arrangements with Britain and were determined not to become a mere colony. A tremendous upsurge of Malay political feeling, led by Dato Onn Bin Jaafar, resulted in the creation in 1946 of the United Malays National Organization (UMNO). In 1948 a federation joining the Malay Peninsula and Penang was formed.

In that year also the Malayan Communist Party (MCP), formed before the war among the Chinese community, rose in armed revolt and opposed the British from enclaves in the jungle. An emergency was proclaimed, as Britain endeavoured to suppress the MCP by military means and by eliminating the political causes of its agitation. These aims finally were achieved by Gen. (later Field Marshal) Sir Gerald Templer, who arrived in 1952. Templer invigorated military measures already planned and, as high commissioner, encouraged the attainment of *merdeka* ("independence") through political cooperation among the races. Under a new leader, Tunku Abdul Rahman, the UMNO in 1952 joined with the Malayan Chinese Association (MCA), led by Tan Cheng Lock and his son Tan Siew Sin. Both parties were anti-Communist and anticolonial. In the national election of 1955 the UMNO–MCA Alliance, led by Abdul Rahman, captured 51 of 52 seats. Britain responded by relinquishing its powers in Malaya. On August 31, 1957, Malaya secured its *merdeka,* and the emergency period ended three years later.

Postwar Malaya has been marked above all by the political drive of the Malays, expressed through UMNO. Only by associating with this powerful organization and its leader, Tunku Abdul Rahman, were other elements in the community able to achieve some of their goals. Malay dominance has caused bitterness, and racial antagonism found expression in rioting in Kuala Lumpur on May 13, 1969. Tun Abdul Razak succeeded the Tunku in 1970.

Tun Abdul Razak continued the peaceful progress of the country until his death in 1976. The third prime minister of Malaysia, Datuk Hussein Onn (son of Onn Bin Jaafar), faced with a deteriorating racial situation, was forced to circumscribe some of the civil liberties, processes of parliamentary government, and economic freedom of the Chinese in order to sustain the economically underprivileged Malays (or *bumiputras*). These steps toward a more traditional Asian leadership produced some friction. The country continued to progress, however, buttressed by new discoveries of petroleum offshore. (K.G.T.)

SABAH

Although there is evidence of Chinese trade from the 7th century onward, Sabah's contacts were confined to the Philippines for centuries. It was known to the Sulu pirates as the Land Below the Wind, because of its position below the typhoon belt.

After the rise of Portuguese power and the capture of Malacca on the Malay Peninsula by the Portuguese, many Muslim merchants moved to Brunei, which became an important centre of Islām. It was one of the great sea states of the Malay Archipelago and exercised suzerainty over Sabah.

During the 16th century, North Borneo was visited frequently by the Portuguese, who established trade with Sabah. At this time the Spaniards were competing with the Portuguese for hegemony, as well as with the Dutch and British. One of the main reasons for Dutch and, particularly, British intervention in North Borneo was the prevalence of piracy in the area and their need as shipping powers to control piracy.

In 1762 a British expedition sent to capture Manila was ceded the Sabah Peninsula, which then became known as North Borneo, by the Sultan of Sulu in gratitude for his release from Spanish captivity. The British also occupied the island of Labuan at this time. North Borneo came under full British control at the end of the 19th century. In 1872 the Sultan of Sulu gave William Cowie, a gunrunner, permission to establish a base on Sandakan Bay. Cowie was also given other trading privileges in North Borneo, but he ran into opposition from an American, Joseph William Torrey, who claimed trading privileges for the area under an older grant from the Sultan of Brunei. Torrey joined with Baron Gustavus de Overbeck, who represented a private syndicate headed by two English brothers, Alfred and Edward Dent, and although the Sultan of Brunei had no right to cede the territory, and despite the protests of the Spanish and Dutch governments, who had claims in the area, the Dents became the possessors of a large part of North Borneo, for which they paid an annual rent to the Sultan of Brunei. They then formed a limited provisional association, which became the British North Borneo Company in 1882, incorporated by royal charter. In 1888 the state was made a British protectorate, and, for the next 20 years, territorial consolidation took place, the final boundaries being defined in 1905.

After Japanese occupation in World War II, Sabah was granted crown colony status, in 1946.

SARAWAK

Little was known of Sarawak's rich prehistory until 1947, and nothing until then was excavated. Since 1947, energetic excavational and related fieldwork has been carried out by the Sarawak Museum throughout Sarawak, the adjacent state of Brunei, and, on a smaller scale, Sabah.

The classic site to date has been excavated on a considerable scale. This is the great cave at Niah, 400 miles northeast of Kuching, the capital of Sarawak, and 15 miles inland along a small river behind the South China Sea. Among the most significant discoveries at Niah is a radiocarbon dating of 40,000 years at what is only a medium level in the deposit, much of which remains to be excavated. From 40,000 years ago and more, there is an almost unbroken succession of human frequentations and occupations of the cave continuing after the arrival of a massive Chinese trade starting in the T'ang and Sung dynasties (AD 618 to 1279).

The Niah site provides a unique sequence of the evolution of stone tools from early hand-chopping axes, which are massive pebbles simply struck on one side to a point; through the development of flake tools; then finely edge-ground tools of the Mesolithic; on into the beautiful black polished adzes and axes of the Neolithic, or Late Stone Age. A fine set of wall drawings, provisionally attributed to the Early Iron Age, has also been found in one of the caves. These, too, are so far exceptional in Southeast Asia. They are associated with decorations showing the journey of the "ship of the dead" to the spirit world. Underneath the drawings, on the floor of the cave, more than 200 feet above the valley floor, beautifully carved model boats have been used as coffins for the deceased.

The Early Iron Age materials at the Niah Cave are closely paralleled by those found elsewhere in the Sarawak river delta, at the southwest corner of the island. There, about 30 places have been mapped as prehistoric monuments, reflecting what must have been an enormous trade between the Asian mainland and western Borneo reaching back more than 1,000 years. Traders from the mainland seem to have brought mainly ceramics, metal, and probably clothing. In return they received edible bird's nests, rhinoceros horn, hornbill ivory (*ho-ting;* one of the most valuable materials for carving in ancient China and to be obtained only from this area), camphor, spices, woods, bezoar stones, rattans, and other goods. With whom they traded is not yet clear. The nature of an earlier people is overlaid by many generations of interbreeding with existing groups. (T.Hn./Ed.)

By the mid-14th century, Sarawak came under the control of the great Hindu–Javan state of Majapahit. With the decline of Majapahit in the 15th century, Sarawak became the southern province of the sultanate of Brunei, one of the most important centres of Islām and one of the great sea states of the Malay Archipelago.

In 1839 the Dayak and the Malays in Sarawak rebelled against the oppressive rule of the Sultan's governor. At this time James Brooke, an English adventurer and a former officer of the East India Company, arrived in Sarawak, and in return for his services in putting down the rebellion, he was promised the title of raja and control of a large area of Sarawak. After some difficulty in getting the Sultan to honour this agreement, Brooke was installed as raja of Sarawak (1841) over the sector from Tanjong Datu to the Batang (River) Samarahan. The next few years he endeavoured to suppress piracy and head-hunting, often with the aid of British naval forces.

During the wars between the Dutch and the Kongsis in the 1850s, there was considerable migration of Chinese into Brooke's domain. The Chinese, aroused by the second Anglo-Chinese war then in progress, formed a secret society intent on taking control from Brooke and establishing an independent state. In 1857 the Chinese seized the capital, Kuching, and forced Brooke to flee, but the Malays and the Dayak of Sarawak put down the revolt and restored order. The Chinese remained in Sarawak, and, aided by migrants, they formed one of the important elements in the country. Chinese also continued to migrate to Brunei, and their migration to Sabah was encouraged in the 19th century by the British North Borneo Company in order to obtain a supply of labour for the exploitation of the country.

Under the provocation of the pirates, who kept moving their bases of operation eastward, Brooke extended his control through purchase and annexation over all of Sarawak west of Rajang River by 1861. By stages, the Brooke family extended control over more Brunei territory, under the rationale that the Sultan's control was either ineffective or oppressive. By 1890 the Sultan of Brunei controlled only a small portion of his original domain. In 1850 the United States recognized Sarawak as an independent domain, and recognition was given by the British in 1864. In 1888 an agreement with the British government placed Sarawak under British protection, but the Brooke family maintained control over all domestic affairs.

The Brooke "dynasty" continued to rule until World War II. In 1941 the third "white raja," Sir Charles Vyner Brooke, abrogated his powers by enacting a constitution designed to establish democratic self-government, but the effort was delayed by the Japanese occupation (1942–45). The territory, devastated by war, was ceded by Brooke to the British crown in 1946. (L.A.P.G./Ed.)

UNIFICATION AND THE FEDERATION OF MALAYSIA

Singapore secured full self-government in 1959. Its leader, Lee Kuan Yew, immediately pressed for "independence

Conflict with Singapore

through merger" with Malaya. Singapore shared much with the peninsula, and Lee felt that its future could be assured only by uniting with the mainland. Tunku Abdul Rahman, the leader of independent Malaya, agreed to the merger in order to forestall the growth of Communist influence among Singapore's Chinese population. To offset the inclusion of the 1,000,000 Chinese of Singapore, however, Malaya suggested in 1961 that Sarawak and Sabah (North Borneo), the other British colonies in Southeast Asia, which had substantial Malay populations, join with Malaya and Singapore in the merger. Both Sabah and Sarawak became independent in September 1963. After considerable discussion, and increasing opposition from the Philippines and Indonesia, the four states established a new, independent federation of Malaysia on September 16, 1963. (August 31, the date of Malaya's founding in 1957, remains the national day.)

Within two years, however, although Malaysia was able to withstand the external pressures of Indonesian armed opposition and "confrontation," internal disagreements worsened between Kuala Lumpur and Singapore. Abdul Rahman believed that civil war was imminent, and Malay political supremacy seemed challenged. On August 9, 1965, Singapore was separated from Malaysia and established as an independent republic.

Indonesian hostility took the form of raids across the borders of Sarawak and Sabah by guerrillas operating from Indonesian Borneo. The raids continued sporadically until 1966, when the two countries signed an agreement. In the late 1960s the Philippines unsuccessfully revived its longstanding claim to the territory.

In the 1970s Malaysia, along with nonaligned Thailand, worked to suppress Communist forces. With the resurgence of Islāmic fundamentalism in the late 1970s, many Muslim Malays joined the Dakwah (missionary) movement that was especially popular among young educated Muslims. Their increasing militancy led to desecration of Hindu temples and racial tension among the ethnically diverse Malaysians.

Race problems were further exacerbated by the arrival of boat people from Vietnam (1979), most of whom were ethnic Chinese. Prodded by Malay protests that the ethnic balance of Malaysia would be upset, the government sought to forcibly expel the boat people and even issued orders that any caught landing on Malaysian shores should be shot on sight, a decision that provoked international criticism.

Racial tensions

Malaysia, as a federation of disparate ethnic, economic, and political components, has had difficulties and problems from the moment of its inception in 1963. The most intractable of these problems—the strained relations between West Malaysia and Singapore—was solved by a political separation. Other problems, no less serious, remain. Racial riots between the Malays and the Chinese in May 1969—which led to the suspension of parliamentary rule and to the declaration of a state of emergency that lasted until February 1971—were an indication of the underlying tensions stemming from ethnic imbalances. These tensions persisted through the 1980s and early 1990s, with Malays constituting a majority of the population in five of Malaysia's six poorest states. The Malays, virtually all of whom are Muslim, have been increasingly attracted to radical forms of Islām, thus further exacerbating racial tensions.

There are also other imbalances—between West and East Malaysia, between urban and rural areas, and between modern and traditional ways of life. There is very little trade between East Malaysia and West Malaysia, indicating the need for closer economic integration between the states. Malaysia also faces the threat of Communist aggression on the Thai and Sarawak borders. Within the country itself, however, the fundamental problem remains that of eliminating ethnic disparities in income while fostering the growth of a Malaysian consciousness and sense of identity among the people. (K.G.T./Ed.)

For later developments in the history of Malaysia, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL.

MYANMAR

Myanmar is an independent socialist republic in Southeast Asia, with an area of 261,228 square miles (676,577 square kilometres). It is bordered by Thailand and Laos on the east, by China (the autonomous region of Tibet and the province of Yunnan) on the north and northeast, by India on the northwest, by Bangladesh and the Bay of Bengal on the west, and by the Gulf of Martaban and the Andaman Sea on the southwest and south.

In 1989 the country's official English name was changed from the Union of Burma to the Union of Myanmar (Burmese: Pyeidaungzu Myanma Naingngandau); in the Burmese language the country has long been known as Myanmar. The change was made because the name Burma connotes Burman, the country's largest ethnic group, although there are several minority ethnic groups. The name of the capital, formerly Rangoon, was changed to Yangôn; many other geographic names were also changed. In this article the name Burma is used for the country during the period of British rule, 1885–1948; the name Myanmar is used in all other contexts.

Myanmar stretches from latitude 10° N to about 28° 30′ N; almost half the country is, therefore, situated outside the tropics, but, because of its configuration, it is generally considered to be a primarily tropical country. The country has roughly the shape of a diamond, with a long tail—running south along the Malay Peninsula—attached to it. Its total length from north to south is 1,275 miles (2,052 kilometres); its width at the widest part, across the center of the country about the latitude of Mandalay, is 582 miles (931 kilometres) from east to west.

In ancient and medieval times, Myanmar was regarded as a gateway to the Indochinese Peninsula, as well as to China; it was known as the Golden Land, because of its abundant natural resources and the wealth that its control of trade routes generated. In the 11th century it became the homeland of Theravāda Buddhism (one of the two great schools of Buddhism, the other being Mahāyāna) at a time when that faith was being suppressed in other countries. After a 60-year series of Anglo-Burmese wars, during which portions of the country were conquered, Myanmar (Burma) was annexed by the British in 1886 and was administered as a province of India until 1937. Burma fell under Japanese rule for a period during World War II; British rule ended in 1948, when the country regained its sovereign independence.

Myanmar is individualistic in its social structure and nationalistic in its outlook. As one of the original nonaligned countries—maintaining independence from both Eastern and Western power blocs—Myanmar achieved some international importance in the first decade of its independence; thereafter, however, it tended to remain aloof and isolated from the international community. The land and air battles that were waged throughout the country during World War II destroyed many towns and villages and dislocated the economy. Although rice exportation was resumed, Myanmar failed to regain its status as the foremost rice-exporting country in the world. The wounds of war had not completely healed, partly because of lack of capital and partly because of insurgency and political unrest. Since independence, some modest industrialization programs have been embarked upon, but Myanmar remains a primarily agricultural country.

running from north to south. The country as a whole can be divided into five landscape regions—the northern mountains, the western mountains, the eastern plateau, the central basin, and the coastal strips.

The five landscape regions

The northern mountains consist of a series of ranges forming a complex knot, with peaks of nearly 20,000 feet. It is in this region that the sources of such great rivers as the Irrawaddy, Salween, Mekong, and Yangtze arise in swirling torrents. They flow through deep gorges within a few miles of each other, separated by peaks rising sheer into the sky. It was across this wild and forbidding region that the ancestors of the present-day Burmans travelled from their original homeland in Tibet.

The western ranges, which originate in the northern mountain knot, continue southward as far as Cape Negrais, the southern tip of the Arakan Peninsula, where they run under the sea, reappearing as the Andaman Islands. Their average height is about 6,000 feet, although some peaks rise to 10,000 feet and more. They are folded mid-Tertiary ranges (formed about 40,000,000 to 20,000,000 years ago), with a core of old crystalline rocks surrounded by hard, tightly folded sedimentary rocks on either side. Forming the border between India and Myanmar, they are given different names according to locality—being known successively as the Patkoi, Lushai, Naga, Manipur, and Chin hills. The southern portion of these mountains lies entirely within Myanmar, forming the Arakan Yoma (*yoma* in Burmese means "main bone"). They separate the Arakan coastal strip from the central plain.

The Shan Plateau in the east rises abruptly from the central basin, often in a single step of 2,000 feet. Occupying the whole of the east of the country, it is deeply dissected, with an average height of 3,000 feet. The plateau was formed during the Mesozoic Era (245,000,000 to 66,400,000 years ago) and thus is much older than the western mountains. But the plateau also shows intensive folding, with north–south longitudinal ranges with heights of 6,000 to 8,600 feet rising abruptly from the plateau surface. Northward, the plateau merges into the northern ranges, and southward it continues into the Tenasserim Yoma, a series of parallel ranges with narrow valleys. The central basin, lying between the Arakan Yoma and the Shan Plateau, is structurally connected with the folding of the western mountains. The basin was deeply excavated by the predecessors of the Irrawaddy, Chindwin, and Sittang rivers; the ancient valleys are now occupied by these rivers, which cover the ancient soft sandstones, shales, and clays with their new alluvial deposits. In the deltaic regions formed by the Irrawaddy and Sittang (total area 12,000 square miles), the landscape is absolutely flat, and the monotony is relieved only by a few blocks of erosion-resistant rocks, never more than 60 feet high. The basin is cut into two unequal halves, the larger Irrawaddy Valley and the smaller Sittang Valley, by the complex folded range of Pegu Yoma.

In the centre of the basin and structurally connected with the Pegu Yoma and its northern extension is a line of extinct volcanoes with small crater lakes and eroded cones, the most impressive being Popa Hill, 4,984 feet.

The coastal strips consist of the narrow Arakan and

Tenasserim coastal plains, which are backed by the high ranges of the Arakan Yoma and Tenasserim Yoma and are fringed with numerous islands of varying sizes.

he rivers

Drainage and soils. Like the mountains, the rivers run from north to south. About two-thirds of Myanmar's surface is drained by the Irrawaddy and its tributaries. Flowing through the entire length of Myanmar, it is navigable for 965 miles. At the apex of its delta, it breaks up into a network of streams and empties into the Andaman Sea through nine mouths. Its great tributary, the Chindwin, drains the western region. The Bassein River drains the southern Arakan Yoma, and the Yangôn (Rangoon) River drains the Pegu Yoma, both entering the Irrawaddy at the delta. The Sittang flows into the Gulf of Martaban of the Andaman Sea and, in spite of its comparative shortness, has a large valley and a huge delta. The Shan Plateau is drained by the Salween, which enters Myanmar from Yunnan in China and empties into the Gulf of Martaban south of the Sittang. It is deeply entrenched and crosses the plateau in a series of deep gorges. Many of its tributaries are more than 300 miles long and enter the Salween in cascades. The Arakan coastal plains are drained by short, rapid streams, which, after forming broad deltas, flow into the Bay of Bengal. The Tenasserim plains are drained also by short and rapid rivers, which enter the Gulf of Martaban.

The highland regions of Myanmar are covered with laterite (red soil, leached of silica and containing iron oxides and hydroxide of aluminum). Protected by the forest cover, it absorbs heavy rain, but, once the forest is cleared, it erodes quickly. The lowland regions are covered with alluvial soil—mainly silt and clay. Low in potash, lime, and organic matter, it is improved by fertilizers. In the central-region dry belt, the alluvial soil develops into a black soil rich in calcium and magnesium. In the same region, however, when the soil has a low clay content, it becomes saline under high evaporation and is recognizable by its yellow or brown colour.

Climate. Myanmar belongs to the monsoon (rain-bearing wind) region of Asia, but its climate is greatly modified by its geographical position and its relief. Although the cold-air masses of Central Asia bring snow to the northern tip for two months of the year, the mountain wall prevents them from moving farther south, so that Myanmar lies primarily under the influence of the monsoon winds. The north and south alignment of ranges and valleys forces the northeast monsoon to blow from the north. When the southwest monsoon winds blow from the Indian Ocean, this alignment of ranges and valleys creates alternate zones of heavy and scanty rainfall.

Elevation and distance from the sea affect both the temperature and the rainfall; although it is a tropical country, temperatures in Myanmar are not high. The daily range of temperature is negligible everywhere, and no locality in Myanmar has a continental type of climate (*i.e.*, characterized by large seasonal differences in average temperature). Even at Mandalay, in the centre of the dry belt, the annual range is only 22° F (12° C), compared with 11° F (6° C) at Yangôn and 7° F (about 4° C) at Moulmein; the average temperature at Mandalay is 82° F (28° C), compared to 81° F (27° C) at Yangôn near the coast, 79° F (26° C) at Sittwe (Akyab) in Arakan, and 71° F (22° C) at Lashio on the Shan Plateau.

There are three seasons: the cool dry season, from October to February; the hot dry season, from March to the middle of May; and the rainy season, from May to October. The coastal regions and the mountains receive annually 200 inches (5,100 millimetres) of rain, while the delta regions receive nearly 100. The central region is not only away from the sea but also in the rain shadow of the Arakan Yoma. Rainfall gradually decreases northward until in the dry zone it is only between 20 and 40 inches. The Shan Plateau, because of its elevation, receives about 65 inches.

he forests

Plant and animal life. Even after centuries of rice cultivation involving clearing of forest, about one-half of the area of Myanmar is covered with forests of various types, depending on elevation and the amount of rainfall. Above the frost line at 3,000 feet, evergreen forests of oak and pine are to be found. In the northern mountains at heights above 6,000 feet are forests of rhododendrons. In regions with more than 80 inches of rainfall, there occur evergreen tropical forests. The trees are of hardwood but of little commercial value. In regions where the rainfall is between 40 and 80 inches, there appear monsoon forests, the trees of which shed their leaves in the hot season. They produce valuable cabinet wood, including teak. Where rainfall is less than 40 inches, the forests gradually merge into scrubland. There are no real grasslands, but, when a patch of forest has been cleared, bamboo, bracken, and coarse grass grow. In the Irrawaddy and Sittang deltas are tidal forests of mangrove trees, growing as high as 100 feet and supplying firewood and charcoal, as well as bark for tanning.

In the jungles of Myanmar are the homes of pheasants, parrots, peacocks, wild fowl, and grouse. The Asiatic two-horned rhinoceros, wild buffalo, bison, and various kinds of deer were once plentiful but are now reduced in numbers and protected. Elephants are numerous, a number of them being caught annually to be trained to work. Tigers, leopards, and wild cats are still common. Bears are found in hilly regions, and gibbons and monkeys of various kinds inhabit the thicker parts of the forests. Snakes include pythons, cobras, and vipers, and crocodiles are found in the deltas. Turtles live in coastal regions, and edible fishes abound in every stream.

Settlement patterns. *Traditional regions.* The Burmans live in the plains, and the tribal peoples in the hills. In the plains the division between northern and southern Myanmar (Upper and Lower Burma) dates from early history, not only because of differences in the geography but also because the Mons, now a small minority, lived in southern Myanmar. The division became more marked during the period from 1852 to 1885, when southern Myanmar became British Burma. The Arakan and Tenasserim coastal plains are traditional regions; the people there speak Burmese in a dialect retaining archaic features.

The villages

Urban and rural settlement. Myanmar is a land of villages. Except for Yangôn, Mandalay, Henzada, Pegu, Myingyan, and Moulmein, there are few large cities, and the towns are merely overgrown villages. The hill peoples, although practicing a shifting agriculture, have settled in villages perched near the tops of mountains and at some distance from the fields. On the Shan Plateau and the plains, the fields adjoin the villages. Older villages are circular in shape, but along the banks of the delta streams and along the railway line the villages are rectangular. Houses are built of timber and bamboo, the roofs thatched or tiled. In the past, houses were typically built on piles, the original purpose being protection from wild animals or floods. The style persists in many villages, especially those on the hills, and farm animals are kept under the houses at night. In small towns the piles have given way to a supporting brick structure with cement flooring, the upper story still being made of timber. Houses entirely of brick were few in number before 1942, but many later sprang up in Yangôn, Mandalay, and larger towns on the rubble of buildings destroyed during World War II. Life in villages and towns is still communal because of tribal custom, the influence of Buddhism, and the "classless" nature of Myanmar society. Even once-cosmopolitan Yangôn regained its native atmosphere after independence.

THE PEOPLE

Language groups

Linguistic and other groups. More than 100 indigenous languages—as distinct from mere dialects—are spoken in Myanmar, most of them by the hill peoples. The common language is Burmese, spoken by both the people of the plains and the hill peoples. All of these languages belong to only three groups. The Burmese language itself, and most of the other languages, belong to the Tibeto-Burman subfamily of the Sino-Tibetan family. The Shan language belongs to the Tai family. Languages spoken by the Mons of southern Myanmar and by the Was and Palaungs of the Shan Plateau are members of the Mon-Khmer subfamily of the Austro-Asiatic family.

Until colonial times, only the Burmans, Mons, and Shans had written languages; writing systems for Karen, Kachin, and Chin were developed later. The archaic Burmese spoken in Arakan and Tenasserim, when written down, shows no difference from the Burmese spoken in the plains. To the majority of the hill peoples, Burmese is the second mother tongue.

During the colonial period, English became the official language, but Burmese survived as the second official language. Both English and Burmese were made compulsory subjects in schools and colleges, and although a knowledge of English became an asset, and many learned to speak it, no English-speaking elite emerged. Burmese remained the language of commerce, and Burmese literature also survived. After independence, English ceased to be the official language and lost its importance in schools and colleges, although an elementary knowledge of English is still required.

Ethnic groups. The original home of the Burmans in the dry zone established the ethnic character of the entire Irrawaddy Valley and the coastal strips. These areas hold the majority of the population.

The Irrawaddy and Sittang deltas were once peopled by the Mons, who entered the country from their kingdoms in the Chao Phraya River Valley in Thailand. They were conquered in the 11th century by the Burmans, a less cultured race at the time. The Mons attempted from time to time to throw off the Burman yoke, but by the end of the 18th century they had been largely absorbed by the Burmans, mainly through intermarriage but partly through suppression. A few hundred thousand still remain in the Sittang Valley and in Tenasserim; although they still call themselves Mon, many of them have Burman blood and no longer speak their original language.

The tribal peoples

In the western hills and the valley of the Chindwin are various tribes called by the comprehensive name of Chin. The Upper Irrawaddy Valley and the northern hills are occupied by tribal groups under the comprehensive name of Kachin. The names Chin and Kachin are Burmese and indicate, respectively, "friend and companion" and "dancing friend and companion." These tribal peoples were indeed friends and companions, for they lived with the Burmans on the southeastern slopes of Tibet and followed them on the long migration into Myanmar.

The Shans of the Shan Plateau have no racial affinity with the Burmans, and their society, unlike that of the Tibeto-Burman peoples, was not democratic.

The Was and the Palaungs are probably Mon-Khmer by race, but, because of the smallness of their numbers and because of their long residency on the plateau, they are usually classified with the Shans. In the same way, the Nāgas on the Myanmar side of the Indo-Myanmar frontier are classified with the Chins, and the Lolo-Muhsos in the northeast are grouped with the Kachins.

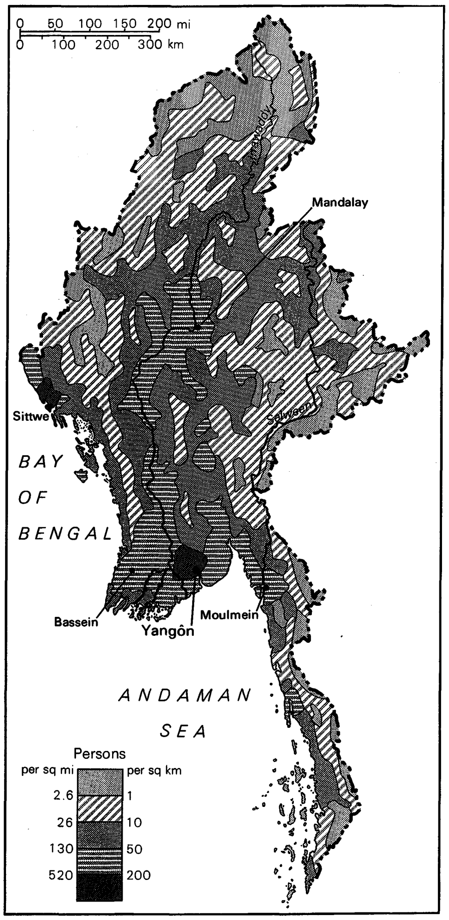
The Karens are the only hill people who have come down to the plains. Although racially and linguistically they are Tibeto-Burman, they were closely associated with the Mons. They are found in the deltas among the Burmans, on the Pegu Yoma, and along both sides of the lower Salween River.

The Kayahs, who live on the southern edge of the Shan Plateau, were known as Red Karens, or Karenni, from their red robes. Although racially and linguistically Karens, they tend to have their own identity.

The number of Indians, Pakistanis, Bengalis, and Chinese in Myanmar decreased as a result of an exodus at the outbreak of World War II and of a second exodus in 1963, when commerce and industry were nationalized.

Religious groups. The vast majority of the population is Buddhist. The Burmans are Buddhists except for minimal numbers of Christians and Muslims; the Shans are also Buddhists. Among the Karens, there are twice as many Buddhists as Christians, and the remainder are animists. The other hill peoples are animists except for a small number of Kayah Buddhists and Kachin and Chin Christians.

Demography. The density of population in each region depends upon its suitability for agriculture. The most populous regions are therefore the Irrawaddy Delta and the dry zone, with the highest densities found in the upper delta, between Yangôn and Henzada. The populations of the Sittang Delta, the sedimented hinterland of Akyab, and the regions of both sides of the lower Chindwin are moderately dense. Arakan (except the Sittwe [Akyab] region), the west bank of the Irrawaddy behind Arakan Yoma, Tenasserim, and the more inaccessible parts of the western and northern mountains and the Shan Plateau are sparsely to minimally inhabited.



Population density of Myanmar.

THE ECONOMY

Agriculture. Myanmar's economy is basically agricultural; more than two-thirds of the people derive their livelihoods directly from agricultural pursuits; of the nonagricultural workers who are employed in the other sectors of the economy, many are indirectly involved in agriculture through activities such as transportation, processing, marketing, and exporting of agricultural goods.

Myanmar may be divided into three agricultural regions: the delta, where paddy rice culture predominates; the dry zone, an area of mixed agriculture; and the hill country, where forestry and shifting agriculture have been the rule.

Although the dry zone was Myanmar's most important agricultural region in the past, it is the rice culture of the delta that now provides roughly half of the country's export earnings and the staple diet of the country's people and on which the short- and long-term health of the economy depends. About one-half of the land in agricultural use is devoted to rice culture, and, despite a climate that would permit much more extensive double-cropping, only about one-tenth of the land is actually so managed. The delta's traditional agriculture consisted primarily of rice in normal years, with the substitution of millet in drier years when there was insufficient moisture for rice; both grains yielded good returns on the alluvial soils of the delta. After Myanmar was officially annexed to British India in 1886, colonial policy called for a more commercially oriented and extensive cultivation of rice; since the indigenous labour force was insufficient to support this new economy, officially encouraged immigration of Indian and Chinese labourers and their families took place during the early decades of the 20th century. By 1942, first-generation immigrants composed about 13 percent of the total population. Despite relatively low growth in rice production after World War II, rice remained both the basic food and the basic export of Myanmar.

Agriculture in the dry zone is much more diversified than that of the delta. Its major products include, in addition to rice, other grains (wheat, millet, and corn, or maize), peanuts (groundnuts), sesame, legumes, tea, and rubber. However, to cultivate much of this land successfully, irrigation is required. The construction of the earliest known irrigation works, in Kyaukse and Minbu districts, can be dated from the 11th century, and, although their maintenance has not been a continuing concern of governments throughout Myanmar history, many are still in active service. As in the delta, the arrival of the British led to increased commercial and public works activities; British authorities renewed and extended many of these ancient systems and, in addition, built new ones during the early years of the 20th century, including the Mandalay (1903), Shwebo (1906–12), Mon (1912), and Salin (1926). Most of Myanmar's irrigated land is in the dry zone, and even here almost all is cultivated in rice. The portions of the dry zone that are not irrigated are utilized for the production of crops that are less sensitive to the seasonality or irregularity of rainfall than rice. In addition to the crops mentioned above, cotton and sugarcane are cultivated in this zone, although neither is of considerable significance. Cattle are also raised in the dry zone.

rigation

The third zone of agriculture, the hill country, occupies perhaps two-thirds of the area of Myanmar, and, although it is of much less economic significance than the other two, it is the home of many of the country's minority (non-Burman) ethnic groups. Their agriculture has been, and to a considerable extent still is, a type of slash-and-burn agriculture called *taungya,* although more sedentary traditional modes also exist and others are imposed with the advance of agricultural technology and central planning. Outside the forest areas of these highlands, the principal foods raised are rice, yams, millet, with swine and poultry ubiquitous. Possibilities, largely unrealized, exist for commercial agriculture in the more fertile river and lake basins.

rincipal
vestock

Bullocks and buffalo are used as beasts of burden, and goats, pigs, and poultry are raised for food in all parts of the country.

Fisheries. The second most important element in the diet after rice is fish—fresh, preserved, or prepared as *ngapi,* a sort of paste that is eaten with rice. Marine fisheries are not well developed, although the reported commercial catch is more than three times as great as the reported catch from inland waters. The latter, however, provides much private, noncommercial fishing in virtually every type of permanent, seasonal, or artificial body of water of any size. Two nonindigenous fish, the European carp and the tilapia of Thailand, have been imported and breed very well in impounded waters.

Forestry. Forestry is particularly important to economic planners; Myanmar has been estimated to contain up to three-quarters of the world's exploitable teak supplies. The trees are found in the mixed deciduous forests of the hills and commonly comprise about 12 percent of forests of which they are a part. The forests are state-owned, and the responsibility for their management and exploitation belongs to the State Timber Board.

Resources. Development of Myanmar's rich mineral deposits began in 1975. Deposits of silver, lead, and zinc, located in the northern Shan Plateau; tin and tungsten, found in Tenasserim; and barite, from the Maymyo area, are mined. Copper mining at Monywa began in 1982. Ruby and sapphire mines in the northern Shan Plateau were heavily exploited during colonial times. Jade is mined in the northern mountains. Petroleum and natural gas are produced to meet domestic needs. Coal of an inferior quality is found in the upper Chindwin Valley.

Manufacturing and power. There was little industrialization until after independence, when a limited program began. Yangôn, Myingyan (in the dry zone), and Arakan State were selected to become the new industrial centres. There are textile factories at Yangôn and Myingyan and one near Paleik in the central region. Oil refineries are located at Chauk, Syriam, and Mann. Yangôn also has steel-processing and pharmaceutical plants, and there is a paper mill in Arakan. Existing food-processing plants (mainly rice mills) and lumber mills have been improved and expanded. Cottage industries are encouraged by subsidies.

Oil
refining

After independence the government built a large thermal power plant in Yangôn and undertook the development of hydroelectric power plants on the Balu Chaung, a tributary of the Salween; at Taikkyi near Pegu; and in northern Arakan. The Balu Chaung plant serves Yangôn and many surrounding villages.

Administration of the economy. All large industrial enterprises, the banking system, insurance, foreign trade, domestic wholesale trade, and 90 percent of the retail trade were nationalized in 1962 and 1963. Small-scale industry (consisting mainly of food and beverage processing, miscellaneous manufacturing, and cottage industries), agriculture, and fishing were left in the private sector. Foreign investment was permitted to resume in 1973, and in 1975–76 the government placed nationalized corporations on a commercial basis, instituted a bonus system for workers, and began to accept financial aid from the Asian Development Bank and the International Bank for Reconstruction and Development.

Enterprises remaining in the private sector after nationalization account for only a small fraction of the nation's tax income. The balance is collected from the public sector. The principal sources of revenue are income, commercial, and customs taxes. There is also a land tax, applicable to the private sector only, and, applicable to both, excise, forest, mineral, fishery, and miscellaneous taxes.

The overall economic objective is the establishment of a fully socialized state. Policy measures include the diversification of agricultural production to promote exports; the substitution, wherever feasible, of essential commodities for imports; the utilization of existing industrial plants to full capacity by providing spare parts and adequate raw materials; and the assignment of priority to mining and petroleum exploration both on land and offshore. The pace of development is based on the availability of foreign exchange. Improvements in the rice market and mineral production enabled Myanmar to achieve a balance of exports and imports.

Transportation. *River transport.* The Irrawaddy River is the backbone of the transport system. Trade in rice is dependent on water transport. There has never been any need for grain elevators, as small country boats can reach any rice field that has surplus rice to sell. The Irrawaddy is navigable up to Bhamo, a distance of 875 miles from the sea; the next stretch of another 90 miles to Myitkyina is navigable only during the dry season when there are no rapids. The Chindwin is navigable for 380 miles from its confluence with the Irrawaddy below Mandalay. The many streams of the Irrawaddy Delta, with a total length of 2,000 miles, are navigable, and there is a system of connecting canals with a total length of 60 miles. The Sittang, in spite of its silt, is usable by country boats; the Salween, in spite of its rapids, is navigable up to 74 miles from the sea. Small steamers and country boats also serve the coasts of Arakan and Tenasserim.

Navigable
streams

Railways. The first railway line, running from Rangoon (Yangôn) to Pye (Prome) and built in 1877, followed the Irrawaddy Valley. At that time Pye was just a few miles from the frontier between British Burma and the Kingdom of Myanmar in the north. The line was not extended to Mandalay; instead, after 1886 a new railway from Rangoon up the Sittang Valley was constructed, meeting the Irrawaddy at Mandalay. From Mandalay it crosses the river and, avoiding the Irrawaddy Valley, goes up the Mu Valley to connect with the Irrawaddy again at Myitkyina. A short branch line connects Naba to Katha on the Irrawaddy below Bhamo.

The Yangôn–Mandalay–Myitkyina railway is the main artery, and from it there are branch lines connecting the northern and central Shan Plateau with the Irrawaddy. Other branches run from Pyinmana across the Pegu Yoma to Kyaukpadaung, and from Pegu to Moulmein to Ye.

The Pye–Yangôn railway has a branch line crossing the apex of the delta to Henzada and Bassein.

Roads. The road system was built without plan or policy, and, until independence, it was confined to the Irrawaddy and Sittang valleys, duplicating the railway route. A road goes from Pye along the Irrawaddy to the oil fields. Government policy is to improve and extend existing highways and to construct new ones.

There were originally three international roads in use during World War II—the road from Lashio to K'unming in China, the road between Myitkyina and Assam in India, and the road between Kentung in the southern Shan Plateau and northern Thailand. The road between Assam and Myitkyina has disappeared, and the other two roads have been neglected and are only in partial use.

Airways and ports. Myanma Airways runs frequent domestic flights from Yangôn and regular flights to Hong Kong, Bangkok, Dacca, Calcutta, and Kāthmāndu. Yangôn and Mandalay have international airports. Yangôn, as the terminus of road, rail, and river transport systems, is an international port with up-to-date equipment and facilities. Bassein, Moulmein, and Sittwe are also international ports.

ADMINISTRATIVE AND SOCIAL CONDITIONS

Government. *Constitution of 1974.* A constitution was approved by a referendum in December 1973 and came into force on January 4, 1974, the 26th anniversary of Myanmar's independence. General elections were held in January and February, and a new government was established on March 2, 1974, the 12th anniversary of the coup d'état that had established a military government.

The 1974 constitution provided for seven states (Arakan, Chin, Kachin, Karen, Kayah, Mon, and Shan) and seven divisions of Myanmar proper (Irrawaddy, Magwe, Mandalay, Pegu, Yangôn, Sagaing, and Tenasserim), with "local autonomy under central leadership." The supreme power was the Pyithu Hlutdaw, which exercised legislative, executive, and judicial authority. The adoption of the name Hlutdaw (or Hluttaw; literally "Place of Release") was significant. Under the Burman kings the Hlutdaw was a supreme council discharging legislative, executive, and judicial functions, but as the historical Hlutdaw was a royal institution the new designation was Pyithu ("People's") Hlutdaw. Thus, Pyithu Hlutdaw was the People's Council at the national level, as distinct from the People's Council at the division or state, township, and ward or village levels. Elections to the Hlutdaw and to the local council were held simultaneously, members being elected for four-year terms.

Pyithu Hlutdaw

Central government structure. The organs of the 450-member Pyithu Hlutdaw were the Council of State, the Council of Ministers, the Council of People's Justices, the Council of People's Attorneys, and the Council of People's Inspectors. The Council of State consisted of an elected representative from each state and division, an equal number elected by the Pyithu Hlutdaw as a whole, and the prime minister as an ex officio member. The Council of State elected its own chairman, who was ex officio president of the republic, and its own secretary. The president and the secretary were also, respectively, the chairman and the secretary general of the Burma Socialist Programme Party (BSPP). The Council of State appointed senior civil servants and deputy ministers and submitted lists of names for election by the Hlutdaw of the prime minister, the Cabinet, and the councils of justices, attorneys, and inspectors. The number of ministers could fluctuate, but the three councils had five members each. The Council of People's Justices was the equivalent of a supreme court in a parliamentary democracy; the Council of People's Attorneys was comparable to an attorney general (but members did not need legal qualifications or experience), and the Council of People's Inspectors to an auditor general.

Local government structure. The local People's Councils followed the pattern of the Hlutdaw; every council had an Executive Committee and a Judicial Committee. All but the village or ward councils also had a Committee of Inspectors. The Committee of Judges, not necessarily composed of lawyers, sat as the local court, exercising criminal and civil jurisdiction.

Political parties. Until 1988 the official political party was the BSPP. Membership was by election after preliminary service as a "friend of the party" and then as an "auxiliary." It was at first restricted to cadres, but the party held its first national assembly in 1971, when its membership was widened so that it became a national party. Civil servants and members of the armed forces, as well as workers and peasants, were members, and senior military officials and civil servants were included in the party's hierarchy.

One-party system

In September 1988 the armed forces took control of the government, creating a new ruling body, the State Law and Order Restoration Council (SLORC). All state organs, including the Pyithu Hlutdaw, the Council of State, and the Council of Ministers, were abolished. The law maintaining the BSPP as the sole political party was abrogated, and new parties were encouraged to register for general elections scheduled for May 1990. By February 1989, 233 parties had registered; of these the most important were the ruling BSPP, which changed its name to the National Unity Party (NUP), and the main opposition party, the National League for Democracy (NLD).

Armed forces. Myanmar's fighting forces consist of an army, a navy, and an air force. The Defense Service Academy is located at Maymyo. The police force, although armed and equipped and often used as a branch of the army in emergencies, remains essentially civilian in character and regional in organization; it deals with the day-to-day maintenance of law and order.

Health and welfare. In social welfare measures, the government has given special attention to workers and peasants and to the hill peoples. The National Housing Board was retained after the coup in 1962, and, in spite of a shortage of imported building materials, the housing problem was stabilized somewhat. A high mortality rate, especially among infants, has been lowered substantially, and every village has a health unit and access to a hospital.

Education. The literacy rate has always been at a high level and continues to improve. Education is free and compulsory between ages five and nine, and in secondary schools and universities fees are nominal. The University of Rangoon and its branch at Mandalay were separated in 1958 into autonomous units now known as the Rangoon Arts and Science University and the Mandalay Arts and Science University. Various institutes and colleges teach medicine, technology, agriculture, economics, etc.

CULTURAL LIFE

Myanmar's traditional culture is essentially a folk culture. Buddhism has pervaded life in Myanmar since the 11th century and has blended harmoniously with folk culture. The emphasis given by Buddhism to equality among all men and women and to the liberty and dignity of the individual fits in with Tibeto-Burman social tradition. The Feast of Merit in Chin animism, for example, has the same folk background as that of a native Buddhist almsgiving ceremony; the dancing, singing, music, and general gaiety of a Kachin sacrificial celebration are reflected in the Myanmar ceremony initiating a boy as a novice in the Buddhist order of monks; and the animals, monsters, trees, flowers, and abstract designs carved on the central post of a Kachin men's club are similar to those carved on the doors of the palace of the kings. Some observers maintain that the culture of Myanmar is animistic, others that it is Buddhist, but all agree that it is unique.

In 1886 the traditional drama appeared to be dying with the passing of the old kingdom. As it was essentially a folk drama, however, it survived and with the regaining of independence gathered new strength.

Woodcarving, lacquerwork, goldwork, silverwork, the sculpture of Buddhist images and mythological figures, and temple architecture also survived under colonial rule; there has been a revival of these indigenous art traditions under the patronage of the Ministry of Culture. The arts of bronze casting among the Burmans and of making bronze drums among the Karens, however, both disappeared. The traditional marionette show also declined, although occasionally there are attempts to revive it. The cinema is the one Western art form that has been accepted in the cultural life of Myanmar.

iterature

Burmese literature remained alive throughout the colonial period, and, both in verse and in prose, native traditions continue to prevail. A later development is biography, which has become more popular than fiction. The Burma Translation Society, which is sponsored by the government, annually awards substantial cash prizes for the best translation, the best novel, and the best biography. There are state schools of dance, music, drama, and fine arts at Yangôn and Mandalay. The National Museum is at Yangôn, and there are regional museums at Mandalay and at the state level. For statistical data on the land and people of Myanmar, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL. (M.H.Au./Ed.)

History

Myanmar lies on the western edge of the peninsula of Indochina and forms part of the region of Southeast Asia. In prehistoric times it was traversed, both along its coasts and down its river valleys, by band after band of migrating peoples on their way farther eastward and southward. During the first 10 centuries of the Christian Era the overland trade route between China and India passed through Myanmar's borders, and merchant ships from India, Sri Lanka, and even farther west converged on its ports, which were also the termini of the portage routes across the narrow isthmus from what is now the Gulf of Thailand. Thus, Myanmar was the gateway of Southeast Asia.

The Indian merchants brought with them not only precious cargoes but also great cultural gifts in the form of religious, political, and legal ideas; and within a few decades Indian cultural traditions had remolded native society, native thought, and native arts and crafts. Although the new cultural treasures passed through to Southeast Asia, Myanmar never allowed its own native culture to be overwhelmed.

Surrounded on three sides by mountain walls and on the fourth by the sea, Myanmar has always been insular; as a consequence its culture, in spite of the many Indian influences and in spite of its close affinity with the cultures of the other countries of Southeast Asia, has remained distinct and separate. For example, it rejected the Hindu Indian theory of a divine king and insisted that men and women are born free and equal.

The first area in Southeast Asia to receive Buddhism, because of its proximity to India, Myanmar became the centre of Theravāda Buddhism almost overnight in the 11th century, when the faith was being assailed not only in India and Southeast Asia but in the whole of Asia itself. The Buddhist doctrine of the equality of all men and women was superimposed with grace and harmony on the native tradition of social equality.

The unique nature of Myanmar society and culture was noticed at the time of the British conquest (late 19th century) even by humble privates, whose conception of Burma as a "cleaner, greener land" was embodied by the British author Rudyard Kipling in "Mandalay." The historian G.E. Harvey wrote in *British Rule in Burma* that "there is, in Burmese life, not only a beauty that delights the eye but also a dignity which makes one proud of the human race."

MYANMAR UNTIL THE ADVENT OF BRITISH RULE (TO 1885)

The origins of civilization in Myanmar. The Irrawaddy River, flowing southward through the entire length of Myanmar, divides the country in two, and its valley forms the central plain. The first human settlements in Myanmar appeared some 5,000 years ago in the middle portion of the Irrawaddy Valley. The stone and fossilized-wood tools used by those Paleolithic and Proto-Neolithic people have their own distinguishing features, and anthropologists have given their culture its own name—Anyathian. A discovery in 1969 by workers from the government's Department of Archeology of some cave paintings and stone tools in the eastern part of Myanmar's Shan State shows that that area, too, had Paleolithic and Proto-Neolithic settlements. Crude shards and ring stones found at the site appear to have been attached to stonecutting tools, to make them more suitable for digging; and the woodcutting tools in the find were probably used in clearing patches of the forest for cultivation, which would indicate that the shift from gathering to agriculture had already begun.

he first iman set- ements in yanmar

The Anyathian people probably migrated down the Irrawaddy River, and the Shan cave people down the Salween. Thus, even during the stone ages, the general pattern of human migration and settlement for both Myanmar and the rest of mainland Southeast Asia had been fixed—tribal groups coming from the north over the mountains and then down the great rivers: the earlier or stronger groups settling in the valley to learn the art of wet-rice cultivation and the later or weaker groups being pushed into the mountainous parts to learn only the method of slash-and-burn rice growing. In those early times the Irrawaddy had not yet formed its great delta; and at its huge mouth and along the coast, the country was stormy, wild, and desolate.

The Stone Age Anyathians stayed far from the sea. The earliest arrivals on Myanmar's coast were Negritos, a fact remembered in folktales, which tell of dark-skinned, short-statured, fuzzy-haired, and human-flesh-eating ogres who dwelled at the mouths of great rivers and on islands in the sea; a Buddhist legend describes how monk-missionaries sent from India saved the people of Thaton from ogres who lived on nearby islands and raided the city in quest of human flesh. As to the Anyathians, even folk memory no longer knows them, and it cannot be said whether they died out or merged with the later arrivals in the Irrawaddy Valley.

Origin of the Mons

The Mons. The first people in Myanmar to leave definite traces of their settlement were the Mons. Speaking an Austro-Asiatic language, they were close cousins of the Khmers, with whom they originally came down the Mekong River. Later the Khmers followed the river southeastward to what is now Kampuchea (Cambodia), and the Mons veered southwestward toward the source of the Chao Phraya River (Mae Nam Chao Phraya) and went down its valley. By at least the 3rd century BC the Mons not only occupied the entire Chao Phraya Valley but had also spread to the Sittang Valley, doubtless through the gaps in the eastern mountain wall of Myanmar. Their port capital was Thaton, not far from the isthmian portage routes; and through this window to the sea they saw India, in its full glory, united and peaceful under the emperor Aśoka and a flourishing centre of Theravāda Buddhism.

Introduction of Indian culture. Aśoka sent a mission of Buddhist monks to Suvarnabhūmi, "the Golden Land"; although a few scholars still remain unconvinced, it seems definite that the Golden Land was the three Mon regions of Upper Chao Phraya, Lower Chao Phraya, and the Sittang Valley. The ancient monastic settlement of Kelasa, situated a few miles from Thaton and claimed by Burmese and Mon chronicles to have been founded by Aśoka's missionaries, was mentioned in early Sinhalese records as being represented at a great religious ceremony held in Sri Lanka in the 2nd century BC.

With the expansion of Indian commerce in Southeast Asia in the 1st century AD, Thaton's prosperity and importance increased. The expansion was sudden and revolutionary but peaceful, and the Indian merchants and seamen came to Thaton as friends rather than as conquistadores or colonists. Their numbers were never great, and their settlements were only temporary. Until the 8th century, when there was a scramble for the new lands of the Irrawaddy Delta, no conflicts developed between the Indians and the Mons. As a result, the Indians' cultural gifts were found acceptable.

Blending of Indian and native cultures. The Mons saw to it that their native culture was not abandoned or displaced, and they worked for a harmonious blending of the old and new cultures. They brought many of their native animistic beliefs into the fold of Theravāda Buddhism. They enhanced the power and prestige of their king by adopting the Hindu ritual of coronation. They developed a new art of sculpture by blending the native tradition of wood carving with the Greco-Indian conventions of making images of the Buddha. They built *stūpa*s on the Indian model and then developed new forms of temple architecture by a mixture of native and Indian traditions.

Mon culture

Within a few decades the Mons became the most advanced people in Southeast Asia, and they assumed the role of teachers to their neighbours, spreading Theravāda Buddhism and their new culture over the entire region. Their cousins, the Khmers, were the first to benefit, followed by the Burmans. Even in the 13th century, when their glory had passed and they were a conquered people in the Chao Phraya Valley, the Mons freely shared their cultural heritage with the new arrivals, the Tais.

The Tibeto-Burman invasions. About the time the Mons were reaching the Chao Phraya Valley, some Tibeto-Burman tribes were leaving their homeland on the southeastern slopes of the Tibetan Plateau. They had reached quite a high level of culture, but their way of life and their social values of individual equality were being threatened by the rival kingdoms of Tibet and China. Preferring physical hardship to political bondage, they started a long trek across the northern mountains of Myanmar; they entered the Upper Irrawaddy Valley, perhaps by the time of the Buddha (*c.* 500 BC). By Aśoka's time their spearhead, the Pyus and allied tribes, had founded their city-kingdoms, perhaps at Tagaung and certainly at Halingyi. They gradually moved southward, leaving along the way settlements that later became city-kingdoms. They stopped for a while at Taungdwingyi, and some tribes crossed the river and the mountains to Arakan. They finally reached the vicinity of modern Prome, only a few miles from what was then the apex of the Irrawaddy's mouth. At about the time of Christ, they founded the city of Śrī Kṣetra near modern Prome.

The Pyu state. There had long been a trade route between China and India that passed through northern Myanmar and then across the Chindwin Valley. The Pyus had gained full control of this route and had even provided an alternative routing—down the Irrawaddy to Śrī Kṣetra and then by sea to India and also to the portage routes and the islands. Because the Pyus were in control of the whole Irrawaddy Valley, Roman embassies to China in AD 97 and 121 chose the overland route through Myanmar for their journey.

Doubtless in the beginning the Pyus learned much from the Mons, but later they came into direct contact with Indian culture. They were so prosperous and powerful that they became the overlords of the Mon kingdom of Thaton and the portage routes. Chinese historical records noted that the Pyus claimed sovereignty over 18 kingdoms, many of them to the south of Myanmar.

Pyu life

The same Chinese records emphasized the humane nature of Pyu government and the elegance and grace of Pyu life. Fetters, chains, and prisons were unknown, and punishment of criminals was a few strokes with the whip. Gaily dressed in blue, the men wore gold ornaments on their hats and the women wore jewels in their hair. The Pyus lived in houses built of timber and roofed with tiles of lead and tin; they used golden knives and utensils and were surrounded by art objects of gold, green glass, jade, and crystal. The walls, the palace, and the monasteries were of glazed brick. Amid this luxury, the Pyus were devout Theravāda Buddhists. Their architects evolved the vaulted temple, which later found its golden age at Pagan. Their sons and daughters were disciplined and educated in monasteries or convents as novices.

Despite their power over the neighbouring regions and the elegance of their life, the Pyus remained a loosely knit medley of tribes. Retaining their old tribal values, the Pyus remained more democratic than the Mons, who possessed the institution of a hereditary chieftain (later king) and a hereditary nobility; but as a consequence, the Pyus were less united and disciplined. There were conflicts between Pyu tribal groups, resulting in changes of dynasties at Śrī Kṣetra.

The huge delta became silted up, and the Pyu city swiftly became inaccessible from the sea. The Mons—politically organized as the confederacy of Ramanna and embracing the three kingdoms of Thaton, Dvaravati, and Haripunjaya—asserted their claim to the newly emerged island of Pegu, in the mouth of the Irrawaddy, by attacking both the Pyus and the Indian merchant ships in the vicinity. In the 6th century a tribal war forced the Pyus and their loyal allies to abandon Śrī Kṣetra. There was a fresh merger of tribes, and in the process the Burmans, a people subject to the Pyus, became prominent for the first time.

Advent of the Pagan Burmans. The Pyus and their allies moved to northern Myanmar, where they set up a new capital. The Burmans, still loyal, established a small settlement of their own. Early in the 9th century the Tai-Shans from their kingdom of Nanchao in South China mounted a series of raids on the cities of Indochina and even besieged Hanoi. The Mon and Khmer cities held firm, but the Pyu capital fell. The leadership of the Tibeto-Burman tribes passed to the Burmans, and in 849 they founded their own city of Pagan and built a wall around it.

The founding of the city of Pagan

The Pagan kingdom (849–1287). By that time the Mons had become supreme in southern Myanmar. They had occupied the whole of the Irrawaddy Delta, building the port of Bassein in the west and founding the city of Pegu in the centre. They could have stepped into the vacuum caused by the destruction of the Pyu kingdom, but they were not politically ambitious and perhaps did not relish going up the river into arid country.

The unification of Myanmar. The Mons' reluctance allowed the infant Burman kingdom to survive and grow. The Burmans had learned much from the Pyus, but they were cut off from the fountain of Buddhist culture, now transferred to Sri Lanka. Theravāda Buddhism had disappeared from India, and in its place were Mahāyāna Buddhism, its offshoot Tantrism, and a resurgent and aggressive Hinduism. The Burmans still controlled the overland route; along it from China and Nanchao came Mahāyāna Buddhism, and from Bengal came Tantrism. There was also a return to native animistic beliefs.

In 1044 Anawrahta came to the throne at Pagan, and his accession coincided with the seemingly final defeat of Theravāda Buddhism in Southeast Asia; the islands and the Khmers went over completely to Hinduism, and the Theravāda Mons were pressured by their neighbours into accepting certain Hindu beliefs. An orthodox monk, Shin Arahan, fled in protest to Pagan, where he was able to convert the young king to the Theravāda faith. The people also accepted it because there was still a vague remembrance that the Pyus had been Theravādins and because the faith's emphasis on the equality and dignity of the individual fitted their society and their prevailing mood. Anawrahta, declaring himself the champion of Theravāda Buddhism, challenged and subdued the Mahāyānist kingdom of Nanchao, annexed the animistic Shan Plateau, and conquered the Theravāda Mons. He united the whole of Myanmar into a single kingdom and founded the Pagan dynasty. His work was continued by his great commander Kyanzittha, who was elected king; and the latter was followed by another great ruler, his grandson (Anawrahta's great-grandson), Alaungsithu.

Anawrahta's subjugation of the Shans checked the flood of Tai-speaking mercenaries and migrants into Southeast Asia, and the strength of his kingdom brought peace to the region, now divided into two great empires, Khmer and Burman. Anawrahta's dynasty of kings lasted until the 13th century. By that time, their great temples had been built and their message of Theravāda Buddhism had been carried not only to the Shans but also to the Khmers.

Destruction by the Mongols

A malaise seemed to have set in by the middle of the 13th century. Then came a demand for submission and tribute by the Mongol Kublai Khan. The proud people of Pagan refused and made a valiant effort to stem the tide of invasion that followed, but it was unavailing, and Pagan fell to the Mongol armies in 1287.

Cultural changes in the Pagan period. Pagan was a fabulous kingdom even to its contemporaries, and Marco Polo was impressed by its splendour. Its many temples and monasteries testified to the prosperity of its people and the richness of its culture. The conquest of the Mon kingdom of Thaton was the foundation of both its economy and its culture. All the ports of the country were in Burman hands, and Pagan's temples were built by free artisans, who were paid their wages not only in money but also in kind and whose clothing, shelter, health, comfort, and safety were the responsibility of their employers (as evidenced by contemporary inscriptions, giving the monetary details connected with the construction and endowment of a temple).

Mon craftsmen, artisans, artists, architects, goldsmiths, and wood carvers—captured at Thaton—were taken to Pagan to teach their skills and arts to the Burmans, whose artistic traditions, inherited from the Pyus, had been lying dormant. They learned quickly and soon were able to stand shoulder to shoulder with Mon and Indian craftsmen. Mon monks and scholars taught the Burmans the Pāli language and the Buddhist scriptures, and the Burmans soon became scholars themselves, making Pagan the centre of Theravāda learning. Some of their religious commentaries came to be accepted as part of the Pāli canon by all Theravādins. The women of Pagan took part in all these activities, their freedom and equality doubly guaranteed by tribal usage and by Buddhist doctrine.

Devout and orthodox, the people of Pagan made Buddhism their way of life but retained those animistic beliefs that were found compatible with Buddhism. They set a pattern of religion, government, and society that later generations followed almost without change. Temple frescoes show the Pagan people to have been simply dressed. Their utensils and implements were not of gold, and so their life was not so elegant as that of the Pyus.

The period of Shan dominion (1287–1531). During the reigns of the last kings of Pagan, many Shans entered royal service as mercenaries. After the fall of Pagan these Burmanized Tai-speaking soldiers of fortune drove out the Mongols; but instead of restoring the fallen dynasty, they founded small kingdoms for themselves. Before invading Myanmar, Kublai Khan had conquered Nanchao and turned it into the Chinese province of Yunnan; when his armies had withdrawn, he encouraged the Shans to leave their old homeland and attack the Burmans and the Khmers. The consequence was the rise of a number of Tai-speaking kingdoms in the Chao Phraya Valley and the restoration of the kingdom of Pegu by the Mons of southern Myanmar. In 1368 northern Myanmar was unified under one kingdom, that of Ava, whose kings were half-Burman and half-Shan and regarded themselves as Anawrahta's successors. They encouraged scholarship and learning, making their period a great age of Burmese literature. They wasted their resources, however, by waging a long war against the Mons.

The Shans of the Chao Phraya Valley fought both Pegu and Ava. In the meantime the small settlement of Burman refugees at Toungoo, on the Pegu–Ava frontier, sought survival by playing Mon against Shan. The Shan refugees from Nanchao who were waiting in the north of Myanmar for an opportunity to win back their old kingdom decided to conquer Ava instead. They had not been won over to Buddhism; and in 1540 there was a massacre of monks, resulting in an exodus of Burmans to Toungoo. In the meantime the Mons at Pegu were achieving another golden age under wise rulers. Under Dhammazedi, Pegu became the centre of Theravādin scholarship and it also entered into close commercial relationship with Malacca, on the Malay Peninsula, an Islāmic kingdom before 1511 and a Portuguese possession thereafter.

The Toungoo dynasty (1531–1752). In 1531 Tabinshwehti became king of Toungoo, and within a few years he conquered northern Myanmar from the Shans and southern Myanmar from the Mons. Transferring his capital to Pegu, he made a great attempt to unite Burmans, Mon, and Shan into a single nation. He died in 1551 and was succeeded by his brother-in-law Bayinnaung. The Shans in the Chao Phraya Valley had consolidated their power under the kingdom of Ayutthaya (Siam), and they cast their eye on the Shan Plateau and southern Myanmar. Bayinnaung marched on to Ayutthaya and conquered the entire Chao Phraya Valley. He used Portuguese mercenaries and Portuguese cannon, but he was determined to keep the Portuguese out of mainland Southeast Asia.

.ule of
ayin-
aung

Bayinnaung's wars had exhausted Myanmar's resources, and after his death the kingdom broke up. Manipur (which had been subjugated in 1560) declared itself a free kingdom. Then the Mons revolted, the Siamese not only regained their independence but also ravaged southern Myanmar, and the Portuguese founded a kingdom at Syriam. Bayinnaung's grandson, Anaukpetlun, by 1613 overcame all three and reunited the kingdom. His successor, Thalun, was peaceful, however, and he abandoned the policy of expansion and moved the capital back from Pegu to Ava. There were no more Mon rebellions, and the kingdom remained at peace. Eventually, the kings became weak and power passed to the ministers.

The fall of the Ming dynasty in China (mid-17th century) resulted in occupation of Myanmar territory by the armies of the fallen emperor and also by the pursuing armies of the new emperor. The raja of Manipur sent his raiders into Myanmar for loot. The Mons rose in rebellion, encouraged by the French in India. Assailed from all sides, Ava fell to the Mons in 1752; and the whole of Myanmar passed under Mon rule.

The Alaungpaya dynasty (1752–1885). It was soon proved, however, that only the king and his ministers had been defeated, not the Myanmar people; before the year had ended, a popular leader, Alaungpaya, drove the Mons out of northern Myanmar and regained the Shan States. By 1758 he had regained Manipur and defeated the Mons and their French garrisons. The Thai became alarmed and attempted to rouse the Shan chiefs to rebel. Alaungpaya retook Tenasserim, the site of the old portage kingdoms, and invaded Thailand. Although his invasion failed and he himself died during the retreat in 1760, the Myanmar now felt that, unless Thailand were conquered, their kingdom would be insecure. The defeats suffered in 1752 had embittered them, and they decided to pursue a policy of aggrandizement and repression. Alaungpaya's son and successor, Hsinbyushin, sent his armies into Thailand in 1766; they captured Ayutthaya in 1767. China, alarmed over the growing power of Myanmar, invaded the country four times during the period 1766–69, without success.

Myanmar then reconquered Arakan and occupied Assam, thus coming face to face with the British power in India. The result was the First Anglo-Burmese War (1824–26), in which Thailand fought on the British side. Myanmar eventually had to sue for peace and lost Assam, Manipur, Arakan, and Tenasserim.

The Anglo-
Burmese
wars

The Second Anglo-Burmese War (1852) was provoked by the British, who wanted to close the gap in their coastline stretching from Calcutta to Singapore; it resulted in the British annexation of Pegu Province. As the British became more and more interested in trade with China through its back door, they waited for a suitable pretext and in 1885 declared war on Myanmar for the third time. To meet international criticism of their action, the British gave the excuses that the last independent king of Myanmar, Thibaw (ruled 1878–85), was a tyrant and that he was intriguing to give France greater influence over the country. Neither of these charges seems to have had much foundation.

The administration of traditional Myanmar. The king was the chief executive and the final court of appeal, but there were checks on his power. He could not make laws, only edicts that would lapse with his death. Custom was the only recognized source of law, and even the king could be sued for civil wrongs. In addition, following the old tribal requirement that each chieftain was to be elected by the council of elders, the king had to be elected by the previous king's council of ministers. With the advent of strong kings, generally the election was merely a formality; but in times of crisis there were real elections.

The king was also the patron of Buddhism and was expected to act as a humane ruler. Buddhist monks were not organized into a church, but there was a primate who, although appointed by the king, often proved to be his sternest critic. Although monks were outside the sphere of politics, they had the right to give sanctuary in that they could ask for the life of a condemned criminal. In practice this right was exercised only when there was some miscarriage of justice. Because monasteries also served as schools for all children, the monks were the teachers of the people and molded public opinion regarding the king's justice.

As a corollary to the long-held belief that all men and women were born free and equal, there were no hereditary nobles. The king's officials were appointed, at least in theory, on their character and talent alone; and their appointments lapsed with the king's death.

The centre of government

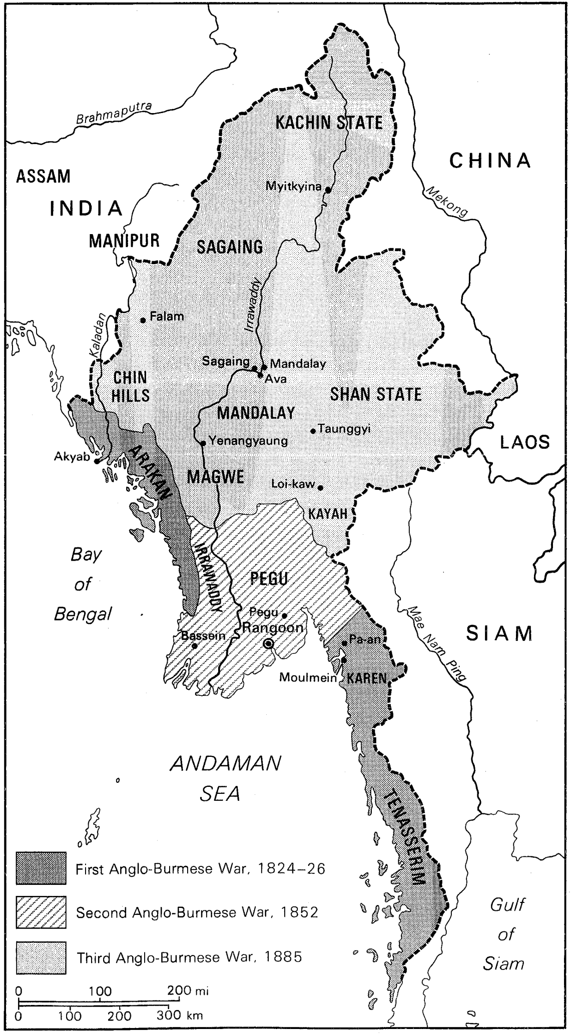
The High Court of Justice was the centre of government. It had three wings—the treasury, the executive, and the judiciary. The judicial wing was the final court of appeal; in theory and often in practice the king presided over its deliberations. All proclamations and appointments that were made by the king became valid only when orders giving effect to them were issued by the executive wing.

Every province had a governor, to whom were delegated certain powers by the High Court of Justice; but there was always a right of appeal against all his decisions to the High Court. Local government was in the hands of "group-village headmen." Villages were grouped together according to their size and geography. Each village in a group was under an elected elder, and these elders together elected the headman, who was then given his appointment by the king. The institution of headman was almost hereditary: because of the need for continuity and experience, the elders usually gave preference to the son, brother, daughter, or even the widow of the former headman. The headman, like a governor, had the right of immediate audience with the king.

THE BRITISH IN BURMA (1885–1948)

The Third Anglo-Burmese War lasted but a week; the Myanmar people never expected that hostilities would break out, and, realizing the hopelessness of the situation because of the disparity in arms, they offered no resistance. They also believed that the British aim was merely to replace King Thibaw with a prince who had been sheltered and groomed in India for the throne; and this belief seemed to be confirmed when the British commander called upon the High Court of Justice to continue to function. The British finally decided, however, not only to annex the whole kingdom, which they called Burma, but also to make it a province of India (effective January 1, 1886).

Adapted from F. Trager, *Burma, From Kingdom to Republic* (1966); Praeger Publishers, Inc.



British territorial acquisitions in Burma.

Anti-Indian feelings

This was a bitter blow to the Myanmar. They had always been prejudiced against the Indians, calling them *kala* ("caste people"). In addition, they remembered that, in Myanmar's three wars with the British, Indian troops had fought for their British masters. It was true that, after the war of 1824, Arakan and Tenasserim had been placed under British commissioners responsible to the British government of India and that, after the province of Pegu had been annexed in 1852, the whole territory of British Burma had been placed under a chief commissioner also responsible to the government of India. But these were temporary and makeshift arrangements, to be reconsidered in the light of experience. Burma seemed too big a territory to be attached to India, and moreover the people were different from the Indians in race, language, society, way of life, attitude, and temperament. The Buddhist culture the Myanmar had received from India had been modified and transformed so that it had become Myanmar-Buddhist culture, while in India Buddhism had been suppressed and discarded many centuries before.

The effects of colonialism. The Myanmar refused to accept the British victory as final, and they resorted to guerrilla warfare against the British army of occupation. There were spontaneous uprisings all over the country, led by former officers of the disbanded royal army, former officials (including village headmen), and princes of the blood. They considered themselves soldiers still fighting the Third Anglo-Burmese War; but to the British the war had ended with the annexation of the kingdom and the fighters were rebels and bandits. For the next four years, although no martial law was proclaimed, the British military officers acted as both judge and jury in dealing with captured guerrillas. Villagers who aided the rebels were also sternly punished. There were mass executions and even cases of wholly massacred villages.

British attempts to end the rebellion

As the guerrillas fought on, the British tried to force the people into submission. Villages were burned; families who had supplied villages with their headmen were uprooted from their homes and sent away to Lower Burma (the southern part of Myanmar, which had been under British control since the second Anglo-Burmese war). Strangers were appointed as headmen for the new villages the British had set up. The guerrillas resorted to cruel and desperate measures against the new village officials. Finally, the might of the British army prevailed, and by 1890—with thousands of guerrillas killed or executed—the struggle was over.

The British did not wish to favour any one religion over another, and they were reluctant to patronize Burmese Buddhism. Queen Victoria, as empress, had proclaimed strict British neutrality in religious affairs of the Indian peoples. The patronage of Burmese Buddhism did not mean financial support, of which Burmese Buddhist monks were in no need (they could own no property, and such simple needs as robes, food, books, and medicine were met by donations from the public). Patronage involved authority; and although the king had been required to kneel before even a freshly ordained monk visiting him, it had been the king's right to appoint the primate, who exercised supervision and discipline among the ranks of the clergy throughout the kingdom. The king had also had the right to attach two royal officials to the primate—the commissioner of ecclesiastical lands and the ecclesiastical censor. The duty of the commissioner had been to see that ecclesiastical lands were exempted from payment of taxes; but at the same time, he had seen to it that bogus and illegal endowments did not escape taxation. The duty of the censor had been to maintain a register of monks, which had given the king an indirect control over the clergy. The power of disrobing a wayward monk had lain only with the primate, but the same result could have been achieved by the censor scratching the monk's name from the register. This arrangement was designed to prevent unworthy persons from taking advantage of the people's respect and devotion for the clergy.

ducation
nder the
ritish

The British refusal of a plea by the clergy and the elders to continue this arrangement resulted in the appearance of pseudo-monks, who lowered the prestige of the Buddhist clergy and contributed to the failure of an attempt by Sir Arthur Phayre (chief commissioner of Lower Burma, 1862–67) to build a modern educational system using the monastic schools as its foundation. Phayre's successors recommended the foundation of government schools, but only a few were actually established. The government of India preferred to encourage foreign Christian missions to found schools by offering them "grants-in-aid."

Many mission schools were founded to which parents were forced to send their children because there were no alternatives. Because the teachers were missionaries, the lessons they gave were marked by repeated criticism of Buddhism and its culture. In the government schools the first teachers, British and Indian, were mere civil servants, unable and unwilling to continue the older traditions.

The British impact on the Burmese economy proved disastrous. This was not so much due to the usual economic exploitation of a country by a foreign ruler (the British were milder in this respect than were other colonial powers) as it was to the British policy of laissez-faire and to Burma's being made an Indian province. The British dream of a golden road to China through Burma could not be realized, but the opening of the Suez Canal in 1869 was equally golden, for it increased international demand for Burma's rice, which had never before been an important item of export. This development came in the wake of a change in Burma from a barter economy to a money economy. The Burmese peasant was both psychologically unprepared for and inexperienced in the use of cash; and under Burmese law, capital accumulations were almost impossible because the Burmese possessed no right of disposing property by will, so that a family estate had to be divided after the death of the parents among all sons and daughters.

The Irrawaddy Delta was swiftly cleared of its mangrove forests to become covered with rice fields. Even in 1857 the price of rice increased 25 percent; by 1890 the 1857 price had more than doubled and it continued to increase until the world depression of the 1930s. Tempted by the prevailing rice prices, the Burmese flocked to the delta; but in order to prepare the land for cultivation they had to borrow capital from Indian moneylenders from Madras at an interest rate of some 120 percent. The British banks would not grant loans on mortgage of rice land, and the British government had no policy for establishing land-mortgage banks or for making agricultural loans. Prevailing prices were high in the international market, but the local price was kept down by a handful of British firms that controlled wholesale trade and by Indian and Chinese merchants who controlled retail trade. Although the Burmese economy developed rapidly from 1890 to 1900, the Burmese people did not benefit from it. A railway had been built through the entire valley of the Irrawaddy, and hundreds of steamboats plied the entire length of the river; but the railway and the boats belonged to British companies. Roads had been built by the government, but they were meant for the swift transport of troops during frequent rebellions. A British company worked the ruby mines until they became nearly exhausted. The extraction of oil and timber was monopolized by two British firms. The balance of trade was always in favour of Burma; but this was only on paper because there was no control or even record of foreign exchange remittances to their home countries by the British and Indian troops; the British, Indian, and Chinese merchants; the British and Indian civil servants; and the Indian labourers who came in thousands without any restrictions because they were merely travelling from one part of the Indian empire to another. With land values and rice prices soaring, the Indian moneylenders foreclosed mortgages at the earliest opportunity. The dispossessed farmers could not find employment even on their lost lands because, with a higher standard of living, they could not compete with Indian labourers. Burmese villagers, unemployed and lost in a disintegrating society, took to petty theft and robbery and soon acquired the reputation of being lazy and undisciplined.

The new
Burmese
leaders

The emergence of nationalism. Those Burmese who attended the new schools managed to gain admission to the clerical grades of government service, but even in those lower grades there was competition from Indians. Because science courses were not available, the professions of engineering and medicine were closed to the Burmese. Those who advanced to the government liberal arts college at Rangoon entered the middle grades of the civil service; a few went on to London to study law. When these young barristers returned to Burma they were looked upon by the people as their new leaders. Their sojourn in the liberal atmosphere of London had convinced these new leaders that some measure of political independence could be regained by negotiation. They first gave their attention to the national religion, culture, and education; in 1906 they founded the Young Men's Buddhist Association (YMBA) and established a number of schools supported by private donations and government grants-in-aid (the movement was not antigovernment). That same year the British, attempting to pacify the Indian National Congress, introduced some constitutional reforms in India. Only a few inferior changes were made in the Burmese constitution, but these confirmed the young leaders' faith in British liberalism. In 1920, however, when it was found that Burma would be excluded from new reforms introduced in India, the barristers led the people in a nationwide protest, which involved a boycott of British goods. In 1886, to humiliate the Burmese, the British had made Burma a part of India; they now found that they could not exclude Burma from sharing benefits granted to India.

The following December, Rangoon College was raised to the status of a full university; but because its control was vested in a body of British professors and government nominees, its students went on strike. Younger schoolboys and schoolgirls followed suit. The strikers camped in the courtyards of monasteries, reviving memories of days when education was the concern of the monks. The general public and the Buddhist clergy gave full support to the strike. The University Act was amended, and the strike was settled; but many strikers refused to go back to mission and government schools. The YMBA schools, now calling themselves "National" schools, opened their doors to the strikers.

The
Thakin
movement

Constitutional reforms were finally granted in 1923; but the delay had split the leaders, some of whom, like the masses, were beginning to doubt whether political freedom could be attained by peaceful protest. In the University of Rangoon itself, students began to resent their British professors. A radical student group began organizing protests, which came to be known as the Thakin movement (a purposely ironic name, taken from *thakin,* "masterly," by which Burmese were required to address the British).

(M.H.Au./Ed.)

In 1931 Burmese peasants, under their leader Saya San, rose in rebellion. Armed only with swords and sticks, they resisted British and Indian troops for two years. The young Thakins won the trust of the villagers and emerged as leaders in place of the liberals. In 1936 university students again went on strike, and two of their leaders, U Nu and Aung San, joined the Thakin movement. In 1937 the British government separated Burma from India, but the masses interpreted this as proof that the British planned to exclude Burma from the next phase of Indian reform.

When World War II broke out in Europe in 1939, the Burmese sympathized with Britain, but they wanted to bargain with the government before giving their support. A warrant was issued for the arrest of Aung San, but he escaped to China, where he attempted to contact radical groups for support. Japanese assistance was offered instead; he returned to Burma in secret, recruited 29 young men, and took them to Japan, where the "Thirty Comrades" received military training. The Japanese promised independence for Burma; hence, when Japanese troops reached Bangkok, Aung San announced the formation of the Burma Independence Army. Independence was not declared, however, and Aung San and his army began to conspire against Japan. When the Japanese administration learned of the plot, they disbanded the Independence Army and formed a smaller Burma Defense Army, with Aung San still as commander.

Ba Maw, the first prime minister under the 1937 constitution and later the leader of the opposition, was appointed head of state, with a Cabinet including Gen. Aung San and U Nu. In 1943, when the tide of battle started to turn against the Japanese, they declared Burma a fully sovereign state. But the Burmese government was still a mere facade, with the Japanese army ruling. Aung San contacted Lord Mountbatten, the Allied commander in Southeast Asia, offering cooperation, and in March 1945, on receiving Mountbatten's approval, Aung San and his army joined the British side.

The AFPFL

After the liberation of Rangoon, Aung San and the Thakins formed a coalition of all parties under the name Anti-Fascist People's Freedom League (AFPFL). At this critical moment the British military administration showed its old prejudices. But Lord Mountbatten hastily sent a major general, Sir Hubert Rance, to head the administration; and Rance, with a conciliatory attitude, regained for the British the trust of Aung San and the general public. When the war ended, the military administration was withdrawn and Rance was replaced by the former civilian governor, who formed a Cabinet consisting of older and more conservative politicians. The new administration arrested Aung San on a criminal charge. Surprised and angered, the Burmese people prepared for rebellion; but the British government in London wisely replaced the governor with Rance, now retired from the army. Rance formed a new Cabinet, including Aung San, and discussions for a peaceful transfer of power began. These were concluded in London in January 1947, when the British agreed to Burma's independence and its leaving the Commonwealth.

Independence

The Communist and conservative wings of AFPFL were dissatisfied with the agreement. The Communists broke away and went underground, and the conservatives went into opposition. In July Aung San and most members of his Cabinet were assassinated by gunmen sent by U Saw, a former prime minister and now a conservative. Rance asked U Nu to form a new Cabinet. On January 4, 1948, Burma became a sovereign independent republic.

MYANMAR SINCE INDEPENDENCE

Constitutional government, 1948–62. With its economy shattered and its towns and villages destroyed during the war, independent Myanmar needed some years of peace; a foreign policy of neutrality was decided upon, but because of internal strife no peace resulted. The Communists were the first insurgents, followed by Aung San's veterans, and then the Karens, the only ethnic minority on the plains; but the other minorities—Chins, Kachins, and Shans—who had been ruled separately by the British but who had enthusiastically joined the Union, stood firm.

A division of Chinese Nationalist troops occupied parts of the Shan Plateau after China had fallen to the Communists in 1949; and, because of the United States' general support for Nationalist China, Myanmar stopped accepting American aid and became prejudiced against all foreign aid. At the UN Myanmar endeavoured to show impartiality. It was one of the first countries to recognize Israel and also the People's Republic of China.

In 1958 Myanmar was well on the road to internal peace and economic recovery when the ruling AFPFL was divided by personal quarrels between U Nu and his closest associates. Amid rumours of a military takeover, U Nu invited the army chief of staff, Gen. Ne Win—who had been a Thakin, one of the Thirty Comrades, and Aung San's second in command—to take the premiership. Ne Win prepared the country for general elections, which took place in February 1960. The opponents were the two sections of the AFPFL, and U Nu was returned to office with an absolute majority.

Socialist takeover. In March 1962 Gen. Ne Win led a coup d'état and arrested U Nu, the chief justice, and Cabinet ministers. Suspending the constitution, he ruled the country with a revolutionary council made up of senior military officers. His stated purpose was to make Myanmar a socialist state. Land had been nationalized in U Nu's administration, and now all major commerce and industry were nationalized as well; the economy did not improve, however. A one-party (Burma Socialist Programme Party [BSPP]) system was established, and measures were introduced to decentralize the administration. In April 1972 Ne Win and other members of the revolutionary council retired from the army.

New constitution

U Ne Win promised a new constitution, and in September 1971 representatives of the party's central committee, of the country's various ethnic groups, and of other interest groups were appointed to draft a document. A referendum to ratify the new constitution was held in December 1973, with more than 90 percent of eligible voters signifying approval. Elections to the Pyithu Hlutdaw—the supreme legislative, executive, and judicial authority—and to local People's Councils were held early in 1974; the new government was established on March 2 with U Ne Win as president.

After the establishment of the new political organization, Myanmar's economy grew steadily but slowly, although in the 1980s mounting trade deficits and external debt payments increasingly hindered growth. Student and worker unrest erupted periodically, and Communist and ethnic insurgency continued in the eastern and northern parts of the country. In May 1980 U Ne Win offered full amnesty to all political insurgents inside or outside Myanmar who reported to authorities within a 90-day period. Most notable among those accepting was U Nu, who returned from India to practice as a Buddhist monk. U Ne Win retired as president and chairman of the State Council in November 1981 but remained in power until July 1988, when he resigned as chairman of the BSPP amid violent protests against his rule. A civilian government was then established, but pro-democracy demonstrations continued. On September 18, 1988, the armed forces, led by Gen. Saw Maung, seized control of the government. The military moved to suppress the demonstrations, and thousands of unarmed protestors were killed. Martial law was imposed over most of the country.

On May 27, 1990, Myanmar held its first multiparty parliamentary elections in 30 years. The result was a landslide victory for the opposition National League for Democracy (NLD). The NLD's leaders, U Tin U, a former colleague of U Ne Win, and Daw Aung San Suu Kyi, the daughter of the nationalist leader Aung San, had been under house arrest since July 1989. The military government had announced before the elections that it would retain power until the new assembly wrote a constitution and formed a strong government. (Ed.)

SINGAPORE

The Republic of Singapore is a city-state situated at the southern tip of the Malay Peninsula, about 85 miles (137 kilometres) north of the Equator. It consists of Singapore Island, which is diamond-shaped and 221 square miles (572 square kilometres) in area, and some 50 other islets, many of which are uninhabited, which make up another 18 square miles (46 square kilometres). To the north the main island is separated from West Malaysia by Johor Strait, a narrow channel crossed by a road and rail causeway more than half a mile long. The southern limits of the state run through Singapore Strait where outliers of the Riau-Lingga Archipelago, which forms a part of Indonesia, extend to within 10 miles (16 kilometres) of the main island. Most of Singapore's population is Chinese.

ze and
gional
portance

The largest port in Southeast Asia, and one of the largest ports in the world, Singapore owes its growth and prosperity to its focal position at the southern extremity of the Malay Peninsula, dominating the Strait of Malacca that leads from the Indian Ocean to the South China Sea. Once a British colony, and now a member of the Commonwealth of Nations, Singapore joined the federation of Malaysia on its formation in 1963. When friction subsequently developed between the Malay-dominated central government and the Chinese-dominated Singapore administration, Singapore accepted Malaysia's invitation to leave the federation and become an independent state, which it did on August 9, 1965.

Since 1965, despite a large and rapidly growing population concentrated on a minute geographical base, Singapore has reduced its birth rate, rehoused many of its people, initiated a program of industrial expansion, and raised national income to the second highest per capita level of any Southeast Asian nation. Singapore was formerly the principal British naval and air base in Asia, but its strategic role has been eroded by developments in nuclear warfare, as well as by the withdrawal of British power from Asia.

Physical and human geography

THE LAND

Relief. Nearly two-thirds of the main island is less than 50 feet (15 metres) above sea level. Bukit Timah, the highest summit, is only 531 feet (162 metres) high; with other peaks, such as Bukit Panjang and Bukit Mandai, it forms a block of rugged terrain in the centre of the island. To the west and south are lower scarps with marked northwest-southwest trends, such as Bukit Faber Ridge. The eastern part of the island is a low plateau cut by erosion into an intricate pattern of hills and valleys. These physical units reflect their geological foundations: the central hills are formed from granite rocks, the scarplands from highly folded and faulted sedimentary rocks, and the eastern plateau from uncompacted sands and gravels.

Drainage and soils. A dense network of short streams drains the island, but floods are locally severe, owing to low gradients and to excessive runoff of water from cleared land. Many streams, especially those draining northwards, have broad mangrove-fringed estuaries that extend far inland. None of the soils is even reasonably fertile, but those derived from the granites tend to be better than most. Soils developed from the sedimentary rocks are variable, but many contain hard pans (compacted layers) that restrict plant roots and impede soil drainage. The soils of eastern Singapore are extremely infertile. All have suffered extensive degradation (loss of material through erosion) as a result of generations of careless exploitation.

limate

Climate. Singapore, being in an equatorial region, experiences uniformly high temperatures throughout the year, with the mean monthly average varying from about 81° F (27° C) in June to 77° F (25° C) in January. The daily range is much greater, averaging 12° F (7° C), but the maritime location and constant humidity keep maximum temperatures relatively modest: the highest temperature ever recorded was only 95° F (35° C). As temperatures are so uniform, the incidence of rainfall defines the seasons; rainfall in turn depends on air-mass movements, which are affected by the presence of the Asian and Australian land masses. Between December and March, for example, the northeast trade winds that blow at that season are reinforced by outflows of surface air from Asia, bringing the strongest winds and heaviest precipitation of the year; rainfall averages more than 10 inches (250 millimetres) a month in both December and January. From May to September surface winds from the southern hemisphere are strengthened by the Australian high-pressure belt and reach the Singapore-Malaya region. Winds are generally light during this season, however, and rainfall drops to about six inches in June and July. From April to May and from October to November sluggish air movements are common, and intense afternoon showers bring monthly rainfall averages of seven to 10 inches. Altogether, the annual rainfall averages about 100 inches, and rain falls somewhere on the island every day of the year.

Plant and animal life. Little remains of the original vegetation or animal life, except for a few thousand acres of second growth rain forest preserved around catchment areas. Some mangrove vegetation survives in the Kranji estuary on the northwest side of the island, but elsewhere tracts of scrub, or of *Imperata* grass called lalang, are common. Many exotic plants have been introduced for ornamental use. The largest native animals are the long-tailed macaque (an Asian species of monkey), the slow loris (a large-eyed tailless nocturnal lemur), and the scaly anteater. Birds are numerous, especially those, such as the Indian mynah bird, the brahminy kite (a kite with reddish-brown plumage and a white head and breast), and the house swallow, which have adapted to a symbiotic relationship with man. Reptiles, such as cobras and lizards, are also common. Fringing coral reefs with their associated fish and wildlife occur around many parts of the coast.

Settlement patterns. The city of Singapore stands on the southern part of the main island. Urbanization has reduced differences between city and country. Today built-up areas cover a large fraction of the main island. In the older parts of the city (along Singapore River, in the Rochore-Kallang floodplain, and in the low hills behind the harbour), rows of narrow-fronted Chinese shops, with their upper floors subdivided into living cubicles, line the streets. Similar shops stand along the main roads that radiate from the city. Behind their facades lie extensive suburbs composed partly of bungalows, semi-detached residences, and apartments, and partly of rural types of dwellings, such as wooden huts roofed with *atap* (thatch made from the *Nypa* species of palm tree) or corrugated iron. Such huts are common in all the rural districts, and in squatter settlements in the city. The traditional Malay *kampong*s (villages built on stilts) are seldom seen, except in fishing villages on some of the smaller islands.

The port of Singapore occupies the southern coast of the main island south of the Singapore River. It consists of two partly sheltered areas of water—the Eastern Roads, which are subdivided by an offshore breakwater, and the Western Roads. The two roadsteads are connected by the deepwater channel of Keppel Harbour, with its miles of berths, docks, warehouses, and other facilities, which runs between the main island and islands to the south. A few miles further west is the new port, Jurong.

THE PEOPLE

As a result of past immigration, the population is diverse. Chinese predominate, forming about three-fourths of the total. Malays form the next largest ethnic group and Indians the third. None of these three major communities is homogeneous. Among the Chinese, almost half originate from Fukien Province and speak the Amoy dialect; about one-fourth are Teochews from Swatow, and roughly one-fifth are from Kwangtung. The Chinese community as a whole, therefore, uses mutually incomprehensible dialects. Linguistic differences are less pronounced among the Malays, but the group includes Indonesians speaking Javanese, Boyanese, and other dialects. The Indian group is most diverse, consisting of Tamils (more than half), Malayalis, and Sikhs; it is also considered to include the Pakistani and Sinhalese communities.

Official
languages

Because of this diversity, no fewer than four official languages are recognized—English, Mandarin, Malay, and Tamil. English remains the main medium for administration, commerce, and industry; more than half of all schoolchildren attend English-language schools. Mandarin, the national language of China, transcends dialect barriers; one-third of the school population is taught in that language. Malay, like English, is widely used for interracial communication and plays an especially useful role in view of the close ties between Singapore and Malaysia.

Religious affiliations reflect ethnic patterns. About three-fourths of all Chinese profess some degree of attachment to Confucianism, Buddhism, or Taoism, or to some combination thereof. Virtually all Malays, and some Indians, adhere to Islām, which is the formal religion of about

one-sixth of the population. The remaining population is either Christian or Hindu.

THE ECONOMY

With an urban population engaged largely in trade, finance, and industry, Singapore's economy differs markedly from that of most Southeast Asian countries, which are primarily based on the production of raw materials. The monetary unit is the Singapore dollar.

Resources. The state has few natural resources, apart from small amounts of brick clays, rock aggregates, and building sand. The natural vegetation provides only firewood and a few poles. Local catchment areas are small, obliging Singapore to use water from Johor state in West Malaysia. The low-lying relief does not permit hydroelectric development, so that energy has to be generated from imported fuels.

Agriculture and fisheries. About one-fourth of the total area of Singapore is devoted to agriculture. Although more than half the agricultural acreage is used for the cultivation of rubber and coconuts, most of the farms produce vegetables, fruit, and livestock for local markets. Singapore is self-sufficient in pig, poultry, and egg production. Large amounts of marine fish are caught in local waters, and ~~supplies are augmented by fish raised in freshwater ponds~~ on farms. Total fish production nevertheless accounts for a fraction of total consumption.

gricul-
ral
oduction

Industry. The manufacturing sector, on the other hand, has expanded rapidly. Manufacturing plants produce transport equipment and petroleum products, and process food. The ship-repairing and ship-building industry is growing rapidly.

Finance. Financial services are available both from modern banks and insurance companies and from traditional thrift societies and moneylenders. So far, most of all bank credit has been advanced for general commerce and trade, but the proportion devoted to industry is growing, with encouragement from such official bodies as the Development Bank of Singapore. Other sources ~~of finance include finance companies, building societies,~~ insurance firms, and co-operatives. Singapore also has a thriving stock exchange. Commodity markets, especially for rubber, pepper, and tin, form an important element in the economy.

Trade. Singapore continues to perform its traditional financial-intermediary function of shipping raw materials from the region in exchange for finished products from the industrial nations. Malaysia, the U.S., the United Kingdom, China, and Vietnam are—after Japan—Singapore's principal trading partners. Rubber and petroleum together account for about one-fourth of the value of all trade. Crude rubber, imported from West Malaysia and Indonesia, is shipped to Japan, the U.S., China, the Soviet Union, and Britain. Petroleum from the Middle East is refined in Singapore, and the resulting fuel oils, diesel oils, gasoline, and other products are exported to Vietnam, Thailand, Japan, and Hong Kong. Other significant items in foreign trade include timber, spices, and rice. The export of machinery, vehicles, and textiles is also increasing.

Administration of the economy. The economy of Singapore is basically of the free-enterprise type. The private sector therefore has an essential entrepreneurial role, and is expected to generate the increased productivity necessary for progress. At the same time the government is strongly committed to developmental goals, and its influence is pervasive.

urces of
venue

The main sources of government revenue are excise duties (mainly on liquor, tobacco, motor vehicles, and petroleum products) and income tax (mostly from companies). Tax relief may be granted to new manufacturing and export enterprises; to encourage the entrepôt trade, free trade zones have been established.

Only one-fourth of all workers are trade unionists. Most of those employed in the public sector and most employees of the larger, foreign-directed firms are unionized. There are numerous separate unions, led by the National Trades Union Congress, whose main objectives are to secure welfare benefits for workers by established procedures. The government regulates collective bargaining and compulsory arbitration, and it also provides a wide range of services, including training courses and a workers' superannuation scheme. Organized management is represented by two bodies, and there are, in addition to these, chambers of commerce representing different ethnic groups.

The country's limited area, a rapid population growth, and a weakening role as financial middleman have virtually obliged Singapore to develop its manufacturing industries. Despite advances in increasing the number of manufacturing establishments, the economy still depends on external factors over which the state has no control, such as fluctuations in the price of rubber on the world market. The internal problem of providing full employment for an expanding population has yet to be solved.

Transportation. As one of the largest ports in the world, Singapore is a major transportation nucleus. Roughly one-half of all ships handled are engaged in the coastal and interisland trade conducted between Singapore and Indonesia, but the extent of this barter trade is poorly documented. Railroads connect Singapore with West Malaysia. Roads are numerous. Both international and pan-Malaysian airlines use the airport at Changi.

ADMINISTRATIVE AND SOCIAL CONDITIONS

~~**Government.** Singapore is a parliamentary democracy~~ based on the Westminster model. The government consists of a head of state, a president with nominal powers, and a fully elected, unicameral Parliament of 58 members. The electorate includes every adult citizen who is a registered voter, and voting is compulsory. The parliamentary majority selects the prime minister and cabinet from its own ranks. In each constituency there is a Citizens' Consultative Committee, designed to act as a link between government and people. Each committee explains official policies and transmits demands or grievances to the government. Similar exchanges are conducted with organized labour, which has six seats in Parliament.

Close liaison is maintained between the political and administrative arms of government. The administra~~tive structure comprises various ministries and statutory~~ boards. These are staffed by civil servants whose technical competence and integrity are monitored by a Public Service Commission, an independent body responsible for controlling standards, appointments, and discipline.

Justice. A similar body maintains the status and assures the independence of the judiciary. Justice is administered by the Supreme Court and by courts of minor jurisdiction such as magistrates' and criminal district courts. Appeals can be made from the lower to the higher courts, with final appeal to the judicial committee of the Privy Council in London. Legal assistance in civil actions is available for the poor. The Shariah Court has jurisdiction in matters of Islāmic law.

Armed forces. The armed forces of Singapore consist of infantry battalions with supporting artillery, armour, engineer, and signal units. The training of fighter pilots and of personnel for local missile defenses has begun. There is also a flotilla of fast naval patrol boats. Military conscription for 18-year-olds was introduced in 1967. Those not selected for the statutory two-year period of service with the regular forces are obliged to serve on a part-time basis with either the Peoples' Defence Force, the Special Constabulary, or the Vigilante Corps (a paramilitary force largely made up of youths).

Education. Primary education in any one of the four official languages is free for children of Singapore citizens, and the learning of a second language is compulsory. Secondary education is available in technical, commercial, and academic subjects; courses are combined to prevent premature specialization. Existing school facilities are sufficient to meet anticipated future demands. There are also technical institutes. The National University of Singapore, founded in 1980 by a merger of the University of Singapore and Nanyang University, provides academic and professional courses to postgraduate levels. There are separate institutes to train teachers, nurses, radiographers, and seamen; many centres offer adult education.

Health and welfare. The range and quality of medical services is notably high, with a large number of doctors

Medical services

and dentists. There are both government and private hospitals, while nonhospital care is dispensed from numerous out-patient clinics and mobile centres. Official campaigns to keep Singapore clean are conducted periodically. Singapore's most significant achievement is in family planning, a distinction that it shares with few other nations; it resulted in a drop in the birth rate.

A housing and development board, established by the government, is responsible for building homes for families with low incomes. The units being built and that have been built have ameliorated somewhat the severe housing shortage that was endemic in Singapore.

The police force comprises regulars and members of the Special Constabulary. The force patrols the islands by land and water in order to maintain internal security. Traffic management, crime prevention, and political subversion are also matters under police jurisdiction. A police academy trains recruits and serving personnel.

Health conditions in Singapore compare favourably with those of the advanced nations. With the reduction in communicable diseases, cardiovascular diseases and malignant neoplasms account for an increased proportion of deaths. The government and voluntary associations, headed by the Council of Social Service, provide welfare services for the aged, sick, and unemployed.

CULTURAL LIFE

Cultural activities in Singapore are largely derivative, springing from one or another of the major civilizations of China, India, Indonesia, or the West. Traditional Chinese and Indian music, painting, and drama are practiced by numerous cultural societies and professional groups. Popular culture, based on modern mass media, is far more widespread. Malay music, which has adopted the rhythms of Western orchestras, has a general appeal. Musical films that popularize Hindustani and Tamil songs have a considerable following, as do films from Hong Kong, Taiwan, and the United States. Several Chinese, English, Indian, and Malay newspapers serve a largely literate population. Magazines published in the West, Hong Kong, and Japan have wide appeal. (Rt.H.)

For statistical data on the land and people of Singapore, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL.

History

The island, originally inhabited by fishermen and pirates, served as an outpost for the Sumatran empire of Śrivijaya. In Javanese inscriptions and Chinese records dating to the end of the 14th century, the more common name of the island is Tumasik, or Temasek, from the Javanese word *tasek* ("sea"). The Cōla ruler Rājendra attacked the island in 1025, and there was another Cōla raid in 1068. In 1275 the Javanese king Kritanagara, when he raided Pahang, probably attacked Temasek. According to a Chinese traveller, Wang Ta-yuan, just before 1349 about 70 Siamese war boats besieged Temasek for a month but had to withdraw. The Javanese *Nagarakritagama* (written 1365) includes Temasek among the conquests of the Javanese empire of Majapahit. At the end of the 14th century, Temasek fell into decay and was supplanted by Malacca (now Melaka). Yet in 1552 it was still a port of call from which St. Francis Xavier dispatched letters to Goa, and João de Barros, in *Décadas da Asia* (1553), described it as "a resort not only of Indian shipping but of traders from China, Siam, Champa, Cambodia, and the Malay Archipelago." Rājendra may have named the city Singapore (City of the Lions), or the name may have been bestowed in the 14th century by Buddhist monks, to whom the lion was a symbolic character. In the *Sejarah Melayu,* a Malay chronicle, the city was founded by the the Śrivijayan prince Sri Tri Buana; he glimpsed a tiger but mistook it for a lion, and thus called the settlement Singapura. (Rt.H./Ed.)

EAST INDIA COMPANY

On January 28, 1819, Sir Thomas Stamford Raffles of the East India Company, searching for a factory site, forestalled by the Dutch at Riau (Riouw, Rhio), and, having found the Carimon Islands unsuitable, landed at Singapore. He found only a few Chinese planters, some aborigines, and a few Malays and was told by the hereditary chief, the *temenggong* (direct ancestor of the sultans of modern Johore), that there were no Dutch there and that the company could purchase land. The *temenggong,* however, was a subordinate of his cousin Abdul Rahman, sultan of Riau, Lingga, Pahang, Johore, and Singapore, who was under Dutch surveillance. Abdul Rahman was a younger son and not a sultan de jure. Raffles, disobeying instructions not to offend the Dutch, withdrew his own recognition of Abdul Rahman as sultan of Singapore and installed Abdul Rahman's elder brother, Husain, to validate the purchase of land there on behalf of the company. The Dutch protested. In London the court of directors, though it decided Raffles had contravened instructions, took no action.

British ru

In 1824 an Anglo-Dutch treaty left Malaya and Singapore in the British sphere, and on August 2 the whole of Singapore Island was ceded to the British for a money payment. In 1826 Singapore, Penang, and Melaka were combined as the Straits Settlements to form an outlying residency of India. In 1830 they were reduced to a residency under Bengal, and two years later Singapore became their capital. When the East India Company lost its monopoly of the China trade (1833), it also lost its interest in Malaya. The settlements were transferred to the direct control of the governor-general of India in 1851. In 1867 they were made a crown colony under the Colonial Office.

DEVELOPMENT OF THE PORT

Meanwhile, the trade of Singapore had suffered from British development after 1842 of a rival port, Hong Kong, as later it was to suffer from the French occupation of Indochina, the development of Saigon and Haiphong, and from the establishment of Dutch ports and shipping lines in the Netherlands East Indies. With the opening of the Suez Canal in 1869 and the advent of steamships, however, an era of prosperity began that led eventually to the construction of three miles of wharves at Tanjong Pagar and finally, in 1921, to a naval base. The economic growth of the Malay states after they became British protectorates enlarged transit trade. (R.O.Wt.)

It was the demand of the industrial West for tin and rubber that made Singapore one of the greatest ports in the world. After World War I steps were taken to modernize Malayan defenses and, with the lapsing of the Anglo-Japanese alliance, to build a large naval base in Singapore.

WORLD WAR II

In World War II the Japanese landed in Kelantan and Thailand on December 7, 1941 (December 8 west of Hawaii). By the end of January 1942 they had overrun the peninsula and were opposite the island of Singapore. The sinking of the battleship "Prince of Wales" and the battle cruiser "Repulse" had given them command of the sea, and a superior air force covered the advance down the peninsula. The Japanese crossed the Johore Strait on February 8, 1942, and the British command surrendered the island and city on February 15. Singapore remained in Japanese occupation until September 1945.

POLITICAL DEVELOPMENTS AFTER THE WAR

British political plans for Malaya excluded Singapore from the Malay Union and later from the Federation of Malaya mainly because Singapore's predominantly Chinese population would be a racial obstacle to a common citizenship. As a separate crown colony (from 1946) Singapore made constitutional progress despite the Communist insurrection in Malaya. Elected ministers and a Legislative Assembly with an elected majority assumed government responsibility in 1955, except for defense and foreign affairs. In 1959 the official and nominated elements were eliminated and Singapore became self-governing, although Britain still retained control of defense and foreign affairs.

Part of Malaysia

Singapore joined the Federation of Malaysia on its formation in September 1963. The ruling People's Action Party (PAP) led by Lee Kuan Yew had refused in 1959 to form a government until eight extreme left-wing leaders who had been detained by the colonial authorities were released. This left wing opposed the concept of Malaysia, broke away to form the Barisan Sosialis Party, and was accused of being a Communist front organization amenable to the control of the Indonesian Communist Party. The PAP faced fresh dangers of subversion when Indonesian opposition to Malaysia took the form of military and economic confrontation (1964). There were a number of attempts to blow up military installations and public utilities.

Confrontation ended in 1966, but Singapore had left Malaysia in 1965, at the invitation of the Malaysian government, because of political friction between the state and central governments. This conflict had racial overtones and continued to affect relations between Singapore and Malaysia. In May 1969 there was some rioting as a result of the racial disturbances in Malaysia after the general election there, but order was quickly restored.

In January 1968 the British government announced that all British defense forces would be withdrawn from the Far East (except Hong Kong) by the end of 1971. In April the unprepared major opposition parties boycotted an election called seven months before it was due. The ruling PAP termed its sweep of all 58 seats (a number newly increased) a mandate for its plans for lessening the economic effects of the British military withdrawal.

At midnight on October 31, 1971, 152 years of British military presence came to an end. The 14-year-old Anglo-Malayan treaty, which also covered Singapore and which had committed Britain to the defense of the region, terminated, and in its place a five-power defense arrangement—involving Britain, Australia, New Zealand, Malaysia, and Singapore as equal partners—came into force.

Since the 1970s, Singapore has experienced phenomenal economic success, its annual rate of economic growth often exceeding 10 percent. Singapore is politically stable, although some critics of the government feel that it is perhaps too stable. The country has been headed by Lee Kuan Yew and his People's Action Party since 1959, with PAP members completely dominating Parliament.

(A.Ke./Ed.)

For later developments in the history of Singapore, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL.

THAILAND

A nation wedged like a keystone into the heart of Southeast Asia, Thailand in the last decades of the 20th century holds a critical position in the attempts of the countries of this area to achieve and maintain a political, economic, and social stability. In 1932 the absolutist monarchy was overthrown and the nation was organized as a constitutional monarchy with a representative legislature. In 1939 the official name was changed from Siam to Prathet Thai, or Thailand—literally, the "Land of the Free." The several ethnic and religious groups represented among Thailand's people are characteristic of the cultural diversity that for centuries has spread across this portion of the continent, a mêlange of influences from the two Asian giants, China and India.

e
ıdscape

Thailand's landscape is one of high mountains at the edge of the Himalayan chain, of fertile, alluvial plains dotted with rice paddies, and of sandy beaches and tropical forests set amid the latitudes of the Asian monsoons. The main body of the country is surrounded by Myanmar on the west and northwest, Laos on the northeast and east, Cambodia on the southeast, and the Gulf of Thailand (Gulf of Siam) on the south. From the southwest corner, part of Thailand stretches southward down the Malay Peninsula as far as Malaysia. This peninsula cuts off shipping using Thailand's capital and chief port, Bangkok, from points westward; Bangkok is, nevertheless, the international air hub of Southeast Asia.

Contacts of long standing between Thailand and the West have affected the forms if not the realities of Thailand's political and economic life. The relative political stability Thailand has maintained in the face of continual Communist guerrilla warfare inside its borders since World War II is largely the result of Western support. Thailand's free-enterprise economy participates vigorously in worldwide commerce yet remains based on primary products and relies on imports for manufactured goods. In addition, the nation's economic balance is maintained by aid from the United States and other nations.

Physical and human geography

THE LAND

Three main geological regions cover most of Thailand's 198,455 square miles (514,000 square kilometres)—the folded mountains in the north, the Khorat uplift in the east, and the Chao Phraya depression, comprising much of the central plains. In addition, the maritime southeast and the long, slender peninsula in the southwest constitute separate physical regions. The monsoon climate prevailing across most of the country has a distinct influence on the landscape, its vegetation and animal life, and its human uses.

Relief. The mountains, a continuation of the Himalayan system from India, Myanmar, and China, extend far southward in Thailand along the western border and the peninsula and into Malaysia. Long granitic ridges were formed when great masses of molten rock forced their way upward through the older sedimentary strata. Peaks average about 5,200 feet above sea level. Doi Inthanon, at 8,514 feet (2,595 metres) the highest in the kingdom, is southwest of the ancient city of Chiang Mai (Chiengmai), which is overshadowed by the peak of Doi Suthep, a tourist attraction and site of the royal resort palace, Phu Phing Ratchanivet. Many of the rugged limestone hills contain caves from which remains of prehistoric man have been excavated.

The lower reaches of the mountains are rich in teak and other commercial timber, while the upper slopes are dotted with tea plantations. The rivers, emptying through narrow valleys into the central plain, are glutted by the monsoons, sweeping along in their steep descent great quantities of sediments that have produced vast, fanshaped heaps of alluvial deposits along the flood plains at the foot of the mountainous regions.

The
Khorat
region

The Khorat region, enfolded on three sides by Laos and Cambodia, consists of a two-sided geological fault that has been tilted rather than a uniform uplift of the underlying sedimentary rocks. At the western edge, the tilting produced north–south ranges whose escarpments look westward over the central plain. To the south, the tilting produced east–west ranges along the Cambodian border; these form steep escarpments that overlook the Cambodian plain. Surface elevations in the Khorat region are about 650 feet; the terrain is rolling, and the hilltops generally slope in conformity with the tilt of the land.

The generally rolling countryside of the southeast has high hills in the centre and along the eastern boundary with Cambodia. Notable peaks are Khao Khieo (2,614 feet [797 metres]), visible from the top of Phu Khao Thong (the Golden Mount) in Bangkok, and Khao Soi Dao ("Reaching for the stars"), which attains a height of 5,471 feet (1,668 metres). The mountains, reaching nearly to the sea, create a markedly indented coastline fringed with many islands, some of which are popular tourist resorts. The short, seaward-running streams have built up small alluvial basins and deltas along the coast, while the mouths of larger rivers consist of tidal flats and mangrove swamps. Long stretches of sandy beach make Chon Buri, Rayong, and some of the islands year-round resorts. On higher grounds plantations produce rubber, sugarcane, pineapples, and cassava. The central plains, which form the Thai heartland, consist of two regions—the heavily dissected rolling plains in the north and the Chao Phraya River Delta.

The peninsula

The topography of the peninsula is rolling to mountainous, with little flat land. A gently sloping sandy coastline, the site of the famous beach Hua Hin, borders the Gulf of Thailand on the east. The Phet is one of several large rivers dammed for irrigation. Massive mountains on the west, reaching about 4,900 feet, contain difficult passes between Thailand and Myanmar. Toward Malaysia mountains look to the Andaman Sea to the west and to the South China Sea to the east. Off the rugged and much-indented west coast lie numerous major islands, including tin-rich Phuket and others rich in bird and fish life.

Drainage and soils. Between the ridges of Thailand's western border lie relatively flat basins drained by the four principal tributaries of the Chao Phraya, Thailand's major river. Important provincial centres, or *changwats*, such as Chiang Mai, Lampang, Phrae, and Nan, grew up along these four streams. The alluvial soils of these intermontane basins provide fertile soil for the cultivation of rice, vegetables, tobacco, and fruit trees.

Monsoon rains over the thin forest cover of the Khorat region produce rapid runoff; flooding occurs almost yearly at Ubon Ratchathani at the junction of the Mun and the Chi. These two major rivers have built up scattered alluvial lands that are used for rice growing.

Close to the Mekong River, which meanders across the north and east of the Khorat region and runs along most of the Laotian border, swampy land and lakes are common, in contrast to the aridity of much of the region. A high underground water table that can be tapped produces mostly unpalatable water, but the Thai government has done much to improve the freshwater situation in this part of the kingdom. The Mekong itself, from about 2,300 to 4,300 feet wide, is either studded with islands or broken up by impassable rapids. The governments of both Thailand and Laos are making efforts to use it in agriculture and industry.

A rolling plain in the north also is heavily dissected, principally by the three rivers—the combined Ping and Wang, the Yom, and the Nan—that merge to form the Chao Phraya and its delta. Like most deltas, that of the Chao Phraya, which stretches southward to the Gulf of Thailand, is braided into many small channels; it is joined by other rivers as it crosses the plains. The usual flooding of the flat delta in the wet season is an asset to the rice-growing activity, although higher ground on the extreme eastern and western edges of the delta requires irrigation. The entire delta was at one time covered by the Gulf of Thailand, but the waterborne sediments from the uplands to the north filled it in over many centuries. Such silting is a continuing obstruction to navigation channels of the Chao Phraya, but it also provides several feet of new land each year at the river's mouth—so much so that a temple once on an island now lies on the river's western bank.

Effects of the monsoons

Climate. The major influences on Thailand's climate are its location on the Indochinese Peninsula within the sphere of the tropical monsoons and certain topographic features that modify the effects of the rains. Beginning in May, warm, humid air masses flow northeastward over the region from the Indian Ocean, depositing great quantities of rain that reach a maximum in September. Between October and February, the wind currents are reversed, and cold, dry air masses are driven in from the northeast. Stagnant air in March and April is associated with the hot, dry season.

Topographic effects are most noticeable on the peninsula, where Ranong on the west receives 188 inches (4,772 millimetres) of rain annually, and Hua Hin on the east receives only 40 inches (1,007 millimetres). Songkhla has its rainy season during the winter months, the result of moisture picked up from the Gulf of Thailand by the cold northeast air masses. In this area a true tropical rain-forest climate prevails.

Nationwide, temperatures are relatively steady throughout the year, averaging between 75° and 86° F (24° and 30° C). The greatest fluctuations are in the north, where frost may occur in December on higher elevations; maritime influences moderate the climate in the south. The cold, dry winter air produces frequent morning fogs that generally dissipate by midday.

Forests

Plant and animal life. About one-half of Thailand is forested, one-fifth covered by grass, shrub, and swamp, and the remainder under settlement or cultivation. Forests consist largely of such hardwoods as teak and members of the dipterocarp family of timber- and resin-producing trees. As elsewhere in Southeast Asia, bamboo, palms, rattan, and many kinds of fern are common. The southeastern forest is dense with undergrowth and aerial roots, while orchids climb the trunks of many trees. Grasses and shrubs have sprung up across many cutover areas, and lotuses and water lilies dot most ponds and swamps throughout the country.

Elephants, buffalo, cattle, horses, and mules are among the important domesticated animals for agriculture and transportation. Some elephants are still found wild in the west and the northeast. Although forestry is now done by machines, elephants remain helpful in difficult terrain. Agricultural machines are rapidly replacing draft animals, and horses and mules increasingly are used only as pack animals along the mountain trails of the north. Wild animals are decreasing in quantity and in number of species due to game hunting. The rhinoceros and tapir are almost extinct. Deer and antelope can still be found, but the big cats are becoming fewer in number. The Siamese cat is popular among foreigners.

Lizards live around houses and prey on insects. Frogs and toads (some of them edible) are numerous, and crocodiles are also found; a crocodile farm in Bangkok raises them for commercial and scientific purposes. Snakes abound, including the king cobra, numerous vipers, and dangerous water snakes. A snake farm in Bangkok raises many kinds for extracting venom. The green turtle of the sandy coast lays hundreds of eggs at a time, which are highly regarded as culinary delicacies.

Both freshwater and marine fish are abundant, as are edible crustaceans, such as shrimp, prawn, and sea crabs.

The most useful insect is the silkworm. Many species are wild, but some are raised for the prosperous silk industry. Mosquitoes still carry malaria, although incidence of the malady is decreasing. White ants and moths are a scourge to clothing and books.

Settlement patterns. In the traditional or popular sense, the regions of Thailand are the Lanna Thai, or northern Thailand; the Isan, or northeastern Thailand; the central plain; the southeast; the Pak Tai, or south Thailand; and west and southwest Thailand.

The people of the mountainous Lanna Thai speak a dialect similar to that of neighbouring Myanmar. The women wear simple blouses and knee-length sarongs; the men wear loose trousers and cotton jackets called *mohom.* Most of the people live on glutinous rather than common rice. The people have a complexion that is fairer than that of other Thai. The fertile valley plains grow rice and such other crops as peanuts, beans, garlic, onions, corn, and tobacco on the irrigated lands. Tea, widely cultivated as a permanent crop, is consumed in the north as both a pickled and a drinking tea. Besides rice, the outstanding export of the region consists of teak and other commercial timbers. The mountains of the north are also the home of the mountain Thai, who migrate from Myanmar, Laos, and sometimes from southern China.

The Isan is situated on undulating terrain bordered on the west and south by rather hilly regions. The people dress much as do the northern Thai, except close to the Cambodian border, where the *pha chong kraben*—a side-rolled skirt for women, also adopted as a belted pantaloon-like garment for men (similar to the Hindu dress of India) is worn instead of trousers. The dialect is like that of Laos, although very similar to that of the central Thai. With some attention, however, the northerners and the northeasterners can understand one another. A glutinous rice is consumed in most of the northeast, except near the Cambodian border. Besides rice, various kinds of timbers, jute, and cattle constitute important exports. In general, the people depend on agriculture, but the scanty rainfall and sandy soil make the living in the region difficult. As a result, migration from the northeast to other parts of the country is common. The highway to the northeast and thence to Laos makes the region a growing crossroads. It is probably the only part of the country to which the government is devoting both attention and money in an effort to raise the standard of living to that of the other regions.

ntral
ain area

The central plain, lying mostly on the undulating to flat delta region, is the major rice-producing area of the country, much of whose surplus is exported. Because of its central position, population and manpower are heavily concentrated, especially in Bangkok, and industrial and commercial enterprises have grown faster there than elsewhere. The eastern, western, and northern peripheries of the central plain, however, remain to be developed. The soil of the northern half of the plain is inferior. People from the northeast and other places have migrated to the central area in hope of a better living.

The southeast, lying close to the sea on an undulating to hilly region, is well watered. Close to the sea fishing predominates; plantations and gem mines are found on the inner hill and mountain slopes. Thai of Chinese descent live here in great numbers. Tapioca and sugarcane are the chief crops, and fish supply the Bangkok and the upper-country markets and are also exported. Chanthaburi and Trat are famous for their sapphires. The beaches are popular and attract foreign tourists.

The people of the Pak Tai region of the peninsula speak a dialect that has a different intonation from that of the central Thai. The extreme south is inhabited by Malay-speaking Thai, the majority of whom are Muslim. The southern economy depends on exports of tin and rubber. Fishing provides income for the people living close to the seas on both sides of the peninsula. Phuket and Songkhla are well-known for their fine beaches, which are lined with beautiful coconut groves.

The west and southwest, consisting mostly of hilly to mountainous terrain adjoining the Myanmar border, is sparsely populated. The forest covers are chiefly mixed deciduous and bamboo. The soils are rich with minerals, such as tin, tungsten (wolfram), and fluorite. The Karen from Myanmar often migrate and live within the Thai border. They clear the land and cultivate the hill slopes in the same manner as the mountain Thai in northern Thailand. The region is also the chief supplier of the bamboo used in the curing of rubber.

Hill settlements depend much on shifting cultivation of upland crops. Such mountain Thai as the Karen, Meo, Yao, Lahu, Lisu, and the lowland Thai who have migrated usually settle on the ridges and the slopes in groups ranging from two or three to 100 or more houses, depending on the resources of the area. The Meo are opium cultivators, preferring to live on high slopes where opium grows well in the cool climate. The Karen live along the stream valleys and grow rice on well-tended, terraced fields. The Thai who have migrated earn a living from their tea and coffee plantations.

ral and
an
ailand

No true plains villages exist in Thailand, although in the northeast the villages are scattered on the higher grounds to escape the floods; the lower grounds are used for rice farming. In the north, where the villages are found on the alluvial basins of major rivers, increased population and transportation have tended to disperse the villages away from the river toward the main railroads and highways, reducing the amount of rice-growing land.

The delta is densely settled, but only on the high ground that is free from flooding. The irrigation canals modify the pattern of settlement; with increasing facility in transportation offered by small motorboats, the villages tend to become dispersed away from the rivers in an east–west direction. New highways also tend to modify the pattern of settlement, especially at the crossings of canals and rivers by highways, where new towns grow up rapidly.

The southern and southeastern plantations, especially the fruit and rubber plantations, are scattered along the fertile slopes, alternating with the low and narrow rice fields, and the villages are therefore arranged accordingly. Most of them are joined by good roads and highways. Alluvial deposits containing tin, no matter how isolated, are accessible to all kinds of land and sea communications. Settlement is almost continuous along both sides of the peninsula. Most of the people live by fishing, except in areas in which bird's-nest collecting (the jelly-like adhesive of which is the basis of a popular soup or sweet dessert) brings a good income. The coastal villages are connected both by land and sea highways.

Urban settlement in Thailand is found mostly on the plains and in the coastal areas rather than on the hills. Bangkok, for example, grew from a small settlement on the east bank of the Chao Phraya. In other large towns, such as Chiang Mai, the old, square city walls are still apparent, with numerous Buddhist temples scattered inside and outside the walls. Thus, urbanization in Thailand can be said to centre around the original sites of the palaces and the temples. Other interesting patterns of settlement can be observed in certain urbanized areas. Phitsanulok, for example, has a number of floating houses along both banks of the rivers. Chon Buri, a seaside town, has a trellis pattern of houses on islands that are accessible by footbridges. Such patterns of settlement reflect the strong demand for living space in the urban areas.

THE PEOPLE

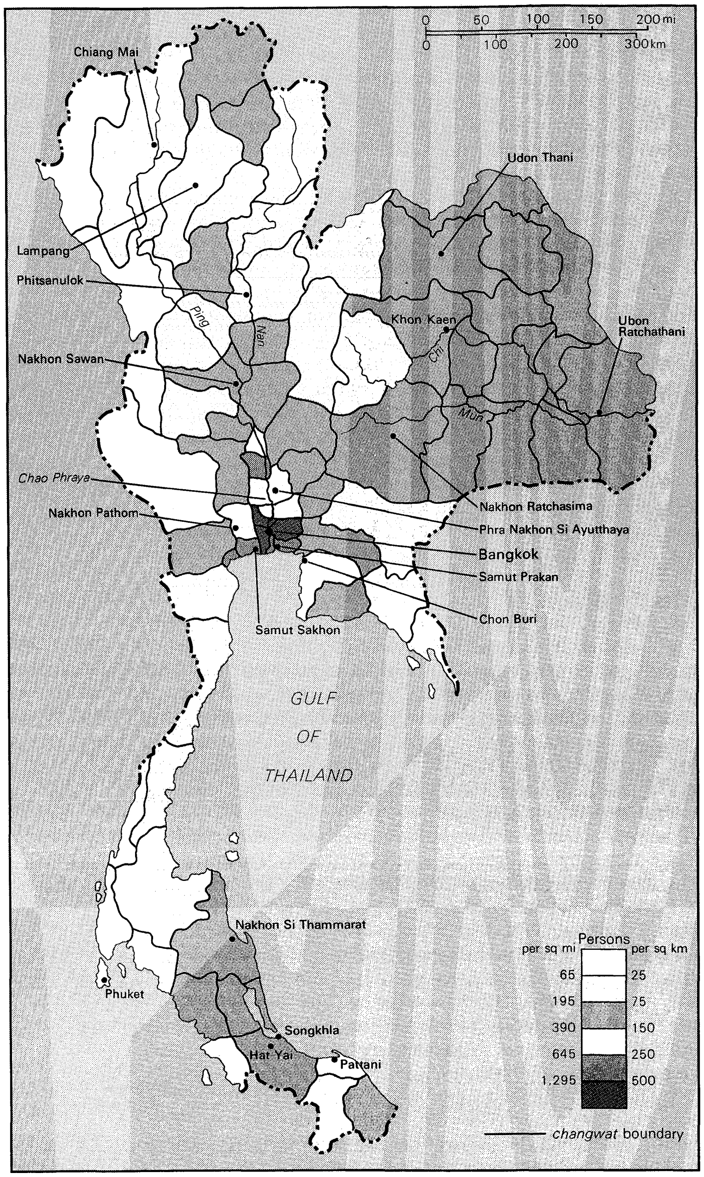
The diversity of ethnic, linguistic, and religious groups in Thailand is characteristic of most nations of Southeast Asia, where shifting political boundaries have done little to impede the centuries-long migrations of people.

Geographical
dispersion
of Thai
peoples

Ethnic distribution. Thai people are found not only in Thailand but also in Laos, Myanmar, India, Vietnam, and southern China. These Thai speak the Thai language, but with different accents and a few different words. Little difference exists between the Thai in Laos, Myanmar, China, and northern Thailand, but there is a noticeable difference between them and the Thai living in the central plain and close to Cambodia. The peninsular Thai are much influenced by the Malay.

Wars between Thailand and Myanmar in the past brought many refugees and prisoners of war into Thailand. The Mon, a Myanmar people, settled in many parts of the north, the centre, and the west; their distinctiveness is evident in their festivals and religious rites. Even the original Thai are not completely free from ethnic intermixture, and the ethnic origin of the modern Thai is even more complex when the Chinese and the Indian descendants are considered. Bangkok is the chief melting pot of the Thai race. Tracing true Thai blood in Bangkok should not be attempted, as a famous Thai scholar (himself of Chinese descent) has said, for what makes the Thai is the institution.

Except the Karen, who mixed rather easily with the northern Thai, the hill tribes, or the mountain Thai, prefer to keep themselves isolated. They occasionally come



Population density of Thailand.

By courtesy of the Royal Thai Survey Department

down to the markets to trade with the lowlanders. They are probably of purer stock than the modern Thai. Two small hill tribes are of special interest, the Lawa and the Semang. The Lawa are believed by some historians to be the original dwellers of the delta plain, driven into the hills of the northwest by the Thai who conquered the area. The Semang of the southern mountains live by hunting with blowpipes and spears. Another ethnic group that often escapes attention is that of the Chao Nam, or sea dwellers. Rarely settling permanently, they live by fishing along the western coast and the adjacent islands of the peninsula.

The mix of tongues and faiths

The Thai, who live in almost all areas, comprise the majority linguistic group. The greatest concentration is in the Chao Phraya Delta. Myanmar, Laotian, and Cambodian influences already have been noted. The people of Tak and Kanchanaburi, near the southwestern Myanmar border, speak Karen and Mon. From Chumphon to the south, the Thai speak a southern dialect. Most of the Thai have been in contact with one another, especially administrative officials and teachers, and the Thai living in remote areas can understand the central Thai.

Chinese is the second major language. In the commercial centres of Bangkok and other cities, Chinese or their descendants operate both large and small commercial enterprises. Those of Chinese descent also make a living as middlemen and storekeepers. Most of them speak Chinese, as do some of the northern hill tribes, such as the Meo and Ho.

Although no reliable statistics exist, English-speaking Thai probably make up the third major linguistic group. English is a required subject in secondary schools and the university, and frequent contact with American military personnel also encourages the speaking of English. The prevalence of various Indian dialects reflects the large number of Indian merchants and their descendants in the commercial centres. Other linguistic groups are found among the mountain Thai. Some of them can speak Chinese, although most of them understand the northern Thai dialect.

Brahmin religious influence

Religion. The religious groups in Thailand, in order of size, are the Buddhists, the Muslims, the Confucians, the Christians, and the Sikhs. Buddhism, professed by the vast majority of the population, is considered the national religion, and Buddhists are scattered throughout the nation. Muslims live mostly in the south, whereas about one-half of the Christians live in the central region. Hindus and the Sikhs are concentrated in the central region, chiefly around Bangkok. Although several of the hill tribes have converted to Buddhism or Christianity, most remain animists. An interesting religious group in Thailand, although totalling only a few thousand families, exerts much influence on the Thai religious life. These are the Brahmins. The royal and the official ceremonies are almost always directed or performed by the Brahmins, whose rites are blended harmoniously with those of the Buddhists. Brahmins are famous for their astrological experiences. The plowing ceremony, carried out in the presence of the king and queen by Brahmins and other officials, is believed to bring a good rice harvest. The Brahmins and the royal astrologers are also responsible for the preparation of the national calendar.

THE ECONOMY

Thailand's economy is still based on the production of basic agricultural, mineral, forest, and other raw materials. The Thai unit of currency is the baht.

Resources. There are numerous tin mines, most of them in the peninsula, making Thailand the world's third-largest producer of tin. Construction of a smelter has made possible domestic smelting of most of the ore. Iron-ore production has risen. Other important mining and quarrying operations produce gypsum, fluorite, tungsten, limestone, and marble.

Primary and fabricated products

Agriculture, forestry, and fisheries. Growing demands have encouraged a stronger and more diversified Thai agriculture. Rice is likely to remain as the major crop, unless radical dietary changes occur in Asia. Sweet corn, cassava, and plants yielding fibres are other major crops. Fine breeds of cattle and pigs have been introduced from the West. Hardwoods, such as teak and yang (a source of gurjun balsam), are major forest products; rubber trees—introduced into the country during the 19th century—are important. Fishery includes both marine species and freshwater fish caught in the rivers or in cultivation ponds.

Industry. So far, manufacturing does not play a large part in Thailand's economy. Most industries are involved in processing agricultural, forest, and mineral products. The main centre for large industry is the Bangkok-Thonburi metropolis, while numerous cottage industries in the north produce textiles teak, carvings, lacquer ware, and similar products. In the southeast, in addition to food processing, oil refining and gem cutting are carried on.

Thailand has several hydroelectric plants, but most electrical power is produced by generating plants using gas and solid fuels, such as lignite, which is mined in Thailand. Small amounts of petroleum are produced domestically, and the government has granted concessions for offshore explorations in the Gulf of Thailand.

Finance. The Bank of Thailand, established in 1942, issues currency, acts as central banker to the government and to the commercial banks, and serves as fiscal agent in dealing with international monetary organizations. Nearly one-half of the nation's retailing and other distribution businesses are located in Bangkok-Thonburi. Middlemen handle most farm commodities. Retail stores are small, except in Bangkok, which has several large department and cut-rate stores. In these, as well as in most food markets, prices are fixed; bargaining occurs mostly in the souvenir and gift shops of larger cities.

Trade. With agricultural and raw materials the basic exports, manufactured goods, such as machinery and transportation equipment, account for the highest value among imports. Thailand's major trading partner, both for exports and imports, is Japan; most other exports are sent to other Asian nations, whereas most other imports are from Europe and the United States.

overn-
ient and
conomic
anning

Administration of the economy. Aiming at diversification, the government has supported a greater number of small industries. To encourage exports, duties are low, except on rice, to which a premium is attached to prevent domestic shortages.

Unions are prohibited and strikes are not allowed unless management representatives fail to agree with employees and Labour Department mediators.

Transportation. Bangkok is the centre of Thailand's water, land, and air transport. The rivers of the delta have been used for transport since antiquity, and modern irrigation canals have added to the inland-waterway mileage. Because of the rains, it is difficult to keep some highways open all year, especially in the peninsula. Mountain trails are often the only means of travel in remote areas. Where roads are inadequate, airplane and helicopter services often compensate. Rail lines radiate from Bangkok in several directions, one linking up with the Cambodian rail system.

The port of Bangkok, at Khlong Toei, is the largest and busiest of the 22 in the kingdom, handling nearly all imports and exports. Don Muang Airport, north of Bangkok, is served by many international airlines, including Thai Airways International, a state-owned line. More than 20 smaller airports are located throughout the country.

ADMINISTRATIVE AND SOCIAL CONDITIONS

Government. Following the revolution of 1932, a provisional constitution was promulgated, stating that supreme power lay in the hands of the people. The monarch, the National Assembly, the Commissariat of the People (later, the State Council), and the law courts were to exercise power on their behalf. Since then, several constitutions have been created because of changes of government, but the provisions are similar.

onstitu-
onal
amework
d legal
stem

Under the present constitution, the king is head of state and of the armed forces. He is held to be sacred and inviolable, and in the name of the people he exercises legislative power, with the advice and consent of the Assembly. He also appoints the prime minister. Executive powers are vested in a Council of Ministers, judicial powers in the courts; both operate in the name of the king. The royal family is very much at the core of modern Thai society, being regarded as the symbol of national unity and the protector of national welfare and traditions.

In form, the Thai government resembles those of Western nations; various ministries are responsible for such matters as finances, agriculture, education, public health, communications, and justice.

The province, or *changwat,* of which there are 70, is the major unit of local government. Beneath these are districts, subdistricts, and communes and villages. The 120 municipalities in the kingdom are classified as cities, towns, or communes, according to their populations; they are run by an elected mayor and councillors.

Justice. Thai law has been influenced by the Hindu code of Manu, which probably was transmitted through the ancient Mon kingdom of central Thailand. Reform in the late 19th century introduced concepts of Western jurisprudence. All judges in the country's 110 courts are professionals, appointed without political consideration; they are bolstered by a system of judge trainees.

Armed forces. Under the king as commander in chief, the army, navy, and air forces are assisted by the Military Assistance Program, and by the Southeast Asia Treaty Organization (SEATO), of which Thailand is a member. Thai soldiers have fought in Korea and Vietnam, but lately they have been fully occupied in containing Communist infiltration from neighbouring countries.

Education. Children under 15 are required to complete seven years of elementary education. Secondary education generally lasts five years, but when it is vocational it lasts six. Only a small minority of students go on to secondary training, however. Ramkhamhaeng University is one of Thailand's newest universities. Eight other institutions, not including military academies, offer degrees in undergraduate and postgraduate fields.

Health and welfare. Thailand's health and welfare services remain far from adequate. The emigration of potential medical practitioners to more lucrative practices in the West has tended to undermine governmental attempts to upgrade services within the country. Mobile medical centres and helicopters attempt to alleviate the lack of widespread facilities. The doctor–patient ratio is quite low, and medical practice on the midwife level is common. Infant mortality and diseases of childbirth are leading causes of death, whereas malaria has been widely reduced through the use of DDT, which has hastened the devastation of forest areas as a side effect.

Only Bangkok-Thonburi and a few other large municipalities have housing shortages. The construction of government-financed housing cannot keep pace with demand, and slum areas have proliferated in some parts of the city.

CULTURAL LIFE

According to many historians, the Thai's original home was in China, perhaps as far north as Mongolia. The Thai brought with them many cultural institutions of the Chinese. They began settlement in the Indochinese Peninsula about 800 years ago, at which time some Indian colonies already were established. Indian culture has been continuously absorbed into Thai life. Modifications were affected by the cultures of the Mon people, the Javanese, and the Khmer and Burman people.

Traditional
arts and
customs

Thai arts are reflected in religion, architecture, porcelain and pottery, painting, music, drama, and literature. In religion artistic expression can be found in the sculpture of Buddha images. Thai architectural style is to be seen in the temples. Wood is usually the basic construction material. The ornamental parts are generally gilded and enriched with glass mosaic, gold leaf, porcelain, stucco, lacquer, and inlaid mother-of-pearl. The multiple-structured temple ground is a paradise for architects. Porcelain and pottery, although at first put to utilitarian uses, were later regarded as objects of art. Thai painting probably derived from India and Ceylon and is mostly religious; the artists are anonymous monks or dedicated laymen. The paintings are usually drawn on the temple walls, which are constructed with bricks and plaster.

Thai music is based on a unique system. It is not derived from the Chinese or Javanese systems, although the instruments used for playing may look the same.

The royal palace plays an important role in leading and preserving Thai culture through frequent royal functions and state ceremonies. Among these is the Kathin ceremony, a colourful pageant marking the end of the Buddhist Lent. It takes place with a procession of royal barges on the Chao Phraya, reconstructing a tradition dating from the earliest days of Buddhism. Thai temples hold ceremonies to mark the special events of the Buddha's life. These are often accompanied by fun fairs to attract large crowds to the temples.

The University of Fine Arts teaches all Thai fine arts, including drama and music. The university also designs architectural structures for the government as well as the religious institutions in a style that will preserve Thai forms. The Royal Institute of Thailand and the Siam Society are responsible for research and publication concerning the Thai way of life. The National Museum acts as an educational and information centre for the evolution of culture in the country.

The first type for printing Thai letters was devised by a British captain in 1828, and the first printing press was brought to Thailand by an American missionary in 1836. The Thai government made use of the printing press for the first time in 1839, when a royal proclamation banning opium smoking and trade was printed. (P.P.A.)

For statistical data on the land and people of Thailand, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL.

History

The present state of Thailand was officially known as Siam before 1939 and from 1945 to 1949.

The Thai peoples emerged out of historical obscurity about a thousand years ago when they began moving southward and westward from the China landmass to the northern parts of the Indochinese Peninsula. They moved into lands, from Assam in the west to northern Vietnam in the east, where most of the indigenous peoples were already under the influence of Indian culture.

EARLY THAI CULTURE

General characteristics

The Thai culture before this time cannot be precisely delineated, since there are no documents describing it. It was once assumed that the Thai peoples were the founders and rulers of the kingdom of Nanchao, an independent state that flourished from the 8th to the 13th century in Yunnan Province of China, but later studies have indicated that the rulers of this state were not Thai. The culture of the Thai, then, can be inferred only on the basis of elements that continue to exist among most peoples speaking Tai languages today. The Thai language itself, in various dialects, is spoken by a wide variety of people living today in Myanmar, Thailand, Laos, Vietnam, and southern China. The Thai are people of the lowlands; their homes are in river valleys, and their economy is dependent on river waters. They are subsistence farmers whose principal crop is rice. In the rice fields, their technology includes the use of the plow and the harrow for breaking the land and the hand sickle for harvest. Individual landholdings are typical, but cooperative efforts to build dikes or to harvest fields are common. Animals are domesticated, including the water buffalo and ox for labour and the pig and fowl for food.

Family relationships are important among the Thai, but they have no concept of the extended family or clan and no caste system. Women occupy a high position; they may inherit property, and widows are free to remarry.

The earliest Thai religious beliefs were animistic. Spirits were thought to inhabit various natural sites—large trees, high rocks or mounds, the living quarters of families, and the rice kernel, the habitat of the rice goddess. Other spirits were the ghosts of the dead. Spirits could be benevolent or malevolent; offerings were made to them and ceremonies performed to ensure their favour.

When the Thai settlers in Southeast Asia began to emerge into history, they possessed sufficient social cohesion and political order to establish a number of petty principalities. Thai chronicles, although written long after the events they describe, point to the emergence by the 13th century of several small Thai states in what is now northern Myanmar, Yunnan Province of China, and Assam in India, as well as in Thailand. In the 13th century several of these states rose to prominence, thanks partly to the rise of the Mongols, who sent armies to defeat Myanmar, Vietnam, and Champa but accepted Thai vassal status, and partly to the weakened condition of the Indianized states that had long been powerful in the area.

Mons and Khmers

In the centre of the Indochinese Peninsula two peoples, the Mons and the Khmers, bore the impress of the culture of India in religion, government, the arts, and literature. The Mons, in southern Myanmar and central Thailand, and the Khmers, in the Mekong Valley, had created distinctive and vigorous cultures and powerful political states. By the 13th century, the Mons had suffered from the depredations of the stronger Khmers, retaining political independence only in a relatively small state, Haripunjaya, in what is now northern Thailand. Mon culture, however, continued to be strong throughout central and northern Thailand. Particularly noteworthy was the devotion of the Mon peoples to Theravāda Buddhism. The Khmers, after an extraordinary burst of military and cultural expansionism under King Jayavarman VII (reigned 1181–*c.* 1219), began to decline in political power. The times were propitious for the emergence of the Thai.

SUKHOTHAI AND CHIANG MAI

Two principal Thai states emerged during the 13th century in the area that is now Thailand: Sukhothai in the Central Plain and Chiang Mai in the north. Sukhothai was founded around 1220 after a Thai revolt against Khmer rule at an outpost of the Khmer empire. Chiang Mai was founded by King Mangrai (reigned 1296–1317) in 1296, shortly after the Thai defeat of the Mon state of Haripunjaya.

From the outset, both Thai states showed that the Thai had already absorbed many elements of the cultures of the peoples around them. There are, in fact, reasons to assume that the political emergence of the Thai did not represent any drastic change in the ethnic character of Thailand. It seems likely that the Thai, who for centuries had been filtering into the area, at the time of their rise were a minority of the population but were able to rise to dominance because of superior organizational ability and military prowess. The subsequent expansion of the Thai may reflect their ability to retain social supremacy and to absorb large numbers of non-Thai peoples.

Among the cultural borrowings of the Thai, one of the most profound and important was their acceptance, from the Mon, of Theravāda Buddhism. Thai animistic beliefs did not disappear—they persist even today—but to them were added the humanistic and philosophic concepts of a popular and egalitarian world religion.

Sukhothai under King Ramkhamhaeng

Sukhothai, regarded by the Thai today as their first historical kingdom, achieved a considerable expansion by the end of the 13th century. Little is known of Sukhothai during its first two reigns, but its third king, Ramkhamhaeng (reigned 1279?–?1317), has left a remarkable stone inscription that is the earliest example of writing in the Thai language. The Ramkhamhaeng inscription, dated 1292, pictures the Thai state as rich and prosperous, active in trade, and benevolently governed by a paternal monarch. According to the inscription, the state taxed its citizens modestly; treated all citizens, including non-Thai, alike; and provided justice for all. And "all its citizenry, all chiefs and nobles, everyone everywhere, all men and women, all groups, believe in Buddhism." The kingdom is described as extensive, covering much of central Thailand down to Nakhon Si Thammarat on the peninsula, but excluding the plain of the Chao Phraya River below Nakhon Sawan, a region once dominated by the Khmer but apparently during Ramkhamhaeng's reign governed as an independent state called Lavo.

Allowing for some royal exaggeration of the virtues of the state, much of Ramkhamhaeng's description rings true. It seems clear that the Thai rulers of Sukhothai were proud of the differences between their social order and that of their Khmer predecessors and adversaries. The emphasis on their human and humane king, on their low tax burden, on their popular Buddhist faith was undoubtedly meant to point out the contrast with the very different "god-king" status of the Khmer monarch, the heavy exactions in taxes and labour of the Khmer state, and the high cost and remoteness of the aristocratically oriented Khmer Hindu cults.

Although much of Sukhothai "high" culture was a result of cultural borrowing—Buddhism from the Mon, the system of writing from the Cambodians, artistic techniques and styles from various sources—many of these cultural borrowings were transmuted into Thai forms. Particularly outstanding were Thai bronze sculptures of the Buddha that were cast with great skill in distinctive and original forms. Thai ceramics, inspired apparently by Chinese Sung ware, were produced in great quantity at kilns in Sawankhalok. The high quality of these ceramics made them prized in trade.

King Ramkhamhaeng combined the abilities of effective ruler, warrior, and patron of Buddhism and the arts. His successors did not have his range. His son, Loe Thai (reigned 1317?–?47), the fourth king of the dynasty, poured his energies into religion, and a weakening of the state was the eventual outcome. Sukhothai apparently regained some power under King Lu Thai (reigned 1347?–74), but it fell under the domination of a new Thai state to the south in 1378.

THE AYUTTHAYA PERIOD (1350–1767)

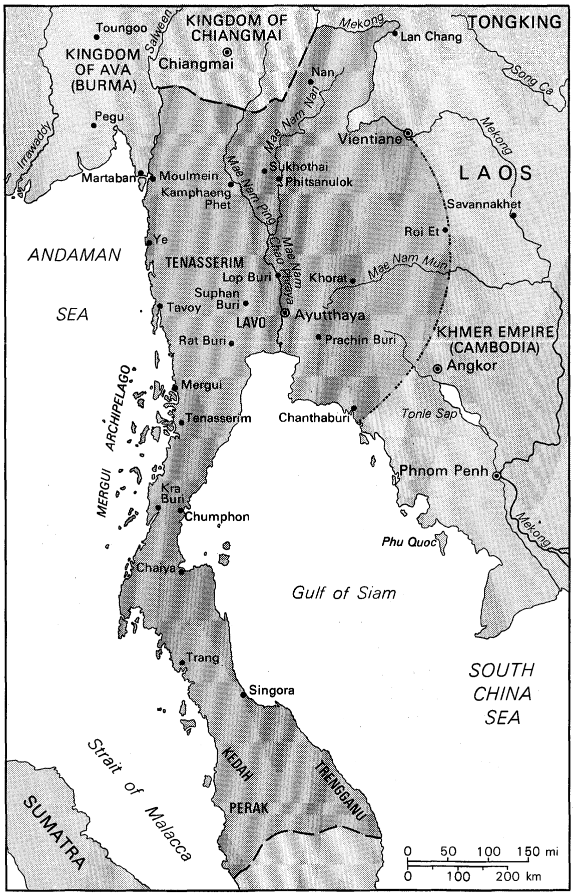
The successor state to Sukhothai was the Thai kingdom of Ayutthaya that had emerged around 1350. According to tradition, Ayutthaya's first king, Ramathibodi I, inherited the states of Lavo and U Thong (their capitals correspond to the towns of Lop Buri and Suphan Buri in Thailand today) and combined them into a single strong kingdom. Ayutthaya was located in the centre of the rich rice plains of the Chao Phraya Basin, a region strongly subject to the influences of the Khmer, the Mon, and the Burmese. From the outset it appears to have competed successfully for power with Sukhothai and with the Khmer. By the early 15th century it had absorbed Sukhothai and devastated the eroding Cambodian kingdom.

During the first century after the foundation of Ayutthaya, many changes reflecting the influence of Cambodia occurred in Thai society, particularly on the upper levels. Under King Trailok (reigned 1448–88) further changes were made and former changes were codified; the character of the Thai state was permanently transformed.

yut-
hayan
overn-
ment

The most significant of the changes concerned the nature and organization of government. The self-image of Sukhothai kings had been that of a father bringing riches, justice, and the benefits of Buddhism to his people. In Ayutthaya these ideals were expanded and overlaid with the Khmer view of the ruler as god-king. Court ceremonials and court Brahmins were introduced to bring to kingship the magical attributes of divine intermediary. The court calendar swelled with ceremonies for the manipulation of cosmic forces to promote the success and prosperity of the state. (These ceremonies are described in a voluminous [718-page] 19th-century work in Thai by King Chulalongkorn, "The Royal Ceremonies of the Twelve Months.") In a practical way, new techniques for centralizing power, including a bureaucratic system of government, were introduced. Members of royalty who had been serving as provincial officials were replaced by appointed nobles. A hierarchy of princes and nobles was established whereby the relative status of each was formalized. A system of patrons and clients extended throughout the population so that, theoretically, every man fulfilled obligations—in loyalty and goods and services—to someone above him and received, in return, protection from a patron. Commoners paid their military service, compulsory labour services, and taxes to local masters who, in turn, were subject to higher masters above them. The apex of the pyramid of patronage was the king himself.

From *Atlas of South-East Asia*



Ayutthaya kingdom *c.* 1400.

The formal hierarchical system awarded each man *sakdi na,* or "dignity marks," in which the position of each man was equated with an acreage of land. Ordinary freemen were actually allowed to take possession of twenty-five *rai* of land, equal to about ten acres, to represent their *sakdi na.* The rank of officials of the government and members of the royal family was also expressed in the acreage terms of *sakdi na;* the acreage indicated could number in the hundreds or thousands. But for nobles and princes the term stood for power and position, for "dignity," and not for actual landed estates. High royal and noble officials were, in fact, required to live and work in the capital.

Many of the principles of government were enacted into codes of law, and a large body of law is reputed to date back to the reign of King Ramathibodi I. The basis of law was Hindu, and the codes were probably transmitted to the Thai from Mon sources. These codes were expanded a century later. They included laws on evidence, on slavery, on robbery, on divorce. A Palace Law spelled out the duties of members of the royal family, rules of succession, and court procedures. The institution of the rank of *uparat* also dates back to the mid-15th century. Often inappropriately termed "Second King" by Western visitors to Thailand, this rank was Indian in origin and was, in fact, the highest princely rank awarded to a member of the royal family. The *uparat* functioned as general of the armies and had some claim to being the heir apparent.

By and large, in the context of the times and in comparison with neighbouring states, Thailand in Ayutthaya was a strong and well-governed state. There were, however, periodic internal disorders, products, it would seem, of contests for power between and within the royal and noble elites. In order to retain power a king had to preserve a balance of strength between princes and nobles. The prime ingredient for power was population, for land was plentiful and people were scarce. If a king allowed too many clients to fall under the control of his relatives, the princes, or even of his own bureaucratic officials, the nobles, political conflict would likely ensue. Many such conflicts are recorded—one of the bloodiest resulting from the usurpation of the throne by a high noble early in the 17th century. This noble, whose position was essentially that of minister of the Southern Provinces, paved his way to the throne by putting two kings to death, and after his accession as King Prasatthong, some 3,000 persons, members of the former ruling dynasty and other potential rivals, were executed. One prince who had followed the established practice of seeking sanctuary by becoming a Buddhist monk was first lured out of his monastery and then put to death.

Ayutthayan society and culture

The mass of the people in Ayutthayan times, the peasant farmers, were divided into two main classes: freemen and slaves. Freemen had the right to till an area of land equivalent to ten acres. The obligations of the freemen to government in taxes and labour were paid to local patron-officials. This link was all-important. The way to improve one's status was to gain special favour through a patron or, if he were unable to help, to find a new patron who might give special favour. Exactions on freemen, it would seem, were seldom excessive. The fact of underpopulation meant that freemen could escape onerous obligations or an overly demanding patron by moving and clearing new land; the existence of numerous decrees against this practice testifies to its existence and prevalence. Another "escape" for freemen was slavery. There were many so-called slaves in Ayutthayan times; the term slave, however, is misleading—the great majority of slaves could better be called bondsmen, for the "slave" was usually also a peasant-farmer who could own land and could redeem his status by repayment of his debt.

Theravāda Buddhism in Ayutthayan times continued to supply an element of social cohesion in the Thai state. From king to peasant, all Thai regarded themselves as Buddhists despite the introduction of court Brahmanism on the top levels of society and the continued persistence of animism on all levels. Buddhism, indeed, was thoroughly acculturated in Ayutthayan times. On the popular level, Buddhist amulets and reliance on monks with magic power interpenetrated the more sublime ideas of the doctrine. At court, one king, Trailok, in 1458 cast 500 images of the Buddha in order to prevent repetition of the great famine that had occurred in 1457. The Buddhist monastic establishment itself played an important social role, providing moral and practical education for boys and giving young men who spent some time as monks the opportunity to "gain merit" for themselves and their parents. For men who chose to remain monks, the monastic order constituted a society parallel to secular society that allowed for considerable social advancement.

In its relationships with outside states, Ayutthayan Thailand was comparatively strong. Warfare was endemic, and the sway, or empire, of Ayutthaya fluctuated considerably during its 400-year history. But Thai dominance of the central Chao Phraya Plain remained unchallenged. Most of the wars were petty campaigns during the dry season, when the terrain permitted the movement of men and the agricultural cycle made their absence from the fields possible. Most of the wars were contests for sovereignty over border principalities. Some were essentially raids to acquire population—*i.e.,* agricultural manpower and skilled artisans—and transportable wealth.

Ayutthaya's emergence in the 14th century in an area once ruled by Cambodia brought on a series of wars with Cambodia. By the early 15th century Ayutthaya had reduced Cambodia to vassal status, and, although Cambodia was frequently able to throw off its dependency, the balance of power between the two states thereafter continued to favour the Thai. Ayutthayan dominance over Sukhothai, achieved early in the 15th century, brought the kingdom into confrontation with the northern Thai states of Chiang Mai and Laos. During the reign of King Trailok these wars reached a peak of intensity, and Ayutthaya went to war with Chiang Mai seven times. In order to improve his military position with respect to Chiang Mai, King Trailok in 1463 moved his capital to the northern town of Phitsanulok, where it remained throughout the rest of the reign. Ayutthaya was unable to retain power over Chiang Mai, and Chiang Mai had periods of independence and periods of dependency on Myanmar throughout the Ayutthayan period; it was not until the late 18th century that Thailand finally succeeded in gaining permanent control over Chiang Mai.

Ayutthayan–Myanmar rivalry

The most powerful rival of the Thai in the Indochinese Peninsula was Myanmar. On two occasions when the ethnically diverse area of Myanmar was welded together into a political whole, Myanmar imperial expansion extended into Thailand. One series of campaigns started around 1549. In the first engagement of this series, according to the Thai chronicles, the Thai king Maha Chakkraphat (reigned 1548–69) found himself in difficulties and was rescued by his wife, Queen Suriyothai, who lost her life in the incident. The campaigns ended in 1569 in a Thai defeat, and the country was overrun by Myanmar forces. Myanmar troops were garrisoned in Thailand, and the Myanmar placed on the throne a Thai king who accepted their suzerainty. Thailand remained a Myanmar vassal-state for 15 years. In 1584–87, a Thai prince, Naresuan, since regarded by the Thai as a national hero, led a successful revolt against Myanmar and reestablished Thailand's independence. In another period of Myanmar unity and expansionism in the 18th century, they succeeded again in 1767 in capturing the Thai capital at Ayutthaya. The Myanmar armies did not remain for long; they withdrew after sacking the Thai capital and thus ending the Ayutthaya period of Thai history.

Ayutthaya's relations with most other Asian states were limited to trade and the exchange of occasional embassies. The pursuit of friendly relations with China, started in Sukhothai times, was carried on throughout the Ayutthayan period. These relations were typical of those existing between China and outlying states: the Thai acknowledged the "elder brother" position of China and sent tributary missions triennially to the Chinese court. This formal suzerain–vassal relationship had little political significance but was willingly maintained by the Thai for the very real benefits it brought in the way of trade. Thailand, as a registered vassal, was permitted to send ships to China to purchase silks, pottery, and other luxury goods that were much in demand among the Thai upper classes. Thai trading vessels, and Chinese ships emanating from Thai ports, also conducted a lively trade in such commercial centres as Malacca, Vietnam, Java, and India.

Relations of a different sort were maintained with Ceylon; they were religious contacts. Some of the principal religious leaders in Sukhothai had come from Ceylon. Ceylon was looked to in Sukhothai and Ayutthayan times as the font of Theravāda Buddhist knowledge, and several religious missions were sent to Ceylon to obtain religious instruction, religious texts, and religious relics. During the 18th century, Buddhism in Ceylon underwent a serious decline, and a reversal in the religious relationship occurred. Ceylon then turned to Thailand for aid in purifying its ordination and other religious practices. One Thai mission that went to Ceylon in 1753 stayed for three years and performed some 700 ordinations for monks and 3,000 for novices. The Thai missions of this period established a Thai school of Buddhism in Ceylon, called Syāmvaṃsa, that still exists.

European contacts

In long-range terms the most significant foreign contacts of Thailand—and the rest of Asia—were those with Europeans, who began arriving in the 16th century. By any standard, however, the European impact on Thai society in Ayutthayan times was slight. Portuguese diplomats, traders, and missionaries began arriving at the court of Ayutthaya shortly after the Portuguese capture of Malacca in the Malay Peninsula in 1511. Portuguese trade and missionary activities never became very important; the largest group of Portuguese in Thailand were adventurers who assumed roles as mercenaries in the Thai armies and who introduced some Western military techniques to Thai warfare. In the 17th century the Dutch and English began to arrive and to establish trading centres near the capital and in peninsular Thailand. The growth of Dutch trading interests throughout Eastern Asia was reflected in the emergence of the Dutch as the leading Western traders in Thailand. By 1664 the Dutch, by threatening the use of force, had obtained a treaty giving them monopolies over certain portions of Thailand's external trade. The Thai, seeking to offset Dutch power, welcomed the arrival of French missionaries in the 1660s, and in 1684 initiated a series of diplomatic exchanges between the courts of Ayutthaya and Versailles. The principal French spokesmen for promoting expansion of French interests in Thailand were clerics who, misunderstanding the characteristic Thai attitude of religious toleration, became convinced that the Thai king Narai (reigned 1657–88) could be converted to Catholicism. The arrival in 1687 of a large French mission that included some 600 soldiers aroused Thai fears, and in 1688 a coup by anti-Western Thai leaders led to the expulsion of the French and the beheading of their chief advocate at the Thai court, Constantine Phaulkon, a colourful Greek adventurer who had become a Thai noble and a leading counsellor of the king. The Thai coup of 1688 inaugurated a new Thai policy of minimizing contacts with Westerners—a policy that was to continue for 150 years.

THE THON BURI AND EARLY BANGKOK PERIODS (1767–1868)

The Ayutthayan Period in Thai history came to an end as a result of the successful Myanmar invasion of 1767. A new period began with the rise of a provincial noble, Phraya Taksin, who succeeded in ousting the Myanmar and eliminating Thai rivals to political power. Taksin established a new capital for the kingdom at Thon Buri, on the Chao Phraya River some 40 miles south of the ruined city of Ayutthaya. The new capital was somewhat less accessible to Myanmar armies and more accessible to foreign merchants—principally Chinese—who brought desired products and whose trade could be taxed to provide significant revenues for the government. King Taksin followed a policy of political reunification, including the reclaiming of vassal states that had broken off from Thai suzerainty at the time of the Myanmar invasion. A campaign in Cambodia led by Thailand's leading general, Chao Phraya Chakkri, was under way in 1781 when a palace coup took place in Thon Buri. Taksin, who had apparently become mad and imagined himself an incarnate Buddha, was deposed. Chakkri hastily returned to the capital, where a group of officials invited him to assume the throne. He did so in 1782, thus establishing a new dynasty, the Chakkri dynasty, that continues to head the Thai state. One of the first acts of the new king was to move the capital across the Chao Phraya River to Bangkok.

ıngs

There is much continuity in the history of Thailand from Ayutthaya to Thon Buri-Bangkok. The ethos of the state, the customs and livelihood of the people, underwent no marked change. Taksin and the first Chakkri kings were primarily engaged in a policy of restoration both internally and externally. Law codes, religious works, and literary texts were rewritten. New temples and palaces were built using the patterns, and even the very bricks, of old Ayutthaya. The first three Chakkri kings were all restorers. Rama I (reigned 1782–1809) continued the policy of military reunification and brought Cambodia and other lost territories back into vassal status. He also gathered whatever evidence survived from Ayutthaya to re-establish court rituals and to set down comprehensive law codes and authoritative texts for the Buddhist canon. Rama II (reigned 1809–24) paid much attention to arts and letters. The King himself was an outstanding poet and, together with a team of court poets, wrote definitive Thai versions of the Hindu *Rāmāyaṇa* and other classical works. Rama III (1824–51), during whose reign the British defeat of the Myanmar kingdom (1826) ended the Thai–Myanmar rivalry, was able to expand the Thai empire in the south and in the north. In the south he strengthened Thai control over vassal states in the Malay Peninsula; in the north he was able to absorb most of the territory of the Lao kingdom of Wiangchan (Vientiane) after he put down a revolt by the leader of that vassal state, Chao Anu. Rama III's armies also fought several campaigns in Cambodia against the Vietnamese, who were extending their power into Cambodian lands during the early 19th century. These campaigns ended in 1845, and negotiations that followed led to an agreement that Cambodia should be a tributary state to both Thailand and Vietnam.

Although the restoration of Ayutthayan society was a primary goal during the early Bangkok Period, there were differences between Ayutthaya and Bangkok. For one thing, restoration is conscious traditionalism, which is not quite the same as tradition itself. For another, the policy of restoration necessarily led to choices, choices that the Thai may have presumed were made on the basis of authority but in fact were often made on the basis of utility. The reform of the law code in 1805, for example, began after the king, Rama I, discovered in a contested divorce case that the law was not just. In the traditional Thai view, law is of divine origin; it is immutable, and the role of government is not to enact law but to administer it. An unjust law, then, could only be explained as a false law. The reform of 1805 was therefore seen as a work of removing falsifications, although in fact it was a work of reformation.

Some basic social changes in the early Bangkok Period seem also to have been introduced in order to prevent the recurrence of the internal weaknesses and political factionalism that had contributed to Ayutthaya's downfall. Labour-service requirements on freemen were reduced, and payment of obligations in money rather than services was encouraged. These moves can be seen as an attempt by the monarchy to focus greater strength in the royal house, to bring more of the population under the patronage of the king rather than that of the princes.

Other changes in the early Bangkok Period came from the outside and reflect general changes in the Asian scene: the growth of commerce, the great increase in Chinese migration, and the revival of European interest in eastern Asia. In the late 18th and early 19th centuries, trade, primarily with China, seems to have undergone rapid expansion, thanks in part to the growth in numbers of Chinese immigrants acting as merchants and entrepreneurs. The principal Thai export item in the early 19th century was sugar, a new industry that began because of Chinese enterprise.

Chinese immigration assumed the proportions of a flood. By the mid-19th century, approximately half of Bangkok's estimated population of 400,000 were Chinese; these newcomers greatly increased commercial activity in Thailand and came to control much of the country's internal trade.

Revival of Western interest in eastern Asia, which at the start was primarily British interest in China, brought Western traders and diplomats to "rediscover" Thailand in the early 19th century. The Westerners were politely received, and the Thai agreed to sign limited treaties (with Britain in 1826 and the United States in 1833).

King
Mongkut's
treaties
with the
West

The acceleration of Western demands for free trade and diplomatic representation in Thailand—emphasized by the British conquests in Myanmar, expansion in Malaya, and forced opening of China—led to a change in Thailand's foreign policy under King Mongkut (Rama IV; reigned 1851–68). Mongkut signed with Britain (1855), the United States (1856), France (1856), and other Western states treaties that held Thai taxation on imports and exports to a low level and permitted the establishment of foreign consulates with extraterritorial powers. They led to greatly expanded trade with the West, to development of commercial rice farming in the Central Plain, and to expansion of foreign influence.

King Mongkut is noted particularly for his realistic evaluation of Western power and his decision to treat peaceably to gain the best terms possible. Concessions in trade were followed by concessions in territory: Thailand relinquished its rights in Cambodia to the French in 1867. Western influence on internal affairs, however, was limited to the acceptance of some innovations introduced by Western missionaries, including printing and vaccination, and the hiring of some Western technicians and teachers; the latter included Anna Leonowens, whose romanticized report of Mongkut's reign became the basis of a musical comedy, *The King and I.* Perhaps more indicative of the monarch's attitude toward Western culture was his sponsorship of a reformed sect of Thai Buddhism, the Thammayut, that aimed at purification of Buddhist practice. This reform reflected the desire to make Buddhism less vulnerable to the criticisms of Western missionaries. In fact, the Thai were (and are) little attracted to Christianity.

KING CHULALONGKORN AND INTERNAL REFORM

King Mongkut was succeeded in 1868 by his 15-year-old son Chulalongkorn (Rama V; reigned 1868–1910), who, after a five-year period of regency, assumed full powers in 1873. Chulalongkorn continued his father's policy of concessions toward the West, and territory was surrendered to the French in Laos and Cambodia and to the British in Malaya. The large concession of all Lao vassal territories east of the Mekong River to France in 1893 was made with extreme reluctance, and the Thai attempted without success to enlist British support against the French. The arrival of French gunboats in the Chao Phraya River with guns trained on the palace gave the Thai little choice. In 1896 the French and British imperial powers agreed to recognize the central part of Thailand as a free neutral buffer zone.

Internal
reform

To the policy of accommodation to the West, Chulalongkorn added the first effective program of internal reform. There were enormous political difficulties in bringing these internal changes about, for many of them undercut the bases of power of influential men at court. The young King proceeded gradually and was aided by a few gifted and far-sighted leaders of "Young Siam," most notably the King's half-brother Prince Damrong. The internal reforms accomplished during Chulalongkorn's reign included the creation of a highly centralized bureaucracy, the strengthening of government revenues, the drawing of vassals and outlying dependencies into the regular provincial administration, the abolition of slavery and labour-service requirements, the end of the formalized system of patron-client relationships, the beginning of new state services such as public education, and the introduction of technical improvements such as railway and telegraph lines. The first tentative move toward internal reform, undertaken in 1873, was aimed at reducing inefficiencies in revenue collection so that a larger share of government revenues would come directly to the King. In 1892 the government was completely reorganized into ministries with functional responsibilities. The model for these reforms was the West; their purpose was to provide Thailand with the internal strength to meet the challenge of the West. This policy was successful: Thailand retained its independence, the country grew stronger, and the monarchy retained its leadership.

Chulalongkorn's policies were continued by his sons Vajiravudh (Rama VI; reigned 1910–25) and Prajadhipok (Rama VII; reigned 1925–35). King Vajiravudh opened (1917) Thailand's first university, which was named after his father; in 1921 he made primary education compulsory. Vajiravudh strengthened the Thai army and navy and created a paramilitary organization, the Wild Tiger Corps, for civil servants. In 1917 he took Thailand into World War I on the side of the Allies, and at the end of the war the Thai won Western assent to new treaties eliminating unequal provisions. King Vajiravudh's major work, however, was the promotion of Thai nationalism; he is best known in Thailand today for a great volume of literary works, much of which stresses the need for the Thai people to be united, to be committed to their nation, religion, and king.

The most notable event during the reign of King Prajadhipok was a coup d'etat that brought an end to absolute monarchy in Thailand in 1932. Prajadhipok did not have the inclination to rule that his elder brother and father had had, and he turned many affairs of state over to his royal relatives, who, believing that government expenses were excessive, embarked on a policy of economy. This policy, enlarged during the worldwide depression of the 1930s, adversely affected many government officials, civil and military, and contributed to the disaffection of younger members of the ruling elite.

THAILAND SINCE 1932

The coup of 1932

The coup d'etat of 1932 was the work of several discontented elements of the educated ruling class who acted from a variety of motives: unhappiness with Prajadhipok's retrenchment policies, with the domination of government by members of the royal family, with disappointment of personal hopes for position and power, with a monarchic institution that they considered anachronistic, and with the lack, as they saw it, of social and economic progress in Thailand. The intellectuals of the coup, led by a young lawyer, Pridi Phanomyong, made plans for a democratic regime that would enact far-reaching social and economic reforms.

On June 24, 1932, the rebels (the People's Party), without bloodshed, seized control of the army, imprisoned the royal officials, and won the King's acceptance of a constitutional regime.

The disparate elements that composed the coup party soon broke up into factions in the new government: conservative military leaders, on the one hand, and more radical civilians, on the other. When it appeared that the newly appointed parliamentary Assembly, composed of coup members, would accept a socialist economic plan presented by the civilian leader Pridi Phanomyong, the King dissolved it. Fearing that the King would regain control of the government, the military leaders forced the reconstitution of the Assembly. This was followed by an attempted royalist countercoup. By the end of 1933, the government was clearly under the control of the military leaders, and for the most part it has remained so ever since. In 1939 a declaration was issued naming the country Thailand, not Siam.

In 1939 Field Marshal Pibul Songgram became premier and embarked on a strongly nationalistic policy that was chauvinist at home, irredentist and pro-Japanese abroad. Thailand's leaders, whose policy was always to promote Thai independence, appreciated the fact that the country was small and defenseless against a big power. In the 19th and early 20th centuries, when the major power was Britain, the Thai government had been pro-British; in 1941, with Japanese armies at the Cambodian border, the Thai government saw no alternative but to become an ally of Japan.

In 1945 civilian governments headed or supported by Pridi Phanomyong came to power, favoured by the Allied Powers. Problems created by the war, corruption, and the death by gunshot in 1946 of the young king Ananda Mahidol (Rama VIII), who had succeeded Prajadhipok after his abdication in 1935, faced the government, and late in 1947 the army, sensing that Allied interest in Thai internal affairs had declined, removed the civilian government, accusing its leaders of regicide. Pibul Songgram again became premier in 1948.

Sarit as premier

During the 1950s and '60s, military dominance remained unchanged. For nine years Pibul played the role of arbiter between competing factions, but by 1957 the army faction led by Sarit Thanarat had gained predominance of power and seized control of the government. Sarit became premier in 1958, and, to emphasize his intention of ruling without interference, he abolished the constitution and dispensed with the formality of elections. After Sarit's death in 1963, his successor as commander in chief, Thanom Kittikachorn, assumed the premiership. In 1968 a new constitution was inaugurated, and in 1969 a partly elected National Assembly was reconstituted. Both constitution and assembly were suspended in late 1971.

The autocratic military-dominated regime faced mounting problems in the early 1970s. Internally, while the economy continued to expand, social and regional imbalances grew more marked; externally, American withdrawal from Vietnam stimulated criticism of a long-standing policy of reliance upon the United States. Discontent exploded in late 1973, led by an organized student protest movement. On October 14, in a clash with military units, some 100 student marchers were killed. The discredited government lost army support. King Bhumibol Adulyadej (younger brother of King Ananda and king from 1946) dismissed the government leaders, three of whom fled the country, and launched a process that led to the inauguration of an elected civilian government.

Democratic government lasted three years. During those years censorship of communications media was lifted, trade unionism was expanded, and the government attempted some programs of economic amelioration. But no national consensus emerged. Polarization of society was evidenced in a plenitude of competing political parties, protest movements, strikes, and virulent leftist and rightist propaganda.

The return of former premier Thanom late in 1976 set off new student protests and clashes and opened the way on October 6 for the military forces to suppress the students, dismiss the civilian government, and resume power. In November 1977 Supreme Commander Kriangsak Chamanand became premier, promising peace and order, internal reforms, and regularization of relations with Communist neighbours. Parliamentary elections took place in April 1979 under a constitution providing for limited democracy. (W.F.V.)

Throughout the 1970s Thailand was a haven for refugees from the rest of war-torn Southeast Asia. As a result of the Vietnamese invasion of Kampuchea in 1979, Thailand was again deluged with refugees. In response, the Thai government, along with international relief agencies, set up huge refugee camps in the areas bordering Kampuchea.

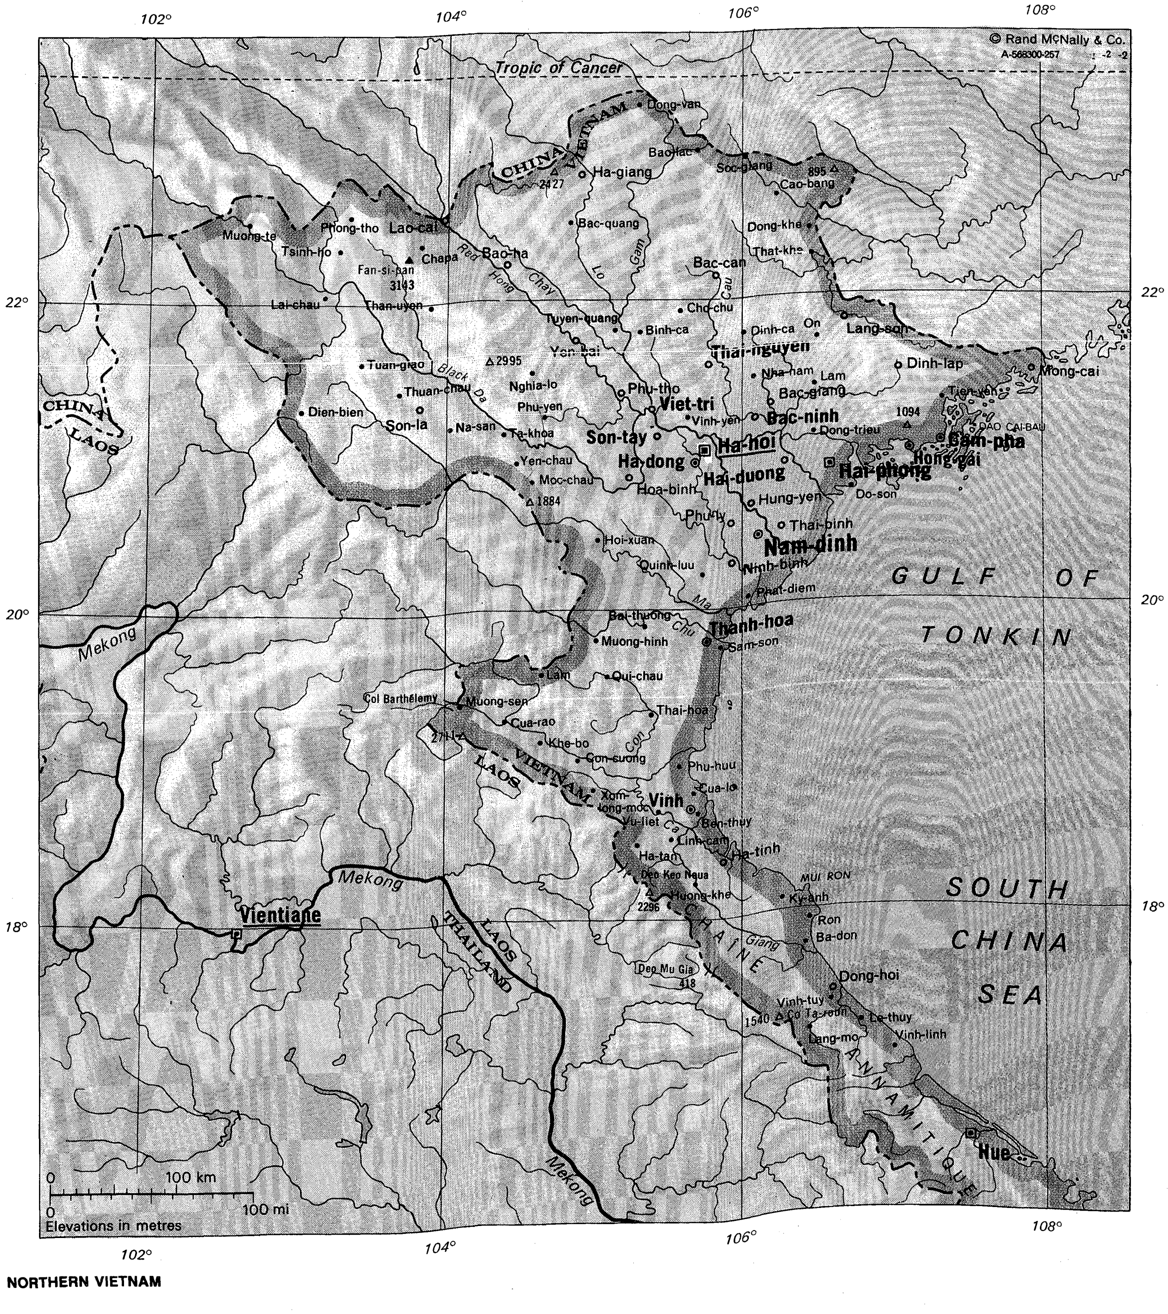
Relations with Vietnam were increasingly strained, and the situation worsened after several Vietnamese incursions into Thai territory. In 1980 the new prime minister of Thailand, Prem Tinsulanond, led the move to deny UN recognition to the Vietnamese-backed Kampuchean regime. Prem Tinsulanond, personally popular and supported by the monarchy, survived abortive coup attempts in 1981 and 1985. (Ed.)

For later developments in the history of Thailand, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL.

VIETNAM

The Socialist Republic of Vietnam (Cong Hoa Xa Hoi Chu Nghia Viet Nam) is a densely populated nation in the southeastern part of the Indochinese Peninsula. It has an area of 127,200 square miles (329,600 square kilometres). From north to south it has a length of about 1,025 miles (1,650 kilometres), and at its narrowest part it is about 30 miles wide. Vietnam is bordered by the People's Republic of China on the north, Laos and Kampuchea on the west, and the Gulf of Thailand and the South China Sea on the south and east. The capital, Hanoi, is located in the north. Ho Chi Minh City (formerly Saigon) is in the south.

On September 2, 1945, following the Japanese surrender that ended World War II, the Democratic Republic of Vietnam was proclaimed in Hanoi. The return of the French, however, precipitated the First Indochina War, which came to a close with the Geneva Accords of 1954. This agreement provided for the temporary military partition of Vietnam at the 17th parallel and promised nationwide elections in July 1956 (the elections were never held). The two political entities that emerged were the Democratic Republic of Vietnam, better known as North Vietnam, and the Republic of Vietnam, usually referred to as South Vietnam. By the late 1950s, insurgency supported by North Vietnam began to spread in South Vietnam, and it intensified considerably following the toppling of the government and the assassination of President Ngo Dinh Diem in 1963. In March 1965, U.S. Marines landed at Da Nang, marking the beginning of direct U.S. military involvement in the conflict; at about the same time, North Vietnamese troops began infiltrating the south. A cease-fire agreement signed in Paris in January 1973 technically ended the war and provided for the withdrawal of the last U.S. forces. The cease-fire was not honoured, however, and an offensive by North Vietnamese armed forces in South Vietnam early in 1975 brought about the collapse of the Saigon government on April 30. The Provisional Revolutionary Government of South Vietnam, which was created by the Communists in 1969, emerged in May 1975 as the official ruling body of the south for a year. Negotiations between delegations from the north and south



NORTHERN VIETNAM

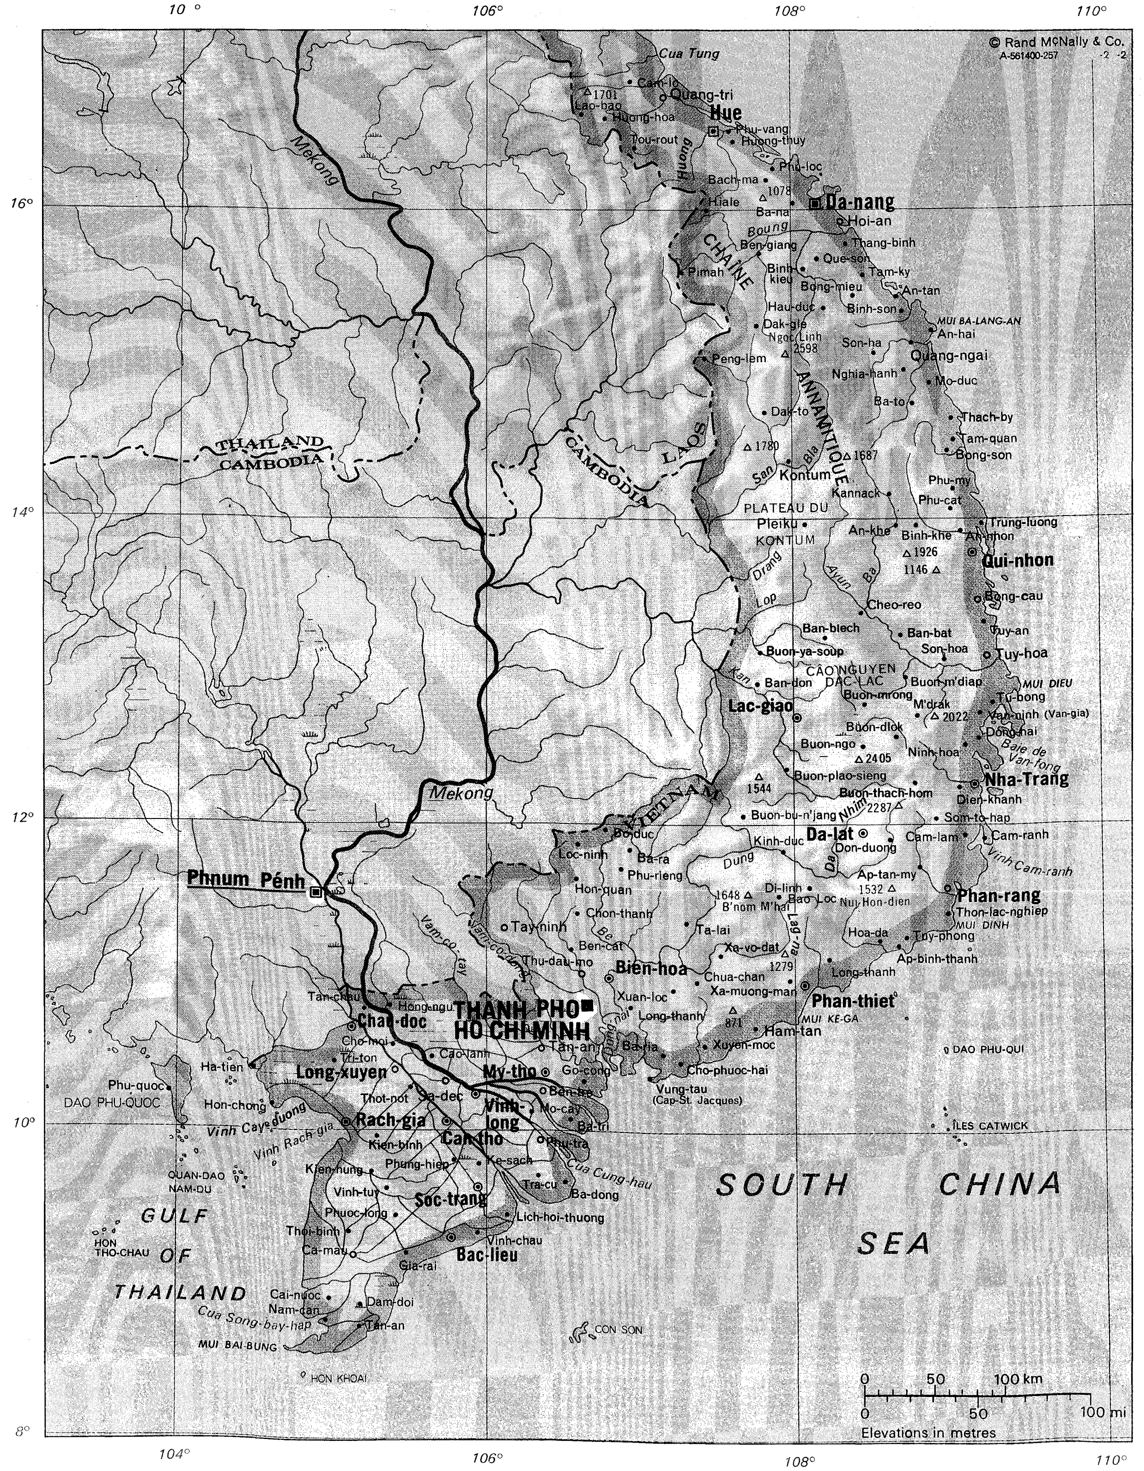
resulted in elections on April 25, 1976, of a new National Assembly for the whole country. This National Assembly convened for the first time in Hanoi on June 24; on July 2 it proclaimed the reunification of the country.

Physical and human geography

THE LAND

Relief. Vietnam encompasses 127,200 square miles (329,600 square kilometres). Its principal physiographic features are the Chaîne Annamitique (Annamite Chain or Cordillera; Truong Son), extending from north to south in central Vietnam and dominating the interior, and two extensive alluvial deltas formed by the Red River (Song Hong) in the north and the Mekong River (Song Cuu Long) in the south. Between these two deltas is a long, relatively narrow coastal plain.

From north to south, the uplands of northern Vietnam can be divided into two distinct regions—the region north of the Red River and the massif that extends south of the Red River into neighbouring Laos. The Red River forms a deep, relatively wide valley that runs in a straight northwest–southeast direction for much of its 130 miles (210 kilometres) from the border with the People's Republic of China to the edge of the delta. North of the Red River, the relief is moderate with two essential regions. One region has heights characterized by a northwest–southeast trend such as are found between the Red River and the Song Lo (Clear River); appended to this is a marked depression from Cao Bang to the sea. The second region is charac-



SOUTHERN VIETNAM

terized by mountains in its eastern portion that form arcs convex to the east and southeast. This region also contains a sub-area of wide terraces, extensive alluvial plains, and low hills; it extends from the Red River delta along the Lo, Chay, Chu, Thuong, Luc Nam, and Ky Cung rivers.

Compared with the area north of the Red River, the vast massif extending southwest across Laos to the Mekong River is of considerably higher elevation and is overlain with poor soils. Among its outstanding topographical features is the Fan Si Pan chain, the highest peaks of which are Mount Fan Si Pan (10,312 feet [3,143 metres]) and Pou Luong (9,796 feet [2,986 metres]). It is a crystalline formation with few plains. South of the Black River are the Ta P'ing, Son La, and Moc Chau plateaus, which are separated by deep valleys.

In central Vietnam, the Chaîne Annamitique runs parallel to the coast, with several peaks rising more than 6,000 feet (1,830 metres). Several spurs jut into the South China Sea, forming compartments isolated from one another. One such spur dissects the coastal plain at Mui Ron (previously called the Gate of Annam) and another rises at the Hai Van pass (the Col des Nuages), just north of Da Nang. Communication across the main chain in central Vietnam is difficult. Located at Lao Bao inland from Quang Tri

is the chief pass, the Ai Lao, which provided an ancient invasion route between the coastal plain and the interior. The southern portion of the Chaîne Annamitique has two identifiable regions. One consists of mountain plateaus of approximately 1,700 feet (518 metres) in elevation that have experienced little erosion, as in the vicinity of Lac Giao (former Ban Me Thuot). The second region is characterized by heavily eroded plateaus; in the vicinity of Pleiku, the plateau is about 2,500 feet (760 metres) above sea level and in the Da Lat area, about 4,900 feet (1,500 metres) in elevation.

The Red River delta

Drainage. Below the northern uplands is the Red River delta. Roughly triangular in shape, the 4,250-square mile (11,000-square kilometre) delta extends 150 miles (240 kilometres) inland and measures 75 miles (120 kilometres) along the Gulf of Tonkin. The Red River delta can be divided into four sub-regions. The northwest section has the highest and most broken terrain, and its extensive natural levees invite settlement despite frequent flooding. The low-lying eastern portion of the delta has bench marks of less than seven feet (two metres) elevation in the vicinity of Bac Ninh. Rivers running through this area form small valleys only slightly lower than the general surface level, so they are subject to flooding by unusually high tides. The third and fourth sub-regions are the poorly drained lowlands to the west and the coastal area, which is marked by the remains of former beach ridges left by continuous deltaic aggradation.

The Mekong River delta

South of the mountain range there is an identifiable terrace region that gives way to the Mekong River delta. The terrace region includes the alluvial plains along the Saigon and Dong Nai rivers. The lowlands of southern Vietnam are dominated by alluvial plains, the most extensive of which is the Mekong River delta, covering an area of 15,600 square miles (40,400 square kilometres). Smaller deltaic plains also occur along the south-central coast of the South China Sea.

Soils. In northern Vietnam, the heavy seasonal rains wash away rich humus from the highlands, leaving slow-dissolving alumina and iron oxides that give the soil its characteristic reddish colour. The soils of the Red River delta vary; some are fertile and suitable to intense cultivation, while others lack soluble bases. Nonetheless, the delta soils are in good condition, without any lateritic tendencies, and are easily worked. The diking of the Red River to prevent flooding deprives the delta's paddy fields of enriching silts, necessitating the use of chemical fertilizers.

There are at least 25 soil associations, but certain soil types predominate. Among these are red and yellow podzolic soils (soils that are heavily leached in their upper layers, with a resulting accumulation of materials in the lower layers), which occupy nearly half of the land area, and latosols (reddish brown leached tropical soils), which comprise about one-tenth. These soil types dominate the central highlands. Alluvial soils account for about one-fourth of the land in the south and are concentrated in the Mekong River delta, as are peat and muck soils. Gray podzolic soils are found in parts of the central highlands and in old terraces along the Mekong River, while regurs (rich black loams) and latosols occur in both the central highlands and the terrace zone. Along the coast of central Vietnam are regosols (soft, undeveloped soils) and non-calcic brown soils.

Climate. The northern part of Vietnam is on the edge of the tropical world. During January, the coldest month of the year, Hanoi has a mean temperature of 62° F (17° C). The annual average temperature is 74° F (23° C). Farther south, the average annual temperature in Hue is 77° F (25° C) and in Saigon is 81° F (27° C); in the highland city of Da Lat (4,920 feet [1,500 metres] in elevation), it is 70° F (21° C). The winter season in northern Vietnam lasts from November to April; from early February to the end of March there is a persistent drizzling rain that the Vietnamese call "dust rain" or "flying rain." The summer in northern Vietnam lasts from April or May to October and is characterized by heat, heavy rain, and occasional typhoons. In central and southern Vietnam, the southwest monsoon winds between June and November bring rains and occasional typhoons to the eastern slopes of the mountains and the lowland plains. Between December and April there is a drier period that is characterized by northeasterly winds and, in the south, by high temperatures.

Plant and animal life. The vegetation of Vietnam is rich and diversified because of the great range of climate, topography, and soils and the varying effects of human habitation. The forests of Vietnam can be divided into two broad categories: evergreen forests, which include the conifers, and deciduous forests. There are more than 1,500 species of woody plants in Vietnam, varying in size from small shrubs to large trees and ranging from hardwoods such as ebony and teak to palms, mangroves, and bamboos. There are also numerous species of woody vines, or lianas, and herbaceous plants. In the aggregate, the dense and open forests, savannas, brushland, and bamboo cover approximately half of the total area of Vietnam.

In most areas the forests are mixed, containing a large number of species within an area of a square mile. Rain forests are relatively limited and pure stands are few. The nearest to pure forest types are the pines—the three-needled *Pinus khasya* and two-needled *P. merkusii* found in the uplands—and the mangrove forests of the coastal swamps. In the mountainous regions there are subtropical species such as varieties of *Quercus, Castanopsis, Pinus,* and *Podocarpus.* Brushwood, bamboo, weeds, and tall grasses invade cutover forests and grow around settlements and along arterial highways and railroads. Between the cutover areas and the upland forests are other mixtures of forest types.

A large part of the forest is of the closed type and rich in broad-leaved evergreens and semi-evergreens, some of which produce valuable timbers. About one-fifth of this forest type is composed of undisturbed (primary) forests. Other types of forests in this region include secondary forests; open forests, which usually have trees of the Dipterocarpaceae family and *Lagerstroemia* (crape myrtle) species; mangrove forests; and barren lands of sand dunes with eucalyptus and small, thorny deciduous trees and *Casuarina* species of flowering plants. Cogon grass (*Imperata cylindrica*) is commonly found in the open forests, and grass savannas occupy large areas formerly covered by forests. Grass and sedge swamps are characteristic of the Dong Thap Muoi (Plain of Reeds), a depression in the Mekong River delta.

Effects of defoliation

During the Vietnam War, herbicides were used by the U.S. Army to defoliate forests in South Vietnam. About one-fifth of the total acreage of South Vietnam was sprayed with defoliant chemicals, which affected all types of vegetation, especially coastal mangrove forests and inland forests.

Permanent cultivation covers large areas of the Vietnam lowlands and smaller portions of the highlands. Much of this acreage is in wet rice, the staple of the Vietnamese diet. Plantations of banana, other fruit trees, coconut, and sugarcane are found in the Mekong River delta, while tea and coffee are grown in the central highlands. Extensive rubber estates occur in the central highlands and the terrace region. Fields, groves, and kitchen gardens throughout Vietnam contain a wide variety of fruit trees (banana, orange, mango, jackfruit, and coconut) and vegetables. Kapok trees are found in many villages, and the Vietnamese cultivate areca palms and betel peppers for their nuts and leaves.

The most common domesticated animals in Vietnam are water buffalo, cattle, dogs, cats, pigs, goats, ducks, and chickens. Wild game in the central highlands includes elephants and tapirs; of the varieties of rhinoceroses (*Rhinoceros sondaicus* and *Didermocerus sumatrensis*), none has been seen since the early 1940s. Also found in the forests are big cats, including tigers, leopards, ounces (*Leo uncia*), and clouded leopards (*Leo nebulosa*); several kinds of wild oxen, including gaurs and koupreys; and various types of bears, among them the black bear and honey bear. Deer are plentiful; they include the small musk deer and barking deer. Other common wild animals are wild boars, porcupines, jackals, otters, mongooses, hares, skunks, and squirrels, including flying squirrels. In the highland villages, traps are placed near granaries to catch rats, which are roasted and eaten.

There are many different kinds of small wild cats and three types of civets—Malagasy civets, binturongs, and palm civets. Primates such as the langur, macaque, gibbon, and rhesus monkey live in the forests. Crocodiles are found on the edges of some lakes and along river banks; other reptiles include several kinds of lizards, pythons, and cobras. Of the wide variety of land and water birds, 586 species have been identified in southern Vietnam alone.

Settlement patterns. Diverse cultural traditions, geographical variations, and the events of history have created distinct traditional regions. The general topographical dichotomy of highland and lowland regions also has ethnolinguistic significance; the lowlands generally have been occupied by ethnic Vietnamese, while the highlands have been the home of numerous smaller ethnic groups that differ culturally and linguistically from the Vietnamese. The highland peoples can be divided into the northern ethnic groups, with affinities to peoples in southern China, and the southern highland populations, with ties to the Mon-Khmer and Austronesian peoples of Cambodia, Indonesia, and elsewhere in Southeast Asia. A north–south variation also evolved among the ethnic Vietnamese as they expanded from the Red River delta along the coastal plain into the Mekong River delta. After the mid-19th century, Vietnam was divided by the French into Tonkin in the north, Annam in the centre, and Cochinchina in the south. The Vietnamese themselves have long made a distinction among the northern region (*bac ky*), with Hanoi as its cultural centre; the central region (*trung ky*), with the traditional royal capital of Hue; and the southern region (*nam ky*), with Saigon (now Ho Chi Minh City) as its urban centre.

Topography has strongly influenced human settlement in Vietnam. In the Red River delta a number of distinct settlement patterns can be identified, the most common of which is the "relief" village associated with topographical features such as levees, hillsides, or beach ridges. Levee settlements, usually located along river banks, often abut each other and form one elongated settlement, while clusters of farmsteads at the base of a hill may cover the hill if it is low. Most villages are enclosed by a bamboo hedge or earthen wall.

Lowland Vietnamese villages on the coastal plain in central Vietnam are characteristically close-knit, small clusters of farmsteads near a watercourse. Fishing villages normally are situated in a sheltered inlet. Vietnamese villages in the Mekong River delta are less varied than those in the Red River delta. Settlements are strung out along the rivers, canals, and streams and major roads. On the deltaic plain, most settlements are loose-knit clusters of farmsteads, although some farmsteads are scattered about the paddy fields.

In some Vietnamese settlements, particularly those in northern and central Vietnam, geomantic principles determine the internal orientation of houses and village buildings such as the *dinh,* the communal meeting hall and sanctuary for the cult of the guardian spirit, and the village Buddhist pagoda. In central Vietnam, houses and the *dinh* traditionally face the sea.

The physical pattern of settlements of the Cham and Khmer minorities closely resembles that of the Vietnamese settlements. Among the highland ethnic groups, settlement patterns vary considerably. Permanent and shifting (slash-and-burn) fields are within walking distance of the village, kitchen gardens are invariably found close to the farmstead, and good water sources are nearby. Internal arrangement of the settlement may not have any particular orientation or it may be dictated by practical considerations or ideational principles. Most groups in the northern highlands have no particular patterns for their settlements. In the central highlands, however, the Sedang prefer not to have the morning sun strike the main entrance of a house, and the Mnong Chil build their dwellings facing away from the prevailing winds. In the same region, many Jarai longhouses have a north–south orientation because of wind and rain patterns; the main entrance always faces south so that the sun may dry the rice, cotton, and other things they place on the veranda. The Katu orient their settlements around a stake to which sacrificial animals are tied and build their communal men's houses (where rituals and gatherings of the leaders take place) facing away from the rising sun.

For the most part, highland people prefer to build their houses on pilings. Exceptions occur among the Hmong (Miao, Meo), Mien (Yao), Stieng, and some Mnong groups. Floor plans for houses vary from group to group depending on whether or not a house will be occupied by an extended family and whether there are cultural prescriptions for certain parts of the house. In the central highlands, for example, the Rhadé trace descent through the female line and husbands live with their wives' families after marriage; their longhouses, therefore, are arranged with compartments for the women of the family and their husbands and children.

Vietnam's traditional major cities are Hanoi, Hue, and Saigon (Ho Chi Minh City). Archaeological research in the vicinity of Hanoi has revealed traces of the ancient citadel of Co Loa, which dates to the 3rd century BC. Throughout Vietnamese history the Hanoi area has been a place of importance and the site of several early capitals. Hanoi served as the French colonial capital from 1902 until 1954, and the city retains the charming architecture that is part of that heritage. Hanoi also has long been a centre of trade and industry for northern Vietnam; the city's outport of Haiphong was developed by the French in the late 19th century as a trade and banking centre.

The city
of Hue

The imperial past is rooted in Hue. The Nguyen family controlled central and southern Vietnam from Hue after 1687, and Emperor Gia Long established his capital there in 1802. Located on the Song Huong (Perfume River), Hue was intended to be the physical and administrative centre of the kingdom and was laid out in the early 19th century according to geomantic principles. The heart of the city is the imperial citadel of Dai Noi ("Great Within"), modelled on the Manchu palace in Peking. Hue was the intellectual and religious heart of Vietnam, and its economic functions were ancillary. Many of the traditions of the mandarins (senior public officials) have been preserved in Hue, and until vast destruction occurred during the Tet Offensive of 1968, traditional Vietnamese architecture was much in evidence.

Saigon, renamed Ho Chi Minh City in 1976, was built largely by the French on a plan devised by Théodore Lebrun, an adviser to Gia Long. As the administrative capital and principal port of the French province of Cochinchina, its riverfront was dominated by the port and commercial establishments. A French-provincial style of life prevailed in the city and its architecture recalled towns and cities in southern France. With the establishment of Hanoi as the capital of the Socialist Republic of Vietnam in 1976, Saigon lost its administrative functions as the capital of South Vietnam. The city of Cholon, adjoining Saigon, was a major centre for the ethnic Chinese until 1978, when large private enterprises were abolished and vast numbers of Chinese left the country.

THE PEOPLE

Ethnic distribution. Vietnam has one of the most complex ethnolinguistic patterns in Asia. The great tradition of China is represented by the ethnic Vietnamese, who were Sinicized during the 1,000 years of Chinese rule. Since the 10th century the Vietnamese have carried this tradition from the Red River delta southward along the coastal plain to the Mekong River delta. Chinese influence permeates all levels of the Vietnamese language, one of the Mon-Khmer languages of the Austro-Asiatic language family.

Cham and
Khmer
minorities

Indian influence is found among the Cham and Khmer minorities. The Cham, whose language belongs to the Austronesian language family, are remnants of a once large population that formed the majority in the Indianized kingdom of Champa, which existed in what is now central Vietnam from the 2nd century AD until its absorption by the Vietnamese between the 15th and 17th centuries. Cham populations remain in the south central coastal plain, where they cling to many customs of the Brahmins (the highest Hindu caste), and in a small pocket of the Mekong River delta close to the Cambodian border, where they have adopted Islām. The Khmer, whose language is one of the Mon-Khmer languages, are scattered throughout the Mekong River delta. They are descendants of a population that was once part of the Khmer Empire, the most spectacular traces of which are to be seen in the ruins of Angkor in neighbouring Cambodia.

The Montagnards

Other minorities include the ethnic groups that inhabit the highlands. In the central highlands are people less advanced than the lowlanders and, while their cultures vary considerably, they still share many characteristics derived from a way of life oriented around kin groups and small communities. Known collectively by the French as the Montagnards ("Highlanders"), they have affinities with other Southeast Asians. Those who speak languages of Austronesian stock include the Rhadé, Jarai, Chru, and Roglai; they have linguistic ties with the Cham, Malay, and Indonesians. Other Montagnards—such as the Bru, Pacoh, Katu, Cua, Hre, Rengao, Sedang, Bahnar, Mnong Maa, and Stieng—speak languages of Mon-Khmer stock, affiliating them with the Cambodians (Khmer). Unlike the lowlanders, the Montagnards historically remained aloof from Chinese and Indian influences, but between the end of the 19th century and 1954 they were exposed to French influence. French missionaries and administrators provided roman script for some of the Montagnard languages and additional orthographies have been devised since. A desire to preserve their own cultural identities has given rise to intense ethnonationalism among the Montagnards. This is the principal ideology that has sustained the United Struggle Front for the Oppressed Races (known by its French acronym, FULRO), which has been active since the mid-1960s.

Population density of Vietnam.

The tribal Tais

The various groups in northern Vietnam have ethnolinguistic affiliations with peoples in southern China. They include the tribal Tai (Thai) groups—the Tai Dam (Black Tai), Tai Khao (White Tai), Nung, and Tay (Tho)—who are generally found in the upland valleys. Representing the largest of the highland ethnolinguistic groups, they speak Tai languages. At higher elevations are scattered the Hmong and Mien, whose languages are of the Sino-Tibetan language family. With the establishment of the Socialist Republic of Vietnam in 1976, a program was begun to move ethnic Vietnamese from the lowlands into the mountain region.

Religion. Beliefs and values of Taoism and Confucianism shape the Vietnamese view of the universal order, the cult of the ancestors is ubiquitous, and the Mahāyāna (Greater Vehicle) tradition of Buddhism is widespread. Animist beliefs are held by many tribal peoples. During the 1920s, the syncretic religion of Cao Dai appeared, and in 1939 the Hoa Hao sect, which claims to be a "pure Buddhism," spread through parts of the Mekong River delta.

Roman Catholicism and Protestantism

Roman Catholicism was first introduced among the Vietnamese in the 17th century, and it spread widely following the French conquest in the mid-19th century. The heaviest concentrations of Roman Catholics in Vietnam were initially in the north; the majority of them, however, fled to the south after the partition of the country in 1954.

In 1959 all foreign clergy were expelled from North Vietnam, leaving only native priests. Though the 1960 constitution guaranteed freedom of religion, the North Vietnamese government tried to supplant organized religion with its own "scientific materialism" and to gain control over the existing faiths by sponsoring patriotic religious organizations. These included the Unified Buddhist Church; the Patriotic Catholic Church, whose clergy and members have renounced allegiance to the pope; the Viet Nam Cao Dai Union; and the Viet Nam Protestant Church.

Protestantism came to Vietnam with a mission in the Mekong River delta in 1911, and it spread primarily among small segments of the urban population in the central and southern regions. Congregations grew in Saigon, in the Mekong River delta towns, and in the highland centres of Da Lat, Ban Me Thuot, and Pleiku. With the conquest of South Vietnam by North Vietnam, all foreign Christian clergy were expelled.

THE ECONOMY

Vietnam has a definite economic potential. Its population is literate and energetic, and it has a number of natural resources. Its geographic position puts it within easy reach of all the other countries of the region. Vietnam's varied topography lends itself to a wide range of agricultural and industrial exploitation, and its long coastline provides excellent harbours and access to marine resources. In addition to vast areas of cultivable land, there are good soils supporting valuable forests and there are deposits of minerals (including coal) and possibly of crude oil and natural gas. A potential for the generation of hydroelectric power exists. Economic development, however, is seriously constrained by a number of social, political, economic, and military factors.

Economic integration

The reunification of Vietnam required the integration of the society and economy of the south into the socialist framework determined for the new nation by the north. During the period of separation between 1954 and 1975, there were three layers to the Vietnamese economy: the bottom layer was based on the cultivation of rice; the middle layer was dominated by mining in the north and rubber estates in the south; and the third layer was a wartime creation with large-scale Soviet and Chinese aid in the north and substantial U.S. aid in the south. The socialist economy of North Vietnam developed one of the most impressive industrial systems in Southeast Asia, although living standards remained low because of basic inefficiencies, the decision during the war years to disperse industry in the face of U.S. bombing, and the need to maintain a large military complex. The economy of South Vietnam was based largely on free enterprise, with less industry but a more important agricultural sector and a higher standard of living than in the north.

Since reunification in 1976, the task of developing the economy has been rendered difficult by the disruptions and destruction of 30 years of war, the need to integrate the two divergent economies, and other factors. In the north, collective ownership accounted for the vast majority of the means of production. State ownership in the south, however, affected only a relatively small part of the economy, covering most of the total industrial output but leaving the greater part of agriculture, trade, and transport in private hands. The stated intention of the unified government was to extend full socialization to the south on the pattern already established in the north.

'he
outhern
armers

Originally it was announced that the two economies would be gradually integrated after unification. It was decided, however, to accelerate the pace of economic integration. But the program of agricultural reform ran into serious barriers. In the rich Mekong River delta, the government had to deal not with large landlords, but with their former tenants, who had become individual proprietors. The majority of the southern farmers in the late 1970s were middle-income peasants who owned enough land and implements to farm successfully without relying on outside labour. With their skill and experience in farm management, they were the central figures in the rural economy of the south. The poor constituted a minority of the peasantry in the Mekong River delta, whereas they had been in the majority in the north.

The government's move to socialize the commercial sector by abolishing major private enterprises in the south was more successful than the attempt to collectivize agriculture. The government's moves against the private commercial sector, which mainly affected the ethnic Chinese, and deteriorating political relations with China precipitated the flight of ethnic Chinese from Vietnam in 1978. This serious loss of economic talent was compounded by the regime's policy of placing anyone associated with the former South Vietnamese government or the U.S. mission in jails or re-education centres. The resettlement program, which affected vast numbers of people, including highly trained and educated individuals, also resulted in a loss of human resources. The large military organization maintained by the Vietnamese further strains the national budget and diverts large numbers of personnel from the reconstruction of war-damaged roads, railway lines, dikes, irrigation projects, and bridges.

Resources. Rich mineral deposits are a major source of wealth. In the north, there are large reserves of anthracite coal. Raw phosphates and high-grade chromite come from Vietnam. There are also significant deposits of tin, antimony, bauxite, gold, iron ore, lead, tungsten, zinc, and lime.

Vietnam has signed an agreement with a West German firm to explore offshore oil deposits. Under the agreement, an area off the Mekong delta coast has been given to the company for exploration. Similar agreements have been signed with Italian and Canadian companies, and Norwegian and French government aid projects involve seismic surveys and drilling off Vung Tau, a beach resort near Saigon.

Forests are potentially a major natural resource. Fish and shellfish from Vietnam's coastal waters and the plains of the Mekong and Bassac rivers are a major resource and the second most important food staple after rice.

Agriculture, forestry, and fisheries. Agriculture is by far the most important economic sector in Vietnam. It is estimated that nearly three-fourths of the population earns its income from farming. In addition, agriculture is the main source of raw materials for the processing industries and a major contributor to exports. The primary agricultural areas are the two large river deltas and the southern terrace region, the Red River delta and the Mekong River delta. The strip of coastal land between the deltas is a region of low productivity; the central highlands area also is of low productivity, but has a significant agricultural potential.

Rice
production

Rice is the most important crop, grown on about three-fourths of the cropped land, principally in the Red River and Mekong River deltas. Rice accounts for more than half of the total agricultural output. Drying and storage facilities remain inadequate, and there are additional losses due to industrial purposes (such as the production of alcohol) and seed requirements. Other food crops are corn (maize), sweet potatoes, and manioc (cassava).

Agriculture is basically labour intensive in Vietnam, but whether the resettlement of millions of people will affect rice production is uncertain. The greater part of the plowing is still done by water buffalo.

Industrial
crops

Industrial crops include rubber, tea, coffee, fruit trees, sugarcane, tobacco, and jute. Located in the south, the rubber industry was seriously disrupted by the war. Coffee production is mainly of Arabica, Robusta, and Chari varieties. Citrus fruits (oranges, limes, and grapefruit) are important crops, as are bananas and pineapples.

The export of seafoods such as lobsters, prawns, shrimp, and crabs is an excellent potential source of foreign exchange, but production methods are inefficient. Government officials have reported that refugees who left the country by sea took more than 5,000 fishing boats, seriously hampering plans to increase production. The most important fisheries are located on the plains of the Mekong and Bassac rivers. The principal fish farmed are species of tilapia, carp, catfish, and snakehead.

Forestry is a major industry. There is little modernization of forest industries. Charcoal is produced in mangrove areas, and there are a number of furniture and pulp and paper factories, as well as wooden handicraft centres. In the south, most timber has been used for reconstruction.

Industry. At the end of the Vietnam War, industries in the southern and northern parts of the country faced different difficulties. Wartime destruction of the industrial plant had not been great in the south, but the supply of imported raw materials and spare parts had been seriously disrupted. Industries that relied on local raw materials resumed operations quickly, but they experienced problems of unreliable supplies and poor logistics. The task of adequate maintenance, repair, and replacement of industrial machinery was complicated by the heterogeneity of equipment that had been purchased from different countries.

Northern
industrial
development

In the north, there was a period of intense reconstruction of industry from 1973 to 1975. Despite the reconstruction progress, there has been serious underutilization of industrial capacity, as well as unsatisfactory levels of production and a deterioration in the quality of output. Industry has been plagued by old equipment that is subject to frequent breakdowns, inadequate protection of equipment against the weather, insufficient maintenance of tools and materials, and inadequate standards and guidelines for the use of equipment.

Finance and trade. Vietnam's major trading partners are the Soviet Union and Japan; the government joined the Council for Mutual Economic Assistance (Comecon) as a full partner in 1978.

Major exports are coal, rubber, light industrial products, handicrafts, fish, and processed agricultural products. The total value of these exports, and especially of coal, was adversely affected by the refugee exodus and the war in Cambodia and political conflict with China in the late 1970s.

Imports are directed toward food, agriculture, and industry; power; and railways. The volume of imports of raw materials, fuels, fertilizers, and insecticides is expected to grow at the same rate as the projected expansion of related economic activities. The government so far is restricting imports of consumer goods apart from food grains and other essential foodstuffs.

Vietnam is a member of the World Bank and has received aid from the International Monetary Fund. Loans from Denmark, The Netherlands, Kuwait, and the Organization of Petroleum Exporting Countries (OPEC) have been received. After protracted negotiations, Hanoi has agreed to pay the debt owed to Japan by the former Saigon government, and in return it has received a promise of a loan for the purchase of nonmilitary goods. Vietnam has also received aid from Comecon, the Asian Development Bank, and the United Nations Development Program.

Trade unions

Administration of the economy. The state has established strong economic controls. The Vietnam General Confederation of Trade Unions, an instrument of the Communist Party, is the only legal labour organization. North Vietnam had adopted the Soviet-style "single manager system" in industry, giving factory administrators a wide margin of latitude in factory management and placing a heavy burden on labour unions to exercise political leadership among the workers.

Much of the money supply has been eliminated by the change to a single Vietnamese currency because the amount of new currency issued is limited and the use of commercial credit has been virtually abolished.

Economic controls

Income is more evenly distributed because wages have been established by the state. Transportation to and from work, education, medicine, and health services are free. Although housing is relatively poor, it is provided to all workers in state-owned enterprises at a charge of one percent of salary. Price controls and rationing are also used throughout Vietnam to influence the level and distribution of personal income. Food is rationed, and food prices on the free market are much higher than the level of controlled prices. Many industrial consumer goods, such as cloth, are also rationed.

Transportation. The geography of Vietnam has rendered transportation between the north and south difficult. Except for air and sea communications, traffic has been limited to the narrow coastal corridor. The two large deltas, where most of the population is concentrated, have good internal transportation systems based on vast networks of navigable inland waterways, roads, and cart trails. Air travel is being further developed.

The war years brought about the major development of roads in the north and the south. In the south, the emphasis was on the construction and improvement of major arterial highways, while in the north priority was given to the construction of secondary roads.

Port facilities

Vietnam's rail system suffered heavy damage during the war years. After unification, a comprehensive reconstruction and modernization program was launched. There is an extensive network of navigable rivers and canals in the Red River delta (3,700 miles, or 6,000 kilometres) and the Mekong River delta (3,000 miles, or 4,800 kilometres). Maintenance work to avoid silting has been hampered by wartime damage to dredging equipment and by general deterioration. Most coastal and ocean shipping is centred in the northern port of Haiphong and the southern port of Saigon. The ports of Hon Gai and Cam Pha are used mainly as export stations for coal, while Vinh and Da Nang serve as transit ports for Laos. The war brought considerable improvements to port facilities at Cam Ranh, Nha Trang, and Qui Nhon.

Noi Bai airport at Hanoi was opened to international traffic in 1978. Soviet, East German, Chinese, and Laotian aircraft have begun using the new facility. Vietnam agreed to open the air route across the central part of the country to international airlines, with some exceptions, notably those based in the United States.

ADMINISTRATIVE AND SOCIAL CONDITIONS

Government. The elections of April 25, 1976, produced a new unicameral National Assembly of 492 members (243 from the south and 249 from the north), the major task of which was to establish a single national government for the unified nation. The principle of universal suffrage for those 18 years of age or older determined the electorate. On June 24 the assembly met for the first time, and on July 2 it exercised its first prerogatives, creating the Socialist Republic of Vietnam and electing the nation's president, two vice presidents, and cabinet, and the members of the Standing Committee of the National Assembly. The primary task of the Standing Committee was to draft a new constitution, which was published in August 1979.

The National Assembly is the supreme organ of the government. The Council of Ministers is comprised of the prime minister and deputy prime ministers, all of whom are named by the National Assembly, and the heads of government ministries and various state organizations. The Council coordinates and directs the activities of the ministries and the various state organizations at the level of the central government and supervises the activities of administrative committees at the level of local government.

Each ministry is headed by a minister, who is assisted by several vice ministers. Responsibilities of the ministries usually are defined along narrow functional lines; there are, for example, numerous economic ministries concerned with subsectors such as grains and food products, marine products, afforestation, water conservancy, light industry, engineering and metals, power and coal, and construction. Larger ministries tend to be relatively self-sufficient, with their own colleges, training institutions, and health, social, and cultural facilities. There are also a number of commissions under the Council of Ministers, including the State Planning Commission, headed by a deputy prime minister; the State Bank, headed by a director general with ministerial rank; and the Central Agriculture Commission. Under the prime minister's office are a number of general departments that have a lower status in the administration than ministries. The more important departments are headed by ministers. Committees under the prime minister's office are also formed to supervise projects, such as the Da River hydroelectric project, that involve more than one ministry.

The traditional administrative units of local government in Vietnam have been the provinces, districts, and villages. Following reunification in 1976, local administration was reorganized into 35 provinces and 3 municipalities (Hanoi, Haiphong, and Saigon) on the provincial level. There are about 500 districts. At either the provincial or district level, the highest government authority is an elected People's Council, the actual work of which is carried out by administrative committees appointed by the councils. Village administration is represented by village people's councils.

The Vietnamese Communist Party

The most important political institution in Vietnam is the Vietnamese Communist Party (Dang Cong san Viet Nam), founded in 1976 from the Vietnamese Workers' Party (Lao Dong) of North Vietnam. Any citizen of the age of 18 or over who "has engaged in labour and not been an exploiter" is eligible to join.

Effective authority within the Vietnamese Communist Party lies with the Politburo's 14 voting members and 3 alternates and the Central Committee's 101 full members and 32 alternates. Of the two bodies, however, the Politburo has more political power. It is not known precisely how decisions are made within the Politburo, but it appears that they result from a process of compromise among its senior members. The secretary general of the Vietnamese Communist Party presides over the party's Secretariat, which is elected by the Central Committee. The Secretariat directs the tasks of the party organization and the coordination of party and state bureaucracies in carrying out the resolutions of the Central Committee and the Politburo; it also has responsibility for implementing party resolutions.

Popular associations for youth, women, and farmers disseminate party policies and serve as training grounds for potential party members. The most important of these organizations is the Vietnamese Women's Union, which reflects the critical role played by women in Vietnam's revolution. The Ho Chi Minh Communist Youth Union is largely responsible for the Youths' Federation, while local party units and agricultural cooperative organizations assume leadership over the Farmers' Federation. The Vietnam Federation of Trade Unions has the responsibility of safeguarding workers' welfare, but does not function as a Western-style bargaining unit.

The National United Front

Non-party political organizations are grouped under the Fatherland Front. In 1955, the Fatherland Front grew out of the Lien Viet Association, an amalgamation of non-communist political groupings opposed to the French during the Indochina War. In 1977, the National United Front was organized with the merger of the Fatherland Front, the National Liberation Front (NLF) of South Vietnam, and the Vietnam Alliance of National Democratic and Peace Forces (which had been formed in 1968); the last two had presented themselves as independent southern movements.

Justice. The judicial system consists of the courts and the People's Organs of Control. The National Assembly supervises the work of the Supreme People's Court, which is the highest court of appeal and the court of first instance for special cases (such as those involving treason). This court in turn supervises the judicial work of local People's Courts, which are responsible to their corresponding People's Councils. The People's Courts function at all levels of government except the village level, where the village administrative committee functions as a primary court.

ople's rgans of ontrol

The People's Organs of Control act as watchdogs for the state; they monitor the performance of government agencies, maintain vast powers of surveillance, and act as prosecutors before the People's Courts. The People's Supreme Organ of Control is responsible only to the Standing Committee of the National Assembly.

Armed forces. Military forces include the army, paramilitary regional and provincial forces, the militia, and the reserves. There are separate military commands in Hanoi, Haiphong, and Saigon.

Education. Because of their Confucianist traditions, education has always been important to the Vietnamese. Rural education in the south was badly disrupted during the war years, and all religious and private schools were nationalized after 1975. The government pursued a policy of education reform. Twelve years of schooling are provided free to everyone. The educational system is divided into three levels; after the first nine years of schooling, students are selected to continue into higher education or to attend technical or vocational training institutions.

The government claims that illiteracy has been abolished in the south, as it already had been in the north. Emphasis is being placed on training in science and technology, although a lack of equipment hinders the program, and several thousand students are sent to study languages and technology abroad. While most of the students sent to other countries go to the Soviet Union and eastern Europe, some study in France, Great Britain, and Australia.

Health and welfare. Before unification, health services were underdeveloped in the rural areas of South Vietnam, but were well developed in North Vietnam. After reunification there was a general increase in health facilities and personnel (physicians, assistant physicians, nurses, and midwives) throughout Vietnam. Health facilities include hospitals, health centres, leprosy centres, sanatoriums, and village health and maternity centres.

CULTURAL LIFE

npor- nce of etry

Chinese influence permeates all aspects of traditional Vietnamese culture, and it is strongly manifest in language, art, architecture, music, theatre, literature, and poetry. Deeply rooted in the Vietnamese oral tradition, poetry was highly regarded by the educated class centred in the royal courts, and it was expressed in Chinese form and style. By the 14th century, however, a demotic script called *chu nom* ("southern characters") came into use among the Vietnamese literati, permitting the emergence of an explicitly Vietnamese "tale in the southern script" (*truyen nom*) that, during the 17th and 18th centuries, evolved into the form of a long narrative poem. This art form reached its culmination in the best known of Vietnamese poems, *Kim Van Kieu* ("The Tale of Kieu") by Nguyen Du (1765–1820). Further evolution of this literary tradition was arrested by the French conquest and the imposition of French culture on the Vietnamese elite. Despite this and later influences from the outside, poetry has retained its importance in the Vietnamese artistic tradition. Vietnamese poetry is now written in a romanized script based on the first Latin script for the tonal language devised by Father Alexandre de Rhodes, a Jesuit priest from Avignon.

Traditional Chinese opera, called *hat tuong* in the north and *hat boi* in the south, is popular among the Vietnamese, as is the more indigenous *cai luong*, a satirical musical comedy. The theatre is strictly controlled and all actors and other performers are unionized employees of the state. Painting has failed to flourish among the Vietnamese; it has been bound for centuries first by rigid traditional Chinese forms, then by a style imitative of French Impressionism, and now by the tenets of Socialist Realism. High quality lacquer ware, however, continues to be produced.

Folk traditions flourish among the peoples of the central highlands, who continue to produce most of the things they need. Precious hardwood is used for carving crossbows and figures, most of which are destined for tombs. Among the Rhadé, a mountain tribal group living mainly in Dac Lac province, hardwood is used in the construction of longhouses built on pilings. Among the highlanders, women weave blankets, blouses, skirts, and loincloths, while the men weave baskets and mats. They have a variety of musical instruments, but gongs are the most common. The Cham and Khmer minorities retain some folk arts, but as they become assimilated into Vietnamese culture, their traditions are fading. (G.C.H.)

For statistical data on the land and people of Vietnam, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL.

History

In spite of a growing number of ethnographic and archaeological studies covering the territory historically occupied by Vietnam, all knowledge about the origin of the Vietnamese people remains hypothetical. A long-held notion that identified the Vietnamese with one tribe of the Viets of southern China (Yüeh in Chinese) has been abandoned. Though the Viets—who about 334 BC were driven by the expanding Chinese from their habitat south of the Yangtze River, moved farther south, and may have entered the Red River Delta—gave the Vietnamese people its name, the theory that regards them as direct ancestors conflicts with ethnographic and biological evidence, all of which points to strong social and cultural affinities between the Vietnamese and peoples of the Tai and Indonesian families. The dominant view is that the Vietnamese people originated in the Red River Delta and represent a racial and cultural fusion, the various elements of which are still not fully determined.

ETHNIC ORIGINS AND CHARACTERISTICS

As is true of all of the peoples of Southeast Asia, diversity characterizes the evolution of the peoples who inhabited the regions of Indochina now occupied by the Vietnamese. There is little controversy concerning the earliest known inhabitants of Southeast Asia: they were Negroid Pygmies who may have arrived in Indochina between 25,000 and 50,000 years ago and of whom remnants are still found in Malaya and the Philippines. They were followed by Australoid and Melanesian Negritos of the Australian and Papuan species. Skulls found along the coast of the South China Sea confirm that Negritos were the earliest known inhabitants of Vietnam. Finds at Hoa Binh and Bac Son belonging to the Paleolithic Period show a preponderance of Melanesian and other Indonesian types, as do, to an even larger degree, Neolithic finds of the 2nd millennium BC.

Early inhabitants of Vietnam

Although the Negritos have disappeared from Vietnam, many racial characteristics among the mountain tribes of South Vietnam appear to support the view that some were absorbed by later arrivals in Indochina. These were the Austronesians (Indonesians), the main groups of whom penetrated from southern China into the eastern regions of the Indochinese peninsula probably between 2500 and 1500 BC, some possibly even earlier.

Soon afterward there arrived the ancestors of two Austroasiatic families. These newcomers, who may have started a movement of the Austronesians toward the island world of Indonesia, never left the mainland. These were linguistically classified groups of Mon-Khmer and Malayo-Polynesian peoples. Descendants of the Mon-Khmer still inhabit Cambodia and the lowlands of Thailand and

Myanmar, and it was a Malayo-Polynesian people that formed the Kingdom of Champa, situated along the east coast of Indochina. Racial and linguistic characteristics indicate that these Austroasiatics have contributed to the formation of the Vietnamese people. Both linguistic groups are still represented among the mountain tribes of South Vietnam and Laos.

Formation of the Vietnamese people

The formation of the Vietnamese people as a distinct ethnic group, however, took place long after the arrival of the Austronesians and Austroasiatics in Indochina. In the Bronze Age, which probably began in Vietnam some time between 600 and 400 BC, the inhabitants of the Red River Delta still were essentially of Indonesian stock. These people, who brought bronze from southern China, were probably the last Indonesian immigrants to Indochina. They were soon followed by immigrants of the Viet and Tai families—who added a Mongoloid strain to the mixed Indonesian stock in the Red River Delta—and, after 111 BC, by Chinese soldiers, administrators, and later Chinese refugee scholars. During these centuries—between *c.* 200 BC and AD 200—the Vietnamese were formed as a separate ethnic entity through a fusion of all these elements.

Language research, which offers a more reliable way of distinguishing the various ethnic groups of Southeast Asia, confirms the mixed racial and cultural origin of the Vietnamese people. Although the Vietnamese language is a distinct entity, it can nevertheless also be described as a fusion of Mon-Khmer, Tai, and Chinese elements. From the monotonic Mon-Khmer language family, Vietnamese derived many of its basic words; from the Tai languages, it took tonality and a number of grammatical elements; and from the Chinese, in a more advanced state of civilization, it took not only a script but also most of its governmental, literary, philosophical, and technical vocabulary.

Ethnography also reveals the extent to which the ancient Vietnamese culture was a composite of elements found among most peoples of the mainland and islands of Southeast Asia. Totemism, animism, tattooing, the chewing of betel nuts, the blackening of teeth, and many marriage rituals and seasonal festivals indicate the relationship between the Vietnamese and peoples of Melano-Indonesian, Khmer, and Tai stock; customs, religion, historical legends, and social organization all underline this relationship. To be sure, Chinese civilization later became the main force in shaping Vietnamese culture, and Indian civilization, via the states of Champa and Cambodia, was a secondary influence. But the failure of the Chinese to absorb the Vietnamese people underscores the fact that strong elements of an authentic local culture must have been developed in the Red River Valley long before China established its 1,000 years of rule over Vietnam.

LEGENDARY AND EARLIEST KNOWN HISTORY OF VIETNAM

According to their most authoritative legends, the history of the Vietnamese people begins with King De Minh, a descendant of a divine Chinese ruler who was also the legendary father of Chinese agriculture. De Minh and an immortal fairy of the mountains produced Kinh Duong Vuong, ruler of the Land of Red Demons, who married the daughter of the Dragon Lord of the Sea. Their son, Lac Long Quan, Dragon Lord of the Lac, is regarded as the first authentic Vietnamese king (Lac was the first designation for the Vietnamese). To make peace with the Chinese, Lac Long Quan married Au Co, a Chinese immortal, who bore him 100 eggs, from which sprang 100 sons. Later, the King and Queen separated; Au Co moved with 50 of her sons into the mountains, and Lac Long Quan kept the other 50 sons and continued to rule over the lowlands. Lac Long Quan's oldest son succeeded him as Hung Vuong (Vuong means king). Hung Vuong is regarded as the real founder of the Vietnamese nation and of the first Vietnamese dynasty—the Hong Bang.

Lac Long Quan

This legend and other related legends, most of which received their literary form only after AD 1200, describe in mythical terms the fusion, conflicts, and separation of peoples from the north and south and of peoples from the mountains and the lowlands near the sea. The legends show the immortals as mountain dwellers, while the people along the sea are represented by the Dragon Lords—a division found in many legends among the Indonesians all over Southeast Asia. The retreat of Au Co and 50 of her sons into the mountains may well be a mythical record of a separation among the proto-Vietnamese in the Red River Delta: those who left the lowlands could be the ancestors of the Muong, who still live in the hills surrounding the Red River deltas and who are the only ethnic minority of Vietnam closely related in language and customs to the Vietnamese.

The Hong Bang dynasty, legend continues, had 18 kings, each of which ruled for about 150 years. Their country, called Van Lang ("Land of the Tattooed Men"), is said to have extended not only over the Red River Delta but also over much of southern China. The last of the Hong Bang kings was overthrown by the ruler of neighbouring Thuc, who invaded and conquered Van Lang, united it with Thuc, and called the new state Au Lac, which he ruled under the name Au Duong Vuong. Au Lac existed only until 208 BC, when it was incorporated by the former Chinese general Trieu Da (Chao T'o in Chinese) into the kingdom of Nam Viet (Nan Yüeh in Chinese).

Nam Viet covered much of southern China and was ruled by Trieu Da from his capital near the present site of Canton. Its population consisted chiefly of the Viets who had earlier been driven by the Chinese from their kingdoms south of the Yangtze River. Trieu Da, after throwing off Chinese sovereignty and killing all officials loyal to the Chinese emperor, adopted the customs of the Viets and made himself the ruler of a vast non-Chinese empire. After it had incorporated Au Lac, Nam Viet included not only the Red River Delta but also the country as far south as modern Da Nang. The end of Au Lac in 207 BC marks the end of legendary history and the beginning of Vietnamese history as recorded in Chinese historical annals.

After almost 100 years of diplomatic and military duels between the Chinese empire and Trieu Da and his successors, Nam Viet was conquered (111 BC) by the Chinese under the Han emperor Wu Ti. Thus did the territories occupied by the ancestors of the Vietnamese fall under Chinese rule. Nam Viet became the Chinese province Giao Chi (later Giao Chau), which was divided into nine military districts. The three southernmost of these covered the northern half of what is now Vietnam.

Early Vietnamese history

When China extended her rule over Vietnam the people of the Red River Delta were about to enter from the Bronze into the Iron Age, although some stone implements were also still in use. These ancestors of the Vietnamese were already experienced in the cultivation of wet rice. They had learned how to irrigate their rice fields by using the tides that backed up the rivers. Ploughs and water buffalo were still unknown (the land was prepared for cultivation with polished stone hoes), but the proto-Vietnamese are thought to have been able to produce two rice crops annually. They also fished and hunted. Their weapons were mainly bows and arrows; the bronze heads of their arrows were often dipped in poison to facilitate the killing of such larger animals as elephants, whose tusks were traded for iron from China.

The social organization of the early Vietnamese, before Chinese rule, was hierarchical, forming a kind of feudal society that until recently still existed among the Tai and Muong minority populations of North Vietnam. Power was held by tribal chiefs at the head of one or several communities. These chiefs were civil, religious, and military leaders, and their power was hereditary; they were large landowners who kept the mass of the people in virtual serfdom. At the head of this aristocracy stood the king, probably the most powerful among the tribal chiefs.

Religion was characterized by animistic beliefs in supernatural beings and spirits common among primitive agricultural and hunting peoples. Some of these were the spirits of dangerous animals, others of deceased important persons who, like spirits generally, needed to be propitiated. A great religious festival, almost a carnival, was held at the beginning of spring and was marked by abandon and promiscuity.

In all these respects, the inhabitants of the Red River Delta, prior to their subjugation by the Chinese Empire, showed numerous affinities with most of the people of mainland and island Southeast Asia—the Tai, the Mon-Khmer, and the Melano-Indonesians. It was not until several centuries after the imposition of Chinese rule that the Vietnamese developed the more distinct ethnic characteristics of a people destined to become a nation of their own.

FUNAN AND CHAMPA

pread
f Indian
ıfluence

The formation of the Vietnamese people proceeded under Chinese political rule, and two states arose in the regions of what is now South Vietnam. The political institutions, religion, philosophy, and art of the people were shaped in part by the spread of Indian influence over the Indochinese peninsula. One of these states, Funan, was founded in the 1st century AD, extending over the Mekong Delta and the entire region of what is now Cambodia. The other state, Champa—founded, according to Chinese annals, in AD 192—occupied the east coast of Indochina from the confines of the Mekong Delta to as far north as the mountain ridge of Hoanh Son ("Horizontal Mountain") near the 18th parallel. A period of Chinese imperial decline explains the ability of the founders of Champa to include in their kingdom the southernmost and strongly Indianized province of Chinese-occupied Giao Chau. The formation of these two states was not due to Indian military conquests. The Austroasiatic peoples of these regions of Indochina became Indianized through lively commercial relations with India and through the penetration of Indian priests and literati before the rise of both kingdoms.

Although Indianized Funan dominated much of Indochina for several centuries and occupied a region that later became a vital part of Vietnam, no direct contacts existed between the people of Funan and the Vietnamese. The kingdom of Funan disappeared during the 6th century, almost 1,000 years before the Vietnamese reached the Mekong Delta. Funan was conquered by a people from the north, the Mon-Khmer, who in the next few centuries founded the powerful Cambodian Empire. Whatever influence the Indianized culture of Funan had on the evolution of Vietnamese culture was exercised indirectly via Champa and later via Cambodia.

Champa was still a strong neighbour of Vietnam after the Vietnamese had made themselves independent of China in the 10th century. Like Funan before it, Champa had a powerful fleet, which the Chams, who lacked enough land for agriculture along the mountainous coast, employed for commerce and in plundering campaigns against their neighbours. For many centuries Champa was a semipiratical country that, from hidden bays, conducted attacks on trading ships along the entire east coast of Indochina and waged border wars even against China.

Cham civilization also was thoroughly Indianized. Sanskrit was used as a sacred language, and Indian influence dominated art and agriculture, as is evidenced by the collection of Cham art in the Museum of Da Nang and by the ruins of a Cham city in the province of Quang Nam.

Champa's aggressiveness and Vietnam's need for territorial expansion explain the centuries of clashes between the two countries, which, toward the end of the 15th century, led to the virtual destruction of Champa. For this reason Champa's history can be viewed to advantage only in connection with the history of Vietnam, both while it was under Chinese rule and after it had become independent in the 10th century.

VIETNAM UNDER CHINESE RULE (111 BC–AD 939)

The history of the Vietnamese people under more than a thousand years of Chinese rule reveals an evolution toward national identity, apparently inevitable when seen under three aspects. The first of these aspects is the introduction into the Red River Delta of the more advanced civilization of China, including technical and administrative innovations and the higher degree of Chinese learning, which made the Vietnamese the most advanced people of the Indochinese peninsula. The second is the efforts of the Chinese governors to achieve complete Sinicization through the imposition of Chinese culture and customs and the employment of political power. The third and most significant aspect of Vietnamese history during this period is the resistance of the Vietnamese people to total assimilation and the use they made of the benefits derived from Chinese civilization in their struggle against Chinese political rule.

on

Soon after extending their domination over what is now North Vietnam, the Chinese constructed roads, waterways, and harbours to facilitate communications with, and to ensure their administrative and military control over, these newly acquired provinces. They improved local agriculture with better methods of irrigation and the introduction of the metal plough and draft animals. They brought with them new tools and weapons, advanced the art of pottery, and used new mining techniques. But for more than 100 years after annexing Nam Viet in 111 BC, they abstained from interfering with the local administration. In the Chinese province of Giao Chau, the hereditary lords exercised control over the peasant population just as they had done while Giao Chau was a province of Nam Viet. Thus, although divided into military districts headed by Chinese governors, Vietnam remained, in fact, a leniently governed Chinese protectorate.

This form of government changed only at the beginning of the Christian Era, when an energetic governor realized that the sway of the local Viet lords over the population was an obstacle to Sinicization. The desire to exploit the fertile Red River Delta and its mountainous backcountry was certainly one reason the expansionist Han dynasty wanted to hold on to Vietnam: there were great forests and precious metals in the mountains and pearls in the sea, there was ivory, and there was a peasantry to be taxed and recruited for forced labour. China's main interest in holding the Red River Delta, however, was its value as an important stopover for ships engaged in China's nascent maritime trade with the Spice Islands, India, and even the Near East. Vessels from many countries with which China developed commercial relations docked at the harbours of the Vietnamese coast, not only bringing new goods but also establishing contacts with a wider world and thus promoting the development of the country. In this process, which began early in the 1st century AD, economic, cultural, and political functions developed that the hereditary local lords were unfit to discharge—another reason why direct Chinese rule through the importation of more and more Chinese officials became necessary.

Attempts
at Sinicization

As in all regions conquered by the Chinese Han dynasty (206 BC–AD 221, with a brief interruption between AD 8 and AD 23), efforts to set up direct Chinese rule were accompanied by a variety of attempts to transform the people of the Red River Delta into Chinese. Local customs were suppressed, and Chinese customs, rites, and institutions were imposed by force. Taoist and Confucian learning was pressed, together with the Chinese language; and even Chinese clothing and hairdress became obligatory. Many of these Chinese innovations were beneficial to the Vietnamese and were readily integrated into the indigenous local culture, but Sinicization never succeeded in reconciling the Vietnamese people and especially their leaders with Chinese political domination. Not only the masses of the people but even the educated Vietnamese who knew Chinese and wrote only in Chinese held on to the local spoken language.

Events in China accelerated the efforts at Sinicization in the Red River Delta. When a usurper, Wang Mang, took power from the Han dynasty between AD 8 and 23, thousands of officials, soldiers, and scholars fled China southward into the province of Giao Chau, the governor of which had refused to recognize the new imperial government. He thus received the manpower needed to push ahead with his policy of replacing local lords with Chinese officials and of spreading Chinese ideas and ways of life. Only then did the hereditary chiefs, after having submitted to Chinese overlordship for more than 100 years, begin to offer resistance.

Vietnamese
resistance

The first major rebellion against Chinese rule broke out in 39, led by the noble lady Trung Trac, whose husband, a tribal lord, had been executed by the Chinese. She and her sister Trung Nhi gathered the tribal chiefs and their armed followers, attacked, overwhelmed the Chinese strongholds, and had themselves proclaimed queens of an independent

Vietnamese kingdom. Three years later a strong army sent by the Han emperor re-established Chinese rule; the local aristocracy was deprived of all power; Vietnam was given a centralized Chinese administration; and Sinicization was resumed with increased intensity.

Although resistance to total Sinicization continued, more than 200 years passed before the Vietnamese were able to stage the next uprising. It too was led by a woman, Trieu Au, but it was crushed, after only six months. Like the Trung sisters before her, Trieu Au is said to have ended her life by throwing herself into a river.

This second uprising, which took place in 248, was preceded by far-reaching changes both in China and in the Chinese occupied Vietnamese lands. The decline of the Han dynasty before its fall in 220 had weakened Chinese power at the periphery of the empire. The rising kingdom of Champa not only took from Chinese control the southernmost regions of Giao Chau but soon began to attack the Chinese possessions farther north and even the coast of China itself. In the Red River Delta the Chinese governor Che Sie (ruled 187–226) had made Giao Chau virtually independent of China, which, after the fall of the Han dynasty, was split first into three contending kingdoms and later, up to 589, into six warring dynasties. During these centuries the number of Chinese immigrants, many of them scholarly officials, in Giao Chau increased; there was continuous intermarriage and a systematic dissemination of Chinese learning among the Vietnamese. A Sino-Vietnamese elite, whose members, although a product of Chinese civilization, nevertheless felt and acted more and more like nationalist Vietnamese, developed; and a representative of this class, Ly Bon, himself of Chinese ancestry, *c.* 542 led another rebellion that broke Chinese rule and for several years established another independent Vietnamese kingdom. Though he was defeated after only three years in power, his followers controlled distant mountainous regions of Vietnam until 603.

Chinese rule, although challenged several more times, remained secure as long as China was effectively ruled by the T'ang dynasty (618–907). But after the fall of the T'ang, the struggle to free Vietnam led to an almost uninterrupted series of uprisings that culminated in a disastrous defeat of a Chinese army in 939, the year from which the Vietnamese date the beginning of their independence.

THE FIRST PERIOD OF INDEPENDENCE (939–1407)

Ngo Quyen, the Vietnamese commander who deafeated the Chinese in 939, became the first head of the new state of Vietnam. To underline the continuity of Vietnam's national existence, he set up his capital at the site from which the country had been ruled before it was conquered by the Chinese. But for more than half a century independence brought to Vietnam neither peace nor political stability. When the reign of Ngo Quyen ended after only six years, Vietnam was torn apart by a dozen local military chiefs who, during the next 22 years, fought each other for power. A measure of stability was created by Dinh Bo Linh, who defeated the local lords, proclaimed himself emperor in 968, and pacified the new Sung dynasty (960–1279) of China with tributes. Still more progress was made under Le Hoan, the founder of the Earlier Le dynasty, who ruled Vietnam from 980 to 1005. But already in 981 he had to fight off the first Chinese attempt to reconquer Vietnam, and soon afterward he conducted several campaigns against the aggressive Chams to the south.

The Ly dynasty. Internal stability and economic progress, through the consolidation of the monarchy at the head of a centralized administration, came to Vietnam only under the first of her three great dynasties—the Ly, who ruled from 1009 until 1225. They called their country Dai Viet, but the Chinese continued to call it Annam. The Ly built many new dykes and canals and were famous as promoters of agriculture. As early as 1044 they began to build roads between the main cities, and they also founded the first postal service. They moved the capital back to Hanoi, then called Dong Kinh, which later as Tonkin became a European designation for northern Vietnam. The Ly gradually replaced the divisive local lords with a hierarchy of state officials trained in a civil service institute set up in 1076. Buddhist learning, widespread in Vietnam long before independence, was vigorously promoted, as were art and literature, the latter chiefly through the dissemination of classical Chinese texts. But although Dai Viet under the Ly made great political, economic, and cultural progress, its prosperity was constantly threatened by external wars. In 1057 the Chinese advanced once more against the Red River Delta, but they were met by the Vietnamese and defeated on Chinese soil in a war that lasted four years. Champa and also Cambodia, which had by then become the greatest power in Indochina, invaded the southern provinces of Vietnam while the Vietnamese were fighting off the Chinese. Cambodia attacked Vietnam again in 1128 and 1132, together with Champa, and staged five more invasions of Vietnam between 1138 and 1216.

The Tran dynasty. By that period, the Ly dynasty was already in decline. It was followed, after many years of civil strife, by the second great Vietnamese dynasty—the Tran, which lasted from 1225 to 1400. For most of their rule, the Tran successfully pursued the same 'olicies that had made the country strong under the Ly; the Tran too were harassed by Champa, but they managed to arrange several periods of peaceful coexistence. In the eyes of the Vietnamese, the greatest achievement of the Tran dynasty was the defeat of the Mongolian armies of Kublai Khan, who was about to make himself master of the Chinese Empire, replacing the Sung dynasty in China in 1279. Three Mongol invasions in 1257, 1284, and 1287 of armies said to have numbered between 300,000 and 500,000 men succumbed to Vietnamese resistance. The Tran general who defeated the Mongolian invaders, Tran Hung Dao, is still venerated as one of the great heroes of Vietnamese history.

Defeat of the Mongols

Vietnam had hardly recovered from these invasions when the war with Champa was resumed. For ten years after 1312 Champa was a feudatory state of Vietnam, but it was freed under a new king, Che Bong Nga, who invaded Vietnam several times and in 1371 actually stormed and pillaged Hanoi.

The drain of these wars on Vietnam's resources, together with the declining vigour of the Tran rulers, led to a deep economic and social crisis, which a high official, Ho Qui Ly, exploited to usurp the throne in 1400. Ho Qui Ly was a capable and bold reformer, and the country began to recover under his reign, but he was not to be given the time needed to consolidate his power. The deposed Tran appealed to the Chinese to help them regain the throne. China, then ruled by the Ming dynasty, which had ousted the Mongols in 1368 but had not broken with China's policy of imperialist expansion, readily complied with the Tran's request and invaded Vietnam in 1407. Vietnam succumbed, largely because the country was politically divided. Instead of re-establishing Tran rule, the Ming set up a direct Chinese administration; the country was ruthlessly exploited, and the old policy of assimilation resumed with such severity that the survival of the Vietnamese people as a separate nation depended once more on their ability to free themselves from Chinese rule.

EXPANSION, DIVISION, AND REUNIFICATION (1400–1802)

By the beginning of the 15th century, the evolution of the Vietnamese people had reached a point at which the attempt to make them Chinese could only strengthen their nationalist sentiments and arouse their determination to throw off the Chinese yoke. Under the leadership of Le Loi, a rich landowner in the province of Thanh Hoa south of the Red River Delta, a movement of national resistance started in 1418 and forced the Chinese to evacuate after ten years of struggle. Le Loi, who ascended the throne shortly afterward under the name of Le Thai To, became the founder of the third great Vietnamese dynasty, the Later Le (sometimes simply referred to as the Le), which, although not actually in power after 1600, headed the state until 1787.

The Later Le dynasty. Like the better rulers of the Ly and Tran dynasties, Le Thai To and some of his successors introduced many reforms. They gave Vietnam the most advanced legal code in Southeast Asia; promoted art, literature, and education; advanced agriculture; protected communal lands against the greed of large landowners; and even enforced a general repartition of land among the entire population at the expense of the large landowners. But the problem of the landless remained acute, due to population increase and the limits of available land in the north. The lack of land was one of the reasons the Le dynasty pursued a policy of territorial expansion and was a chief motive behind their efforts to drive the Chams from the small but fertile deltas to the south. Most of Champa was in fact conquered in 1471 under the leadership of Le Thanh Tong (reigned 1460–97). Masses of landless people were settled during the next decades in soldier-peasant villages all the way south from the vicinity of Da Nang to the neighbourhood of Nha Trang, the first great push in the Vietnamese march to the South. The elimination of Champa was followed by incursions into the Cambodian territory of the Mekong Delta, which the declining Khmer Empire was no longer able to defend. Saigon became Vietnamese shortly before 1700, and the rest of the south followed during the next 60 years. With the exception of the province of Soc Trang, which was not annexed until 1840, Vietnam had reached its present size by 1757.

This extension of Vietnam to a length of 1,000 miles altered the historical evolution of the state, the chief characteristic of which had been the existence of a strong central power at the head of a unified administration. Vietnam was divided twice, and its partitioned governments were at war with each other for countless years.

Two divisions of Vietnam. The first and shorter division of the country occurred soon after the elimination of Champa. The governor of Hanoi, Mac Dang Dung, made himself master of Vietnam in 1527. The deposed Le rulers and the generals loyal to them regained control of the lands south of the Red River Delta in 1545, but only after almost 50 years of civil war could they reconquer Hanoi and the north.

Expansion of precolonial Vietnam.

Of much longer duration and greater historical significance was the second division of Vietnam, which occurred about 1620, when the noble family of the Nguyen, who had governed the country's growing southern provinces from Hue since 1558, refused obedience to Hanoi. In Hanoi the Le monarchs were rulers in name only after the country was reunited following its first division; all real power was in the hands of the Trinh family, who had made themselves hereditary princes in charge of government. For 50 years the Trinh rulers tried in vain to regain control of the southern half of the country by military means. The failure of their last campaign in 1673 was followed by a 100-year truce, during which both the Nguyen and the Trinh paid lip service to Vietnamese unity under the Le dynasty but maintained separate governments over the two halves of the country.

National unity was re-established only after a period of revolution, political chaos, and civil war, which lasted from 1772 until 1802. Although the revolution started in the south, it was directed against the ruling houses of both south and north. It was led by three brothers, whose name in history—Tay Son—was that of their native village. The Tay Sons overthrew the southern regime in 1777 and killed the ruling family. While the Tay Sons waged war against the north, one member of the southern royal family—Nguyen Anh, who had escaped the massacre—regained control of Saigon and the deep south in 1778, but he was driven out again by the Tay Sons in 1783. When the Tay Sons also defeated the Trinh in 1786 and occupied Hanoi, Vietnam was briefly reunited under their rule. In 1788 the Chinese tried to exploit the crisis of Vietnam, but the Tay Son rulers, who had abolished the Le dynasty, were able to defeat the Chinese invaders. During the same year, however, Nguyen Anh succeeded, with French military assistance, in occupying Saigon and the Mekong Delta. In a series of campaigns that lasted 14 years, Nguyen Anh defeated the Tay Sons and gained control of the entire country. When Hue and Hanoi fell to his armies in 1802, he proclaimed himself emperor of reunited Vietnam under the name of Gia Long.

STATE AND SOCIETY OF PRECOLONIAL VIETNAM

Organization of the state

The rule of Gia Long and his successors up to the conquest of Vietnam by France in the late 19th century brought no innovations in the organization of the state, the basic character of which had already been firmly established by the Ly emperors during the 11th century. The Ly had successfully fought the revival of a local feudalism, which was rooted in the powers exercised by the tribal chiefs before the coming of the Chinese. From the 11th century on, Vietnam remained a centralized state headed by a monarch whose absolute powers were said to derive from a mandate from Heaven—one aspect of the thoroughly Confucian character of the Vietnamese state. Following the Chinese model, the Ly established a fixed hierarchy of state officials with nine degrees of civil and military Mandarins, appointed by the emperor and responsible only to him. All Mandarins—those at the very top at the imperial court as well as the lowest ranks in the provincial and local administration—were recruited in only one way: through civil service examinations taken after years of study. As a rule, only the wealthy could spend the time required for these studies. Nevertheless, except in periods of dynastic decline when offices were sometimes for sale, the road to positions of power was scholarship, not wealth.

The concept of a division of powers was alien to the precolonial rulers. The emperor, with the help of high-court Mandarins, was not only the supreme lawmaker and head of all civil and military institutions but also the dispenser of justice in both criminal and civil cases, and he delegated his powers to the hierarchy of Mandarins in the provinces and villages. Even public functions of a religious character were the sole prerogative of the emperor and his representatives on the lower levels of the administration. No military caste ever exercised control over the state, no religious hierarchy existed outside the Mandarins, and no aristocracy with political influence was allowed to arise. Titles of nobility, bestowed as honours, were not hereditary.

The economic policies of the great Vietnamese dynasties also favoured the maintenance of imperial and Mandarin power. Through the 900 years of independence between Chinese domination and French colonial rule, the country's economy remained almost exclusively agricultural. Villages of artisans and fishermen existed, and there was some mining; but the mass of people were engaged in the cultivation of rice, and neither national nor international trade was systematically promoted. No property-owning middle class of merchants ever threatened the authority of the scholar Mandarins, and the periodically rising power of great landowners was diminished from time to time through the redistribution of land. Gia Long and his successor, Minh Mang, actually abolished all huge landholdings during the first half of the 19th century. Theoretically the emperor owned all land, and it was by imperial decree that the settlers on newly conquered territories received their plots in the villages that sprang up all the way south from the Red River Delta to the Mekong.

Vietnam's rigid absolutism was somewhat limited because of a Confucian concept, according to which the family was the basic unit of civilized society; submission to the authority of the family head thus was the foremost moral obligation of every citizen. The absolutism was also eased slightly by the limited authority granted to the village administration, whose purely local affairs were dealt with by a council of notables elected as a rule from the more prosperous or otherwise prominent citizens; among these notables' duties were the enforcement of law, the levying of army and forced labour recruits, and the assessment of taxes. Next to devotion to family, loyalty to the village was traditionally the first duty of every Vietnamese.

Apart from periods of dynastic decline and civil war, Vietnam was competently ruled under the Ly, Tran, and Le dynasties. Its administration was probably well in advance of any other native administration in Southeast Asia. But Mandarin rule also had its drawbacks: the static nature of the economy and a firm opposition to any innovation, technical, social, or cultural. The Mandarins and the scholarly rulers of Vietnam looked for enlightenment only to the past. Their hostility to change hardened in the early 17th century, when innovation appeared to them more and more to be a Western means to penetrate and undermine traditional Vietnamese society.

WESTERN PENETRATION INTO VIETNAM

Early Western contacts

As early as 1516 a number of Portuguese adventurers had inaugurated the modern era of Western penetration into Vietnam. They were followed in 1527 by visiting Dominican missionaries, and in 1535 by the first military man, Captain Antonio da Faria, who established a Portuguese trading centre at Faifo (Hoi An), some 15 miles south of present-day Da Nang. More Portuguese missionaries arrived during that century, and a mission was set up at Faifo in 1596, but it became permanent only after 1615, when Jesuits expelled from Japan were allowed to enter Vietnam. The Portuguese, Spanish, and Italian missionaries were joined in the same year by a French Jesuit, the famous Alexandre de Rhodes, who completed a transcription of the Vietnamese language into Latin characters and became the first French author on Vietnam.

From the very beginning, French Catholic missionary work developed hand in hand with French efforts to establish trade relations with Vietnam. Rhodes propagated the advantages of trade as fervently as he preached the need for greater missionary efforts, but to establish profitable trade with Vietnam was a difficult task, as the Portuguese, Dutch, and English had already learned. The Dutch had established a trading centre in Hanoi in 1637, the English in 1672, and both did poorly. Based on information supplied by the missionaries, the French East India Company and the Society of Foreign Missions, both founded in 1664, nevertheless pursued their efforts untiringly. A French trading centre was established in Hanoi in 1680, but it failed as dismally as did those of the English and the Dutch. By 1680 the war between the north and south had come to an end, and with it ended the interest of the two Vietnamese governments in the acquisition of modern weapons and other goods from the West. After 1700 only the Portuguese at the port of Faifo were able to maintain some trade with Vietnam.

The continued decline of Portuguese power in the Far East and the withdrawal of the Dutch and English from Vietnam encouraged renewed French efforts during the 18th century to establish trade with both halves of the country. They failed for two reasons: the first was the rising hostility of the Mandarins toward missionaries and Westerners generally; the second was the poverty of the people, as one persistent Frenchman, Pierre Poivre, who had visited Vietnam several times, pointed out in 1750. The Mandarins, realizing that their own moral authority was being undermined by the teachings of Christianity, began to persecute the missionaries who had converted about a tenth of the Vietnamese. The rulers of both Vietnams became more and more anti-Western, an attitude that subsequently convinced all Frenchmen who entered Vietnam that only through military intervention could Vietnam be made a base for French colonial expansion in the Far East. But France, unable after 1760 to defend its Indian possessions against the English, lacked the resources for military action in Vietnam.

Growth of French influence

The fortunes of the French took a turn for the better only toward the end of the 18th century, when another missionary—Pigneau de Béhaine, titular bishop of Adran—succeeded in making himself political and military adviser to Nguyen Anh, who, after 1778, was engaged in the struggle to wrest the country from the Tay Sons. The Bishop, after failing to persuade Paris to send an army in support of Nguyen Anh on the eve of the French Revolution, privately recruited sailors, soldiers, officers, and engineers from French overseas possessions, and their military expertise contributed decisively to the victory of Nguyen Anh over the Tay Sons. As Emperor Gia Long, Nguyen Anh remained grateful to the French for their help and kept many as advisers at his court (Pigneau de Béhaine died in 1799). But Gia Long did not favour the Christian religion, and under his strongly anti-Western successor Minh Mang (reigned 1820–1841), all French advisers were dismissed. Subsequent efforts by Paris to establish trade and diplomatic relations with Vietnam were politely rejected, and the persecution of the missionaries and their followers was intensified. Seven missionaries and an unknown number of Vietnamese Christians were executed between 1833 and 1838—some because they were involved in open rebellion against the rule of Minh Mang. After these events, France abandoned its efforts to get into Vietnam by diplomatic means. From 1840 on, French Catholic propaganda openly asked for military intervention in favour of the persecuted missionaries.

Under Minh Mang's successor, Thieu Tri, who reigned from 1841 to 1847, most missionaries were expelled; some were sentenced to death after returning clandestinely, but none was executed. Nevertheless, the French took reprisals against Vietnam by bombing the harbour of Tourane (Da Nang) in April 1847. But only 10 years later, when France under Napoleon III was ready to participate in the Western policy of colonial expansion, missionary propaganda, strongly supported by naval officers operating in the Far East, succeeded in persuading the government to prepare a military expedition against Vietnam.

THE CONQUEST OF VIETNAM BY FRANCE (1858–83)

The decision to invade Vietnam was made by Napoleon III in July 1857. It was the result not only of missionary propaganda but, after 1850, also of the upsurge of French capitalism, which generated the colonialist concept of a need for overseas markets and the collateral request for a larger French share in Asian territories conquered by the West. The naval commander in the Far East, Adm. Rigault de Genouilly, long an advocate of French military action against Vietnam, was ordered to attack the harbour and city of Tourane and to turn it into a French military base. The execution of his order, however, was delayed until the summer of 1858 by the Anglo-French operation of 1857–58 against China. Genouilly arrived at Tourane on August 31, 1858, with 14 vessels and 2,500 men; the French

French invasion o Vietnam

stormed the harbour defenses on September 1 and occupied the town a day later. But Genouilly made no progress on land beyond Tourane, and because he lacked the necessary shallow-draft vessels to go on the Perfume River from the ocean up to Hue, he was unable to threaten the Vietnamese capital. The collaboration of the Vietnamese Catholics with the invaders, which missionary propaganda had promised, failed to come about. Furthermore, French casualties from tropical diseases soon exceeded their battle dead, and when the rainy season started in October, Genouilly's army was completely immobilized.

Genouilly recognized that he could make no further progress around Tourane and decided to attack Saigon. Leaving a small garrison behind to hold Tourane, he sailed southward on February 2, 1859. Saigon was taken on February 17, but strong Vietnamese resistance prevented Genouilly from going beyond Saigon. There too the Catholic uprisings, which had been predicted by Genouilly's missionary advisers, failed to materialize. To save his troops threatened by Vietnamese attacks at Tourane, Genouilly returned there in April 1859, leaving a Franco-Spanish garrison at the fortress of Saigon. (The Spanish, whose Dominican missionaries were also persecuted in Vietnam, took part during the first phase of the invasion with troops from the Philippines, but they withdrew from it in 1862.) Again completely frustrated at Tourane, Genouilly resigned his command; his replacement, Admiral Page, arrived in October 1859 with orders to evacuate Tourane. The last French soldier left the city and harbour on March 22, 1860.

The second phase of the Anglo-French war against China once more tied down the Far Eastern fleet of the French during 1860, and they made no progress at all in their attempted conquest of Vietnam. Only in February 1861 was the garrison at the fortress of Saigon relieved by a new expedition under the command of Adm. Léonard Charner. By the end of June 1861, after receiving new reinforcements from the French operating in China, Charner had conquered Saigon and three adjacent provinces. The Mandarin administrators, though they refused to collaborate with the French, were unable to offer effective military resistance against an invader equipped with modern weapons. The Court of Hue, ruled since 1847 by Tu Duc, the last emperor of precolonial Vietnam, was forced by Charner's successor, Adm. Louis-Adolphe Bonard, to sign away Saigon and the three lost southern provinces in a peace treaty concluded with France in June 1862. In addition to Saigon and its environs, it conceded to the French the island of Poulo Condore (Con Son), three open ports for trade with Vietnam, full freedom of action for the missionaries, and a heavy financial indemnity. Tu Duc finally ratified this treaty in April 1863, in part because the French, with new reinforcements from Africa and Algeria, had suppressed the first Vietnamese uprising but also because Tu Duc needed his troops to fight a local rebellion against his rule, which had broken out in the north. Tu Duc was also helpless four years later, when the next French governor at Saigon, Adm. Pierre-Paul-Marie de la Grandière, under the pretext of forestalling an anti-French uprising, annexed the Vietnamese provinces west of the Mekong River and thus extended French rule over the whole of Cochinchina. (Cochinchina had been the name given to Vietnam by the first Westerners to visit the country, but it was used by the French only for the south. The north became known in the west as Tonkin, while Annam, under French rule, was the name used both for the centre of Vietnam and for the country as a whole. The people of Vietnam, generally referred to as Annamese or Annamites, never used these foreign designations. They called the north Bac Bo, the centre Trung Bo, and the south Nam Bo.)

French military and diplomatic successes

French penetration of Indochina.

The French had taken more than eight years to make themselves masters of Cochinchina (a protectorate had been imposed on Cambodia in 1863), and it would take them 16 more years to extend their control over Tonkin and Annam and complete their conquest of Vietnam. They made a first attempt to enter the Red River Delta in 1873 after a young explorer and adventurer named Francis Garnier had shown, in a hazardous expedition, that the Mekong River could not serve as a trade route for the French into southwestern China. Garnier, with the reluctant consent of the Court of Hue, was sent to Hanoi to arbitrate a conflict between the local authorities and a weapons-smuggling French trader commanding a band of mercenaries. He arrived there in November 1873 at the head of a small force supplied by Saigon; he sided with the French trader and, after receiving reinforcements from Saigon, stormed the citadel of Hanoi. In a short time Garnier extended his control, through the reckless use of artillery, over all of the important cities of the north. But when Garnier was killed in December 1873 in a battle with Chinese pirates hired by the Vietnamese authorities, the first attempt to conquer the north collapsed. France, scarcely recovered from a defeat suffered at the hands of Prussia in 1871, was in no mood to supply Saigon with the money and manpower needed to extend and maintain French control over Tonkin. The anticolonial faction in the Paris government contended that it was costly enough to control and develop Cochinchina and more important for France to rebuild her strength in Europe than to undertake doubtful colonial adventures.

Only after ten more years of rapid economic progress was France again ready to join the race of the Western powers for colonial expansion. In April 1882 the administration at Saigon, with the blessing of Paris, sent a force of 250 men to Hanoi under Capt. Henri Rivière; and when Rivière, in May 1883, met the same fate as Garnier, the French Chamber of Deputies immediately voted the necessary credits for the imposition by force of French control over Tonkin. A strong expeditionary corps moved into the Red River Delta in August 1883, while the French fleet bombarded Hue, where, unknown to the French, the emperor Tu Duc had died a few weeks earlier. With Tonkin occupied and Hue at the mercy of the French, the court Mandarins decided to submit. On August 25, 1883, they signed a treaty that made Tonkin and Annam protectorates of France, an action that turned out to be only another step toward the establishment of direct French rule over the whole of Vietnam.

Ten years later the French annexed Laos also. In the case of Cambodia, the French had laid claim to the rights that Vietnam had exercised over its weakened neighbour; Laos, although no longer controlled by Vietnam but by Siam (Thailand), was taken under the same pretext. It was added to the so-called Indochinese Union, which was created by the French in 1887 and consisted, after 1893, of Vietnam, Cambodia, and Laos.

COLONIAL VIETNAM (1883–1939)

The lack of a consistent policy, which characterized the period of conquest, continued to plague the French in Vietnam during the next decade and a half. Though it is true that Vietnamese armed resistance and Mandarin sabotage, particularly in Annam and Tonkin, impeded constructive economic and social measures, the chief reason for the lack of progress in any field was the absence of agreed-upon purposes and of a firm direction in running the colony. For years the French were unable to decide how to administer their new possessions and how to develop them economically.

Paul Doumer. All this changed quickly and drastically after the arrival in 1897 of Governor General Paul Doumer, who completed the pacification of the country, destroyed the old organization of the Vietnamese state, and established direct French rule on all levels of the administration. His autocratic and centralized regime left the Court of Hue and its Mandarins without a trace of real power. Emperors, as well as Mandarins who refused to be mere figureheads, were replaced by men willing to serve the French. The administration was staffed from top to bottom with officials imported from France; even as late as the 1930s, after several periods of reforms and concessions to local nationalist sentiment, Vietnamese officials were employed only in minor positions and at very low salaries, and the country was still administered along the lines laid down by Doumer.

Establishment of direct French rule

Doumer's economic and social policies also determined for the entire period of French rule the development of French Indochina, as the colony became known in the 20th century. The railroads, highways, harbours, bridges, canals, and other public works built by the French were almost all started under Doumer, whose aim was a rapid and systematic exploitation for the benefit of France of Indochina's potential wealth; Vietnam was to become a source of valuable raw materials and a market for tariff-protected goods of French industries. The exploitation of natural resources for direct export was the chief purpose of all French investments, with rice, coal, rare minerals, and later also rubber as the main products. Doumer and his successors up to the eve of World War II were not interested in promoting industry, the development of which was limited to the production of goods for immediate local consumption. Among these industries—located chiefly at Saigon, Hanoi, and Haiphong—were breweries, distilleries, small sugar refineries, rice and paper mills, and glass and cement factories; the greatest industrial establishment was a textile factory at Nam Dinh, which employed more than 5,000 workers. The total number of workers employed by all industries and mines in Vietnam was 100,000 in 1930. Because the aim of all investments was not a systematic economic development of the colony but the attainment of immediate high returns, only a small fraction of profits was reinvested.

Effects of French colonial rule. Whatever economic progress Vietnam made under the French after 1900 benefitted only the French and the small class of rich Vietnamese created by the colonial regime. The masses of the Vietnamese people were deprived of such benefits by the social policies inaugurated by Doumer and maintained even by his more liberal successors, such as Paul Beau (1902–07), Albert Sarraut (1911–14, 1917–19), and Alexandre Varenne (1925–28). Through the construction of irrigation works, chiefly in the Mekong Delta, the surface of rice land was quadrupled between 1880 and 1930; but the individual peasant's rice consumption decreased during the same period without compensation by other foods. The new lands were not distributed among the landless and the peasants, who had too little acreage; they were sold to the highest bidder or given away at nominal prices to Vietnamese collaborators and French speculators. These policies created a new class of Vietnamese landlords, together with a class of landless tenants who worked the fields of the landlords for rents of up to 60 percent of the crop, which was sold by the landlords at the Saigon export market. The mounting export figures for rice were due not only to the increase in cultivable land but no less to the mounting degree of peasant exploitation.

The peasants who owned their land were rarely better off than the landless tenants. The peasants' share of the price of rice at the Saigon export market was less than 25 percent. Peasants continually lost their land to the large owners because they were unable to repay loans given them by the landlords and other money lenders at exorbitant interest rates. As a result the large landowners of Cochinchina—a mere 2.5 percent of the total number of landowners—owned 45 percent of the land, while the small peasants—who accounted for 71 percent of the owners—owned no more than 15 percent of the land. The number of landless families in Vietnam before World War II was estimated at 50 percent of the population.

The peasants' share of the crop after the landlords, the money lenders, and the middlemen (mostly Chinese) between producer and exporter had taken their share, was still more drastically reduced by the direct and indirect taxes Doumer had imposed to finance his ambitious program of public works. The most hated of these taxes was that on salt, the production and sale of which became a state monopoly and the price of which rose 3,000 percent over its precolonial rate. Other ways of making the Vietnamese pay for the projects undertaken for the benefit of the French were the recruitment of forced labour for public works and the absence of any protection against exploitation in the mines and rubber plantations, although the scandalous working conditions, the low salaries, and the lack of medical care were frequently attacked in the French Chamber of Deputies. The mild social legislation decreed in the late 1920s was never adequately enforced.

These policies had a negative effect also on France. Although France accounted for almost 60 percent of all Indochinese imports between 1920 and 1939, Indochina never became an important market for French industry. The absence of a really developmental economic policy prevented any significant increase in the wealth of Vietnam, and the social policies of the colonial regime perpetuated the poverty of the masses, of whom more than 80 percent remained peasants. Only through a more enlightened economic and social policy could they have become consumers of French goods. The French themselves and the 6,000–7,000 large Vietnamese landowners were the only people in the market for most goods imported from France.

Effects on France of policies in Vietnam

The statistics of the French seem to contradict their own claim that much was done for the Vietnamese in the areas of medical care and education. In 1939 no more than 15 percent of all school-age children received any kind of schooling, and about 80 percent of the population was illiterate, in contrast to precolonial times when the majority of the people possessed some degree of literacy. With its more than 20,000,000 inhabitants in 1939, Vietnam had one university, with fewer than 700 students. Only a small number of Vietnamese children were admitted to the lycées (secondary schools) for the children of the French.

Medical care was well organized for the French in the cities, but in 1939 there were only two physicians for every 100,000 Vietnamese, compared with 76 in Japan and 25 in the Philippines.

Two other aspects of French colonial policy are important in considering the attitude of the Vietnamese people, especially their educated minority, toward the colonial regime: one was the absence of any kind of civil liberties for the native population; the other, the exclusion of the Vietnamese from the modern sector of the economy, especially industry and trade. Not only rubber plantations, mines, and industrial enterprises were in foreign hands—French, where the business was substantial, and Chinese on the lower levels—but all other business too, from local trade to the great export–import houses. The social consequence of this policy was that, apart from the landlords, no property-owning native middle class developed in colonial Vietnam. Thus capitalism appeared to the Vietnamese to be a product of foreign rule, a fact that, together with the lack of democracy, profoundly influenced the nature and orientation of the national resistance movements.

THE MOVEMENTS OF NATIONAL LIBERATION

arly
esistance
French
ule

The anticolonial movement of the Vietnamese people can be said to have started with the establishment of French rule. Most local Mandarins of Cochinchina refused to collaborate with the French; instead they led guerrillas, composed of the remnants of the defeated armies, in attacks on French outposts and early in 1863 in a general uprising that the French were able to suppress within a few weeks. A much broader movement of resistance developed in Annam in 1885, led by Mandarins of the court; it was not defeated until 1888. A few years later armed resistance was resumed in Annam under the leadership of the great scholar Phan Dinh Phung, whose rebellion collapsed only after his death in 1895. Equally troublesome for the colonial administration was a chain of uprisings in Tonkin, the suppression of which took the French 14 years (from 1883 to 1897).

Apart from its local nature, the main characteristic of the national movement during this first phase of resistance was its political orientation toward the past. Its leaders were Mandarins and scholars. Filled with ideas of precolonial Vietnam, they wanted to be rid of the French in order to re-establish the old imperial and Mandarin order. Because this aspiration could have little meaning for the generation that grew to maturity after 1900, the national movement led by the royalist Mandarins, after being defeated militarily, was also dead politically.

new
ational
ovement

Phan Boi Chau. A new national movement arose soon after the turn of the century. Its most prominent spokesman was Phan Boi Chau, with whose rise the old traditionalist opposition gave way to a modern nationalist leadership that rejected French rule but not Western ideas, science, and technology. Although still a monarchist at the outset, Chau was a modern thinker for his time; his aim was a new Vietnam under a progressive emperor. He chose Prince Cuong De, a direct descendent of Emperor Gia Long, as his candidate.

In 1905 Chau went to Japan, and Prince Cuong De followed him in 1906. Abroad they founded the Association for the Modernization of Vietnam, thus reviving their country's name, of which the French had deprived them. Chau's plan, mildly encouraged by some Japanese statesmen, was to free Vietnam with Japanese help; he smuggled hundreds of young Vietnamese into Japan, where they studied sciences and underwent training for clandestine organization, political propaganda, and terrorist action. Inspired by Chau's effective writings, nationalist intellectuals in Hanoi opened the Free School of Tonkin in 1907, which soon became a centre of anti-French agitation and was consequently suppressed after a few months. Also under the inspiration and guidance of Chau's followers, mass demonstrations demanding a reduction of high taxes took place in many cities in 1908. As a symbol of their rejection of the past, a movement to cut off the men's traditional long hair was started and spread quickly over the whole country. Hundreds of demonstrators and suspected organizers were arrested—some were condemned to death, others sent to the island of Poulo Condore, which the French turned into a concentration camp for Vietnamese nationalists.

Chau was forced to abandon the hope that Vietnam could be freed with Japanese help when, after Japan had received a loan from France, he and Prince Cuong De were expelled from Japan in 1910. They went to China, where a revolution had broken out in Canton. There in 1912 they set up a republican government in exile, with Prince Cuong De as president. Chau also united a number of nationalist groups in the League for the Restoration of Vietnam, but a temporary setback in the Chinese Revolution enabled the French to have Chau thrown into prison in China. He was freed only in 1917 after the triumph of the revolution in southern China. Chau continued to work from exile, but his movement declined rapidly after World War I. In 1925 he was kidnapped by French agents in Shanghai, taken to Vietnam, and condemned to death; the liberal governor general Varenne changed the sentence to life confinement in his house in Hue. There Chau died in 1940.

During the years between the outbreak of World War I and the arrest of Chau, the movement for national liberation, disorganized and persecuted by the colonial regime, nevertheless manifested its existence in a variety of terrorist acts, demonstrations, and local revolts. In 1916, the 18-year-old emperor Duy Tan led an unsuccessful revolt, whose participants were either executed or deported; the Emperor himself was exiled to Reunion Island. In 1917 the indigenous garrison at Thai Nguyen staged an uprising and took the town, but it was quickly defeated by French troops from Hanoi. After 1920 a number of prominent intellectuals, among them Pham Quynh, pursued the hope of obtaining political concessions from the colonial regime through collaboration with the French. In the south, Bui Quang Chieu, who was one of the first Vietnamese to become a French citizen, was allowed to found the Constitutionalist Party of Cochinchina. But the total failure of these "reformist" efforts led to a revival of clandestine and revolutionary groups, especially in Annam and Tonkin; among these were the Vietnam Revolutionary Party, founded in Annam in 1925, and the more important Vietnamese Nationalist Party (Viet Nam Quoc Dan Dang, founded in 1927 and usually referred to as the VNQDD), whose leader, Nguyen Thai Hoc, was a 23-year-old teacher. The VNQDD preached terrorist action and penetrated the garrisons of indigenous troops with a plan to oust the French in a military uprising. On the crucial night of February 9–10, 1930, the troops of only one garrison, Yen Bai in Tonkin, killed their French officers, but they were overwhelmed a day later and summarily executed. A wave of repression followed that took hundreds of lives and sent thousands into concentration camps; Nguyen Thai Hoc and 12 of his collaborators were arrested and beheaded. The VNQDD was virtually destroyed, and for the next 15 years it existed mainly as a group of exiles in China supported by the Kuomintang (Chinese Nationalist Party).

Ho Chi Minh. For yet another reason, the year 1930 was an important one in the history of the national liberation movement. In 1925, the year of Chau's arrest, a new figure, destined to become the most prominent leader of the national revolution, had appeared on the scene as an exile in Canton. He was Nguyen Ai Quoc, better known as Ho Chi Minh, the name he adopted in 1943. In June 1925 Ho Chi Minh founded the Revolutionary League of the Youth of Vietnam, which became the nucleus of the Vietnamese Communist Party.

Ho Chi Minh had left Vietnam as a young seaman in 1912 and travelled widely before settling in Paris in 1917; he joined the Communist Party of France in 1920 and later spent several years in Moscow and China in the service of the international Communist movement. After making his Revolutionary League the most influential of all clandestine resistance groups, he succeeded in 1930 in forming the Indochinese Communist Party from a number of competing Communist organizations. In May 1930 the Communists exploited the existence of near starvation conditions over large regions of central Vietnam by staging a broad peasant uprising, during which numerous Vietnamese officials as well as many landlords were killed and "Soviet" administrations were set up in several provinces of Annam. It took the French until the spring of 1931 to suppress this movement and to re-establish, in an unparalleled wave of terror, their own control.

Unlike the dispersed and disoriented leadership of the VNQDD and some smaller nationalist groups, the Communist Party, relying on hundreds of cadres trained in Russia and China, recovered quickly from the setback of the entire liberation movement in 1930–1931. After 1936, when the French Popular Front government extended some political freedoms to the colonies, the clandestine apparatus of the Communist Party skillfully exploited all opportunities for the creation of legal front organizations, through which the party's influence on intellectuals, workers, and peasants was increased. In the south the Communists had to compete with a strong Trotskyite faction, and the spread of their influence was somewhat checked in regions where religiopolitical sects dominated—the Cao Dai, founded in 1926, and the Hoa Hao, which arose in 1939. But when all political freedoms were again suspended at the outbreak of World War II, the Communist Party, unified and in command of a well indoctrinated and disciplined following, was no doubt the most effective faction in the entire movement of national liberation.

WORLD WAR II AND INDEPENDENCE (1940–45)

Wartime liberation activities

For five years during World War II, Indochina was a French-administered possession of Japan. On September 22, 1940, Adm. Jean Decoux, the French governor general appointed by the Vichy government after the fall of France, concluded an agreement with the Japanese that permitted the stationing of 30,000 Japanese troops in Indochina and the use of all major Vietnamese airports by the Japanese Army. The agreement made Indochina the most important staging area for all Japanese military operations in Southeast Asia. The French administration cooperated with the Japanese occupation forces and was ousted only toward the end of the war (in March 1945), when the Japanese began to fear that the French forces might turn against them at the hour of approaching defeat. After the French had been disarmed, Bao Dai, the last French-appointed emperor of Vietnam, was allowed to proclaim the independence of his country and to appoint a Vietnamese national government at Hue, but all real power remained in the hands of the Japanese Army of occupation.

Apart from Cochinchina, where the religiopolitical sects and a few other small groups maintained themselves under Japanese protection, the movement of national liberation during these years was confined largely to the activities of the Vietnamese exiles in southern China. There, in May 1941, Ho Chi Minh succeeded in forming the Viet Nam Doc Lap Dong Minh Hoi, known subsequently as the Viet Minh, which was a united front of several nationalist groups under Communist direction. Under Nationalist Chinese pressure, a counterfront was organized under the name of Dong Minh Hoi ("Vietnam Revolutionary League"). On orders of Chiang Kai-shek, Ho Chi Minh was imprisoned in 1942. But the anti-Communist leadership of the Dong Minh Hoi proved incompetent, and the Allies—Chinese as well as U.S.—who needed intelligence about the Japanese in Vietnam and help in rescuing downed pilots, began more and more to rely on the Viet Minh. Under the direction of Vo Nguyen Giap, the Viet Minh organized a tight net of political agents and groups of guerrillas in northern Tonkin and thus made themselves useful to the Allies. Ho Chi Minh was released in 1943, made head of the Dong Minh Hoi, and given financial assistance and even some weapons from the United States OSS (Office of Strategic Services) for the anti-Japanese activities of the Viet Minh inside Vietnam. Ho Chi Minh used his position to advance the cause of the Viet Minh; he himself entered Vietnam in October 1944. When the Japanese surrendered in August 1945, the Communist-led Viet Minh ordered a general uprising. As the only group whose leaders were in the country and heading a well-organized political and military movement, the Viet Minh was able in the second half of August 1945 to take power in Hanoi without meeting any significant opposition. The Bao Dai-appointed government at Hue resigned on August 22, and the Emperor himself abdicated in favour of the government set up under Ho Chi Minh in Hanoi. A Provisional Executive Committee of South Vietnam, installed in Saigon and dominated by the Viet Minh, placed itself under the authority of the Hanoi government on August 25. When Ho Chi Minh proclaimed the independence of Vietnam on September 2, it was evident that in the struggle for power among the various groups in the movement for national liberation, the Communists had gained the upper hand.

The French—whose claim to reoccupy Indochina had been confirmed by the Potsdam Conference of the victorious Allies—rather than Vietnamese opponents prevented the Viet Minh from establishing themselves firmly in the whole country. But in denying to Ho Chi Minh's government the control of Vietnam, the French denied to all national liberation movement groups their common goal—the independence of Vietnam.

French oppositio

The Potsdam agreement provided that the British disarm the Japanese in the south of Vietnam and the Chinese disarm them in the north. The Chinese under Chiang Kai-shek did not favour the return of the French to Indochina, and Chinese occupation forces, after entering Tonkin in September 1945, therefore refrained from interfering with the established government. The British, who arrived in the south on September 12 after freeing French soldiers interned by the Japanese, not only armed them but also supported them in their struggle to depose the local Vietnamese administration set up by the Committee of the South. The French reconquest of Vietnam, which started on September 23, drove the Vietnamese—Communists and anti-Communists—into armed resistance. With the arrival of reinforcements at the end of September, the French broke this resistance after several weeks of fighting in and around Saigon. At the beginning of 1946 the French controlled the cities and highways of the south, but armed guerrilla resistance, morally and materially supported by the Hanoi government, continued all over Cochinchina and southern Annam. (J.Bu.)

THE FIRST INDOCHINA WAR (1946–54)

Negotiations between the French and Ho Chi Minh led to an agreement in March 1946 that appeared to promise a peaceful solution. Under the agreement France would recognize the Viet Minh government and give Vietnam the status of a free state within the French Union. French troops were to remain in Vietnam, but they would be withdrawn progressively over five years. For a period in early 1946 the French cooperated with Ho Chi Minh as he consolidated the Viet Minh's dominance over other nationalist groups, in particular those politicians who were backed by the Chinese Nationalists.

Despite tactical cooperation between the French and the Viet Minh, their policies were irreconcilable; the French aimed to re-establish colonial rule, while Hanoi wanted total independence. French intentions were revealed in the decision of Adm. Georges-Thierry d'Argenlieu, the high commissioner for Indochina, to proclaim Cochinchina an autonomous republic in June 1946. Further negotiations did not resolve the basic differences between the French and the Viet Minh. The First Indochina War began with the French bombardment of Haiphong on November 23, 1946, which caused at least 6,000 civilian casualties, and the subsequent Viet Minh attempt to overwhelm French troops in Hanoi on December 19.

Outbreak of war

Between 1946 and 1951 the Viet Minh waged an increasingly successful guerrilla war, aided after 1949 by the new Communist government of China. Despite large amounts of U.S. financial and military aid, the French were on the defensive by 1952.

Initially confident of victory, the French long ignored the real political cause of the war—the desire of the Vietnamese people, including their anti-Communist leaders, to achieve unity and independence for their country. French efforts to deal with this problem were devious and ineffective. Reuniting Cochinchina with the rest of Vietnam in 1949, they appointed a former emperor, Bao Dai, as chief of state. Anti-Communist nationalists, among them the Roman Catholic leader Ngo Dinh Diem, denounced these maneuvers, and leadership of the struggle for independence from the French remained with Ho Chi Minh.

By the end of 1953 the Viet Minh controlled much of Vietnam and neighbouring Laos. The deteriorating French military position became dramatically worse in March 1954, when their strong garrison at Dien Bien Phu was besieged by Viet Minh forces under Gen. Vo Nguyen Giap. A mounting demand in France for an end to the war in Indochina and the refusal of the U.S. Congress to intervene to save the French at Dien Bien Phu, which fell on May 7, 1954, led to French readiness to negotiate to end the war at an international conference already in session in Geneva.

THE TWO VIETNAMS (1954–65)

An agreement concluded at Geneva on July 21, 1954, and signed by French and Viet Minh representatives provided for a cease-fire and for a temporary division of the country at the 17th parallel of latitude into two military zones. All Viet Minh forces were to withdraw north of the 17th parallel, and all French and State of Vietnam troops south of the parallel; permission was granted for refugees to move from one zone into the other within a given time limit. An international commission was established, composed of Canadian, Polish, and Indian members under an Indian chairman, to supervise the execution of the agreement.

ɪrth
ɜtnam

This agreement left the Hanoi regime—recognized since 1950 by China and the Soviet bloc governments as the Democratic Republic of Vietnam—in control of only the northern half of the country. But the Viet Minh leaders had been convinced before they went to Geneva that total victory was within reach, and they agreed to this division only because they regarded it as provisional. Most of the conference participants—which included, in addition to the French and the Indochinese, delegations of the United States, the United Kingdom, the Soviet Union, and the People's Republic of China—approved a Final Declaration, which provided for all-Vietnamese elections supervised by the commission in July 1956 to unify the country; Viet Minh leaders appeared certain to win these elections. The U.S. and South Vietnam would not approve the unsigned Final Declaration.

In the meantime, reconstruction of war-ravaged North Vietnam was begun with great energy, and great sacrifices were imposed on the population. Assistance from China, the Soviet Union, and other Communist states enabled the Hanoi regime to embark on an ambitious program of industrialization. Except for some local revolts in 1956 against a brutally conducted campaign to collectivize agriculture, no serious social or political obstacles interfered with the north's steady economic progress between 1955 and 1965.

uth
ɜtnam

In contrast to the north, where the leaders in 1965 were those who had made the revolution 20 years earlier, South Vietnam went through several periods of turbulent political changes during the same span of time. On June 16, 1954, Emperor Bao Dai called upon the Roman Catholic leader Ngo Dinh Diem to form a new government. Diem succeeded against tremendous odds in mastering the existing political chaos in the south and, with political and profuse financial aid from the United States, in stabilizing his anti-Communist regime. He eliminated the pro-French leadership of the army and abolished the local autonomy of the religio-political sects. He also resettled an estimated 900,000 refugees from the north. In a government-controlled referendum in October 1955 that removed Bao Dai as chief of state, Diem made himself president of the Republic of Vietnam.

Diem's early success did not continue. Plans for land reform were sabotaged by entrenched interests. With U.S. financial backing the regime's chief energies were directed toward building up the army and a variety of intelligence and security forces to counter the still influential Viet Minh. Totalitarian methods were directed against all who were regarded as opponents, and the favouritism shown to Roman Catholics alienated the Buddhist population. Loyalty to the President and his family was made a paramount duty and Diem's brother, Ngo Dinh Nhu, founded a secret party to spy on officials, army officers, and prominent private citizens. Under these conditions, a Communist-led insurgency began in 1957, a year after the constituent assembly in Saigon reiterated Diem's refusal to participate in the all-Vietnamese elections described in the Final Declaration in Geneva. The insurrection appeared close to success when Diem's army overthrew him on November 1, 1963. Diem and his brother Nhu were killed following the coup, and there were nine changes of government before the military firmly seized control in June 1965 under Air Vice Marshal Nguyen Cao Ky.

THE SECOND INDOCHINA WAR

The military regime that brought an end to the period of rapid changes of government in Saigon was not noticeably different from the dictatorship of Ngo Dinh Diem. The militant Buddhists who had helped overthrow Diem strongly opposed Ky's government; but he was able to break their resistance, centred at Hue and Da Nang, in late spring 1966. Civil liberties were restricted; political opponents—denounced as "neutralists" and as helpful to the Communists—were imprisoned, usually without trial; and political parties were allowed to operate only if they did not openly criticize government policy.

The
military
regime

This character of the regime remained largely unchanged after the presidential elections on September 3, 1967, which the candidates of the military forces—Gen. Nguyen Van Thieu and his running mate Ky—won with only 35 percent of the vote (the opposition, whose 65 percent of the vote was split among 10 civilian candidates, charged that the victory was fraudulently obtained).

No less evident than the oppressive nature of the Thieu-Ky regime was its inability to cope with the Communist-led insurrection, which appeared to be even closer to victory in 1965 than it had been before the fall of Diem. In December 1960 the various groups engaged in the armed struggle against the Saigon regime had formed, under Communist direction, the National Front for the Liberation of the South (NFL; also called National Liberation Front, NLF), whose program—neutralization of South Vietnam, withdrawal of all foreign troops, and gradual reunification with the north—was endorsed by Hanoi in January 1961. With an openly Communist People's Revolutionary Party, founded in 1962, the Communists maintained their dominant position within the NFL. A steady infiltration of weapons and military experts from the north and effective recruitment in the south rapidly increased the number of NFL fighters, commonly called Viet Cong. The fighting strength of the Viet Cong grew from about 30,000 men in 1963 to about 150,000 in 1965 when, in the opinion of many U.S. military experts, the survival of the Saigon regime was most seriously threatened.

American-
ization
of the
war

American involvement in Vietnam. This danger set in motion early in 1965 the process described as the Americanization of the Vietnamese War. Until 1960 the United States had supported the Saigon regime and its army only with military equipment, financial aid, and, as permitted by the Geneva agreement, 700 advisers for the training of the army. The number of advisers had increased to 17,000 by the end of 1963, and they were joined by a rising number of U.S. helicopter pilots. All this assistance, however, proved insufficient to halt the advance of the Viet Cong, and at this critical point, Pres. Lyndon B. Johnson of the U.S., in February 1965, ordered the bombing of North Vietnam, hoping to prevent further infiltration of arms and men into the south. The bombing failed to stop Hanoi's support for the Viet Cong. On the contrary, according to U.S. military intelligence, the Hanoi government, four weeks after the start of the bombing, began to infiltrate its first regular army units, a battalion of about 400 to 500 men.

Four weeks after the systematic bombing of the north had begun, the United States sent its first combat troops to Vietnam—3,500 U.S. marines landed at Da Nang on March 7, 1965. By July 1965 the number of U.S. combat troops had reached 75,000; it continued to climb from month to month until it stood at more than 510,000 early in 1968. The Americans fought at the side of some 600,000 regular Vietnamese troops and several hundred thousand regional and local defense forces. (They were also joined by nearly 50,000 South Koreans and smaller numbers of troops from Thailand, New Zealand, and Australia.) The number of regular North Vietnamese army troops in the south was said to have been 50,000 at this time, and all Viet Cong combatants numbered about 230,000. (All these figures, as well as those of enemy casualties, are estimates thought by most observers to be highly unreliable.)

Nearly three years of intensive bombing in the north and of fighting in the south with the enormous quantity of modern equipment the U.S. was able to supply had devastated vast regions of Vietnam, both north and south, but seemed unable to weaken the will and strength of the NFL and North Vietnam. This situation became evident in the so-called Tet Offensive of February 1968, during which the Viet Cong and North Vietnamese attacked more than 100 cities and military bases, holding on to some for several weeks. After that, a growing conviction in Washington that a military victory was impossible and that continuation of the war at the current levels was no longer politically acceptable led President Johnson to reject the request of his commander in Vietnam, Gen. William Westmoreland, for an additional 206,000 U.S. soldiers. Instead, the President ordered a restriction of the bombing in the north, and this decision opened the way for U.S. negotiations with Hanoi, which started in Paris on May 13, 1968. After the bombing was halted over the entire north in November 1968, the Paris talks were enlarged to include representatives of the NFL and the Saigon regime.

Negotiations and U.S. troop withdrawals

Although a gradual withdrawal of U.S. troops was begun by Pres. Richard M. Nixon, the war, with United States participation, widened in Laos and, in April 1970, was taken by the U.S. into Cambodia, thus becoming again a truly Indochinese war. By April 1970, 115,000 U.S. troops had been withdrawn, and Nixon announced a plan to withdraw another 150,000 over the next 12 months. The withdrawal of all United States troops was made contingent, however, on the so-called Vietnamization of the war—the ability of the Saigon regime and its armed forces to contain the fighting, while peace talks went on in Paris and renewed U.S. bombing on a scale unprecedented in history continued all over Indochina.

Withdrawal of American troops. Finally, in January 1973, a cease-fire agreement was signed by the United States and all three Vietnamese parties. It provided for complete withdrawal of U.S. troops within 60 days and gave the Provisional Revolutionary Government (formed in 1969 by the NFL and other groups opposed to the regime) equal recognition with Saigon. (J.Bu./M.E.O.)

The signature of the Paris agreements did not bring an end to the fighting in Vietnam, however. The Saigon regime made a determined attempt to eliminate Communist power in the Mekong delta, and by late 1973 the northern leadership decided to resolve the situation through military means. Fierce fighting took place during 1974, and the Communists made important advances in the highland region of southern Vietnam. In early 1975 the Saigon regime still had control of the coastal littoral from north of Hue to the Mekong delta, but the strategic balance soon tipped sharply against the Saigon forces. The fall of Ban Me Thuot in the highlands was followed by the loss of Hue and Da Nang in March. Xuan Loc fell to the Communists on April 21, and the Communists entered the southern capital on April 30. The Second Indochina War was finally at an end.

REUNIFICATION

Following the Communist victory, Vietnam remained theoretically divided, with the Provisional Revolutionary Government responsible for the territory of southern Vietnam. After national elections in April 1976, formal reunification took place, and the actual situation, in which power lay with the Vietnamese Communist Party and the government in Hanoi, was ratified. The Socialist Republic of Vietnam was officially proclaimed on July 2, 1976.

Problems of peace

Vietnam at peace faced formidable problems. In the south alone, 57 percent of the population had been made homeless between 1965 and 1974, and more than 16 percent of the population had been killed or wounded during the same period. The costs in the north were probably higher. Plans to reconstruct the country following the devastation of the long years of war called for the expansion of industry in the north and of agriculture in the south. Within two years of the Communist victory, however, it became clear that Vietnam faced major difficulties in achieving its goals.

With only limited personnel trained to deal with peacetime problems, the Vietnamese government encountered considerable resistance to its policies, particularly in the vast urban concentration of Saigon (renamed Ho Chi Minh City in 1976). The former commercial community, the members of which were mostly ethnic Chinese, sought to avoid cooperating in the implementation of new socialist economic measures, and many ethnic Vietnamese city-dwellers were reluctant to become pioneer agricultural workers in "new economic zones." Vietnam also suffered major floods and drought that severely decreased rice production. One result of these circumstances was the flight of 545,000 refugees from both southern and northern Vietnam by 1980. These refugees were in addition to the 135,000 who had fled at the time of the fall of Saigon in 1975.

Internal difficulties were compounded by Vietnam's problems in the field of foreign affairs. Perhaps unrealistically, Vietnam had hoped to gain U.S. economic aid following the end of the Second Indochina War. When such aid was not forthcoming, and in circumstances of acute economic distress, Vietnam turned to the Soviet Union and developed an even closer relationship with that country. In June 1978 Vietnam became a member of the Council for Mutual Economic Assistance (Comecon), the east European Communist economic bloc dominated by the Soviet Union. Subsequently, in November 1978, Vietnam signed a 25-year treaty of friendship and cooperation with the Soviet Union. This strengthening of both political and economic ties with the Soviet Union took place at a time when Vietnam's relations with the People's Republic of China and Cambodia (Kampuchea) were rapidly deteriorating. Savage fighting between Vietnam and Cambodia grew more intense through 1978 and concurrently Vietnam and China traded charges of subversion and armed aggression. It was in these circumstances that the first significant exodus of ethnic Chinese refugees from northern Vietnam into China took place.

Invasion of Kampuchea

Vietnam invaded Kampuchea at the end of 1978. Following a short campaign, Vietnam overcame resistance from the regime of Pol Pot in the central Cambodian region and installed a new protégé regime in Phnom Penh in early January 1979. Resistance to the Vietnamese and their Cambodian protégés continued on a significant scale, however, and it was not until the middle of 1979 that the remnants of Pol Pot's forces were driven back to remote regions in the northern and western parts of Cambodia.

China's invasion o
Vietnam

With Vietnam heavily engaged in Cambodia, where some 200,000 Vietnamese troops had been committed, China embarked on a month-long punitive invasion of northern Vietnam beginning in mid-February 1979. This invasion to "teach the Vietnamese a lesson" for their actions in Cambodia involved 100,000 troops, some of whom penetrated as deeply as 30 miles inside Vietnamese territory. In 17 days of campaigning, the Chinese destroyed major Vietnamese towns and inflicted heavy damage on Vietnam's economic infrastructure. The invasion was not a one-sided affair, however. Although taking heavy casualties themselves, the Vietnamese were able to inflict substantial losses on the Chinese.

Events following the Vietnamese invasion of Cambodia and the subsequent Chinese invasion of Vietnam confirmed Vietnam's increasing isolation in Southeast Asia. Apart from the protégé regime in Phnom Penh and the government of Laos, which was also heavily dependent on Vietnamese assistance for its survival, Vietnam was at odds with the remainder of its regional neighbours. Condemnation of Vietnam's presence in Cambodia by the members of the Association of Southeast Asian Nations (ASEAN) stood in the way of Vietnamese efforts to gain international recognition for its regime in Phnom Penh. Peace talks between Vietnam and China aimed at settling the major differences between those two countries were unproductive. (M.E.O.)

Vietnam also experienced continuing major social and economic difficulties. Following intense international pressure to prevent a further outflow of refugees, Vietnam agreed to curtail refugee departures in July 1979. But the continuing number of persons leaving Vietnam during the 1980s, both ethnic Vietnamese and Chinese, underlined the harsh nature of prevailing economic conditions. The cost of maintaining troops in Cambodia and Laos and of keeping combat-ready troops along the Sino-Vietnamese border was particularly heavy. In addition, there were continuing difficulties in integrating the southern part of the country into a socialist economy. Internal security was not seriously threatened by the continued existence of anti-government groups. There was, however, sufficient resistance from discontented minorities, particularly in the central highlands, to add a further burden to the Hanoi government. During 1986 the death of longtime Vietnamese Communist Party boss Le Duan and the resignation of several other top party leaders constituted a major changing of the political guard. (M.E.O./Ed.)

BIBLIOGRAPHY

Kampuchea: L.P. BRIGGS, *The Ancient Khmer Empire* (1951), the most comprehensive work in English on the subject, drawn from all the major French scholars; JEAN DELVERT, *Le Paysan cambodgien* (1961), a classic study of Cambodian geography and rural life; DAVID P. CHANDLER, *The Land and People of Cambodia* (1972), a historical treatment aimed at high school students; CLAUDE-GILLES GOUR, *Institutions constitutionnelles et politiques du Cambodge* (1965), an intensive analysis of Cambodia's constitutional institutions; FRANK M. LEBAR (ed.), *Ethnic Groups of Mainland Southeast Asia* (1964), one of the best sources of information about the country's many tribal groups; CHARLES MEYER (ed.), *Cambodge* (1962), a beautifully illustrated volume devoted to all aspects of life in Cambodia; JACQUES MIGOZZI, *Cambodge: Faits et problèmes de population* (1973), a detailed analysis of demographic trends; MILTON OSBORNE, *Politics and Power in Cambodia* (1973), an analysis of Cambodia in the 1950s and 1960s; FRANCOIS PONCHAUD, *Cambodge année zéro* (1977; *Cambodia: Year Zero,* 1978), an account of Democratic Kampuchea; REMY PRUD'HOMME, *L'Economie du Cambodge* (1969), a penetrating analysis of the economy; WILLIAM SHAWCROSS, *Sideshow: Kissinger, Nixon, and the Destruction of Cambodia* (1979), an analysis of U.S. policy toward Cambodia during the Khmer Republic period; D.J. STEINBERG *et al., Cambodia: Its People, Its Society, Its Culture,* rev. ed. (1959), a compendium of information drawn from numerous published sources, somewhat outdated, but still useful; W.E. WILLMOTT, *The Chinese in Cambodia* (1967), one of the rare books devoted to the Chinese in Cambodia and their relations with the Khmer. Much of the important material concerning Cambodian history until the fall of Angkor is in journal articles, mostly in French. Among the more valuable and readily available sources are: G. COEDES, *Les États hindouisés d'Indochine et d'Indonésie,* rev. ed. (1964; Eng. trans., *The Indianized States of Southeast Asia,* 1968), *Les Peuples de la Péninsule Indochinoise* (1962; Eng. trans., *The Making of South East Asia,* 1966), and *Pour mieux comprendre Angkor* (1943; Eng. trans., *Angkor: An Introduction,* 1963), three studies by the most distinguished French scholar of Cambodia to the end of the Angkorian period; J. BOISSELIER, *Le Cambodge* (1966), the most complete archaeological survey of the end of the Angkorian period; B.-P. GROSLIER and J. ARTHAUD, *Angkor: Hommes et pierres,* rev. ed. (1965; Eng. trans., *Angkor: Art and Civilization,* 1966), a fine pictorial study with concise text; M. GITEAU, *Les Khmers* (1965; Eng. trans., *Khmer Sculpture and the Angkor Civilization,* 1965), by a former curator of the Phnom Penh National Museum; L.P. BRIGGS, *The Ancient Khmer Empire* (1951), a detailed survey of Cambodian history to the fall of Angkor, now in need of revision; O.W. WOLTERS, "The Khmer King at Basan (1371–3) and the Restoration of the Cambodian Chronology during the Fourteenth and Fifteenth Centuries," *Asia Major,* 12:44–89 (1966), an important journal article suggesting a revision of the date of the fall of Angkor; and D.G.E. HALL, *A History of South-East Asia,* 3rd ed. (1968), for a summary of Cambodian history. B.-P. GROSLIER, *Angkor et le Cambodge au XVI^e^ siècle d'après les sources portugaises et espagnoles* (1958), discusses the economic basis of Angkorian times and the "Spanish interlude"; D.P. CHANDLER, *Cambodia Before the French; Politics in a Tributary Kingdom, 1794–1848* (1974), a valuable study; J. MOURA, *Le Royaume du Cambodge,* 2 vol. (1883), an early French study; A. LECLERE, *Histoire du Cambodge*... (1914), a monumental but flawed pioneering history; M.E. OSBORNE, *The French Presence in Cochinchina and Cambodia: Rule and Response (1859–1905)* (1969), treats the first 50 years of French rule; D.J. STEINBERG *et al., Cambodia: Its People, Its Society, Its Culture,* rev. ed. (1959), a useful but dated survey; R.M. SMITH, "Cambodia," in G.M. KAHIN (ed.), *Governments and Politics of Southeast Asia,* 2nd ed. (1964); *Cambodia's Foreign Policy* (1965), a sympathetic study of Sihanouk's policies; M. LEIFER, *Cambodia: The Search for Security* (1967), critically evaluates foreign policy issues; W.E. WILLMOTT, *The Chinese in Cambodia* (1967), a valuable study of the Chinese minority in Cambodia; M.E. OSBORNE, *Politics and Power in Cambodia; The Sihanouk Years* (1973); and NORODOM SIHANOUK, *War and Hope* (1980), a plan to rescue Cambodia from its invaders.

Laos: RENE DE BERVAL *et al., Présence du royaume Laos, pays du million d'éléphants et du parasol blanc* (1956; Eng. trans., *Kingdom of Laos: The Land of the Million Elephants and of the White Parasol,* 1959), a general symposium by French and Laotian writers on the country's history, economy, society, and culture; FRANK M. LE BAR and ADRIENNE SUDDARD (eds.), *Laos: Its People, Its Society, Its Culture* (1960), a general survey by American scholars; T.D. ROBERTS (ed.), *Area Handbook for Laos* (1972), a highly readable survey. E.H.G. DOBBY, *Southeast Asia,* 10th ed. (1967), a standard work; C. ROBEQUAIN, *L'Évolution économique de l'Indochine française* (1939; Eng. trans., *Economic Development of French Indo-China,* 1944), an older but useful study. J.M. HALPERN, *Government, Politics and Social Structure in Laos: A Study of Tradition and Innovation* (1964), a detailed treatment by a leading authority; *Economy and Society of Laos: A Brief Survey* (1964), a good detailed overview; P. SASORITH, *Contribution à l'histoire du mouvement d'indépendance nationale Lao* (1948), on the Lao Issara movement, by its chief spokesman; H. TOYE, *Laos: Buffer State or Battleground* (1968); D.K. WYATT,"Siam and Laos 1767–1827," *Journal of South East Asian History,* 4:13–32 (1963); and *Iron Man of Laos,* by PRINCE PHETSARATH RATANAUONGSA (1978), in effect, a history of Laos during the Vichy rule, Japanese domination, and immediate postwar period.

Malaysia: S.T. ALISJAHBANA *et al.* (eds.), *The Cultural Problems of Malaysia in the Context of Southeast Asia* (1967), articles on aspects of the culture, religion, and languages of the peoples of Malaysia; SUDHIR ANAND, *Inequality and Poverty in Malaysia: Measurement and Decomposition* (1982), a study that discusses poverty and income distribution in Malaysia; the national atlas of Malaysia, *Atlas Kebangsaan Malaysia* (1977), features a wide range of geographic and demographic information; JASBIR CHHABRA *et al., The World Tin Economy: An Econometric Analysis* (1978), an account of particular relevance to Malaysia; C.A. FISHER, *South-East Asia* (1964), an important work on the geography of Southeast Asia, with a substantial section on the states of Malaysia; D.W. FRYER, *Emerging Southeast Asia,* 2nd ed. (1979), a wide-ranging analytical study of the economy of Southeast Asian countries, with a perceptive chapter on Malaysia; J.C. JACKSON, *Sarawak: A Geographical Survey of a Developing State* (1968), a comprehensive, well-documented survey; L.W. JONES, *The Population of Borneo* (1966), a demographic study of the peoples of Sarawak, Sabah, and Brunei, based on 1960 census statistics; V. KANAPATHY, *The Malaysian Economy: Problems and Prospects* (1970), a series of essays by an economist on manpower, agriculture, industrialization, financial institutions, and international trade; FRANK M. LEBAR (ed.), *Ethnic Groups of Insular Southeast Asia,* vol. 1, *Indonesia, Andaman Islands, and Madagascar* (1972), a discussion of the ethnic groups of East Malaysia; YONG LENG LEE, *North Borneo (Sabah): A Study in Settlement Geography* (1965), an examination of the problems and features of settlement in an equatorial environment, *Population and Settlement in Sarawak* (1970), a well-documented

study of the peoples and their impact on the landscape of Sarawak; CHONG-YAH LIM, *Economic Development of Modern Malaya* (1968), a detailed study of the evolution and growth of the West Malaysian economy from 1874 to 1963. NENA VREELAND *et al.* (eds.), *Area Handbook for Malaysia* (1977), a comprehensive compilation of basic information on the social, political, and economic background and national security of Malaysia; DIPAK MAZUMDAR, *The Urban Labor Market and Income Distribution: A Study of Malaysia* (1981), an analysis of Malaysia's urban work force; JIN-BEE OOI, *Peninsular Malaysia,* new ed. (1976), a comprehensive study of the physical environment, resources, population, and economy of West Malaysia; N.J. RYAN, *The Cultural Heritage of Malaya,* 2nd ed. (1971), a well-written, neatly organized book on the culture of the main ethnic groups of West Malaysia; B.C. STONE (ed.), *Natural Resources in Malaysia and Singapore* (1969), proceedings of a symposium held in 1967 containing numerous articles; GUNGWU WANG (ed.), *Malaysia: A Survey* (1964), studies on the history, geography, politics, economy, and societies of Malaysia; E.L. WHEELWRIGHT, *Industrialization in Malaysia* (1965), an enquiry into the industrial structure and the industrialization policies of Malaysia (and Singapore); KEVIN YOUNG, WILLEM C.F. BUSSINK, and PARVEZ HASAN, *Malaysia: Growth and Equity in a Multiracial Society* (1980), an argument for rapid growth in Malaysia to overcome the nation's economic and social problems. For contemporary information, see *Information Malaysia* (annual; formerly the *Malaysia Yearbook*). K.G. TREGONNING, *Southeast Asia: A Critical Bibliography* (1969), numerous annotated entries devoted to recent books and articles, including many bibliographical references on Malaya, and *A History of Modern Malaysia and Singapore,* rev. ed. (1972), a substantial survey; P. WHEATLEY, *The Golden Khersonese: Studies in the Historical Geography of the Malay Peninsula Before A.D. 1500* (1961, reprinted 1973), a brilliant analysis; J.M. GULLICK, *Malaysia* (1969), a comprehensive and valuable account; V. PURCELL, *The Chinese in Southeast Asia,* 2nd ed. (1965); W.R. ROFF, *The Origins of Malay Nationalism* (1967), an examination of the growth of the dominant political factor in the peninsula; CHONG-YAH LIM, *Economic Development of Modern Malaya* (1968); E. THIO, *British Policy in the Malay Peninsula, 1880–1910* (1969), a scholarly examination of the expansion of British control; C.N. PARKINSON, *British Intervention in Malaya, 1867–1877* (1960); J.-B. OOI, *Peninsular Malaysia,* new ed. (1976), a comprehensive geography; R. ALLEN, *Malaysia: Prospect and Retrospect* (1968), a discussion of the effects of colonial rule on Malaya.

Myanmar: E.H.G. DOBBY, *Southeast Asia,* 11th ed. (1973), gives a general description of Myanmar as a part of Southeast Asia and also contains a special section on the country itself, with detailed maps. O.H.K. SPATE, *Burma Setting* (1943), gives a brief but detailed introduction to the physical and social geography and some details of the economic geography up to the outbreak of World War II. H.L. CHHIBBER, *Physiography of Burma* (1933, reprinted 1975) and *Geology of Burma* (1934); and the *British Burma Gazetteer,* 2 vol. (1880, reprinted as the *Gazetteer of Burma,* 1983), are standard works. R. KAULBACK, *Salween* (1939); and L.D. STAMP, "Irrawaddy River," *Geogrl. J.,* 95:329–356 (1940), describe the drainage system. J.R. ANDRUS, *Burmese Economic Life* (1948); and J.S. FURNIVALL, *Political Economy of Burma,* 2nd rev. ed. (1938), describe the economy during the colonial period. FRANK N. TRAGER, *Burma: From Kingdom to Republic* (1966), contains an account of the economy before and after independence, up to the years of extensive nationalization in 1962–63. MAUNG HTIN AUNG, *A History of Burma* (1967); and MELFORD E. SPIRO, *Kinship and Marriage in Burma* (1977), give the historical background and contain accounts of Myanmar society and culture. JOSEF SILVERSTEIN, *Burmese Politics: The Dilemma of National Unity* (1980), is a useful analysis of contemporary politics. U AUNG THAW, "Neolithic Culture of Padhalin Caves," *Journal of Burma Research Society,* vol. 52 (1969), contains a good account of the Stone Age in Myanmar. See also the articles by G.H. LUCE on the Pyus, Mons, and Early Burmans, *ibid.,* vol. 27 (1932), vol. 34 (1950), and vol. 43 (1959); to be read with MAUNG HTIN AUNG, *Burmese History Before 1287: A Defence of the Chronicles* (1970). A.P. PHAYRE, *A History of Burma* (1883, reissued 1969); and G.E. HARVEY, *A History of Burma* (1925, reissued 1969), are standard works for the pre-British period (*i.e.,* to 1824). G.E. HARVEY, *British Rule in Burma, 1824–1942* (1946, reprinted 1974), attempts to justify British rule. DOROTHY WOODMAN, *The Making of Burma* (1962); MAUNG MAUNG, *Burma in the Family of Nations,* 2nd ed. rev. (1957); and MAUNG HTIN AUNG, *The Stricken Peacock: Anglo-Burmese Relations, 1752–1948* (1965), deal with the history of Anglo-Myanmar relations. The history for the post-independence period is given in H. TINKER, *The Union of Burma,* 4th ed. (1967); FRANK N. TRAGER, *Burma: From Kingdom to Republic* (1966, reprinted 1976); JOSEF SILVERSTEIN, *Burma: Military Rule and the Politics of Stagnation* (1977), and *Burmese Politics: The Dilemma of National Unity* (1980); and DAVID I. STEINBERG, *Burma's Road Toward Development: Growth and Ideology Under Military Rule* (1981), and *Burma: A Socialist Nation of Southeast Asia* (1982). D.G.E. HALL, *A History of Southeast Asia,* 4th ed. (1981), contains chapters on Myanmar history that give the British view.

Singapore: E.H.G. DOBBY, "Singapore, Town and Country," *Geogrl. Rev.,* 30:84–109 (1940); OOI JIN-BEE and CHIANG HAI DING (eds.), *Modern Singapore* (1969). Current information may be found in the (Singapore) *Monthly Digest of Statistics,* the *Singapore Year Book,* and the *Yearbook of Statistics.* R. HO, "The Physical and Human Background," in *Impact of Man on Humid Tropics Vegetation* (1960); S. NIEUWOLT, "Uniformity and Variation in an Equatorial Climate," *J. Trop. Geogr.,* 27:23–39 (1968); I.E.M. WATTS, "Rainfall of Singapore Island," *Malay. J. Trop. Geogr.,* 7:1–68 (1955). W. NEVILLE, "The Areal Distribution of Population in Singapore," *J. Trop. Geogr.,* 20:16–25 (1965); YOU POHSENG, "The Population of Singapore, 1966," *Malay. Econ. Rev.,* 12:59–96 (1967). C.T. EDWARDS, *Public Finances in Malaya and Singapore* (1970); FIRST NATIONAL CITY BANK, *Singapore: Foreign Investment Guide* (1969); GOH KENG SWEE, *Decade of Achievement* (1970); H. HUGHES and YOU POH-SENG, *Foreign Investment and Industrialization in Singapore* (1969). A. JOSEY, *Lee Kuan Yew and the Commonwealth* (1969); TAE YUL NAM, "Singapore's One-Party System," *Pacif. Affairs,* 42:465–480 (1969–70). M. FREEDMAN and M. TOPLEY, "Religion and Social Realignment among the Chinese in Singapore," *J. Asian Stud.,* 21:3–23 (1961); C. GAMBA, "Some Social Problems in Singapore," *Aust. Q.,* 26:99–106 (1954); B.B. Thailand: The annual *Thailand Official Year Book* is the best source for current information. An excellent, well-illustrated pamphlet of the TRIBAL RESEARCH CENTER OF THAILAND, "Tribesmen and Peasants in North Thailand, 1967" (1969), briefly describes all the tribesmen in Thailand. The ROYAL THAI SURVEY DEPARTMENT, *Thailand National Resources Atlas* (1969), is the only atlas that can be used authoritatively as a reference. MASASHICHI NISHIO, "Public Health in Thailand," *Southeast Asian Studies,* vol. 11, no. 1 (1964; Eng. trans. JPRS 32217, 1965), based on scholarly research, gives a true picture of health conditions in Thailand. On physical geography, see ROBERT L. PENDLETON, *Report to Accompany the Provisional Map of the Soils and Surface Rocks of the Kingdom of Siam* (1953); and the SIAM, MINISTRY OF COMMERCE AND COMMUNICATIONS, *Nature and Industry* (1930). General histories include: W.A.R. WOOD, *A History of Siam,* 2nd ed. (1933), essentially a chronicle of reigns; and PRINCE CHULA CHAKRABONGSE, *Lords of Life* (1960), a sympathetic account stressing the Bangkok period. A general account of the Chinese minority is G.W. SKINNER, *Chinese Society in Thailand: An Analytical History* (1957). On the Ayutthaya period, see CHARNVIT KASETSIRI, *The Rise of Ayudhya: A History of Siam in the 14th and 15th Centuries* (1977); GEORGE V. SMITH, *The Dutch in Seventeenth-Century Thailand* (1977); and E.W. HUTCHINSON, *Adventurers in Siam in the Seventeenth Century* (1940). The early Bangkok period is discussed in KLAUS WENK, *The Restoration of Thailand under Rama I, 1782–1809* (1968); WALTER F. VELLA, *Siam under Rama III, 1824–1851* (1957); and AKIN RABIBHADANA, *The Organization of Thai Society in the Early Bangkok Period, 1782–1873* (1969). For developments that followed the opening of the country to the West, see ABBOT LOW MOFFAT, *Mongkut: The King of Siam* (1961); JAMES C. INGRAM, *Economic Change in Thailand Since 1850* (1955); and DAVID K. WYATT, *The Politics of Reform in Thailand* (1969); TEJ BUNNAG, *The Provincial Administration of Siam, 1892–1915* (1977); WALTER F. VELLA, *Chaiyo!* (1978); and THAWATT MOKARAPONG, *History of the Thai Revolution* (1972). JOHN L.S. GIRLING, *Thailand: Society and Politics* (1981), a comprehensive overview.

Vietnam: A general view of the geography of Vietnam can be found in E.H.G. DOBBY, *Southeast Asia* (1950, 11th ed., 1973), while more regional information is contained in P. GOUROU, *Les paysans du delta Tonkinois* (1965), and F.R. MOORMAN, *The Soils of the Republic of Viet-Nam* (1961). Information on Vietnamese forests is included in L. WILLIAMS, *Vegetation of Southeast Asia: Studies of Forest Types, 1963–1965* (1965?). H. DE MONESTROL, *Chasses et faune d'Indochine* (1952) deals with wild game and hunting, while P. WILDASH, *Birds of South Vietnam* (1968) is a comprehensive ornithological work. J. BUTTINGER, *The Smaller Dragon: A Political History of Vietnam* (1958) and *Vietnam: A Dragon Embattled* (2 vol. 1967); G. COEDES, *Les Peuples de la péninsule Indochinoise* (1962; *The Making of South East Asia,* 1966); LE-THANH-KHOI, *Le Viêt-Nam: Histoire et civilisation* (1955); D.G.E. HALL, *A History of South-East Asia* (1955, 3rd ed., 1968); and D. DUNCANSON, *Government and Revolution in Vietnam* (1968). More specific historical books are L. BEZACIER, *Le Viêt-*

Nam (1972), on prehistory, and A. WOODSIDE, *Vietnam and the Chinese Model: A Comparative Study of Nguyên and Ch'ing Civil Government in the First Half of the Nineteenth Century* (1971), which focuses on the reigns of Gia Long and his son, Minh Mang. J.F. CADY, *The Roots of French Imperialism in Eastern Asia* (1954); V. THOMPSON, *French Indo-China* (1937); and D. LANCASTER, *The Emancipation of French Indochina* (1961). M. OSBORNE, *The French Presence in Cochinchina and Cambodia* (1969) concerns the late 19th and early 20th centuries in southern Vietnam and Cambodia, while C. ROBEQUAIN, *L'Évolution économique de l'Indochine français* (1939; *The Economic Development of French Indo-China,* 1944) treats French colonial economic policies. Sources on the Indochina War include P. MUS, *Viêt-Nam: Sociologie d'une guerre* (1952); E. HAMMER, *The Struggle for Indochina* (1954); P. DEVILLERS, *Histoire du Viêt-Nam de 1940 à 1952* (1952); and P. DEVILLERS and J. LACOUTURE, *La fin d'une guerre: Indochine 1954* (1960; *End of a War: Indochina, 1954,* 1969). D. WARNER, *The Last Confucian* (1963, rev. ed., 1964); G. MCT. KAHIN (ed.), *Governments and Politics of Southeast Asia* (1959, 2nd ed., 1964); R. SCIGLIANO, *South Vietnam: Nation Under Stress* (1964); R. SHAPLEN, *The Lost Revolution: The U.S. in Vietnam, 1946–1966* (1966); and D. HALBERSTAM, *The Making of a Quagmire* (1965). WILLIAM J. DUIKER, *The Communist Road to Power in Vietnam* (1981), a history of the rise of the communist party in Vietnam. Some works on the Vietnam War are G. MCT. KAHIN and J.W. LEWIS, *The United States in Vietnam* (1967); R. SHAPLEN, *The Road From War: Vietnam 1965–1970* (1970); D. WARNER, *Not With Guns Alone* (1977; *Certain Victory: How Hanoi Won the War,* 1978); and G. LEWY, *America in Vietnam* (1978). W. BURCHETT, *North of the Seventeenth Parallel* (1956, rev. ed., 1957); B. FALL, *Le Viet-Minh: La République Démocratique du Viet-Nam, 1945–1960* (1960); HOANG-VAN-CHI, *From Colonialism to Communism: A Case History of North Vietnam* (1964); J. LACOUTURE, *Ho Chi Minh* (1967, rev. ed., 1977; Eng. trans., *Ho Chi Minh,* 1968); P.J. HONEY (ed.), *North Vietnam Today* (1962); and D. PIKE, *Viet Cong: The Organization and Techniques of the National Liberation Front of South Vietnam* (1966). A general work on traditional Vietnamese society is P. HUARD and M. DURAND, *Connaissance du Viêt-Nam* (1954). A comprehensive work on traditional religious practices is L. CADIERE, *Croyances et pratiques religieuses de Vietnamiens,* 3 vol. (1958). HUYNH SANH THONG, *The Heritage of Vietnamese Poetry* (1979), and (ed.), *The Tale of Kieu* (1973), are analytical studies of Vietnamese traditional poetry. More recent works on Vietnamese society, economy, and politics include J. HENDRY, *The Small World of Khanh Hau* (1964); G.C. HICKEY, *Village in Vietnam* (1964); P. GHEDDO, *Cattolici e Buddisti nel Vietnam* (1968; *The Cross and the Bo-Tree: Catholics and Buddhists in Vietnam,* 1970). NGHIEM-DANG, *Viet-Nam: Politics and Public Administration* (1966); R. SANSOM, *The Economics of Insurgency in the Mekong Delta of Vietnam* (1970); J.C. SCOTT, *The Moral Economy of the Peasant: Rebellion and Subsistence in Southeast Asia* (1976); S.L. POPKIN, *The Rational Peasant: The Political Economy of Rural Society in Vietnam* (1979); and B. FALL, *The Two Viet-Nams: A Political and Military Analysis* (1963, 2nd rev. ed., 1967). Books on the ethnic groups of Vietnam include FRANK M. LEBAR, G.C. HICKEY, and J. MUSGRAVE, *Ethnic Groups of Mainland Southeast Asia* (1964); G. CONDOMINAS, *Nous avons mangé la forêt* (1950; *We Have Eaten the Forest,* 1977); J. DOURNES, *Coordonnées: Structures Jörai familiales et sociales* (1972); and P.B. LAFONT, *Toloi Djuat: Coutumier de la tribu Jarai* (1963). GEORGES COEDES, *Les Peuples de la Péninsule Indochinoise* (1962; Eng. trans., *The Making of Southeast Asia,* 1964), an authoritative history of the evolution of the peoples and nations of Indochina; L. BEZACIER, *Le Viêt-Nam* (1972), a major survey of Vietnam's archaeology; PIERRE HUARD and MAURICE DURAND, *Connaissance du Viêt-Nam* (1954), the most comprehensive study of Vietnamese civilization; LE THANH KHOI, *Le Viet-Nam: Histoire et civilisation* (1955), the first modern history of Vietnam by a leading Vietnamese historian; JOSEPH BUTTINGER, *The Smaller Dragon* (1958), a political history to 1900; GEORGES MASPERO, *The Kingdom of Champa* (1949), a translation of ch. 1 of *Le Royaume du Champa,* by the leading authority on the history of Champa; J.F. CADY, *The Roots of French Imperialism in Eastern Asia* (1954), a study of French policy of the two decades prior to military intervention in Vietnam and during the first decade of French rule in Indochina; M.E. OSBORNE, *The French Presence in Cochinchina and Cambodia* (1969), describes the establishment of French power in southern Vietnam up to the early 20th century; VIRGINIA THOMPSON, *French Indo-China* (1937), the standard work in English on the French colonial regime in Indochina. DAVID G. MARR, *Vietnamese Tradition on Trial: 1920–1945* (1981), an intellectual history. CHARLES ROBEQUAIN, *The Economic Development of French Indochina* (1944), the basic work on the French colonial economy; PHILIPPE DEVILLERS, *Histoire du Viêtnam de 1940 à 1952* (1952), the best account of French policy and Vietnamese reaction to it that led to the Indochina war; JOSEPH BUTTINGER, *Vietnam: A Dragon Embattled,* vol. 1, *From Colonialism to the Vietminh,* vol. 2, *Vietnam at War* (1967), a history of the period from the early years of French rule in Vietnam to the fall of the Diem regime in 1963; DONALD LANCASTER, *The Emancipation of French Indochina* (1961), a well-documented survey of French Indochina from the conquest to the establishment of the two Vietnams and the early years of the Diem regime; K.C. CHEN, *Vietnam and China, 1938–1954* (1969), the definitive work on North Vietnamese–Chinese relations before the 1954 Conference of Geneva; J.T. MCALISTER, JR. and PAUL MUS, *The Vietnamese and Their Revolution* (1970), excerpts from Paul Mus's untranslated profound study, *Viet-Nam: Sociologie d'une guerre* (1952); J.T. MCALISTER, JR., *Vietnam: The Origins of Revolution* (1969), an up-to-date history and perceptive analysis; W.J. DUIKER, *The Rise of Nationalism in Vietnam, 1900–1941* (1976), traces the rise to dominance of the Vietnamese Communists; M.E. GETTLEMAN (ed.), *Viet Nam: History, Documents, and Opinions on a Major World Crisis* (1965), a wide-ranging collection of documents relating the history of Vietnam to the contemporary conflicts; PHILIPPE DEVILLERS and JEAN LACOUTURE, *End of War: Indochina, 1954* (1969), a scholarly, detailed description of the failure of the French in 1954 and the Geneva Conference. B.B. FALL, *The Two Viet-Nams: A Political and Military Analysis* (1963), an account of both North and South Vietnam by an outstanding authority; NGO VINH LONG, *Before the Revolution: The Vietnamese Peasants Under the French* (1973), provides telling insights into the life of the peasantry; A.B. WOODSIDE, *Vietnam and the Chinese Model* (1971), a major study of Vietnam's complex historical relations with China, and *Community and Revolution in Modern Vietnam* (1976), a study of the evolution of modern Vietnamese society; D.G. MARR, *Vietnamese Anticolonialism, 1885–1925* (1971), an account of early reaction against the French; G. PORTER, *A Peace Denied: The United States, Vietnam, and the Paris Agreement* (1975), a detailed account of the negotiations to end the war; J. RACE, *War Comes to Long An: Revolutionary Conflict in a Vietnamese Province* (1972), a detailed analysis of the war in a major southern province; J. LACOUTURE, *Ho Chi Minh* (1967, rev. ed., 1977; Eng. trans., *Ho Chi Minh,* 1968), the best biography available in English translation; ROBERT SCIGLIANO, *South Vietnam: Nation Under Stress* (1963), the best political analysis of South Vietnam under the regime of Ngo Dinh Diem; ROBERT SHAPLEN, *The Lost Revolution: The U.S. in Vietnam, 1946–1966* (1966), a description of the failure of anti-Communist nationalism, especially under Diem; G.M. KAHIN and J.W. LEWIS, *The United States in Vietnam* (1967), a history and critical analysis of American involvement in Vietnam; DOUGLAS PIKE, *Viet-Cong: The Organization and Techniques of the National Liberation Front of South Vietnam* (1966), the standard work on this subject.

Southeast Asian Arts

The term Southeast Asia refers to the huge peninsula of Indochina and the extensive archipelago of what is sometimes called the East Indies. The region can be subdivided into mainland Southeast Asia and insular Southeast Asia. The political units contained in this region are Burma, Thailand, Laos, Kampuchea (Cambodia), Vietnam, Malaysia, Singapore, Indonesia, and the Philippines. The Philippines originally was not included because Philippine history has not followed the general historical pattern of Southeast Asia, but, because of its geographic position and the close affinities of its primitive cultures with the primitive cultures of Southeast Asia, it is now usually regarded as the eastern fringe of Southeast Asia. A common geographic and climatic pattern prevails over all of Southeast Asia and has resulted in a particular pattern of settlement and cultural development. Mountain people generally have a cultural level less developed than that of the valley dwellers. As a consequence, Southeast Asia is culturally fragmented. (For a discussion of the traditional cultures of the area, see ASIA: *Traditional cultures: Southeast Asia.*)

The article is divided into the following sections:

The cultural setting of Southeast Asian arts

Southeast Asia has been the crossroads of many races who have been contending against each other for centuries. At present, all the peoples of Southeast Asia are Mongoloid in racial origin. The first to come were the Austronesians (Malayo-Polynesians), sometimes described as Proto-Malays and Deutero-Malays. At one time they occupied the eastern half of mainland Southeast Asia, but later they were pushed toward the south and the islands by the Austro-Asiatics. At present, peoples of Austronesian origin occupy Malaysia, the Republic of Indonesia, and the Republic of the Philippines. There were three main Austro-Asiatic races, the Mons, the Khmers, and the Viet-Muong. The Mons were at one time dominant, but they lost their racial identity in the 18th century and became absorbed by the Burmese and the Tais; only a few thousand Mons are now found living near the Burma–Thailand border. The Khmers from the 9th century to the 15th built a great empire, but much of its territory was lost to its neighbours so that only the small kingdom of Cambodia remains today. The Viet-Muongs now occupy Vietnam. A Tibeto-Burmese tribe, the Pyu, founded an empire of city-kingdoms in the Irrawaddy Valley in the early centuries of the Christian Era, but the Pyus disappeared, and the Burmese, taking the leadership, founded their kingdom of Pagan and have occupied Burma up to the present day. In the 13th century the Tai-Shans lost their kingdom of Nanchao in Yunnan, China, and entered the Mae Nam Chao Phraya Valley to found kingdoms that gradually evolved into the kingdoms of Siam (Thailand) and Laos.

EXTERNAL INFLUENCES

The India influence

In Southeast Asia winds of change often came as storms. Indian commerce expanded into Southeast Asia in the early centuries of the Christian Era and, in spite of its peaceful nature, caused revolutionary changes in the life and culture of the peoples of the region. The Indians would sojourn in the region in small numbers for two or three monsoons only. The success of their commercial venture and the safety of their persons depended entirely on the goodwill of the inhabitants. At that time, the Indians were at a higher level of culture, and they brought new ideas and new art traditions. Since these ideas had some affinity with indigenous ideas and art forms, the natives, who had already reached a high level of culture themselves, accepted them but were not overwhelmed by an influx of new traditions. The Hindu–Buddhist culture of the Indians made a tremendous impact and came to form the second layer of culture in Southeast Asia, but the first layer of native ideas and traditions has remained strong to the present day.

European influence

Changes often came to Southeast Asia, usually because it possessed a commodity that was in great demand by the rest of the world. The Indians came because they were looking for fresh sources of gold after the Roman imperial source had run dry. In the 15th, 16th, and the 17th centuries, insular Southeast Asia attracted Islāmic merchants from India and farther west and later the Portuguese and the Dutch as a rich source of spices. As with the Hindu–Buddhist merchants of the past, the Islāmic traders came not as missionaries, though they did spread their religion in the region. The Portuguese came as conquerors and as militant missionaries of their Roman Catholic form of Christianity, and, for those reasons, their cultural traditions were found unacceptable to the natives. In the 17th century the Dutch came as conquerors and colonists for whom the attraction was first spices and then coffee, rubber, and petroleum. Since mainland Southeast Asia produced no spices for export, it was less vulnerable to the navies of Portugal and the Netherlands, so the region was not greatly affected by the Muslims, Portuguese, and Dutch. In the 19th century, Britain and France became interested in mainland Southeast Asia as the back door to China and sought to possess it as a colony. By the end of the 19th century, Burma had fallen to Britain, Siam was allowed to retain its independence only with the tacit permission of the two powers, and the rest had fallen to France. When in the mid-20th century the whole of Southeast Asia became free again, it was found that the arts of the peoples had remained merely static during the years of colonial rule; in some regions they had been driven underground by long neglect, but European culture and European art forms had made only a small impact.

INDIGENOUS TRADITIONS

The peoples of Southeast Asia were once thought to have shared a lack of inventiveness since prehistoric times and to have been "receptive" rather than "creative" in their contacts with foreign civilizations. Later excavations and discoveries in Burma and Thailand, however, inspired some scholars to argue against the accepted theory that civilization came to Southeast Asia from China in prehistoric times; rather, these scholars contend, the peoples of mainland Southeast Asia were cultivating plants, making pottery, and working in bronze about the same time as the peoples of the ancient Middle East, and therefore civilization spread from mainland Southeast Asia to China and India. Southeast Asians have never produced any theory of art or literary or dramatic criticism, for they are always more concerned with doing the actual work of producing beautiful things. Because the Southeast Asians, especially in the western half of the mainland, worked on nondurable materials, it is not possible to trace the development and evolution of art forms stage by stage. The region has always been thickly forested, so it was natural that the first material to be used for artistic purposes should have been wood. The wood-carving tradition, begun in primitive times, was retained even when they learned to work with metals and with stone and continued to flourish long after the great age of stone sculpture and stone architecture, which ended in the 13th century. Proto-Neolithic paintings discovered in a cave near the Salween River in the western Shan state of Burma have very close affinity with the later carvings on posts of houses among the Nāgas on the western hills of Burma. Similarly, cave paintings of a pair of human hands with open palms, one holding the sun and the other holding a human skull, are reflected in the later aesthetic tradition of Southeast Asia: the sun symbol is found as an art motif all over the region, and a suggestion of awe, triumph, and joy at acquiring a human head is found in carvings under the eaves of the Nāga houses. The cave painting testifies to the continuity of the magico-religious tradition connected with all the arts of the area.

The art of casting the bronze drums found at Dong Son, near Hanoi, which are similar to the bronze drums used by mountain tribes throughout Southeast Asia, was thought to have come from China, but recent excavations in Thailand proved that the drums and the so-called Dong Son culture itself are native to mainland Southeast Asia. In any case, the continuity of the aesthetic tradition of Southeast Asia can be seen in the bronze drums that were cast by the Karens of Burma for centuries until the early years of the 20th century. The mountains of mainland Southeast Asia provided gold, silver, and other metals, and the art of metalworking must have developed quite early. Silver buttons, belts, and ornaments now made and worn by the hill peoples in Southeast Asia have behind them a very ancient tradition of workmanship. The same artistic tradition is found in textile designs.

Music, dance, and song were originally associated with tribal rituals. From the beginning, the main characteristic of Southeast Asian music and dance has been a swift rhythm. The slow and stately dances of the Siamese court were of Indian origin; when they were introduced into Burma in the 16th century, the Burmese quickened the tempo, but, even with that modification, the dances were still called Siamese dances to distinguish them from the native ones. In their oral literature—namely, in folk songs and folktales—the emphasis is on gaiety and humour. Typically, Southeast Asians do not like an unhappy ending.

rature

The role of royal patronage and religious institutions. In all the regions of Southeast Asia, the arts flourished under the patronage of the kings. About the time of the birth of Christ, tribal groups gradually organized themselves, after some years of settled life as rice cultivators, into city-kingdoms, or conglomerations of villages. A king was thus little more than a paramount tribal chieftain. Since the tribes had been accustomed to worshipping local spirits, the kings sought a new spirit that would be worshipped by the whole community. One reason why the gods of Hinduism and Buddhism were found so readily acceptable to Southeast Asia was this need for new national gods. The propagation of the new religions was the task of the kings, and consequently the period from the 1st to the 13th century was a great age of temple building all over Southeast Asia. Architecture, sculpture, and painting on the temple walls were the arts that flourished. In the ancient empires of eastern Indochina and the islands, scholars of Sanskrit, the language of the sacred works of Hinduism, became part of the king's court, producing a local Sanskrit literature of their own. This literary activity was confined to the hereditary nobility and never reached the people, except in stories from the great Hindu epics *Mahābhārata* and *Rāmāyaṇa*. Because the Hindu religious writings in Sanskrit were beyond the reach of the common people, Hinduism had to be explained to them by Hindu stories of gods and demons and mighty men. On the other side of the peninsula, in the Pyu-Burmese empire of Prome, which flourished before the 8th century, there was no such development—first, because Hinduism was never widely accepted in Burma and, second, because the more open Burmese society developed neither the institution of a god-king nor that of a hereditary nobility. Although Pāli scholars surrounded the king in later Pagan, Pāli studies were pursued not at the court but at monasteries throughout the kingdom so that even the humblest villager had some faint contact with Pāli teachings. While the courts of the kings in Cambodia and Java remained merely local centres of Sanskrit scholarship, Pagan became a centre of Pāli learning for Buddhist monks and scholars even from other lands. As in the case of stories from the Indian epics, stories of the *Jātaka*s (birth stories of the Buddha) were used to explain Buddhism to the common people, who could not read the scriptures written in Pāli. Just as scenes from the great epics in carving or in fresco adorned the temples in Cambodia and Java, scenes from the *Jātaka*s adorned the Pagan temples.

Musicians of the Pyu kingdom played before the Emperor of China in 801, and the various musical instruments at the performance have their counterparts at the present day, not only in Burma but throughout Southeast Asia. At Pagan the people were so fond of music that even the collection of taxes became an occasion to dance and sing, and a royal official, endowing a temple, inscribed a prayer asking that in all his future existences until he reached Nirvāṇa "might he be woken up every morning to the strains of music sweetly played on flute and violin." In spite of this love for music and dance, no dramatic art seems to have developed in Burma, perhaps because Sanskrit, in which there was a dramatic tradition, was not studied. In contrast, at the courts of Cambodia and Java, the Sanskrit drama, Hindu dances, and native dance traditions combined and produced the court opera ballets. These dramatic elements later reached the common people by way of the shadow play.

Significance of the temples

The patronage of the king and the religious enthusiasm of the common people could not have produced the great temples without the enormous wealth that suddenly became available in the region following the commercial expansion. With the Khmer and Javanese empires, the wealth was produced by a feudalistic society, and so the temples were built by the riches of the king and his nobles, combined with the compulsory labour of their peasants and slaves, who probably derived some aesthetic pleasure from their work because of their religious fervour. Nonetheless, their monuments, such as Borobuḍur, in Java, and Angkor Wat, in Cambodia, had an atmosphere of massive, all-conquering power. At Pagan, where wealth was shared by the king, the royal officials, and the common people, the temples and the monasteries were built by all who had enough not only to pay the artisans their wages but also to guarantee their good health, comfort, and safety during the actual construction. The temples were dedicated for use by all monks and lay people as places of worship, meditation, and study, and the kings of Pagan did not build a single tomb for themselves. The Khmer temple of Angkor Wat and the Indonesian temple of Borobuḍur were tombs in that the ashes of the builders would be enshrined therein; the kings left stone statues representing them as gods for posterity to worship, whereas at Pagan there was only one statue of a king, and it depicted him on his knees with his hands raised in supplication to the Buddha. Consequently, the atmosphere that pervaded the temples of Pagan was one of joy and tranquillity.

This golden age of wealth and splendour in Southeast Asia ended in the 13th century with a sudden violence, when Kublai Khan's Tatar Chinese armies destroyed both the Burmese and the Khmer empires and his navy attacked Vietnam and Java. The tiny kingdoms that subsequently sprang up all over Southeast Asia continually fought among themselves; their kings were neither powerful nor rich, and the royal courts became centres of military planning and political intrigue. During the 13th and 14th centuries, in the new Javanese kingdom of Majapahit and the new Burmese kingdom of Ava, vernacular literatures came into being. Again, differences in social structure had aesthetic repercussions. In Majapahit the king was powerful and gave his patronage to the newly arisen literature, confining it to the court. At Ava the vernacular literature bloomed throughout the kingdom, and the king, lacking power and prestige, prevailed upon some established writers to join the court circles and give them glamour.

After Majapahit, a new cultural force—namely, Islām—reached insular Southeast Asia, and over the two layers of primitive and Hindu–Buddhist cultures was added the third layer of Islām. In mainland Southeast Asia, a new Burmese empire arose over the ruins of the old and continued its task of spreading Buddhism. Hindu tradition reached the Burmese court secondhand in the 18th century as the result of the Burmese conquest of Siam and was one of the factors that contributed to the rise of a Burmese drama. On the other side of the peninsula, Vietnam, reconquered by China, fell more and more under the influence of Chinese culture. After a short period of Islāmic bloom, native culture in insular Southeast Asia was subjected to alien rule. In Burma and Siam alone among the states of Southeast Asia, native arts continued to flourish because, after centuries of warfare, they finally emerged as strong kingdoms.

Predominant artistic themes. The predominant themes of Southeast Asian arts have been religion and national history. In religion the main interest was not so much in actual doctrine but in the life and personality of the Buddha and the personalities and lives of the Hindu gods. In national history the interest was in the legendary heroes of the past, and this theme appeared only after the great empires had fallen and the memories of their glory and power remained. The Buddha image, which went through various stages of development, remained the favourite motif of sculpture and painting. The depiction of scenes from his previous lives in fresco and relief sculpture also had the purpose of teaching the Buddhist ethics to the people, as the *Jātaka*s emphasized certain moral virtues of the Buddha in his previous lives; it also gave an opportunity to the artist to introduce local colour by using, as background, scenes from his own contemporary time. The depiction of scenes from the Hindu epics also had the same purpose and gave the same opportunity to the artist. Many figures from the Buddhist and Hindu scriptures, such as gods and goddesses, heroes and princesses, hermits and magicians, demons and dragons, flying horses and winged maidens, became fused with similar native figures, and, gradually, folklore plots became merged in the general religious themes.

The *nāga*s

The *nāga,* a superhuman spirit, was taken from Buddhist and Hindu texts and merged with native counterparts, with the result that different images of the *nāga* appeared in various regions. The Burmese *nāga* was a snake with a crested head. The Mon *nāga* was a crocodile, and the Khmer and Indonesian *nāga* was conceived as a nine-headed snake. The demons of various kinds from all over Southeast Asia became merged under one name of Pāli-Sanskrit origin, *yakkha* or *yakṣa,* but they retained their separate identities in sculpture and paintings of their own different countries. The lion, which was unknown to the monsoon forest but was a figure of Hindu and Buddhist mythology, evolved into a native symbol and art motif. The primitive worship of the snake-dragon as a god of fertility was retained in the Khmer Empire; the nine-headed *nāga* became a symbol of security and of royalty, and stone *nāga*s guarded the palaces and temples. Buddhism frowned upon *nāga* worship. In Burmese and Mon sculpture the *nāga* was always shown as a servant of the Buddha, putting his body in coils to make a seat for his master and raising his great hood as an umbrella over his master's head. According to tradition, the guardian figure of a Mon temple was a two-bodied lion with a man's head, and the guardian figure of a Burmese temple was the crested lion. The Tais made themselves heirs to both the Khmer and the Mon art traditions relating to the *nāga,* but the guardian figure of their temples was the benevolent demon.

Primitive symbols and animal imagery merged with Indian animals and entered the arts. The Pyus embossed the primitive symbol of the sun on their coins as insignia of their power, and the Burmese transformed it into their favourite bird, the peacock, on the excuse that Buddhist mythology associated the peacock with the sun; the Mons adopted the red sheldrake as their symbol, and in Indonesia the mythical bird called Garuḍa, the vehicle of Vishnu, became merged with the local eagle. The figures of these birds also became decorative motifs. Animals of the Southeast Asian forests whose figures had adorned primitive dwellings of wood and thatch were stylized and came to adorn palaces and monasteries. Primitive geometrical patterns mixed with new spirals and curves from India, and Indian floral designs merged with those of trees and fruits and flowers copied from the monsoon forests.

THE UNIQUE AESTHETIC OF THE REGION

The arts of Southeast Asia have no affinity with the arts of other areas, except India. Burma was always an important route to China, but Burmese arts showed very little Chinese influence. The Tais, coming late into Southeast Asia, brought with them some Chinese artistic traditions, but they soon shed them in favour of the Khmer and Mon traditions, and the only indications of their earlier contact with Chinese arts were in the style of their temples, especially the tapering roof, and in their lacquer ware. Vietnam was a province of China for 1,000 years, and its arts were Chinese. The Hindu archaeological remains in southern Vietnam belong to the ancient kingdom of Champa, which Vietnam conquered in the 15th century. The Buddhist statues in northern Vietnam were Chinese Buddhist in style. The essential differences in aesthetic aim and style between the arts of East Asia and those of Southeast Asia could be seen in the contrast between the emperors' tombs of Vietnam and the temple-tombs of Cambodia and Indonesia or the opulent and dignified Buddha images of Vietnam and the ascetic and graceful Buddha images of Cambodia and Burma. Islāmic art, with its rejection of animal and human figures and its striving to express the reality behind the false beauty of the mundane world, also has no affinity with Southeast Asian arts. Both Hinduism and Buddhism taught that the sensual world was false and transitory, but this message found no place in the arts of Southeast Asia. The world depicted in Southeast Asian arts was a mixture of realism and fantasy, and the all-pervading atmosphere was a joyous acceptance of life. It has been pointed out that Khmer and Indonesian classical arts were concerned with depicting the life of the gods, but to the Southeast Asian mind the life of the gods was the life of the peoples themselves—joyous, earthy, yet divine. The European theory of "art for art's sake" found no echo in Southeast Asian arts, nor did the European division into secular and religious arts. The figures tattooed on a Burmese man's thigh were the same figures that adorned a great temple and decorated a lacquer tray. Unlike the European artist, the Southeast Asian did not need models, for he did not strive to be realistic and correct in every anatomical detail. This intrusion of fantasy and this insistence on the joyousness of human life have made Southeast Asian arts unique.

Literature

GENERAL CONSIDERATIONS

Regional distinctions. From the point of view of its "classical" literatures, Southeast Asia can be divided into three major regions: (1) the Sanskrit region of Cambodia and Indonesia; (2) the region of Burma where Pāli, a dialect related to Sanskrit, was used as a literary and religious language; and (3) the Chinese region of Vietnam.

There are no examples of Chinese literature written in Vietnam while it was under Chinese rule (111 BC–AD 939); there are only scattered examples of Sanskrit inscriptions written in Cambodia and Indonesia; yet most of the literary works produced at the court of Pagan in Burma (flourished *c.* 1049–1300) have survived because the texts were copied and recopied by monks and students. But in the 14th–15th centuries, vernacular literatures suddenly emerged in Burma and Java, and a "national" literature appeared in Vietnam. The reasons behind the development of each were the same: a feeling of nationalistic pride at the final defeat of Kublai Khan's invasions, the desire of the people to find solace in literature amidst change and struggles for power, and the lack of wealth and patronage to channel artistic expression into building temples and tombs. In Vietnam and Java literary activity centred on the courts; but in Burma the first writers were the monks and, later, the laymen educated in their monasteries. In the new Burmese kingdom of Ava (flourished after 1364), the Shan kings were proud of their Burmese Buddhist culture, and they appointed the new writers into royal service, with the result that courtiers became writers also. The Tai kings of Laos and Siam led their courts in learning Pāli from the Mons, whom they had conquered, and Sanskrit from the Khmers, whom they harassed; nevertheless, seized with national pride and influenced by the Burmese example, they developed their own vernacular literature. But Cambodia itself declined. Although the monks in the Theravāda Buddhist (*i.e.,* the Southeast Asian form of Buddhism) monasteries produced a few works in Pāli, no vernacular literature emerged until finally Khmer-speaking people (those living in the area comprised approximately of modern Kampuchea) were borrowing many words from the Tais.

For its vernacular literatures, Southeast Asia can be divided into (1) Burma; (2) Thailand, Laos, and Cambodia; (3) Vietnam; (4) Malaysia and Indonesia; and (5) the Philippines (which produced a vernacular literature only in the 20th century, after the imposed Spanish and English languages and literatures had made their impact).

ne era

tronage

Prestige of the writer. During the time of the kings, a Southeast Asian writer enjoyed patronage and a prestigious position in society. He could not, however, make a living by writing as a profession. Manuscripts had to be written by hand, and only in the case of famous works might one or two duplicates be made, again by hand. There was no question of selling the manuscript. A writer could only hope to attract the notice of his king and obtain a monetary reward or a royal office. By the time that printing presses were introduced, in the colonial period in the 19th century, the kings were gone and with them their writers. Colonial rule overwhelmed and destroyed vernacular literary traditions, leaving intact only oral literatures in the forms of folktales and folk songs. Literary criticism, as understood in Western cultures, had never been known, either in the ancient or modern literatures of Southeast Asia. Apart from a few stray writings on versification, therefore, no works of literary criticism or literary history existed until the colonial period. Even then, the interest of European scholars was chiefly confined to archaeology, and only a few made the attempt to study some special type or period of a vernacular literature (for example, vernacular versions of the *Rāmāyaṇa,* the great Sanskrit epic of India, or of 14th-century Javanese verse). There is a work in French dealing with Thai literature and a work in Burmese dealing with Burmese literature; but apart from these no study of any Southeast Asian literature as a whole has yet been made. For this neglect, native scholars are much to blame. Works on literary criticism and the history of literature would help give perspective to indigenous writers in the 20th century, both to those who want to cling to their native traditions (as is the case with writers in Burma and Thailand) and those who want to make a complete break with the past (as is generally the case in Vietnam, Indonesia, and Malaysia).

PRE-EUROPEAN COLONIAL PERIOD

Burma. The Burmese borrowed many words from Pāli but not to the extent that the Indonesians, Khmers, and the Thais borrowed Sanskrit words. The Burmese language was monosyllabic and tonal, and since there was no accent or stress, the feature that distinguished verse from prose was the regular occurrence of rhyme. They modelled their literature not on classic examples from Pāli or Sanskrit but on their own traditional folk songs.

The 15th century. In the 15th century, four types of verse existed: (1) *pyo* (religious verse), which retold stories of Buddha's birth and teaching and were taken from the *Jātaka*s (a collection of folktales adapted to Buddhist purposes and incorporated into the Pāli canon), to which were added imaginative details and a Burmese background; (2) *linkar* (shorter religious verse), or a devotional poem, characterized by a metaphysical flavour comparable in many ways to that which informs the work of the early 17th-century English poets George Herbert and Robert Herrick; (3) *mawgoon* (historical verse), half ode, half epic, written in praise of a king or prince and developing out of military marching songs; (4) *ayegyin* (lullaby), an informative poem usually addressed to a young prince or princess and written in praise of his royal ancestors.

Poets at
court

Literature in the 15th century is dominated by three monks: Shin Maha Rahta Thara, who wrote for the court of Ava, and Shin Maha Thila Wuntha and Shin Uttamagyaw, both of whom were of village stock and did not go to court but remained on in their village monasteries. Shin Maha Thila Wuntha, in the closing years of his life, turned to prose and wrote a chronicle history of Buddhism. In this period several courtiers, both men and women, also began to achieve some literary success, and the genre called *myittaza* (epistle) first evolved, which is a long prose letter written by a monk and addressed to the king to advise him of his duties.

The 16th century. In the 16th century, the Burmese conquered Siam, and their subsequent knowledge of Thai romantic poems gave rise to a new verse form called the *yadu* (the seasons). They borrowed only the theme, however, and not the form, and they developed it as an emotional poem, passionate, yet with something of the cool intellectual strength of the poems of the English metaphysical poets John Donne and Andrew Marvell. The most famous writers of the *yadu* were two court poets, Phyu and Nyo; a general of the army called Nawaday; and Natshinnaung, king of Toungoo. The wide popularity of the poems eventually gave rise to a mock-heroic form called *yagan* ("Kick the *yadu*").

Golden age of literature. In the early years of the 18th century, U Kala compiled a history of Burma, written in precise and clear prose; the closing years, which coincided with the establishment of the third Burmese Empire, saw a great period of literature. The Thai court, brought as captives to the Burmese capital, introduced to the Burmese poetic romances and their *Rāma* play (based on the *Rāmāyaṇa*). Contact with the Thais stimulated the growth of a Burmese court drama and led to the appearance of Burmese court romances in poetic prose. The king's treasurer, however, made fun of the Thai importations and wrote the *Rama Yagan,* in which the high romance and courtly elegance of the 4th-century-BC *Rāmāyaṇa* ("The Life of Rāma") were given a rustic setting, with hilarious results. From the quiet of their monasteries, the monk Awbatha wrote novel-like rendering of the *Ten Long Jātakas* and the monk Kyeegan Shingyi wrote homely, pithy, and sometimes even humorous myittaza ("epistles") from villagers to their relations in the cities.

The defeat suffered by the Burmese in the Anglo-Burmese War of 1824–26—their first defeat since the time of Kublai Khan in the 13th century—introduced a note of melancholy to Burmese literature. During this first half of the 19th century, many of the new melancholy lyrics were set to music. Two great writers were a product of this period: the dramatist U Kyin U and the courtier U Pon Nya, the greatest writer of the time, whose plays, epistles, and songs are full of humour and zest for life.

Thailand. Until 1824 Thai literature was entirely the province of the king and his court: the king maintained a corps of writers, and it was the custom to attribute authorship of any literary work to the king himself. Thai vernacular literature began with verse, based on Sanskrit models but relying on an elaborate rhyme scheme because the

Elaborate rhyme scheme of Thai poetry

Siamese language was tonal. The two earliest known poems were *Yoon Pai* ("The Defeat of the Yoons"), an epic-ode having similarities to the Burmese *mawgoon* genre, and *Mahajati* ("The Great *Jātaka*"), a poem stressing ethical ideas, similar in form to the Burmese *pyo.* Both poems, written during the period 1475–85, give ample proof that Thai writers, using Sanskrit, Khmer, and Burmese models, could nonetheless produce a truly Thai work.

First golden age: King Narai (1657–88). All literary activity ceased in the 16th century because of the unsettled conditions that prevailed before and after the annexation of the country by the Burmese. Independence was regained toward the close of the century, and under King Narai (1657–88), at his court in Ayutthaya, Siamese literature achieved its first golden age. Narai was himself a great poet, and during his reign new verse forms were evolved. He wrote poetic romances, based on stories from the "Fifty Jātakas," which were in fact folktales belonging to the region retold in Pāli and disguised as *Jātaka*s by an unknown Tai monk. Narai also wrote the final version of the poem of tragic romance, *Pra Lo* ("Lord Lo"), which had first been composed by an anonymous author in a much earlier reign. Among courtier poets of this time, the most famous were Maharajaguru; Si Prat, a wild young gallant who wrote the romantic poem *Aniruddha* (the name of the hero of the poem) and some passionate love songs; Khun Devakavi, author of cradle-songs using many Sanskrit and Khmer words but modelled on the Burmese *ayegyin;* and Si Mahosot, the author of an ode-epic in praise of King Narai. A new genre, the travel poem, also became popular; and the first versions of the plays *Rāma* and *Inao* (based on Hindu–Khmer–Javanese models) were composed by the King and his corps of writers. Perhaps the only prose work of the period was the *History of Ayutthaya* by Luang Prasroeth, which was lost and came to light only in the 20th century. It showed some signs of being influenced by U Kala's *History* (of Burma).

Second golden age: King Rama II (1809–24). Siam was conquered by the Burmese in 1767, and a new dynasty was established in a new capital, Bangkok. Some effort was made to revive the country's culture, largely destroyed following the sack of the old capital of Ayutthaya; and under the poet-king Rama II a second golden age of Thai literature occurred, during which women achieved prominence as poets for the first time. The King, with his writers, composed the final versions of *Rāma* and *Inao* and also a popular romance, "Khun Chang and Khun Pẹn," based on an incident in Thai history. The most famous poets were Prince Paramanuchit, whose ode-epic *Taleng Phai* ("The Defeat of the Mons") testified to his greatness, and Sunthon Phu, the King's private secretary, who was born of humble parents but made his way in the court by the excellence of his poetry. A strongly religious king, Rama III disbanded the corps of writers and discouraged the performance of plays at his court. Sunthon Phu lost his position but wrote his most famous poem, *Phra Aphaimani,* away from the court. A long fantasy-romance, this work can be regarded as the end of court domination in literature. Further, a royal official composed a Thai translation in prose (*Sam Kok*) of the Chinese classic *Romance of the Three Kingdoms.* The author, Pra Klang, was admittedly a royal official; nevertheless, the work was meant for the people rather than the court. It was followed by a spate of imitations and finally resulted in the development of the historical novel.

Final version of *Rāma*

Laos, Cambodia, and Vietnam. Laotian literature was in many respects a dialect branch of Tai literature, and, as in Thailand, it was the creation of the royal court. A number of popular romantic poems and prose lives of famous monks were composed, but their authors were unknown: all works, in fact, were by custom written anonymously.

The kings of Cambodia, fallen from high estate and often mere vassals of Thailand, could not inspire the rise of a vernacular literature. Only in the monasteries was there any literary activity, and this was written in the Pāli language.

In Vietnam, the emperors of the Tran dynasty (13th–14th century) were themselves poets and patronized a new literature—which, nevertheless, was still written in Chinese and was therefore national rather than vernacular. The writings themselves, however, were by no means a mere branch of Chinese literature. The country was afterward conquered once more by China and it was not until it regained independence that, under the patronage of the Le dynasty emperors (15th–16th century), a new age of literature began. Although the Chinese language was still used, some writers were beginning to use the vernacular (employing Chu-nom script, consisting of modified Chinese characters). Nguyen Trai, Emperor Le Thanh Tong, and Nguyen Binh Khiem were the great poets of this period. In 1651 Father Alexandre de Rhodes, a Roman Catholic missionary priest, invented a new romanized script (Quoc-ngu) that became the national script. Literature then began to reach the common people.

The national script

Literary works written before the end of the 18th century have not survived; the best known are those written in the 19th century, before the country became a French colony in 1862. Ho Xuan Huong, Nguyen Cong Tru, Chu Manh Trinh, and Tran Ke Xuong were famous court poets. Nguyen Du (1765–1820) wrote moral tales in verse that appealed not only to the court but to the common people. His most famous work was *Kim Van Kieu,* a poem of 3,253 lines, showing a strong Chinese influence (the plot was taken from a Chinese historical novel, and its ethical basis was both Confucian and Chinese Buddhist). The plays of the period, although written in Vietnamese, followed Chinese dramatic traditions because the Vietnamese theatre was still Chinese in style and practice.

Malaysia and Indonesia. Malaysia and Indonesia together have about 300 different languages and dialects, but they have a single common linguistic ancestor. Before the coming of Islām to the region in the 14th century, Javanese had been the language of culture; afterward, during the Islāmic period, Malay became the most important language—and still more so under later Dutch colonial rule so that, logically, it was recognized in 1949 as the official Indonesian language by the newly independent Republic of Indonesia.

During the period of Indian cultural influence, Sanskrit flourished in the great empires that included both the Malay Peninsula and the islands of present-day Indonesia. In the 11th century, at the court of Emperor Airlangga, a national literature (as distinct from a vernacular literature) emerged. It was written in courtly Javanese mixed with Sanskrit words, and it used Sanskrit metres and poetic style. In the 14th century in Majapahit (the new Javanese Empire that had been established after the final defeat of Kublai Khan's forces) a vernacular literature based on the speech of the common people came into being. The most important work of this new literature was *Nāgarakertāgama* (1365), a long poem in praise of the king (though it was not a product of the court) that also contained descriptions of the life of the Javanese people at the time. Although it employed a number of Sanskrit words, the style and metre were Javanese, not Sanskrit.

The Indian Hindu epics had already been popularized in the Malay Peninsula and in the islands of Indonesia (by way of the shadow-puppet play), and in this period fresh versions began to be written in the new Javanese. Romances, called *hikayat,* both in verse and in prose, also appeared—having as their source native myth and legend. Soon Malay, Balinese, Sundanese, and Madurese vernacular literatures emerged, all dealing with the same themes.

Romance themes from myth and legenc

The coming of Islām coincided with the rise of Malacca and the decay of Majapahit; but the popular fantasy-romances were able to survive by adopting a Muslim, instead of a Hindu, guise. New romances, telling the stories of heroes known to Islām, such as Alexander the Great, Amīr Hamzah, and Muḥammad ibn al-Ḥanafiah, were added to their number, and translations of Persian Muslim stories and of works on Muslim law, ethics, and mysticism further enriched Malay literature.

The finest work of all in the Malay language was the *Malay Annals,* written in about the 15th century. It gave a romanticized account of the history of the kingdom of Malacca and a vivid picture of life in the kingdom. Although a court record that begins with ancestral myths, it goes on to describe latter-day events of the kingdom with realism and humour.

In the Malay Peninsula, the coming of colonial rule did not at once overwhelm the existing native literature. As at the courts of the sultans of the British federated Malay states, the old traditions continued for some time. In Indonesia, however, a complete break was made with the cultural tradition.

EUROPEAN COLONIAL AND MODERN PERIODS

mpact of
olonial
ule

The entire region of Southeast Asia, with the single exception of Thailand, fell under colonial rule, and Thailand itself survived more as a buffer state than as a truly independent kingdom. At the courts of the kings of Laos, Cambodia, and Vietnam, which fell under French suzerainty, and in the palaces of the sultans of the British Malay states, vernacular literatures managed to survive for a time; but since these literatures had long ago ceased to develop—as a result of harassment by the Thais in the case of Laos and Cambodia, by the Portuguese in the case of Malaya, and by the French in the case of Vietnam—they soon became moribund. In all of Southeast Asia, except Burma and Thailand, the vernacular languages themselves lost their status, as the languages of the colonial rulers became the languages of administration and of a new elite. A revival of interest in the native languages and literatures occurred only toward the close of the colonial period, as a consequence of national movements for freedom.

Burma. In Burma, unlike India and other parts of the British Empire, English did not fully replace Burmese as the language of administration. In the almost classless Burmese society the language of the court and of literature was also the language of the people, which prompted the British government to retain Burmese as a second official language and to make both languages compulsory for study in schools and colleges. As a result, no English-speaking elite emerged, English literature did not dazzle native scholars, and, although its growth was retarded, Burmese literature did not disappear. With the intensification of the movement for freedom, around 1920, political tracts, novels, short stories, and poems reflected a political bias against colonial rule. In 1930, at the University of Rangoon, a group of young writers developed a new style of Burmese prose and poetry, a style little influenced by Western literature. In the post-independence period, novels and poems became centred on biographical and historical writings.

Thailand. Administrative and educational reforms introduced by King Mongkut (1851–68) as an answer to the threat of colonial conquest created a liberal atmosphere and a new reading public, and soon many of the old courtly writings were popularized in the form of romantic prose fiction. About 1914, King Vajiravudh, a graduate of Cambridge University, attempted to win back for the palace the leadership in literature; although he produced some fine adaptations of Shakespeare's plays, they made no impact on the people, with whom romantic fiction remained popular. Because of increased contact with the West, after World War II novels and short stories based on western models began to rival the earlier prose romances.

Laos, Cambodia, and Vietnam. Because of France's restrictive colonial educational policy, French language and literature never reached the common people. Moreover, the French-speaking elite, engrossed in French literature, neglected the native literature. With the growing vehemence of the freedom movement in the 1930s, however, there developed in Vietnam a new school of vernacular poetry that was less traditional and more nationalistic. But in the turbulent years that followed, the poets, including Ho Chi Minh himself, became occupied more with war than with literature.

lalaysian
lalay

Malaysia and Indonesia. The first Malaysian newspaper in the vernacular language, which appeared in 1876, introduced a new style of prose, less literary and nearer to the spoken Malay. Becoming immensely popular, the new style was further developed by other newspapers. (Although the early innovators were influenced by the English language, their followers were influenced by Arabic.) In about 1920 this new "Malaysian Malay" finally replaced the old literary Malay. The Translation Bureau, established by the British government in 1926, translated a great number of English books into the new Malay. In Indonesia, also, the old cultural language, literary Javanese, ceased to be used; by the end of the 19th century young Indonesians, overwhelmed by Dutch literature, started to write in Dutch. For example, a young girl, Raden Adjeng Kartini, wrote in Dutch a remarkable series of letters, containing criticism of Indonesian society, that were later collected and published; and a group of young men wrote poems in Dutch, although with an Indonesian background. By about 1920, however, the Dutch government itself had decided for political reasons to discourage further development of a national literature in Dutch, and the nationalist leaders had become eager for a new literature in the native language. This common aim bore fruit in 1933, when a literary journal under the editorship of Takdir Alisjahbana appeared, containing poems and essays written by various authors in the new Malay, which they now called Indonesian. The editor himself later wrote in Indonesian a number of popular novels containing social criticism, which were imitated by other writers. During the Japanese occupation of Indonesia and Malaya, this new Indonesian literature became popular also in Malaya. The adoption of Bahasa Malay (Indonesian) as the official language of Indonesia in 1949 gave further impetus to the development of the vernacular literature in both countries. The new tradition developed after independence, and its outstanding writers in Indonesia were, in poetry, Chairil Anwar and Sitor Situmorang. Important novelists include Ananta Toer and Takdir Alisjahbana.

19th-century intellectual renaissance

The Philippines. Philippine literature had its beginnings in great epics that were handed down orally from generation to generation and sung on festive occasions. When the Philippines became part of the Spanish Empire in the 16th century, printing was introduced, and all the early published works in the vernacular (Tagalog) were of Christian religious subjects. Eventually, some individual romantic legends taken from the epics were published, but they had acquired a European flavour. An outstanding work in the early years of the 19th century was an epic romance called *Florante at Laura* by the first native writer to achieve prominence—Francisco Balagtas—who wrote in Tagalog. In the latter half of the 19th century, an intellectual renaissance coincided with the beginnings of a national movement toward freedom; writers began using Spanish, for their work was part of the nationalist propaganda. The most famous author was José Rizal, who wrote a series of brilliant social novels, beginning with *Noli me tangere* ("Touch Me Not"). Other prominent writers, all essayists, were Mariano Ponce and Rafael Palma. There were poets also—for example, José Palma, whose poem "Filipinas" was later adopted as the national anthem. After the United States had taken over the Philippines, Spanish was gradually replaced by English, and new writers began to use that language as their medium. But before a new national literature could evolve, World War II took a heavy toll of writers, and those who survived became caught up in the political changes that followed. Many still write in English—the Spanish tradition, too, remains strong—but more and more writers are turning to Tagalog for literary expression. (M.H.Au.)

Music

GENERAL CHARACTERISTICS

Society and music. *Rural and urban music.* A general musical division exists between the urban and rural areas of Southeast Asia. Urban centres comprise the islands of Java and Bali and places in Thailand, Laos, Kampuchea, and Burma, where big ensembles of gong families play for court and state ceremonies. Rural areas include other islands and remote places, where smaller ensembles and solo instruments play a simpler music for village feasts, curing ceremonies, and daily activities. In cities and towns influenced by Hindu epics such as the *Rāmāyaṇa* and *Mahābhārata,* shadow and masked plays and dances utilizing music play important communal roles, while in less urbanized areas, in lieu of musical plays, chants and songs in spirit worship and rituals are sung in exclusive surroundings—a ritual procession on the headwaters of

Borneo, a drinking ceremony in the jungles of Palawan, a feast in the uplands of Luzon.

In both regions the physical setting is usually the open air—in temple yards and courtyards, under the shade of big trees, in house and public yards, fields and clearings. Many musical instruments are made of natural products of a tropical environment, and their sounds are products of this milieu. The music of buzzers, zithers, and harps is thus akin to sounds heard in the tropical vegetation of Southeast Asia. In Bali, for example, special ways of chanting and sounds of the jew's harp (also jaw's harp) ensemble (*genggong*) imitate the croaking of frogs and noise of animals.

Relation to social institutions. Music in Southeast Asia is frequently related to ceremonies connected with religion, the state, community festivals, and family affairs. In Java, important Islāmic feasts, such as the birthday of Muḥammad or the fast of Ramaḍān, as well as animistic ceremonies marking the harvest and cycles of human life, are celebrated with shadow plays (*wayang* [*wajang*]). In Bali, the *gamelan gong* orchestra opens ceremonies and provides most of the music for temple feasts. The *gamelan selunding,* an ensemble with iron-keyed metallophones (like xylophones but with metal keys), plays ritual music, and the *gamelan angklung,* so called because it formerly included tube rattles, or *angklung,* is used to accompany long processions to symbolic baths near the river.

In Malaya the court orchestra, or *nobat,* was held almost as sacred as the powers of the sultan himself. Among the Land Dayak and Iban in Borneo, ceremonial chants are sung in feasts related to rice planting, harvesting, and honouring the omen bird *kenyalang* and other spirits.

Musicians' knowledge of the dance

The relation of music to dance and theatre. In the Thai masked play, or *khon,* dancers, chorus, soloists, and orchestra are all coordinated. The musicians know the movements of classical dance and coordinate musical phrases with dance patterns, turns, and movements. In the shadow play, or *nang sbek,* the dancer, who manipulates a leather puppet, must keep his foot movements in time with vocal recitations. During pauses in which the gong ensemble plays an interlude, the dancer must change steps accordingly. In general, when there is solo singing, the instrumental ensemble remains silent or plays only a few instruments in contrast to interludes of acrobatic shows or scenes of fighting, when the full orchestra clangs on all the instruments. In Balinese dancing, body movements, paces, and directions are dependent on drum strokes and signals from a wood block (*keprak*) and cymbals (*tjengtjeng*). The dancers generally rehearse with the musicians to know exactly when choreographic changes take place.

As theatre, the stories of *Rāmāyaṇa* and *Mahābhārata* have different musical supports, depending on the country. In Bali, *Mahābhārata* shadow plays are presented to the accompaniment of a quartet of metallophones known as *gender wayang.* In Cambodia, where the preference is for stories of the *Rāmāyaṇa* (which is called *Ramker* in Cambodia), the music is a full gong ensemble similar to the Thai *pi phat* ensemble, while in Burma, a percussion orchestra of drums and gongs in circular frames accompanies singing, dancing, and dialogues in all types of plays.

Voice quality and dramatic meaning

Musical traditions and practice. *Vocal music.* The role of the voice in music making differs from that of European music in both concept and execution. Men's and women's voices are each not divided into high and low ranges but are used for their colour qualities. In the Javanese shadow play, for example, the narrator (*dalang*) assumes many singing and speaking qualities to depict different characters and scenes. Arjuna, the chief *wayang* hero, is represented with a clear voice, speaking in a single tone. Puppets with bigger bodies are given lower, resonant voices. In Thai masked plays there is no desire to produce full open tones, as in Italian bel canto. A vocal tension accounts for shades of "nasal" singing that can be discerned in commercial recordings of Thai, Javanese, Cambodian, and Vietnamese music. In the Javanese orchestra (gamelan) the voice tries to imitate the nasality of the two-stringed fiddle (*rebab*). In Bali, a particular use of men's voices is in the *ketjak,* a ritual in which groups seated in concentric circles combine markedly pronounced syllables into pulsing rhythmic phrases. In village settings among the Kalinga of Luzon, in the Philippines, singing, speaking, or whispering of vowels is so subtle as to blur the border line between speech and song. On the Indonesian island of Flores, leader–chorus singing, with the chorus divided into two or more parts, is accompanied by a prolonged note (drone) or by a repeated melodic, rhythmic fragment (ostinato). In Borneo, or Mindanao and Luzon in the Philippines, a man or woman may sing an epic or a love song in a natural voice with little or no attempt to nasalize it. Epic singing, with long or short melodic lines, goes on for several nights, and some of the sounds are mumbled to give words and their meanings a particular shading. Further, a sensuousness in the quality of Islāmic singing is achieved through the use of shades of vowel sounds, vocal openings, and a bell-like clarity of tones.

Homogeneous and heterogeneous sound

Instrumental music. Although gong orchestras consisting of gongs, metallophones, and xylophones bind Southeast Asia into one musical cultural group, the types of ensembles and sounds they form may be classified into four areas. Java and Bali make up one unit because of their predominant use of bronze instruments in orchestras that make one homogeneous sound. Thailand, Laos, and Cambodia form another subdivision, with families of musical instruments producing heterogeneous sounds: the bronze group makes slowly decaying sounds, wooden xylophones play short sounds, and a reed blows a penetrating melody accompanied by a fourth group of cymbals, drums, and another gong. The Burmese orchestras differ from the Indonesian and Thai groups by the unique use of a row of tuned drums (sometimes called a drum circle), with sounds consisting of sharp attacks and quick-vanishing waves. The fourth area, Indonesia, Malaysia, and the Philippines, uses several types of suspended and horizontally laid gongs. These gongs produce various combinations of sounds. In Nias, an island west of Sumatra, one group of three heavy suspended gongs plays three rhythms of homogeneous sounds. Suspended gongs with a wide rim and a high knob are played alone, with another gong or with a drum on the Philippine islands of Mindanao and Palawan and the Indonesian island of Kalimantan (Borneo). Gongs laid in a row, called *kulintang,* are melody instruments accompanied by a percussion group. The most developed melodies are found in Mindanao, and the area of distribution extends to Borneo, Sumatra, and Celebes, in Indonesia. The sets of tuned gongs found throughout Southeast Asia are also called gong chimes, gong kettles, and gongs in a row.

Tonal systems. In contrast to the Western diatonic-scale system (based on seven-note scales comprised of whole and half steps) and its association with relatively "fixed" pitches, there prevails a gapped system in Southeast Asia (*i.e.,* scales containing intervals larger than a whole step) with elastic intonation. Examples include the five-tone *slendro* and the seven-tone *pelog* of Java and the seven-tone scale of Thailand. In each of these systems the distances between corresponding tones in two different sets of octaves are not exactly the same. For example, one Javanese *slendro* octave has the following intervals expressed in cents (a unit of pitch measurement; 1,200 cents make 12 semitones or one octave): 246, 241, 219, 254, 246; another has 245, 237, 234, 245, 267. In contrast, two tunings of the Western chromatic scale theoretically always have 12 semitones of 100 cents apiece.

Modal systems

Related to tonal systems are modes, which in Southeast Asia use tones of a particular scale system to form melodies. Associated with a given mode are a hierarchy of pitches, the principal and auxiliary tones, endings of melodic phrases (cadential formulas), ornaments, and the vocal line. Modes express emotions and are applied to different times of the day and night and to particular situations in stage plays. They are clearly present, with local variations, in Java, Vietnam, and Burma but are less distinct in Bali, Thailand, Laos, and Cambodia.

In rural areas a multitude of scales with mixed diatonic and gapped systems and no modes are used.

Musical time and improvisation. Musical time is generally divisible in units of two or four in urban music, but it occurs more freely and without a metric pulse in rural areas, especially in singing. Musical improvisation or the use of variations based on a melodic theme is not universal. It is essential to the playing of the *rebab* and singing in the Javanese gamelan, the tappings on the Burmese circle of drums, and the percussive playing on the *kulintang.* But, in fast playing in the Balinese gamelan, exact repetitions of patterns are necessary, for there is no time for the performer to think of alternative formulas. Similarly, the separate rhythmic patterns of five instrumental parts do not change in the gong (*gangsa*) music of the Ibaloi of Luzon. Repetition is the essence of the music.

HISTORICAL DEVELOPMENTS

Origins. *Early bamboo instruments.* The widespread use of bamboo musical instruments in practically all parts of Southeast Asia points to the antiquity of these instruments and, probably, that of the music they play. A historical citation of mouth organs and jew's harps in the Chinese *Shih Ching* ("Classic of Poetry") shows that these instruments were known in the 8th century BC. Previous to this time, other bamboo musical instruments were probably in use, just as bamboo tools were used in pre-Neolithic times.

)rones
nd
stinato

The music of pre-Neolithic types of bamboo musical instruments, such as are played in the 20th century, may be just as old as these instruments. One general feature that points to this antiquity is the widespread and frequent use of a very simple musical element: a sustained tone (drone) or repetition of one or several tones (ostinato). Sustained tones appear in the mouth organ, where one or two continuous sounds are held by one or two pipes while a melody is formed by the other pipes. Prolonged tones may also be heard in rows of flutes played by one person in Flores. One flute acts as ostinato and the rest make a melody. In group singing, an underlying held tone is common. Repetition of tones occurs in bamboo instruments (jew's harps, percussion tubes and half percussion tubes, zithers, clappers, slit drums) as well as in nonbamboo instruments. In the *kudjapi,* a two-stringed lute, one string is used for the ostinato and the other to pluck the melody. In the log drum, two players play fast rhythms of continuous sounds while another player taps improvised rhythms.

Bronze instruments in gong families of Indonesia, Thailand, and Burma employ repeated sounds acting as ostinati. A widespread and preponderant use of dronelike or repeated sounds in Southeast Asia shows that they are probably an ancient fundamental musical element.

Early bronze instruments. The earliest bronze musical instruments are kettle gongs (deep-rimmed gongs), which date back to about 300 BC and are found in Vietnam, Bali, Sumatra, Borneo, Thailand, and Burma. In Burmese gongs the use of a heavy beater for the centre and a lighter stick to strike the side denotes an opposition of a full and a tiny sound applied today also to the *babandil* and other gong ensembles in Palawan and Borneo.

Gongs that predominate in Southeast Asia are those with a boss, or central beating knob. The many varieties differ according to their shapes, chemical properties, playing position, number in a series, manner of playing, musical function, and sound. Flat gongs without a central boss are not as widely used. They are found in the hills of Thailand, Laos, Cambodia, Vietnam, in some parts of Indonesia, and in the northern Philippines and may have come to Southeast Asia either through China in the 6th century or from the Middle East.

ingling
fluences

Musical traditions. The influence of the great traditions of Asia—Indian, Chinese, Islāmic, and Khmer (Cambodian)—on native Southeast Asian music varies in different countries. From India come principally two ancient Sanskrit epics—the *Mahābhārata* and the *Rāmāyaṇa.* Deep attachment to themes from the *Rāmāyaṇa* pervades the whole Southeast Asian region, except the Philippines, where Indian influence was weakest. Musical instruments attributed to India and appearing in 9th-century reliefs at the Buddhist temple of Borobuḍur and Hindu temple of Prambanan, in Java, are bronze bells, bar zithers, cymbals, conical drums, flutes, shawms, and lutes. They may still be found in several islands of Indonesia. Khmer gong circles, stringed instruments, mouth organs, drums, and oboes still in use in rural Cambodia and Vietnam are depicted in the 12th-century ruins at Angkor Wat in Cambodia. Prehistoric lithophones, or stone chimes, excavated in Vietnam in 1949, may have been the ancestors of kettle gongs. Chinese-type musical instruments (two- and three-stringed fiddles, bells, and drums), the use of the Chinese pentatonic (five-tone) scale, and duple and quadruple time (typical Chinese metres) are used in Vietnam, Burma, Thailand, Laos, and Cambodia, Islāmic musical instruments—drums, two-stringed fiddles (*rebab*), and three-stringed lutes—may be heard in Java, while melismatic singing (many notes to one syllable), especially in Islāmic rituals, is usual among the Malay groups on Borneo.

There are also musical instruments and elements that have developed locally. The mouth organs of Borneo, Laos, and Cambodia are probable ancestors of the Chinese *sheng* and the Japanese *sho* (mouth organs). Jew's harps, tube zithers, ring flutes, buzzers, xylophones, two-stringed lutes, and various types of gongs with boss (knobbed centre) are some of the most typical instruments of Southeast Asia. A probably ancient manner of measuring flute stops in Mindanao—dividing flute segments into proportional lengths to produce the octave, fifth, and other intervals—recalls a very old Chinese account of cutting bamboo tubes into lengths that would sound these same intervals.

In general, music in Southeast Asia is a tradition taught to each succeeding generation without the use of written notation. From exclusive families of musicians in courts, gamelan music was transmitted to the people. Epic and ritual songs are learned by rote and handed down from older to younger generations. Hence, skill in instrumental music is developed by imitation and practice.

Burma. Just as today all types of Burmese plays are accompanied by the traditional Burmese orchestra, the beginnings of Burmese theatre contained a music that, like the theatre, was probably based on primitive religious rituals. Before Indian and Chinese musical influences, the inspirational source of Burmese music and dance was the miracle plays (*nibhatkhin*), which, in turn, were based on singing, dancing, and entertainment in local folk feasts that date back to antiquity. The worship of spirits (*nats*) at Chinese festivals was accompanied by women who, through song and dance, communicated with and were possessed by these spirits. Following this practice, professional entertainers taking the place of women danced, sang, and played instruments during the first *nibhatkhin.* These practices led to the dancing and singing associated with the *pwe,* a popular play for public and courtly entertainment.

Foreign musical influences came from India, China, and Thailand. Indian elements appear in musical terms, theories about scales, and in some musical instruments—oboe, double-headed drums, cymbals, and the arched harp. Chinese influence appears to be older and is apparent in the use of the pentatonic scale and such musical instruments as table zithers (related to the Chinese *ch'in*), a dragon-head lute resembling a Chinese *p'i-p'a,* and two- and three-stringed fiddles. From Thailand and the Khmer civilization of Cambodia probably came both the use of gongs in a circular frame and the dramatization of episodes from the *Rāmāyaṇa.* In the traditional orchestra for state ceremonies, for the theatre, and, formerly, for royalty, three simultaneous variations of the same theme are performed by two sets of melodic percussion—a circle of about 21 tuned drums (*saing-waing*) and a circle of about 21 tuned gongs (*kyi waing*)—and at least one oboe (*hne*) or a flute (*pulwe*). To this is added a playing of a percussion group comprising a double-headed drum (*patma*), a pair of cymbals (*la gwin*), and clappers playing a duple or a quadruple metre. In three rhythmic patterns applied by these percussion groups to specific song types, the strong beats are always marked by the clappers.

Melodic
traits

Melodies played on traditional instruments (*saing-waing,* harp, *pattala* or xylophone) are frequently broken by rests and consist of segments of two, three, or four notes that form phrases, usually of eight or 16 beats. Several phrases make up a number of verses to complete a musical rendition. Melodies, based on modes, are constructed according to the previously discussed elements usually found in the modal music of Southeast Asia. Song types exist in Burmese music and are assigned to specific modes.

The Burmese arched harp (*saung gauk*) has features that may be traced back to pre-Hittite times and the Egyptian 4th dynasty (*c.* 2613–*c.* 2494 BC). Scarcely existent outside of Burma, this instrument has undergone a renascence in the 20th century. A more popular solo instrument is a wooden xylophone *pattala.*

The following instruments may be found among ethnic groups in rural Burma: idiophones, or resonant solids—bamboo jew's harps, clappers, cymbals, wooden slit drums, bronze kettle gongs, drums; membranophones, or vibrating-membrane instruments—goblet drums; chordophones, or stringed instruments—crocodile zithers, monochords with calabash resonators, three- and four-stringed fiddles; aerophones, or wind instruments—lip-valley flutes, ring flutes, panpipes, double-reed winds, buffalo horns, and mouth organs.

Thai ensembles

Thailand, Laos, and Cambodia. Although their individual political histories differ, the music practiced in Thailand, Laos, and Cambodia is almost identical. The musical instruments and forms of this region spring from the same sources: India, the indigenous Mon-Khmer civilizations, China, and Indonesia. In Thailand, three types of orchestras, called *pi phat, kruang sai,* and *mahori,* exist. The *pi phat,* which plays for court ceremonies and theatrical presentations, uses melodic percussion (gongs in a circle, xylophones, metallophones) and a blown reed. The *kruang sai* performs in popular village affairs and combines strings (monochords, lutes, and fiddles with two and three strings) and wind instruments (oboes and flutes); while the *mahori,* as accompaniment of solo and choral singing, mixes strings (floor zithers, three-stringed fiddles, and lutes) and melodic percussion (gongs and xylophones) with the winds (flutes and oboes). All three ensembles are provided with a rhythmic group of drums, cymbals, and a gong to punctuate the melody parts. Some of the above musical instruments and their functions may best be illustrated in the *pi phat* ensemble below.

A slow-moving theme is played by gongs arranged in a circle (*khong wong yai*) with variations in smaller gongs (*khong wong lek*), two wooden xylophones (*ranat ek, ranat thum*), and two box-shaped metallophones (*ranat thong ek, ranat thong thum*). The last three pairs of instruments vary the theme by playing twice as fast or by repeating, anticipating, and revolving around it. A double-reed oboe (*pi nai*) hovers above the melodic percussion, providing the only blown sound in the ensemble. Together with the punctuating gongs and drums, the whole orchestra displays a polyphonic (many-voiced) stratification of instrumental parts, using unisons and octaves mainly in the strong beats.

A melody may be broken down into phrase units consisting of two or four measures that may be joined by four other phrase units to make a phrase block, and a given number of blocks constitutes one musical composition. Three speeds of rendition—slow, medium, fast—in either duple or quadruple time are marked by two alternating strokes in a pair of cymbals; a dampened clap marks a strong beat, and a ringing vibration denotes a weak beat.

The tuning system is made up of seven tempered (approximately equidistant) tones to an octave. But the melodies constructed out of this system use only five tones out of seven—which sound close to a Chinese pentatonic scale. This scale may be constructed in any of seven levels or tones of the Thai tuning system. Further, through a process called *metabole,* melodies may move from one level to another.

Shadow-play music and dance

In the Cambodian shadow play (*nang sbek*) two narrators alternate in chanted recitative to explain the role of the leather puppets. Dancers parading these figures across the screen and simulating their actions are accompanied by an orchestra. A limited number of tunes is played to eight dance positions (walk, flight or military march, combat, meditation, sorrow or pain, promenade, reunion, and metamorphosis). In the play these poses are assumed by princes, princesses, monkeys, demons, peasants, or ascetics.

Among different ethnic groups, such as the Khmer Saoch, Pwo Karen, Bu Nuer, Kae Lisu, Kuoy, and Samre, a rural music related to that of the ancient Khmer peoples is played by aerophones (buffalo horns, mouth organs, vertical flutes), idiophones (flat gongs, gongs with boss, cymbals, jew's harps), chordophones (bamboo zithers), and membranophones (circle of drums). Other important instruments for solo performance or as accompaniment to songs are the three-stringed crocodile zither (*chakhe*), a four-stringed lute (*grajappi*), a plucked monochord with a gourd resonator (*phin nam tao*), and a bamboo whistle flute (*khlui*).

Traditiona court music

Vietnam. Although Vietnamese music belongs to the great Chinese musical tradition, which includes the music of Korea, Mongolia, and Japan, some of its musical elements are indigenous or come from other parts of Southeast Asia, and some derive from Champa, an ancient Hinduized kingdom of Vietnam. Archaeological finds in the village of Dong Son revealed that the ancient Vietnamese used kettle gongs, mouth organs, wooden clappers, and the conch trumpet. From the 10th to the 15th century a joint Indian and Chinese element left its musical imprint. The Chinese seven-stringed zither (*ch'in*) and a double-headed drum were played together, or a Champa melody was accompanied by a drum. It was at this time that two traditional Chinese ensembles—Great Music and Little Music—and an elementary Chinese theatrical art were introduced. From the 15th to the 18th century the Chinese influence reached its height. Court music (*nha nhac*) was played by two orchestras. One, located in the Upper Hall of the court, consisted of a chime of 12 stones, a series of 12 bells, a zither of 25 strings (Chinese *se*), a zither with seven strings (Chinese *ch'in*), flutes, panpipes, a scraper in the shape of a tiger, a double-headed drum, a mouth organ, and a globular whistle. The second orchestra in the Lower Hall used 16 iron chimes, a harp with 20 strings, a lute with four strings (Chinese *p'i-p'a*), a double flute, a double-headed drum, and a mouth organ. Ceremonial music, almost nonexistent in the 20th century, was patterned after court music.

In Buddhist ceremonies, prayers were recited in three ways: as recitation in a low voice, as a cantillation (sung, inflected recitation) following the six tones of the Vietnamese language, and as chant accompanied by an orchestra of two drums, bell, gong, cymbals, and fiddles.

Music as entertainment is mostly a vocal art played without ritual outside the court and still enjoyed by many people. The *hat a dao* found in the north is the oldest form. It is a woman's art song with different instrumental accompaniments, dances, a varied repertoire, and a long history of evolution.

From the 19th century to World War II, Vietnamese music reaffirmed its character. Although the playing of court music was restricted, popular music was encouraged, leading to northern and southern styles that were patronized by both the aristocracy and commoners. Western musical influence in this period was manifest in the use of the mandolin, the Spanish guitar, and the violin, as well as by the introduction of European classical music and composition following Occidental forms. In the late 20th century traditional Vietnamese music began to disappear, but attempts to revive it began in the early 1970s.

Vietnamese rural folk music is built on the same musical principles as court music. The main difference lies in its application to village activities—work, games, courting, marriage, cure for the sick, entertainment, feasts.

Elements of Vietnamese music

Common elements characterize and unify all Vietnamese music. It is based on an oral tradition, with written notation serving only as a reading guide. Melodies are generally built out of a pentatonic system (for example, C, D, F, G, A) to which two auxiliary tones (E, B) may be added to make other pentatonic melodies. A song, usually preceded by a prelude, may be sung in slow, moderate, or fast tempo divisible by two or four, with a simple contrapuntal (countermelody) accompaniment using unisons and octaves at beginning points of phrases. Outside of the first beats, intervals of fifths, fourths, thirds, and even seconds are allowed. An important aspect of melodies is the idea of mode (*dieu*), the elements of which do not essentially differ from those of Javanese and Burmese music.

ıstrument
roups
f the
ımelan

Indonesia and Malaysia. *Java.* A Javanese philosophical concept based on mysticism, refinement (*halus*), and the inner life as related to Hindu, Islāmic, and Indonesian thought may best be represented in music by the Javanese gamelan, an orchestra made up mostly of bronze instruments producing homogeneous blended sounds. The instruments in the ensemble may be divided into three groups of musical function. The first group comprises thick bronze slabs (*saron demung, saron barung, saron panerus*) on trough resonators playing the theme usually in regular note values without ornamentation. The second group consists of elaborating or panerusan instruments, which add ornaments to the main theme. In this group gongs in double rows (*bonang panembang, bonang barung, bonang panerus*) play variations with the same ratio of speed as the *saron* group. In softer sounding music for indoor performance, other panerusan instruments with very mellow sounds come in. These are three sizes of thin bronze slabs with bamboo resonators—*gender panembung* or *slentem, gender barung,* and *gender panerus.* Other elaborating instruments are the wooden xylophone (*gambang*), the zither (*tjelempung*) with 26 strings tuned in pairs, an end-blown flute (*suling*), and a two-stringed lute (called a *rebab* by the Javanese), which leads the orchestra. In loud-sounding music, the soft-sounding instruments are not played, and the drum (*kendang*) leads the orchestra. The third group provides "colotomic," or punctuating beats in four rhythmic patterns played separately by four types of heavy, suspended, or horizontally laid gongs.

:ales and
ıodes

Two tuning systems prevail. The *slendro* tends to have five equidistant but flexible (or varying) pitches in an octave, while the *pelog,* with seven equally flexible tones, has a more varied structure. One tuning with intervals expressed in cents (140, 143, 275, 127, 116, 204, 222) may roughly be represented by the following notes in a descending scale: C↑, A♯, G♯, G↓, F↑, D♯↓, C♯↑, and C. (Arrows up are tones slightly higher than Western tempered tuning [in which a semitone is equivalent to 100 cents] and vice versa for arrows down.) Melodies from these tunings are governed by a modal structure (*patet*) the elements of which are similar to those of Vietnamese and Burmese music.

In West Java the most popular ensembles use a vocal part, a two-stringed fiddle (*rebab*) or a bamboo flute (*suling*), and a zither (*kachapi*). In the gamelan, submodes (*surupan*) are formed by the use of vocal tones—sung or played on the *suling* or *rebab*—which amplify the number of scales in both the *pelog* and *slendro* systems.

ırieties
Balinese
melan

Bali. In contrast to the introspection of Javanese music, the Balinese gamelan exudes a music of brilliant sounds with syncopations (displaced accents) and sudden changes, as well as gradual increase and decrease in volume and speed and feats of fast, precise playing. The tuning system, musical instruments, and polyphonic stratification are similar to those of the Javanese gamelan, although in Bali the seven-tone *pelog* is not popular. Most gamelan are tuned to a five- or four-tone system, and the concept of modes is not as clearly developed as in Java. A variety of gamelan exists, each with a special function, instrumentation, repertoire, and tuning system. The *gamelan gong* orchestra is among the most extensive in its number of instruments. A modern version, *gong kebjar,* omits the *trompong* (gongs in a row) and *saron* (bronze slabs over a trough resonator) and replaces them with *gangsa gantung* (metallophone with bamboo resonators) and *rejong* of four gongs to produce exuberant outbursts of sound. The *gamelan gambuh,* now rare, comprises four end-blown flutes, one *rebab,* and a group of percussion. The *gamelan semar pegulingan,* played formerly in royal courts but now almost disappeared, emphasizes the *trompong* as a solo instrument. The *gamelan pelegongan* is a virtuoso orchestra that accompanies *legong* dances, while the *gamelan pedjogedan* is an orchestra of xylophones for dance (*djoged*) and entertainment in the marketplace. The *gender wayang* is a quartet of *slendro* tuned metallophones specially employed for shadow plays. The *gamelan angklung,* a village orchestra assembled during ceremonies, anniversaries, and cremations, originally consisted of rattling tubes that are now replaced by metallophones. The *gamelan ardja* is characterized by a soft timbre (tone colour) and the use of a one-stringed bamboo zither, the *guntang,* to accompany musical comedy and popular plays.

Other parts of Indonesia. In the islands of Flores, Nias, New Guinea, Celebes, and Borneo idiophones make up perhaps the most varied collection of musical instruments—gongs of various profiles, slit drums, jew's harps pulled with a string, clappers, bells, xylophones, percussion sticks, bull-roarers, and stamping tubes. Particularly interesting are idiophones made of bones, shells, skulls, fruits, seeds, planks, pellets, crab claws, clogs, coconut, and shark bones. Membranophones are represented by drums shaped like a cylinder, goblet, vase, round frame, hourglass, cone, cup, barrel, or a tube. Aerophones present an array of vertical and transverse (horizontally played) flutes, panpipes, ring flutes, shawms, clarinets, gourd trumpets, conch shells, ocarinas, and flutes with different mouthpieces. Chordophones include bamboo zithers, spike fiddles (in which the neck skewers the body), one- and two-stringed lutes, musical bows, monochords, guitars, *rebabs*, bar zithers, and sago zithers. In Flores, part singing with a sustained drone is frequent. Songs in Nias use diatonic (whole and half steps), chromatic (half steps), and gapped melodies largely less than an octave in range. In Sarawak descending melodies make up a tetrachord (four adjacent tones forming the interval of a fourth). In Indonesian New Guinea departures from songs with gapped scales include fanfare, stair descent, and tiled melodies (the last consisting of short phrases repeated at different pitch levels).

Malaysia. At least three principal cultural influences—Indonesian, Hindu, and Islāmic—left their musical marks in Malaysia. The Indonesian influence is seen principally in musical forms, participants, and paraphernalia of the Malaysian shadow play (*wayang kulit*). It is said that the Indian epics and, especially, the *Pandji* tales of Java came to Malaysia via Indonesia, but there are songs in certain plays and musical instruments (*e.g.,* the double-headed drum and oboe) that could have reached Malaysia from India through other routes. Islāmic traces are evident in melismatic songs among the Malay groups in songs connected with religious rituals and in choral singing in the *ma'yong* plays. Chinese music, a more recent development, is largely practiced among the Chinese communities, principally in Singapore.

Before Malaysian independence, the *nobat,* an old royal instrumental ensemble dating back to about the 16th century, played exclusively for important court ceremonies in the palaces of the sultans of Perak, Kedah, Selangor, and Trengganu. Today, in Kedah, the ensemble consists of five instruments: one big goblet drum (*negara*), two double-headed drums (*gendang*), one long oboe (*nafiri*), one small oboe (*nafiri*), and one gong. The music, which consists of ten surviving pieces, is broadcast today and performed live.

Three shadow plays exist, principally in the state of Kelantan. The *wayang gedek* is the Thai form; *wayang Djawa,* a Malay form, is almost extinct; and the *wayang Siam,* which is a combination of Thai and Malay influences, is the most popular form of puppet shadow play. The operator of the performance is the narrator (*dalang*), who manipulates the leather figures, introduces important characters, and describes different scenes with the accompaniment of the orchestra. The music is led by a two-stringed lute (*rebab*) in the *Rāmāyaṇa,* or an oboe (*serunai*) in *Mahābhārata* and *Pandji* cycles. The melodic instruments are supported by a percussion group consisting of pairs of goblet-shaped drums (*gedombak*), cylindrical drums (*gendang*), barrel drums (*geduk*), gongs lying on a support (*chanang*), suspended gongs (*gong*) or, sometimes, a row of gongs played by two or three men, and one pair of cymbals (*kesi*). The music usually begins with a prelude followed by a list of pieces the sequences of which are dictated by the narrator.

The *ma'yong,* a dance drama that probably dates back to more than 1,000 years, was introduced in Kelantan under the patronage of the royal courts. In the 20th century it exists as a folk theatre with an all-female cast. The music that accompanies 12 surviving stories is played by an orchestra of one bowed lute (*rebab*), two suspended gongs, and a pair of double-headed drums (*gendang*). A heterophony (simultaneous variation of the same melody) between a solo voice, a chorus, and the *rebab* creates a music with a Middle Eastern flavour.

Variety in instruments

A rich musical heritage in the rural sections of Malaya is shown in musical instruments used by Malay, Thai, Semang, and Sakai groups. Idiophones include shell and coconut rattles, the jew's harp (mostly pulled by a string, rather than plucked), bull-roarers, bamboo clappers, and the bamboo slit drum. Aerophones include the buffalo horn, wooden and clay whistles, nose flutes, end-blown flutes, and the oboe. Chordophones are two- and three-stringed fiddles with coconut resonators, monochords, and tube zithers. One membranophone is a double-headed cylindrical drum.

In Borneo among the Malay, Kadazan, and Iban groups, the principal instruments are gongs in a row (*gulintangan*) played with suspended gongs of different types (*chanang, gong, tawak-tawak*). Among the Murut, Kenyah, and Iban the mouth organ with a calabash resonator (*sompoton*) plays a melody with a drone accompaniment. The jew's harp (*ruding*), bamboo zither (*tongkungon*), nose flute (*tuali*), hourglass drum (*ketubong*), and vertical flute (*suling*) may be heard among different ethnic groups. Iban ceremonial songs are sung in connection with rice festivals and rituals to prevent sickness, while mourning songs make up a rich repertoire of solo and leader–chorus singing. The Kenyah are particularly adept at blending low voices of men singing a melody supported by a drone.

The Philippines. Two musical cultures—Western and Southeast Asian—prevail in the Philippines. Western music is practiced by about 90 percent of the population, while Southeast Asian examples are heard only in mountain and inland regions, among about 10 percent of the people.

The Western tradition dates back to the 17th century, when the first Spanish friars taught plainchant and musical theory and introduced such European musical instruments as the flute, oboe, guitar, and harp. There subsequently arose a new music related to Christian practices but not connected with the liturgy. Processional songs, hymns in honour of the Blessed Virgin, Easter songs, and songs for May (Mary's month) are still sung in different sections of the country. A secular music tradition also developed. Guitars, string ensembles (*rondalla*), flute, drum, harps, and brass bands flourished in the provinces among the principal linguistic groups and still appear during town fiestas and important gatherings. Competing bands played overtures of Italian operas, marches, and light music. Young men, like their counterparts throughout the Hispanic world, sang love songs (*kundiman*) in nightly serenades beneath the windows of their ladies. It was not uncommon in family gatherings for someone to be asked to sing an aria, play the harp, or declaim a poem. Orchestral music accompanied operas and operettas (*zarzuelas*), while solo recitals and concerts were organized in clubs or music associations. With the advent of formal music instruction in schools, performance and composition rose to professional levels. In the 20th century several symphony orchestras, choral groups, ballet companies, and instrumental ensembles performed with varying regularity.

Gong ensembles

A Southeast Asian musical tradition exists completely apart from the Western tradition. In the north, flat gongs are played in different instrumental combinations (six gongs; two gongs, two drums and a pair of sticks; three gongs). In the ensemble with six gongs, four are treated as "melody" instruments, one as ostinato, and another as a freer layer of improvisation. The melody consists of scattered tones produced by strokes, slaps, and slides of the hands against the flat side of the gong. Other musical instruments in the northern Philippines are bamboo. These are the nose flute (*kalleleng*), lip-valley or notched flute (*paldong*), whistle flute (*olimong*), panpipes (*diwdiwas*), buzzer (*balingbing*), half-tube percussion (*palangug*), stamping tube (*tongatong*), tube zither (*kolitong*), and jew's harp (*giwong*). Leader–chorus singing among the Ibaloi is smooth and sung freely without a metric beat, while the same form among the Bontoc is emphatic, loud, and metric. Scales in songs and musical instruments use from two to several tones within and beyond an octave and are arranged as gapped, diatonic, and pentatonic varieties.

In the southern Philippines (the islands of Mindanao and Sulu), the more developed ensemble is the *kulintang,* which consists of eight gongs in a row as melody instruments accompanied by three other gong types (a wide-rimmed pair; two narrow-rimmed pairs; one with turned-in rim) and a cylindrical drum. The *kulintang* scale is made up of flexible tones with combinations of wide and narrow gaps sometimes approaching a Chinese pentatonic variety and oftentimes not. Its melody is built on nuclear tones consisting of two, three, or more tones to form a phrase. Several phrases may be built, repeated, and elongated to complete one rendition lasting two to three minutes. Pieces of music are played continuously for a long period during the night.

In the central west Philippines on the island of Mindoro, love songs are sung that are based on reciting tones with interludes played by a miniature copy of the Western guitar or a small violin with three strings played like a cello. (Jé.Ma.)

The performing arts

In variety of dance and theatrical forms and in the number of performing groups, no area in the world except India and Pakistan compares to Southeast Asia. Some form of the performing arts is a normal part of life throughout the several nations. Sophisticated performing groups cluster in and around the present and former court cities—Jogjakarta and Surakarta in Java, Ubud and Gianjar in Bali, Bangkok in Thailand, Mandalay in Burma, Siem Reap near Angkor and Phnom Penh in Kampuchea (Cambodia), Hue in Vietnam—where drama, puppetry, dance, and music have been cultivated for ten centuries or more. Hundreds of commercial theatrical and dance groups perform in such newer centres as Rangoon, Saigon, and Jakarta and in scores of provincial cities and towns. Wandering troupes of actors, puppeteers, singers, and dancers travel from village to village in areas adjacent to these population centres. There are few communities in which some form of folk dance is not performed by local people.

Richness c form and experience

In the West, music, dance, and drama are usually separate arts, whereas in all areas of Southeast Asia, drama, dance, mime, music, song, and narrative are integrated into composite forms, often with masks or in the form of puppetry. The spectator's senses, emotions, and intellect are bombarded simultaneously with colour, movement, and sound. The result is a richness and a vividness in the theatre that is absent in most Western drama, so much of which rests on a literary basis.

More than 100 distinct forms or genres of performing arts can be distinguished in Southeast Asia. These can be grouped, according to which of the various stage arts is emphasized, into (1) masked dance and masked dance-mime, (2) unmasked dance and dance-drama, (3) drama with music and dance, (4) opera, (5) shadow-puppet plays, and (6) doll- or stick-puppet plays.

DIVERSE TRADITIONS IN THE PERFORMING ARTS

Four relatively distinct traditions exist in the performing arts: folk, court, popular, and Western.

The folk tradition. Dances in the folk tradition are exceptionally numerous and widespread. Some are performed as religious ritual, others, particularly on the Indonesian island of Bali, by highly trained and respected artists, and still another kind as entertainment in which the community participates. Folk theatre is more complex than folk dance and thus less widespread, but it has deep connections with religious ritual. Although the origins of most folk performing arts lie in remote times, later court forms exerted important influence on many of the folk forms. Conversely, folk forms have been a source of inspiration to court artists.

Shadow plays

The court tradition. The shadow play and masked and unmasked dance are court arts reflecting centuries of subtle refinement under the patronage of kings and princes. In Southeast Asia the shadow theatre is a major classic art. Leather puppets of mythological figures, the bodies intricately incised to allow light to pass through, are attached to sticks for manipulation. A lacy shadow is created by a flaming lamp as the puppet is pressed against the back of a vertical screen of white cloth. The flickering and insubstantial shadow seen from the other side creates for the understanding viewer a mystic world with deep symbolic meaning. In Java, Bali, Malaysia, Cambodia, and Thailand shadow plays and their techniques have been emulated by human actors and dancers and have been the models for marionette and doll-puppet theatre.

Dance troupes have been a part of court life at least since recorded history began. In the mainland courts of Cambodia, Thailand, Laos, and Burma, concubines of the ruler's harem who performed female dances were segregated from male performers, giving rise to separate forms of female unmasked dance and male masked dance-mime. Although certain dances traditionally are performed only by men or only by women in Indonesia and Vietnam, mixed casts have a long history, especially in dramatic pieces. Court dance on the mainland and in Indonesia has been influenced by Indian dance style, and Vietnamese dance by the dance styles of Chinese opera, but they have acquired a distinctly Southeast Asian character. Court dance reached its greatest development when applied to mythological and legendary themes, often taken from the shadow theatre. The resulting dance-dramas and masked dance-mimes of Thailand, Cambodia, and Java are world famous for their magnificent scale and elegance of execution. Some of these court arts are no longer performed, and others face increasing difficulty securing financial support, yet they remain important.

The popular and Western traditions. In the popular traditions are those 400 to 500 professional troupes who perform, except in the Philippines, in commercial theatre buildings of major cities for an urban ticket-buying audience. Some forms of popular theatre are directly modelled on court dance-drama, but most are spoken drama in which court-derived music, song, and dance movements have been inserted. Local legend and history provide the subject matter for many of these plays. As in much of Asia, the performer in the popular tradition is seldom accorded status and may be despised as a vagabond.

The spoken drama, the ballet, and the modern dances are known only superficially in Southeast Asia. The sole exception is the Philippines, where amateur performances of Western plays constitute the country's main theatrical tradition. Southeast Asian audiences generally find Western plays based mainly on dialogue to be uninteresting and deficient in artistic qualities. European and American films and television programs, however, are widely shown and appreciated, and popular Western dances are found in major urban areas. Undoubtedly the impact of these forms on local audiences will continue to increase, possibly to the detriment of the indigenous traditions.

CHARACTERISTICS OF DANCE

Dramatic and nondramatic forms. In the parts of Southeast Asia influenced by Indian forms—everywhere except for Vietnam and the Philippines—nondramatic and dramatic dance are both known. Nondramatic, or "pure," dances that do not express emotional states of characters are numerous in both folk and court traditions. Among court dances, the Javanese *bedaja* is typical. Nine dancers move in unison, without emotional expression, in precisely fixed choreographic patterns designed to demonstrate sheer grace of movement. The *maebot,* composed as a Thai "alphabet of dance," is used to train pupils in the basic movements of court dance. Other dances that include character impersonation yet are not explicitly storytelling dances lie between nondramatic and dramatic dance. In the Thai *praleng,* two performers wearing god masks and holding peacock feathers in both hands perform an offertory dance to the god before the main dance-play begins. The Balinese *legong,* danced by a pair of preadolescent girls, may have only the most tenuous dramatic content. Its interest lies in the girls' unison rapid foot movements and fluttering movements of eyes and hands. Dramatic dance is seen at its best in full dance-dramas and in the excerpts from them that are sometimes danced in concert form.

se of eyes
d hands

Styles and conventions of movement and costuming. General characteristics of both dramatic and nondramatic dance are (1) slowness of tempo except in battle scenes, (2) controlled and reserved movements rather than expansive ones, (3) little of the leaping typical of Western ballet but, instead, a feeling of closeness to the ground, and (4) extensive use of arm and hand gestures. From Indian dance has come an open and flexed position of the legs, a side-to-side sliding movement of the head and neck, and a rigidly codified vocabulary of hand and finger gestures known as *mudrās* or *hastās* in India. In most cases the Indian elements have been altered greatly over their 1,000-year period of assimilation. In Thai, Cambodian, and Lao dance, the 24 to 32 Indian *mudrās* have been reduced to nine; in Javanese dance seven can be recognized, and in Bali only one or two. They have also been altered in their shape, and the many specific meanings attached to each in India have become fewer, while in some cases a gesture has no specific meaning. Such hand gestures as shading the eyes and tying the sash, which appear in Javanese dances, are unknown in India. Foot movements in India typically follow the rhythm of a drum, often with vigorous stamping sounds that are emphasized by bells on the ankles, but such movements are virtually absent in Southeast Asia. The exaggerated eye, eyebrow, cheek, mouth, and chin movements through which the Indian dancer expresses a broad gamut of emotions are nowhere to be seen. Balinese dancers use darting eye movements, but the court dancer's face is composed into an almost unchanging expression of aloof gentility.

Close contact between neighbouring countries has led to the development of two regional Indian-influenced dance styles, one for Thailand, Cambodia, Laos, and Burma and one for Indonesia and Malaysia. Characteristics of the former style include the soft *pi phat* music of bamboo xylophones, drums, gongs, and oboe as accompaniment, bent-back finger positions not seen elsewhere in Asia, similar and often identical movements for male and female roles, courtship dances in which lovers touch each other and move in unison, and, in dance-drama, lengthy pure-dance pieces inserted solely for their beauty. In the latter style, the performance is accompanied by music of the gongs and metal bars of the gamelan orchestra. Scarves draped from the waist or neck are flicked for effect and manipulated to indicate strength or flying, and male and female dance are clearly distinguished by the powerful masculine lunges of the men and the tiny steps of the women, who also dexterously manipulate the train of the skirt with their feet. Visually, the mainland dance sparkles. Costumes of brilliant silk are covered with sequins and even jewels, and golden crowns and sparkling body ornaments glitter with reflected light. The male dancer in Indonesia wears a soft batik skirt of brown and white, the female a black velvet bodice. Arms and shoulders are bare and powdered golden brown, creating a subdued and warm effect.

Courtship
dances

The main style in Vietnam, apart from folk dance, is dramatic and highly pantomimic, like the movements of Chinese opera. In classical opera, the flowing white sleeves and the pheasant feathers bobbing from the general's headdress are twirled and flicked by the actor in many conventionalized movements derived from Chinese forms. Battle scenes are choreographed into precise dance patterns, but the acrobatic movements common in Chinese opera are seldom seen.

CHARACTERISTICS OF DRAMA

Thematic origins and materials. Most traditional plays and dramatic dances are derived from mythological and legendary sources. The tribal epics that relate the origin of the Ifugao and the Bicolano peoples in the Philippines and a number of animistic stories in Indonesian shadow theatre are indigenous myths of great age, while the widely used, romantic *Pandji* cycle from Java and the Thai *King Abhai Mani* and *Khun Chang Khun Phan* are more recent local legends. The most important dramatic sources, however, are borrowed from the Indian *Rāmāyaṇa* and *Mahābhārata* epics, from the *Jātaka* Buddhist birth stories, from Chinese novels (such as *The Romance of the Three Kingdoms*) and Chinese operas, and from a host of Islāmic stories, including the *Thousand and One Nights* and the Amīr Ḥamzah tales. These foreign stories are turned into local legends. For example, the Indian Prince Rāma becomes a Thai, a Balinese, or a Javanese prince, embodying the heroic traits admired in each of these countries.

Theme of the restoration of earthly harmony

Plays are invariably extensive and have many scenes. It is not unusual for a play to present action over several generations, an indication of the value placed on cultural continuity. A recurring theme concerns restoration of harmony on earth by a ruler acting in accord with divine law. A kingdom is restored, a prince unjustly exiled returns to assume his throne, a usurper is punished, or the prosperity of the land is assured by consummating a particularly desirable marriage. As in Western drama, the hero gains his ends through struggle. Because he acts as the human representative on earth of the known cosmic will, however, his actions exhibit a natural sweetness and serenity, even in the midst of violence, that is foreign to Western drama. Meditation is often the means whereby the hero gains the power to achieve his goal. In more recent plays based on local history and on contemporary events, the assumption of cosmic harmony has been muted, and emphasis has shifted to depicting human conflicts—nationalist versus Western colonialist, modern daughter versus conservative parents, for example—that may or may not resolve happily.

Characters. Gods, demigods, kings descended from the gods, and princes and princesses are the heroes and heroines of traditional drama and dance. Powerful religious seers advise them, allies and ministers serve them, crude foreign ogres oppose them, and grotesque, slapstick clown-servants are their attendants. The clowns have been the subject of much speculation. Like the *vidūṣaka* clown of Indian Sanskrit drama, they are gluttons, practical and even cynical, and confidants to their masters' passions and weaknesses. Scholars have theorized that the chief Javanese clown figure, Semar, is derived from an ancient Javanese god who was deposed from his supreme position by the introduction into the drama of the later Hindu gods. In the midst of mythological plays, the clowns comment irreverently on political or social issues of the day, seemingly as spokesmen for the common man in an otherwise aristocratic world. Comic and serious scenes alternate.

Improvisation by variation

Dramatic materials. A written script may be used as the starting point for performance, but usually actors, dancers, musicians, and stage crew improvise from a brief scenario. Specific musical selections are matched to certain kinds of scenes, characters, or actions, and standard movements for entrances and exits are known. Standard descriptive phrases of the kind common in all oral literature are used to introduce the hero and his kingdom, and more than a dozen types of recurring scenes are identifiable. A major interest in playgoing lies in perceiving the skill with which performers rearrange and subtly vary these familiar elements from play to play. Narrative commentary accompanying the dances often interprets a specific action in its broad context, thus helping to universalize the theatrical experience.

Costumes, makeup, and settings. Costume and makeup have great importance in plays and dances. By means of elaborate systems of changing the cut, colour, and ornamentation of costume, the shape of the hairdress, the configuration of the crown, or the facial delineation and colour of masks, at least 300 different dance and dramatic characters can be identified. Doll- and shadow-puppet figures are carved according to similarly elaborate means of identification. Persons familiar with a dance or theatrical form can identify most characters by name or by type. Costumes, masks, and puppets may be works of art highly prized in themselves. Court and folk performances once used no scenery at all. Canvas scenery depicting stock scenes is now used by most popular troupes, but unfortunately it is often as inartistic as it is inexpensive. Only the Thai National Theatre, major troupes performing the popular *cai luong* drama in Vietnam, and troupes performing in the Western tradition throughout Southeast Asia attempt to design three-dimensional scenery for each play.

ORIGINS AND DEVELOPMENT OF THE PERFORMING ARTS

Prehistory and links to the present. Knowledge of prehistoric performing arts is necessarily slight. That the performing arts were known and apparently widely practiced by the prehistoric peoples who had settled the mainland and the island archipelagoes is suggested by large bronze drums cast before the time of Christ, numerous pre-Hindu tribal myths in remote areas of the Philippines and elsewhere, masked dances of many types still performed by isolated tribes in Kalimantan (Borneo) and in New Guinea, and descriptions of music and dance by Chinese visitors beginning as early as the 1st century AD. Simple dances were almost certainly accompanied by rhythmic percussion sounds and probably by the tuned metal bars or gongs thought to be indigenous to Southeast Asia. Some scholars suggest that tribal ancestors, animistic spirits, and animals were represented, perhaps in shadow form. Whatever their nature, these were folk performances, in part religious rites connected with seasonal festivals and in part joyful entertainment.

The *trott*, *barong*, and *nat*

A number of existing dances and dramatic forms show prehistoric links. In the *trott*, a Cambodian deer-hunting dance, masked dancers representing hunter, demon, bull, girls, and deer enact the ritual of a deer hunt to ensure its success in real life. The Dayak of Kalimantan perform a dance to exorcise sickness. The *barong* dance-drama of Bali is staged by a village in which malicious spiritual forces are believed to have gained dominance over protective ones. By enacting the stand-off battle between the protective Barong lion figure and the destructive Rangda witch figure, the village ritually restores an equilibrium between the contending forces. A local *nat*, or animistic spirit, of which there are 37 in Burma, can be invoked by the dance of a professional "spirit wife," or *natkadaw*, through whom the *nat* communicates with the living. A disputed theory holds that the shadow play began as a ritual in which the spirits of magically powerful tribal ancestors were called to earth, in their natural form as shadows or shades, for advice.

Spreading of styles. Between *c.* AD 100 and 1000, dance and drama in Southeast Asia were profoundly affected by

Apsaras, heavenly dancing girls, bas-relief from Angkor Wat, Angkor, Cambodia, early 12th century.

the introduction of dance style and the vast Hindu historical epics of India. First in Cambodia, then in turn in Thailand, Laos, and Burma, the epic *Rāmāyaṇa* became the source of dance and shadow plays. In Java the *Mahābhārata* dominated, whereas in Bali and Malaysia both epics were popular. Indian influence, however, can be exaggerated. There is no evidence that Sanskrit play texts or written dramatic treatises such as the *Nātya-Śāstra* became known. Strong local performing traditions made it possible to assimilate elements of Indian dance and Hindu stories, and, in subsequent development, Southeast Asian dance and theatre grew ever farther away from Indian styles.

Copper inscriptions from Java identify clowns, actors, musicians, and possibly puppeteers in the 9th century, and epic literature of succeeding centuries contains numerous descriptions of shadow plays that were popular and emotionally gripping. By at least the 4th century, epic recitations were a part of the Brahmanic worship of ancient Cambodia. Carvings of the beautiful *apsaras*, or heavenly dancing girls, adorning the temples of Angkor attest to the importance of court dance in Cambodia between the 10th and 13th centuries.

ay

Accidents of history often carried the performing arts across national boundaries. It is believed King Jayavarman II brought dancers and musicians from Java when he left there in 802 to establish the Khmer dynasty in Cambodia, and shadow puppeteers may have accompanied him as well. Another theory suggests that Cambodia received the shadow play from India by way of Malaysia, through conquest by a Malay prince in 1002. Accidents of war took Khmer dance (and perhaps shadow theatre) first to Laos, when in 1353 a prince who had been raised at Angkor established an independent Lao court at Luang Prabang. Next, it reached the Thai capital at Ayutthaya in 1431, when Angkor fell to invading Thai armies. These returned to their court with the Cambodian court-dance troupe, thereby beginning the traditions of Thai court dance and dance-drama. In 1767 the Thai court was captured, in turn, by the Burmese, who brought to Burma the Thai-modified Khmer dance and created Burmese court drama. By this time, also, Javanese shadow theatre had been taken by colonists to Bali and to Malaysia, from whence it later entered southern Thailand.

When Indonesia was converted to Islām and Chinese influence became strong in the northern tier of mainland states beginning in the 13th and 14th centuries, existing court dance and dramatic forms were scarcely affected. Instead, new Islāmic plays were devised in Indonesia and Malaysia for shadow presentation and for the doll-puppet theatre. Islāmic influence was very strong in Malaysia, however, and even such pre-Islāmic forms as the shadow play absorbed Islāmic prayers, characters, and themes. Bali was never converted to Islām, and its performing arts are thought to reflect, even today, an older tradition than is seen in Java.

Chinese performing arts came to dominate Vietnam during the 1,000-year rule of northern Vietnam by the Chinese. Long after the Chinese were expelled, Vietnamese kings patterned their dances and opera on Chinese models. In time, however, local Vietnamese melodies and stories took their place alongside those of Chinese origin; and play scripts, at first filled with Chinese loan words, were rewritten in more colloquial Vietnamese.

Popular theatre and Western rule. From the 19th century onward, the incursion of Western culture brought about a variety of developments. A steady decline in the power of the royal courts precipitated the death of court drama in Burma; the shifting of support for dance and drama from the court to national bureaus of education and culture in Thailand, Cambodia, and Vietnam; and the movement of the court dance-drama into the popular theatre tradition in Java. In every country, new popular forms of theatre were created. These were based on historical events, on Islāmic and Chinese stories (but romances rather than Hindu and Buddhist myths), on national heroes fighting colonial rule, and on stories about contemporary events. It was not Western drama that sparked the burgeoning of popular theatre, though these plays were largely spoken dramas interspersed with music and dances. Rather, it was more of an indirect response to colonial rule, which caused an upsurge of nationalist feelings, and to the rapid growth of cities that created large populations without access to either folk or court theatre yet eager for some form of entertainment.

DIVERSE NATIONAL FORMS AND TRADITIONS

Although most of the dance and dramatic forms of Southeast Asia are related at least in the distant past, except in Vietnam and the Philippines, they acquired a very distinctive national and local character over the centuries. An examination of a few of these myriad forms will provide a more precise picture of the dense texture of the performing arts in Southeast Asia.

Cambodia. Court performing arts that had flourished during the Angkor period (802–1431) almost ceased in the centuries following the fall of the Khmer dynasty. Whether there was an organized court life or not is uncertain because of the scarcity of records, but in the 18th and 19th centuries performances in Thai form were produced by the Thai rulers of the western provinces of Cambodia. At Phnom Penh a classical ballet troupe was established by the royal family in the 19th century.

Puppet
tableaus

Court styles. The chief court forms are *nang sbek* shadow theatre, *lakon* female dance and dance-drama, and *lakon kawl* male masked pantomime. The puppets of *nang sbek* stand four to five feet in height, have no movable arms, and are manipulated from beneath by two fixed handles or sticks. The standing puppeteer either sways the puppet with his arms or he dances with it. In processional scenes, as many as ten puppeteers parade completely around the screen, front and back. An entire tableau may be carved on one puppet, including several figures, forest scenery, or palace buildings, as if to bring to life the epic scenes carved in relief on the temples of Angkor Wat. Two narrators alternate a slow chant with dialogue. During dance sections, the large *pi phat* ensemble, augmented by a large drum, is played. Only plays based on the *Rāmāyaṇa* are performed, and major puppet figures represent Rāma, his consort Sītā, the monkey Hanumān, and Rāvaṇa, a ten-headed demon king who kidnaps Sītā, Khmer peasant figures have been inserted as rustic clowns in every *nang sbek* play. Performance has religious significance, the gods being invoked and honoured, and a performance may be arranged to assure rain or to halt an epidemic. It is not certain when and how *nang sbek* originated, but it seems probable that it was taken to Thailand in the 15th century and then brought back. This would explain the details of costume and headdress of today's puppets that are in Thai style.

The lithe *apsaras* carved in Angkor's stone show details of the *lakon* style of female dance, but neither these nor other records are evidence that their lively dance was used in relating the epic stories. The 19th-century Thai rulers of western Cambodia reintroduced *lakon* dance and dance-drama, which was indigenous to Thailand as well. At the same time, Thailand's male masked pantomime was brought to Cambodia, as far as is known for the first time, and it became known as *lakon kawl.* Both male and female dance-plays were translated into Cambodian. Recently, costumes and headdresses have been redesigned in the style of the Angkor carvings. The stories, music, dance, and dramatic styles of *lakon* and *lakon kawl* are much like their Thai counterparts.

Popular forms. *Lakon bassac,* performed by some 20 professional troupes in Cambodia, is a highly eclectic form. Musical selections, dances for female characters, and costuming are borrowed from court *lakon.* The form was created by Khmers living in the Bassac River region of Vietnam. Villains wear Vietnamese costumes and move with Vietnamese opera movements, an evidence of the historical conflicts of the two peoples. Chinese, *Jātaka,* or Khmer stories may be performed. *Pi phat* music alternates with Chinese–Vietnamese instruments and with the Western saxophone and piano. Prince Sihanouk, chief of state between 1941 and 1970, encouraged a few French dramatic productions, but such drama is scarcely known outside the Western-educated elite.

Thailand. Folk *lakon jatri, lakon nai* female dance and dance-drama, *khon* masked pantomime, and *likay* popular theatre are Thailand's chief performing arts.

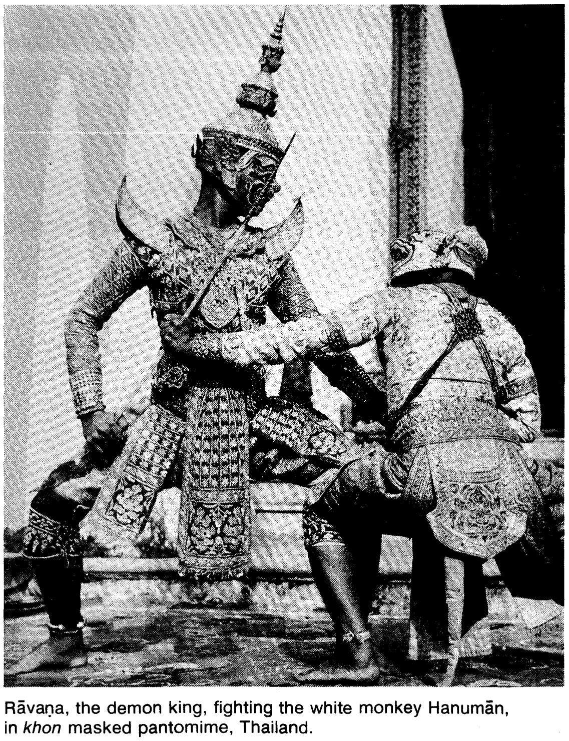
Folk performance. *Lakon jatri* began in the south, when male dancer-sorcerers performed, in simple folk style, the *Manora* Buddhist birth story as a dance-play. A troupe of three players was usual. One played the beautiful half-bird, half-human princess, Manora; a second played the hero, Prince Suton; and the third, often masked, played clown, ogre, or animal as needed. Flute, bell cymbal, and drums provided the music. The full *Manora* cycle of plays, staged in a village in the open, could last for two weeks. Probably after the 14th century, some *jatri* troupes moved to the Thai capital, where they established commercial theatres and staged a new all-male drama, *lakon nok* (*nok,* "outside" [the palace]), that emphasized plot and an often obscene humour. Advances in dramatic form were accomplished by court writers of *lakon nok* between 1800 and 1909. *Likay* troupes succeeded and completely supplanted *lakon nok* troupes in the early decades of the 20th century, but such popular *lakon nok* plays as *Sang Thong* ("The Prince of the Golden Conch") are presented today in modified form by the Thai National Theatre.

Bawdy humour

Female court dance-dramas. The *lakon nai* (*nai,* "inside" [the palace]) female dance-drama of the court was created in the mid-18th century from a confluence of three previously separate elements: female court dance, the *lakon nok* drama, and the Javanese *Pandji* stories as subject matter. Romantic episodes from the long *Pandji* tale were ideal for staging in the elegant and delicate style of female court dance, accompanied by songs and the music of a large *pi phat* ensemble. In the unhurried court atmosphere, dance scenes lasted an hour or more, and dance figures might be repeated many times. In time, other stories came to be staged in *lakon nai* and were given other names, but the *Pandji* plays composed by the daughters of King Boromokot (1733–58), by Rama I (1782–1809), and by Rama II (1809–24) remain favourites. In this form, *lakon nai* was introduced into Cambodia within the past two centuries.

Masked mime. Until recent years, a Thai version of the Khmer *nang sbek* shadow play, *nang yai,* occupied an important place in court as a Brahmanic-related ritual performance of the *Rāmāyaṇa.* Thai scholars describe it as the source of *khon* masked pantomime, citing celebrations for King Ramathibodi II in 1515 that included a *nang yai* performance without puppets. Wearing heavy makeup, the puppeteers themselves danced the usual *Rāmāyaṇa* episode as narrators told the story and spoke dialogue. Later, masks took the place of makeup, the screen was eliminated, and *khon* was born. In present-day Cambodia (Kampuchea), one troupe can perform both forms. A number of *lakon nai* elements entered *khon* in later years, so that today a *khon* performance mixes the vigorous, masculine *khon* with gentle *lakon nai* singing style and female dance. All of the Thai dance-drama traditions (*lakon jatri, lakon nok, lakon nai,* and *khon*) are taught at the Department of Fine Arts in Bangkok, and representative plays from them are staged, often mixing traditions, at the Thai National Theatre.

Marie Mattson—Black Star



Rāvaṇa, the demon king, fighting the white monkey Hanumān, in *khon* masked pantomime, Thailand.

Development of the *khon*

Popular plays and puppets. The major popular theatre form is *likay,* which evolved in part out of *lakon nok.* It is now performed by more than 100 troupes in most parts of Thailand. Actors are skilled in improvising not only the dialogue and lyrics but also the plot of a play as well, weaving romantic scenes and fragments of *lakon nai* dance, set to *pi phat* music, into a story from a well-known *Jātaka,* history, or court play. *Likay* plays are set to music of the Lao *khen,* a reed organ, in northeast Thailand. A type of shadow play called *nang talung,* in which a single, seated puppeteer moves small puppets of individual figures with movable arms, is very popular in southern Thailand. The performance technique undoubtedly came from Malaysia, while the plays and the identifying features of the puppet figures, mostly from the *Rāmāyaṇa,* are from Thai *khon* and *lakon nai.* A similar shadow play exists in Cambodia, suggesting that the form travelled from southern Thailand to Cambodia, perhaps in the 19th century.

Laos. From the time Laos became a kingdom in 1353, the performing arts at the relatively small Lao court at Luang Prabang followed those of the more illustrious courts to the south, Angkor in Cambodia and then Ayutthaya and Bangkok in Thailand. Today, Lao dancers study in Bangkok, and the style of dance, music, and drama of the Royal Lao Ballet, the only remaining court troupe in Southeast Asia, is almost identical with that of *lakon nai* in Thailand. It is usual to perform excerpts from the very long dance-plays, the staging of a full-length spectacle being beyond the means of the court at present. Male *khon* dance is known but seldom performed. A number of Lao folk dances are studied and performed by the royal ballet troupe.

Balladeers of Laos

Scores of popular troupes perform plays derived from Thai *likay* and set to the lively and melodic Lao folk song style known as *mohlam. Mohlam* balladeers, accompanied by the *khen* (a complex reed organ), have for centuries travelled the Lao-speaking countryside, which includes Laos and northeast Thailand, singing bawdy songs of physical love and weaving into their performance local gossip and bits from the epics and court plays. When *likay* troupes from Bangkok played in northeast Thailand, the *pi phat* music and court dancing were not popular, although the plays themselves were. Enterprising *mohlam* performers then set the *likay* plays to the familiar *mohlam* song style, thereby creating a new popular theatre form, *mohlam luong,* or "story *mohlam.*" Of the *mohlam* troupes, a few large ones are located in major cities in the two countries, but most are small and travel from village to village, performing for a few days or weeks in each.

Burma. In spite of an old Burmese tradition of spirit dances stemming from animism and early contact with Indian culture, formal theatre did not begin until 1767, with the introduction of Thai *khon* and *lakon nai* to Burma following the capture and sack of Ayutthaya. Burmese courtiers and dancing girls immediately learned the two forms, and the plays were translated into Burmese. Because Rāma was viewed as a previous incarnation of Buddha, pious Burmese were reluctant to alter *khon* scripts. For a time *Jātaka* plays, including *Rāmāyaṇa* episodes, were forbidden to live actors. Instead, marionette troupes doing plays based on *khon* brought the Rāma stories to the Burmese countryside. But the *Pandji* plays were not considered *Jātakas*, and even the first Burmese version, by U Sa under the title *Inao,* departed from its Thai model, thus setting the stage for the creation of court drama, or *zat pwe,* based on myth and legend but capable of being independently developed. The three *zat* written by U Kyin

U portray the futility of political strife and urge a life of Buddhist renunciation. U Pon Nya created a freer form of dramatic verse, and his *Water Seller* is noted for its comparatively realistic treatment of court life.

Court drama ceased after 1866, when the British conquered Burma. Thereafter, drama was staged by professionals in public theatres, primarily in Rangoon. U Pok Ni in *Konmara* (*c.* 1875), U Ku in *The Orangoutan Brother and Sister* (1875), and others created a new type of drama, *pya zat,* that mixed royalty and commoners, emphasized humour, and added songs to appeal to a popular city audience. Hundreds of these works were published. Popular troupes in Burma today perform a long bill of attractions that lasts most of the night. It comprises songs and dances, a new contemporary play, and, as a final number, a classic *zat* in which remnants of old court music and dance are preserved. British touring companies in the late 19th and early 20th centuries brought examples of contemporary European melodrama and some classics to Burma. Subsequently a number of plays were written in Burmese and in English, following Western conventions and without songs or dance. Of these, *The People Win Through* (1950), by former prime minister U Nu, is among the most interesting examples.

Indonesia. The sober, majestic, and profound court arts of eastern and central Java, where Javanese is spoken, include *wayang kulit* shadow theatre, *wayang orang* unmasked dance, and *wayang topeng* masked dance.

Wayang kulit (shadow-puppet theatre), Java.

Shadow-puppet theatre. It is uncertain whether the shadow theatre is indigenous to Java or was brought from India, but the *wayang kulit* technique of having a single seated puppeteer who manipulates puppets, sings, chants narration, and speaks dialogue seems to be an Indonesian invention. Unlike most court arts, *wayang kulit* has had centuries of performance in the folk tradition as well, so that today, with several thousand puppeteers active, it is the strongest traditional theatre form in Southeast Asia.

Plays are set in mythological times, some relating to indigenous animistic festivals and worship of local spirits, some directly dramatizing episodes from the *Rāmāyaṇa* and *Mahābhārata* epics, while the majority—the Pandawa (Pāṇḍav in Sanskrit) cycle of about 100 plays—are essentially Javanese creations in which the five heroic Pandawa brothers are placed in different situations. Three and sometimes four god-clown-servants and a set of ogre-antagonists who are not in the epics at all suggest how far removed the shadow plays are from the epics.

Conventions in puppet performances

The *wayang* puppeteer works within one of the world's most carefully organized performing arts, making possible a virtually solo performance without intermission, from around nine at night until the gray before dawn. Each play is in three parts, coordinated with three keys of music played by the gamelan ensemble. Certain standard scenes appear in a standard order, though some may be dropped. "Opening Audience" introduces the play's conflict, "Inner Palace" shows the king meeting his queen(s), and in "Outer Audience" the army is dispatched. In "Forest Clearing" the first battle scene occurs, and in "Foreign Audience" the antagonist kingdom, usually one of overseas ogres, is introduced. Concluding part one are "Foreign Outer Audience," in which the second army marches forth, and "Opening Skirmish," a battle scene between the two armies. The puppeteer chooses from among 150 musical selections, matched to scene type, character, mood, or action. The puppet figures are carved to indicate character type and status according to fixed patterns for nose, eyes, gaze, stance, body build, and costume. The puppeteer can choose one or another puppet of the same character, coloured gold or black or with a stern or relaxed countenance, to indicate the mood of the figure in a particular scene. In battle scenes, he develops individual encounters between opponents, drawing upon a repertory of 119 movements that are classified for use by god, female, refined hero, muscular hero, ogre, or monkey. Formula narrative phrases describe famous kingdoms and characters, and battles are preceded by challenges couched in standard phrases. Although the puppeteer works only from a brief scenario, he is able to extemporize each performance, adding contemporary jokes for the clowns and molding the performance to suit the occasion and the audience. He and his supporting musicians and female singers are improvising within completely known, although exceptionally complex and subtle, artistic conventions.

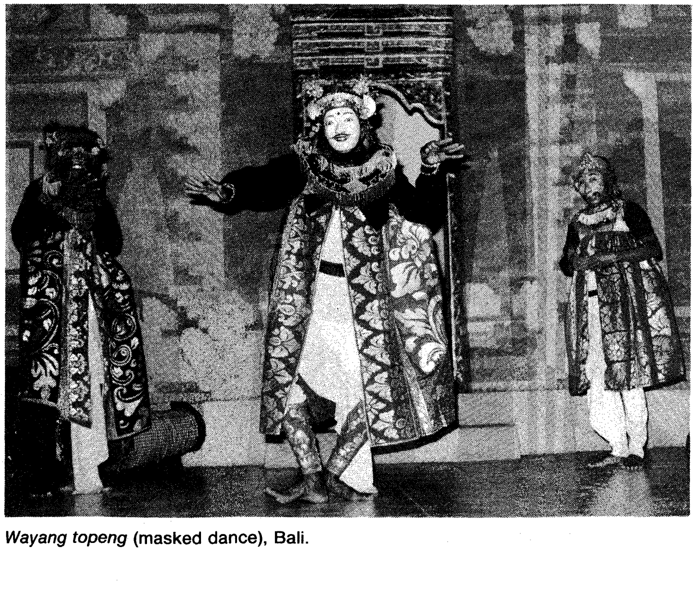
This artistic system, developed within the shadow theatre for performance of Pandawa plays, has proven to work so well that it has been widely imitated. The entire body of *wayang kulit* drama was adopted in Bali and in Malaysia. At least 25 other play cycles have been performed in Indonesia as shadow drama within this system, including the *Pandji* cycle (*wayang gedog*), Islāmic Amīr Ḥamzah plays (*wayang menak*), and plays dramatizing the revolutionary struggle against the Dutch (*wayang suluh*). The Pandawa *wayang kulit* repertory was transposed to the doll-puppet theatre (*wayang golek*) in Sunda, the western part of Java, and to dance-drama in eastern and central Java (*wayang orang*) and in Bali (*wayang wong*).

Performances are commissioned for special occasions and usually can be interpreted in religious or mystical fashion. There may be offertory plays at harvest time or animistic, ritualistic exorcisms protecting children from being devoured by the voracious god Kala. In *The Reincarnation of Rāma* the divine attributes of the god Wisnu (Vishnu in Sanskrit) reincarnate in Ardjuna (Arjuna), hero of the Pandawa cycle and ancestor of the Javanese race. The translucent screen can be interpreted as heaven, the banana-log stage as earth, the puppets as man, and the puppeteer as god, and the Pandawas can symbolize the manifold attributes of righteous behaviour.

Masked dance

Wayang topeng. Masked dance was also popular at the eastern Javanese courts (*c.* 1000–1400) and may be re-

© Pascal Grellety—Bosviel, Paris



Wayang topeng (masked dance), Bali.

lated to ancient animistic masked dance seen throughout the Pacific islands. Later, Indian dance style was assimilated, and sometime after the 15th century at the earliest, the *Pandji* story was dramatized. This is *wayang topeng,* widely performed as both a sophisticated and a folk art throughout Indonesia. Unlike the large-scale unmasked dance-drama, *topeng* dance focusses on interpreting character through solo dance.

Wayang orang. Java's spectacular dance-drama, *wayang orang,* grew out of the strong unmasked dance tradition that is illustrated in reliefs of female dancers carved on the 9th-century Borobuḍur and Prambanan temples in central Java and that produced the carefully cultivated female group dances of the Surakarta and Jogjakarta courts after their establishment in the 16th century. Of the latter dances, two stand out, the almost sacred *bedaja,* which even today is danced only in court surroundings, and the *srimpi,* in which two pairs of girls execute a delicate slow-motion duel with daggers and bows. In the middle of the 18th century, *wayang kulit's* Rāma and Pandawa plays were set to court dance to form *wayang orang,* or "human" *wayang.* The music, narrative, and dramatic organization of the shadow play was kept largely intact, many of the actors' movements mimicking the stiff actions of the puppets, while new dance sections were added. Court performances stopped with World War II, but *wayang orang* continues to be performed by some 20 to 30 professional troupes in major cities. In popular performances, attractive actresses play the roles of such refined heroes as Ardjuna and humour and spectacle take precedence over dance.

Actresses as refined heroes

Ketoprak and ludruk. Two other types of popular theatre, *ketoprak* and *ludruk,* were performed in Java by 150 to 200 professional troupes. *Ketoprak,* created by a Surakarta court official in 1914, evolved into a spoken drama of Javanese and Islāmic history in which the clown figure is a spokesman of the common man. Whereas *ketoprak* is performed primarily in central Java, *ludruk,* a spoken drama that handles mainly contemporary subject matter, is performed in eastern Java by both amateur and professional troupes. Though *ludruk* is relatively realistic, male actors play all roles. Songs and dances, accompanied by gamelan music, are performed between acts in both forms.

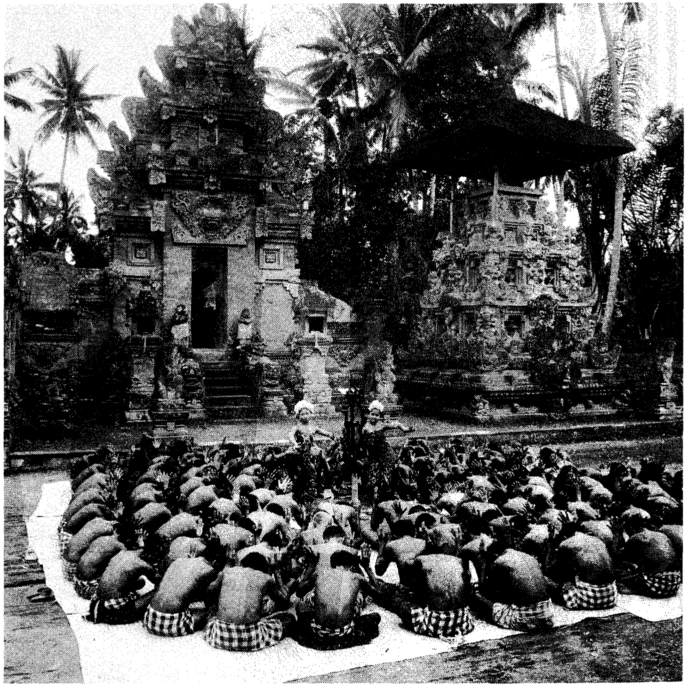
Sundanese performing arts. There are three main performing arts in the Sundanese area of western Java. *Reog,* a kind of urban folk performance, can be seen especially in the streets of Jakarta: two or three men improvise popular songs, dances, and dramatic sketches for a neighbourhood audience in this type of entertainment. *Wayang golek* is a performance based on *wayang kulit* but using doll puppets without a screen. Approximately 500 Sundanese puppeteers perform *wayang golek.* Female singers, who are almost as important as the puppeteer, respond to requests and gifts of money by singing song after song and virtually stopping the play. *Sandiwara* troupes in Jakarta, Bandung, and a score of other cities perform both *wayang* stories in the form of Sundanese dance-drama and spoken historical and contemporary dramas for popular audiences. Sundanese-style court dances and *topeng* masked dances are often performed solo at festivals and for circumcision or wedding celebrations in private homes. Sundanese dance is more sensuous than Javanese and broader in style.

Balinese dance-drama. Of the many factors that have contributed to the remarkable flourishing of dance and drama on the island of Bali for more than a millennium, three are of particular note. First, Bali remained isolated from both Islām and the West. Second, there was a merging of folk and court performance styles into a single communal tradition appreciated by all. Third, dances and plays are indissolubly linked to the recurring cycles of local festivals and rituals whereby the well-being of the community is maintained against constantly threatening malicious forces in the spirit world. From the verve and brilliance of Balinese performances it is clear not only that the people like to perform but also that there exists some culturally determined compulsion to do so.

Balinese dance and dramatic forms are so numerous that only a few can be noted. Balinese villagers playing in the *barong* exorcism dance-drama are not merely actors exercising theatrical skills. The actors' bodies, going into a trance, are believed to receive the spirits of Rangda and the Barong, and it is the spirits themselves that do battle. Thus the performance is actually more a ritual than a piece of theatre. The *sanghyang* dance is usually performed by two young girls who gradually go into a state of trance as women sing in chorus and incense is wafted about them. Supposedly entered by the spirit of the nymph Supraba, the girls rise and dance, often acrobatically, though they have been chosen from among girls untrained in dance. The dance's purpose is to entice Supraba to the village to gain her blessing when evil forces threaten. In the *ketjak,* or monkey dance, as many as 150 village men, sitting in concentric circles around a flaming lamp, chant and gesticulate in unison until, in trance, they appear to have become ecstatically possessed by the spirits of monkeys. This performance, however, has no ritual function of altering an earthly condition.

Hypnotic possessio of Balines dancers

Tor Eigeland—Black Star



Ketjak, or monkey dance, Bali.

That the Balinese *wayang kulit* may represent the older style of *wayang,* known on Java before the coming of Islām, is suggested by the less stylized shape of the puppets, by the shorter performing time of four to five hours, and by the simple music of only four *gender,* a bronze instrument similar to a xylophone with resonance chambers underneath, from the gamelan ensemble. In one type of shadow play having a special religious significance, the puppets perform before a screen during the daytime, and the puppeteer is seen in his role as a Brahman priest, bare to the waist. In the *redjang* processional dance, village women symbolically offer their bodies to their temple gods.

Because Balinese performing arts are vitally alive, they change from decade to decade, even from year to year. The *gambuh,* respected for its age, contains elements of dramatic dance, song, narrative, and characterization found in later forms. It is thought dull, however, and is seldom performed, though it is believed to have provided the model for the singing style of popular *ardja* opera troupes and the dance style of the lovely girls' *legong. Wayang wong* is analogous to the Javanese *wayang orang,* but masks are worn and the repertory is limited to Rāma plays. Pandawa plays are staged in identical style but are called *parwa.* It has been suggested that these forms also stem, at least in part, from *gambuh. Wayang topeng* masked-dance plays are ancient, being mentioned in a palm-leaf document of 1058. The Javanese chronicle of the Majapahit period (*c.* 1293–1520), the *Pararaton,* in which Ken Angrok is the hero, is a favourite *tapeng* story. This points to the strong influence exerted by Javanese on Balinese arts after the Majapahit court was transferred to Bali in the 16th century to escape Islāmic domination.

Malaysia. The Malay peninsula, in the geographical centre of Southeast Asia, has assimilated repeated intrusions of neighbouring cultures. The dances of the former princely states on the east coast show the influence of Indian nondramatic dance.

The multiform wayang. Rulers from Java in the 13th and 14th centuries and later large colonies of Javanese introduced their *wayang kulit* shadow theatre. The puppets of *wayang Djawa,* or "Javanese" *wayang,* are identical with the two-armed, long-nosed, highly stylized puppets of today's Javanese *wayang kulit.* Those of *wayang Melayu,* or "Malayan" *wayang,* have only a single movable arm and are less sophisticated in conception, which suggests that they are either descended from old Javanese puppets, before both arms were made movable, or are a degeneration of the more complex form. Rāma, Pandawa, and Pandji plays are staged. The puppets of *wayang Siam,* or "Siamese" *wayang,* though manipulated by a single seated puppeteer, represent a Thai conception of the figures from the *Rāmāyaṇa;* and costumes, headdresses, ornamentation, and facial features follow those of *khon.* The plays include Islāmic elements as well, while the chief clown figure, Pak Dogol, is thought to be a recent Malay creation that has supplanted Semar, the Javanese clown of *wayang kulit.*

ulti-
ıgual
rfor-
ances

In a performance, puppets of all types may appear together. Either such Thai instruments as the *lakon jatri* drum and small bell cymbals or gamelan instruments play the accompanying music. Song lyrics can be in ancient Javanese; animistic, Islāmic, and Hindu-derived invocations to the gods are offered in the Thai and Malay languages; and the play proper is in colloquial Malay. Puppeteers once performed throughout the peninsula, including the five Malay-speaking provinces of southern Thailand, but today puppeteers are found primarily in northeast Malaysia.

Chinese and popular entertainments. Chinese immigrants introduced various forms of opera during the 19th century. Troupes perform for Chinese Buddhist temple festivals, for local fairs, or on national holidays. In Singapore troupes occasionally perform in public theatres as well. Young people of Chinese descent in both Malaysia and Singapore have little interest in the opera, however, because their Chinese is limited. Occasionally troupes import star performers from Hong Kong or tour Chinese communities in Thailand.

Bangsawan was created by professional Malay-speaking actors in the 1920s as light, popular entertainment. Songs and contemporary dances were added to a repertory of dramatic pieces drawn from Islāmic romances and adventure stories. Troupes travelled to Sumatra, Kalimantan, Sunda, and Java, where their melodramatic plays found large audiences and influenced local performers of *sandiwara, ketoprak,* and *ludruk.* The cinema and television, however, have captured much of this audience.

Vietnam. An indication of the antiquity of the performing arts in Vietnam is a large bronze drum of the 3rd century BC found near Haiphong, in northern Vietnam, which is ornamented with instruments and musicians playing for dancers. Chinese performing arts presumably were a part of court life in northern Vietnam during the period of Chinese rule (111 BC–AD 939), and between the 10th and 13th centuries the dances and music of the Hinduized Cham peoples, living in what is now central Vietnam, were welcomed there. The melancholy Cham songs were particularly popular, and most authorities believe that the sad southern style of Vietnamese singing is derived from them.

Satirical drama. Hat cheo is a popular, satirical folk play of northern Vietnam that combines folk songs and dances with humorous sketches criticizing the people's rulers. Some scholars theorize that it is an indigenous folk art, whereas others, to show that it reached the people from the court, cite the legend of a Chinese actor who in 1005 was hired by the Vietnamese king to teach "Chinese satirical theatre" to his courtiers. *Hat cheo* is widely encouraged by the government.

The opera. The classic opera, known as *hat boi, hat bo,* or *hat tuong,* is a Vietnamese adaptation of the Chinese opera long supported by kings and provincial mandarins as a court art and performed for popular audiences as well, especially in central Vietnam. The introduction of Chinese opera is attributed to the capture of a troupe of performers attached to the Mongol army that invaded northern Vietnam in 1285. The actors' lives were spared in return for teaching their art to the Vietnamese. In 1350 another Chinese performer was engaged by the northern court as an instructor. Almost exclusively a court art in the north, *hat boi* was made a form of popular entertainment in central Vietnam by the playwright Dao Duy Tu in the 16th century. It was introduced to southern Vietnam under the Nguyen dynasty in the 18th and 19th centuries, but its future was jeopardized by the decades of war in the mid-20th century. The last large troupe of court musicians, dancers, and actors at Hue in southern Vietnam disbanded in 1945. The postwar government of the late 20th century did not provide *hat boi* with strong support, and the popular troupes lacked audiences.

Blighting
effects
of war

In form and content, *hat boi* is a blend of China and Vietnam. Direct imitation of Chinese costume and acting techniques was encouraged under the reign (1847–83) of Emperor Tu Duc and it is probable that the present form of *hat boi* dates from this period. At Tu Duc's court in Hue, the playwright and scholar Dao Tan gathered 300 actors and with them wrote out texts of the standard repertory that previously had been preserved orally. He then had the texts published and distributed them to actors and troupe managers. In the 20th century there has been a movement to loosen the rigid structure of *hat boi* and to reduce the high proportion of Chinese loan words that makes the operas difficult for the ordinary Vietnamese to appreciate.

Following Chinese practice, the operas are classified as military or domestic. The former, which may be derived from Chinese and Vietnamese legend or history or may be purely fictional, concern struggles for power between kings. The Chinese novel *The Romance of the Three Kingdoms* furnishes material for many military plays. The latter, dealing with the lives of commoners, contain humorous scenes alternating with scenes of suffering that are played to the accompaniment of sad southern-style songs. The Confucian ethic of obligation to one's superior—of wife to husband, of son to father, or of subject to king—underlies plays of both types.

Hat boi staging is modelled on conventions of Chinese opera. Actors perform on a stage that is bare except for a table and two chairs. These can serve as a castle, a cave, or a bed as well as for sitting and eating. A single embroidered drop at the rear has an entrance right and an exit left. Costume and makeup indicate character type: black for boldness, red for anger or rashness, white for treachery, and gold as the colour of the gods. Conventionalized mime may be used alone or in conjunction with symbolic properties. The actor mimes stepping over an imaginary threshold or sewing without needle and thread, but he indicates riding a horse by gestures with a riding crop and travels in a carriage when a stage assistant holds flags with wheels painted on them at each side of his body. Percussion instruments accompany stage action, and songs—which may be in falsetto Chinese style, in soft southern Vietnamese style, or in a form of prose recitative—are accompanied by stringed instruments.

The love
lament

The popular stage. Southern-style singing is the basis of another type of theatre, *cai luong,* begun in the 1920s by popular singers who performed plays in which they sang the love lament *Vong Co.* Today, regardless of whether a historical or contemporary play is being performed as *cai luong* or which of many troupes is staging it, this melody will be heard throughout the play many times, underlying different lyrics. *Cai luong* stars are lionized, and the best troupes maintain high artistic standards. Among popular theatre forms in Southeast Asia, only *cai luong* plays are fully scripted and directed as they would be in the Western theatre. In contrast to the operetta form of *cai luong,* modern spoken drama is known as *kich.* It is a young dramatic form performed mostly by amateurs who are trying to put Western dramatic conventions into practice.

The Philippines. Whatever indigenous theatrical forms may have existed in the Philippines, other than tribal epic recitations, were obliterated by the Spanish to facilitate the spread of Christianity.

The comedia. The earliest known form of organized theatre is the *comedia,* or *moro-moro,* created by Spanish priests. In 1637 a play was written to dramatize the recent capture by a Christian Filipino army of an Islāmic stronghold. It was so popular that other plays were written and staged as folk dramas in Christianized villages throughout the Philippines. All told similar stories of Christian armies defeating the hated Moors. With the decline of Spanish influence, the *comedia,* too, declined in popularity. Some professional troupes performed *comedia* in Manila and provincial capitals prior to World War II. Today it can still be seen at a number of church festivals in villages, where it remains a major social and religious event of the year. Much in the manner of the medieval European mystery-play performances, hundreds of local people donate time and money over several months to mount an impressive performance.

By courtesy of Philippine Embassy

Comedia, or *moro-moro,* folk drama based on the battles between the Christians and the Moros, the Philippines.

Styles from Europe. Dances and dramas from Spain were brought in, some of which took root. The "María Clara," a stately minuet, and the "Rigodón de Honor," a quadrille, were adopted by local European society for its formal balls. Spain's sprightly operetta, the *zarzuela,* became the favourite light entertainment in Manila and other cities. Professional *zarzuela* troupes continued to flourish in the early decades of the 20th century but had disappeared by World War II. New plays with original music were produced in profusion. A number of them based on topical themes and criticizing American colonial policies were banned.

Western drama is studied and widely performed in both English and Tagalog. There are no professional companies, but amateur university and community groups abound. Western classics and recent popular successes are staged, and in recent years many original plays have been written to celebrate the Filipino heritage.

(J.R.B.)

Visual arts

GENERAL CONSIDERATIONS

Religious–aesthetic traditions. The visual arts in Southeast Asia have followed two major traditions.

Indigenous magical and animist tradition. The first is a complex inheritance of magical and animist art shared by the different tribal peoples of the mainland, where it evolved from Paleolithic origins, and of the islands. Such art gave the peoples who made it a sense of their identity in relation to the forces of their natural environment, to the structure of their society, and to time. It consists of types of potent emblem, mask, and ancestral figures broadly similar to those that hunters and early farmers the world over have used in connection with seasonal ceremonies, life and death rituals, and ecstatic shamanism (belief in an unseen world of gods, demons, and ancestral spirits responsive only to the shamans, or priests). The spiritual powers that the arts name and invoke are local and vary from group to group of the population. The rich formal artistic languages have been subject to successive episodes of influence from inland Asia, but each of the tribal groupings has developed its own artistic language on the basis of a common fund of Southeast Asian thought forms.

Indian tradition. The second major tradition was received from India during the early centuries of the Christian Era, when seagoing merchants from that subcontinent so fertile in ideas were expanding their trading activity. Into many parts of Southeast Asia—especially Burma, Thailand, and the coasts of Cambodia and Indonesia, where Indian traders settled and married into the families of local chieftains—they brought with them a script and literature in the sophisticated Sanskrit language. They also brought a highly developed conceptual system dealing with kingship, statecraft, and hydraulic engineering, integrated and authenticated by profound metaphysical ideologies of Indian pattern, both Hindu and Buddhist. These ideologies claimed to be universal, embracing all human diversity within a cosmic frame of reference. And this explains why the culture was adopted. For there was no Indian conquest of terrain; instead, the Indian conceptions, along with the art that expressed them, were used by dynasties in the colonial kingdoms as a method of overcoming divisions in their population, of centralizing effort, and of uniting their religions into viable states based upon cities. Although the new religious conceptions must have offered deep personal satisfaction to the general population, the architecture and sculpture in stone and bronze in which they were artistically expressed were expensive in materials, labour, and skill and were thus available primarily to patrons who were claiming for themselves a royal (*i.e.,* divine) status and using the resources of art to demonstrate that status.

Why the Indian culture wa adopted ir Southeast Asia

The Indianizing traditions were continually refreshed by direct influences from India and Ceylon. There can be very little doubt that, during the early centuries after the birth of Christ, Indian artists and craftsmen travelled to work in the distant trading colonies of Southeast Asia, for they would have been needed to set up local traditions with proper formulae and methods. And there can be no doubt either that works of art made in India were continuously exported to the colonial kingdoms, thus keeping the local art styles in touch with developments "at home." It is also clear, however, that within a very short space of time the Southeast Asian kingdoms produced their own distinctive local versions of Indian styles; and some of their work shows skill, finesse, and invention on a colossal scale unrivalled even in India.

Although the art styles were to some extent sectarian, and sectarian partisanship played a part in political events, it was by no means unusual to find Hinduism and different forms of Buddhism flourishing side by side. In both Burma and Thailand, however, dynastic options were early exercised in favour of that particular form of Buddhism known as Theravāda (Hīnayāna), which adheres to the nontheistic ideal of purification of the self to Nirvāṇa. These countries follow the same form to the present day. It was also adopted in Cambodia and southern Vietnam after prolonged and successful periods of Hindu and Mahāyāna (a theistic branch teaching compassion and universal salvation) Buddhist dominance. The strongly Sinicized population of the region around the Gulf of Tonkin, which pushed gradually down the coast of Vietnam to become the modern plains Vietnamese, began to adopt Theravāda Buddhism with its artistic types by about the 13th century AD, partly because this form could be best adapted to its self-contained and antidynastic cellular social structure.

Theravādε and Mahāyānε Buddhism

Relations between the two traditions. Even in those regions where Indian influence became strongly entrenched, the older layers of more primitive religion and artistic consciousness remained very much alive. Indian deities were readily identified with local spirits. The tribal populations retained, as many still do, their old animist customs, especially those connected with fertility and practical magic, often with an art (in perishable materials) in which to express them. These arts were influenced by and exercised a reciprocal influence upon the styles of officially imposed Indianized arts. In many parts of Southeast Asia, where the official Indian styles were not completely established (most of Borneo) or where they died out (colonies in Celebes), in inaccessible areas beyond the reach of dynastic influence, or on isolated islands, primitive styles have survived unmodified. Even in Indianized regions where a strict formula, say, for a necessary building type, had not been imported, a native pattern was adopted into the official canon (*e.g.,* Laos). In the Indonesian island of Bali, which has remained nominally Hindu, the Indian and the folk elements were thoroughly assimilated to each other, producing a quite individual style of both religion and art. In Sumatra and Java, whose populations were gradually converted to Islām from India during the 13th–16th centuries, the primitive cult of the ancestors was revived and encouraged by Muslim rulers, with folk versions of denatured Hindu art adapted to it. Decorative styles based on this art have flourished there and have been officially revivified during recent years. In the Philippines, notably in and around Manila, Spanish Roman Catholic art flourished after the Spanish colonization of 1571.

he royal
mple

Artistic styles. The royal temple is the basis for the classic Indianizing styles of Southeast Asia. Each Hindu temple is centred on a shrine, symbolizing heaven upon earth, which is crowned by a roof tower representing the cosmic Indian mountain, Meru, conceived as the hub of creation. Since all the peoples of Southeast Asia already believed the natural habitat of spirits and gods to be a mountaintop, the Indian pattern was readily accepted. The temple usually stands upon a lofty terraced plinth (a block serving as a base), which itself also symbolized a mountain. Towered shrines could be multiplied on the terraces, though one of them remained the principal focus. Within the cell of this main shrine was a sacred image carved in stone or cast in bronze. The local Hindu ruler identified the subject of this image as his transcendent patron, or celestial alter ego. This was normally one of the Indian high gods, Śiva (represented perhaps by a phallic emblem, the *liṅga*) or Vishnu. In Mahāyāna Buddhist kingdoms a royal *bodhisattva* (a being that refrains from entering Nirvāṇa in order to save others) was sometimes adopted to fulfill the same role, a favourite form being known as Lokanātha, or Lokeśvara, Lord of the World. Subsidiary shrines, niches, or terraces sometimes contained subsidiary images, including goddesses representing at the same time wives of the god and queens of the king. These images were worked in smooth, deeply rounded, and sensuously emphatic styles derived from Indian art but with varying inflections characteristic of each region and time. The whole exterior of the shrine was usually adorned with rhythmic moldings, foliage, and scrollwork, with figures representing the inhabitants of the heavens. Ideally, the building was constructed and carved in stone; but, particularly where good stone was not readily available (for example, in Burmese Pagan), it could also be brick, coated and sculptured with stucco after northeast Indian patterns. Temple complexes tended to grow as successive kings strove to outdo their predecessors with the magnificence of their buildings. Hindu rulers, influenced perhaps by vestiges of tribal custom, would sometimes retain their own family's temples and images while destroying those of earlier dynasties.

Buddhism, however, is a religion based on a doctrine of transcendent merit and sustained by an order of monks who have, ultimately, no vested interest in kings and gods. They may, however, take a great interest in the world of spirits and the operations of astrology, just as the local population does, even though they regard such matters as subordinate to the ultimate Buddhist aim of universal Nirvāṇa. Buddhist monasteries, therefore, tended to expand around stupas (domed monuments emblematic of the Buddhist truth, also called pagodas or *dāgabas*) of ever-increasing size and number; the preaching halls, libraries, and living quarters for monks were continually enlarged and repeatedly rebuilt, often as a testimony to the piety of royal patrons. Although, strictly speaking, Theravāda Buddhism has no place for a "divine ruler" whose identity an actual king may adopt, provision was made in legend and in court and monastic ritual for the ruler of a Theravāda country to assume a magical role as the dominant sponsor and patron of the Buddhist truth. His legendary prototype was usually not identified, therefore, with an icon of the enlightened Buddha but with images such as the chief disciple at the knee of the enlightened Buddha, as Prince Siddhārtha (the Buddha-to-be), or figuring in scenes of the Buddha's life that lined the monastery halls and corridors.

Prescriptive
formulas
for art

Both Hindu and Buddhist art were produced according to prescriptive formulas. If the formulas were not followed, the art was believed not to fulfill its transcendent function. In practice, however, there has been room for styles and types of image to change and develop fairly quickly. Hindu and non-Theravāda art recognized what could be called aesthetic values as a component in religious expression. Theravāda Buddhism, however, which might be called fundamentalist, has always attempted to preserve the closest possible connections with the Buddha's recorded original deeds and sayings; its art, therefore, has concentrated on repeating in its main Buddha figures the most exact possible imitations of authentic ancient images. This had led to a relative monotony of style in Theravāda icons (see below *Burma; Thailand and Laos*). In the subsidiary sculptured and painted figures, however, which illustrate scenes from sacred history, Theravāda art has had greater freedom of invention. In the 20th century, Theravāda Buddhism is the only form of Indian religion to survive in Southeast Asia, save for the modified Hinduism of Bali. Its architecture in recent centuries has been decorated with a vigorous, sometimes coarse fantasy and made gaudy with gilt paint and coloured glass.

General development of Southeast Asian art. Most of the works made under the inspiration of the primitive, magical, and animist tradition are in perishable materials such as wood. Because the climate is so hostile, the works that survive are relatively recent; and any that is even 100 years old generally owes its preservation to Western interest. There are, however, a large number of Neolithic stone implements and prehistoric stone monuments (megaliths), as well as bronzes, which provide a solid archaeological basis for interpretation of Southeast Asian primitive art.

For the art of the classic Indianizing civilizations, French archaeology played the major role in clearing, excavating, and reconstructing major sites in Cambodia, Laos, and Vietnam; Dutch archaeology in Indonesia; British in Burma. Old bronzes have been found in fair quantities; apart from those of the early Dong Son culture (see below *Bronze Age: Dong Son culture*), all belong to one or other of the Indianizing traditions. Many old brick and stucco buildings survive, notably the medieval work at Pagan and in central Thailand, though an enormous number are known to have perished. Little very old painting is known, save a few Indianizing medieval rock and wall paintings on plaster. In spite of the fact that Buddhist monasteries are able to act as agents for preserving their own artworks, most of the surviving Buddhist pictorial art on wooden panels or other fragile material is less than 300 years old.

The stone of dynastic buildings, of course, has survived far the best. Scholars thus know much more about Indianizing stone architecture, with its sculpture, than about any other Southeast Asian visual art. But, where good relief sculpture flourished, one can legitimately assume that vanished pictorial arts also flourished; and from details carved in stone and incised on bronze, as well as from the scattered enthusiastic references in Chinese sources, one can be sure that throughout their history the Southeast Asian peoples have been intensely creative and have lived their lives surrounded by a wealth of imaginative art in many different mediums.

Unexcavated sites

There are many sites yet to be discovered and excavated. Twentieth-century knowledge of the history of art in many parts of Southeast Asia, especially of important episodes in Burma, Thailand, and Sumatra, is still scantily documented.

Neolithic period. The earliest works in Southeast Asia that can be called art are the rectangular polished axheads of a familiar late Neolithic type that have been found at many sites in Malaya, Indochina, and Indonesia. Some of the later Neolithic (*c.* 2000 BC to early centuries AD) implements are extremely beautiful and polished with the greatest care. They include practical adzes and axes; but some, made of semiprecious stone, were clearly intended for purely ritual purposes. Even in the 20th century a few such blades are preserved and revered as sacred objects in certain Indonesian farming communities and similar objects have continued to be made in some very remôte regions. These tools, with their fine edges, suggest that their owners were capable of very high quality woodworking and might well have decorated their wooden houses with designs of which we know nothing.

During the Neolithic Period, metal—both bronze and iron—came into use for implements but did not greatly alter the material culture. In many regions, notably Cambodia, Borneo, and Sumatra, numerous works of megalithic, or stone, art survive, including menhirs (single upright monoliths), dolmens (two or more upright monoliths supporting a horizontal slab), cist graves (Neolithic graves lined with stone slabs), and terraced burial mounds, all dating from the late Neolithic epoch. Some remarkable large stones are worked in relief with symbols and with images of animals and men, notably in the Pasemah region of Sumatra. Shaped stone sarcophagi and skull troughs (containers to hold the skulls of ancestors and of enemies at village shrines) are also known. These megalithic art objects suggest a highly developed cult of a spirit world connected with the remains of the dead (see below *Cambodia and Vietnam; Indonesia*).

Bronze age: Dong Son culture (c. 4th–1st centuries BC). By about 300 BC a civilization with elaborate arts based on bronzeworking existed, extending probably from the Tongking region into Laos, Vietnam, Cambodia, and Indonesia. This is called for convenience, after a major site, the Dong Son culture, though it may not have been a true cultural unity. A variety of bronze ritual works, many decorated with human and animal figures and with masks, were cast by the cire perdue method (metal casting using a wax model). The chief objects were ceremonial drums, large and small; the largest was found in Bali and is called "the Moon of Bali" (see below *Indonesia*). Extremely elaborate bronze ceremonial axes were made—probably as emblems of power. Certain relief patterns on the bronzes suggest that "ship of the dead" designs, like those still woven in textiles in both Borneo and Sumatra, may well have been woven even then. The spiral is a frequent Dong Son decorative motif; later Dong Son art was probably responsible for transmitting—especially into Vietnam, Cambodia, and Borneo—versions of the contemporary Chinese Chou dynasty's asymmetrical squared-hook patterns.

1st to 10th century. During the 1st century AD, Indian influence began to spread through Southeast Asia in the wake of trade, both overland, through Burma and Thailand, and by sea traders settled at especially favourable spots along the inland roads and along the sea routes around the coasts and into the islands. Buddhism, which was particularly popular among the Indian merchant classes, took root at a large number of trading cities, where monasteries were set up under the patronage of local kings. Many fragmentary Buddha images based upon Indian types of *c.* AD 300–400 have been found in Burma, Thailand, and Cambodia, produced in the kingdoms of the Mon people, the chief of which, in Thailand, was called Dvaravati. By the 5th century the first Hindu kingdoms had been established in western Java and Borneo. These kingdoms produced dynastic cult images, fragments of which have been found.

The first Hindu kingdoms

Perhaps the most splendid of the earlier Indianizing kingdoms, lasting till the 9th century AD, was that of the Pyu people in the upper Irrawaddy River Valley. The Pyu were the people most directly in touch with eastern India by land routes. Only one of their enormous cities has been explored archaeologically (see below *Burma*). The remains of Buddhist buildings, east Indian Buddhist images, and Hindu sculptures of Vishnu have been found there.

In the 1st century AD the predominantly Hindu kingdom known as Funan (the name given it by Chinese historians) was established in Cambodia. It seems to have controlled an empire that included kingdoms in Malaya and even parts of southern Burma. Its population was probably Mon and shared the culture of the Mon in the lower Irrawaddy Basin. (The Funan kingdom really represents the earliest phase of what became, in the 9th century, the great Cambodian Khmer Empire.) Between *c.* 550 and 680 the kingdom retreated from the coast up the Mekong River into Laos, where it was called by the Chinese Chenla. This joint Funan–Chenla tradition produced some of the world's most magnificent stone cult images. Though Buddhist icons are known, these images principally represent Hindu deities including Vishnu, his incarnation Krishna, Śiva, and a combined Śiva-Vishnu figure called Harihara. The images were housed in wooden or brick shrines, now vanished.

During the Chenla retreat the Theravāda Buddhist kingdom of Dvaravati flourished in southern Thailand, on the lower reaches of the Mae Nam Chao Phraya; the kingdom lasted until the 11th century, when it was captured by the Khmer. What little of its art is known is close to that of eastern India and provided the basis for later Buddhist art in the Khmer Empire, as well as for some of the later forms of Thai art.

The centra Javanese kingdom

Almost contemporary with Chenla was the rise of the central Javanese kingdom. Soon after AD 600 the earliest surviving Hindu temples were built. In *c.* 770 the Śailendra dynasty began its long series of superb stonecut monuments both Hindu and Buddhist, which culminate in two enormous symbolic architectural complexes: the Mahāyāna Buddhist Borobuḍur (*c.* 800) and the Hindu Lara Jonggrang, at Prambanam (*c.* 900–930). These monuments were decorated in an individual and exceptionally accomplished style of full-round and relief sculpture. Many small bronze religious images have survived. The art of the Śailendra dynasty testifies to the imperial and maritime power of the central Javanese kingdom, which seems to have influenced politics and art in Khmer Cambodia. It also took over the possessions of a major Theravāda Buddhist kingdom called Śrivijaya, which had flourished in Malaya and Sumatra and was centred at Palembang. The Javanese Śailendra ruled most of Malaya and Sumatra and installed themselves there in the mid-9th century, when their home terrain in Java was taken over by the Mataram dynasty, heralding the eastern Javanese period, which began in 927. Śrivijaya, under Śailendra rule, declined in the mid-11th century, and most of its remains still await discovery.

In Vietnam *c.* the 2nd century AD the predominantly Hindu kingdom of Champa was founded. Its capital was at My Son, where many temples have been found. This kingdom suffered much from attacks by the Chinese, and, after it began to lose the north to the Sinicized Vietnamese in 1069, the Cham capital moved in 1069 to Vijaya (Binh Dinh), in the south. There it was involved in continual warfare with the Khmer, who finally annexed southern Vietnam in 1203. The art of the northern Vietnamese as a whole has always been so strongly under the influence of China that it can best be characterized as a provincial Chinese style.

The Khmer Empire

10th century to the present. In Cambodia the Khmer Empire succeeded to the old territories of Funan–Chenla. About 790 the first major Khmer ruler, Jayavarman II, who was related to the old Funan royal family, came to Cambodia from the Śailendra court in Java. In 802 he set up a religious capital on a hill at Phnom Kulen; he seems to have called in artists from Champa and Java, thus giving to Khmer art a distinct new impetus. At another site, Sambhupura (Sambor), he built temples with sculpture based upon the old Funan–Chenla tradition. At Amarendrapura, about 800, he built a brick pyramid—an artificial mountain—to support a quincunx of temples.

It was Indravarman I (877–889) who laid the foundations of the fabulous temple complex known as Angkor. His plan was based on a rectangular grid of reservoirs, canals, and irrigation channels to control the waters of the river system. Later kings elaborated this original design to a colossal scale. Indravarman built the first great works of Khmer architecture: the Preah Ko, at Roluos, and at Angkor his temple mountain, the Bakong, ornamented with sculpture. Successive kings built their own temple mountains there, including the Bakheng (*c.* 893), Pre Rup (*c.* 961), the Ta Keo (*c.* 1000), and the Baphuon (*c.* 1050–66) and culminating in Angkor Wat, built in the first half of the 12th century by Suryavarman II. After a disastrous invasion by the Cham, Jayavarman VII undertook the most ambitious scheme of all, the Mahāyāna Buddhist Angkor Thom and Bayon (*c.* 1200). Thereafter, for a variety of reasons, including conquest by the Thai, no more large-scale work was done by Angkor and the country became Theravāda Buddhist. The modern dynasty has adapted remnants of traditional splendour, and the craftsmen of Cambodia have remained capable of work in the same vein as but often superior to the Thai.

Hindu Javanese art continued to be made under the eastern Javanese dynasties (1222–14th century), although their structures are not nearly as ambitious as the central Javanese works. There are many temple enclosures and volcanic bathing places with modest stonecut architecture. Some of the stone sculptures from these sites, however, are now world famous. In the 20th century the east Javanese tradition still survives, modified by folk elements, in Bali, to which the east Javanese Hindu kings retreated in the 16th century to maintain their religious independence in the face of Muslim expansion. Muslim monuments in the form of mosques and tombs are found in various parts of Indonesia. They adapt older forms of Indonesian art.

In 1056 the great Burmese king Anawrahta decreed Theravāda Buddhism to be the religion of his country, replacing earlier cults. He removed the Mon monks and artists from the capital of the old Mon kingdom in southern Burma, transporting them to his own northern capital, Pagan. There they built a city, with many large brick and stucco temples (pagodas) based on Indian patterns, that remains one of the most impressive sites in Asia. The Mongol invasion of 1287 put a stop to work there.

The Mon kingdom, Dvaravati, of southern Thailand, was annexed to the Khmer Empire in the 11th century and Khmer imperial shrines were built there. After the decline of the Khmer and the Mongol invasion of 1287, a powerful alliance of racially Thai kings established the first major Thai empire, retaining Theravāda Buddhism as the state religion. Thailand was divided into two principal regions, northern and southern, with capitals, respectively, at Chiang Mai and Ayutthaya, possession of the trade city of Sukhothai being an issue between them. In all the Thai cities, brick and stucco temples were built on variants of Indian and Burmese patterns. Many fine bronze Buddha figures, large and small, were cast in canonical Theravāda Buddhist styles. Most of these figures were accommodated in monastery halls built in impermanent materials.

In both Burma and Thailand a very large number of monasteries, usually surrounding one or two principal pagodas, were constructed during the later Middle Ages and into modern times. The major cities of Rangoon, Mandalay, and Bangkok contain the most elaborate examples, although there are many elsewhere. Because the pagodas were repeatedly enlarged and redecorated and the wooden monastic buildings and their many smaller stupas continuously reconstructed and renovated, no absolute chronology has been established for the arts of this epoch.

In Laos and Vietnam Theravāda monasteries, with brick stupas, were similarly built and rebuilt of wood. An outstanding stupa is the That Luang at Vientiane, in Laos, founded in 1566 but much restored in the 18th–19th centuries. In Vietnam local variants of Chinese styles were adapted during the Middle Ages to the planning and decoration of palaces and of Confucian, Taoist, and Buddhist temples.

The primitive styles that prevailed in the Philippines were modified by the conversion of various groups—the Moro people, especially—to Islām in the 15th–16th centuries. When, in 1571, the Spanish took control, Manila became the capital of a Spanish colony, and Roman Catholic Spanish art was adopted via Mexico. A local school of church architecture and figure sculpture flourished until the 20th century, when Manila became the centre of a modern commercial society, with its attendant architecture and art.

BURMA

One date is crucial in the art history of Burma: AD 1056. In that year King Anawrahta of Pagan decreed Theravāda Buddhism to be the state religion of all Burma. This signalled the unity of what had been a divided country, consummating tendencies apparent in earlier Burmese history.

6th to 11th century. The only major Burmese art known to scholars is based upon Indian and Ceylonese Buddhist art. In the period preceding Anawrahta's decree there had been three major historical eras in what is now the country of Burma, the first two of which produced Indianized art known to scholars only fragmentarily: the rule of the racially Mon kingdom of the lower Irrawaddy (9th–11th centuries), the contemporaneous dominion of the Pyu people in central and Upper Burma, and the subsequent decisive incursion of racially Burmese people from the northeast (11th century).

Major historical eras

The earliest concrete evidence of Indian culture in Burma is a Buddhist inscription from Pye (Prome) dated *c.* AD 500. This and later inscriptions from the same area were cut probably in the western Mon kingdom, which followed Theravāda Buddhism and was confederated with the Theravāda Buddhist eastern Mon kingdom of Dvaravati (see below *Thailand and Laos*) in southern Thailand and part of Cambodia (AD 6th–12th centuries).

During this same period, in Upper Burma, the people called Pyu, speaking a Tibeto-Burman language and perhaps originating in Central Asia, built cities whose magnificence was known to contemporary compilers of the Chinese Tang dynasty history. In the 8th century one city was recorded as being some 50-odd miles (80 kilometres) in circumference, containing 100 Buddhist monasteries lavishly painted and decorated with gold and silver. The Pyu were in direct contact with northeast India, where various forms of Mahāyāna Buddhism, which embraced philosophies and rituals unacceptable to the Theravāda, flourished; their Ari priesthood was later proscribed by Anawrahta. Their capital city, Śrī Kṣetra (modern Hmawza, near Pye), which was once larger than even Pagan or Mandalay, has been partly excavated. Three huge Buddhist stupas—one 150 feet high—survive there. They illustrate the pattern from which all later Burmese stupas were developed. Enshrining revered relics of Buddhist saints, they consist of tall, solid brick cylinders mounted on shallow, circular, stepped plinths and crowned by what was probably a tapering bell-like pinnacle. Other excavated halls, one on a square plinth with four entrance doors, follow Indian examples. A few Hindu fragments survive as well.

The Pyu were conquered by a neighbouring kingdom, probably before AD 900. During the following century their terrain and cities were infiltrated by the racially Burmese people. These people were of common tribal stock with the Thai and northern Vietnamese and were probably on the move under pressure of the Chinese colonization of their home terrain around the Gulf of Tonkin. They were converted to Buddhism by the Pyu and later by the western Mon; but they never completely abandoned their own original cult of nature spirits, known today as the *nats*. The *nats* are a mixed collection of spirits that act supernaturally, each according to its character. The *nats* were worshipped with orgiastic ceremonies and trance rites of spiritual possession. Certain mountaintops were sacred to them. Even in the 20th century the *nats* exert a powerful influence on the lives of the ordinary people; every village has its own *nat* house—a fragile pavilion built into a tree, after the pattern of the tribal house, and adorned with shreds of coloured cloth, glass, and other offerings. The Buddhist temple in Burma is conceived essentially as an enormous *nat* house, a section of the domain of the

Louis Frederic—Rapho/Photo Researchers

spiritual located upon earth. And, since the Buddha was adopted as the last and greatest of the *nat*s, the same symbols of supernatural splendour that adorn the *nat*s adorn the Buddha's images, and a *nat*-like spirituality attaches to the ubiquitous monks in whom the presence of Buddhism is experienced as an everyday reality.

11th century to the present. When King Anawrahta came to the throne, he captured the Mon city Thaton in Lower Burma and carried off its royal family, many skilled craftsmen, and most of the Theravāda monks to his own northern city of Pagan. The king recognized the superior culture of the Mon captives; he established their main form of Buddhism by decree and gave them the task of organizing and civilizing the new united Burmese kingdom and producing for it a Buddhist art. Under Anawrahta's successor, links with the Buddhist homeland were forged. Embassies were sent to Buddh Gaya, in Indian Bihār, and the great Mahābodhi temple there—marking the spot where the Buddha achieved enlightenment—was restored with Burmese money and somewhat in Burmese taste. A smaller copy, with its large rectangular block crowned by the characteristic pyramidal, storied tower, was built at Anawrahta's Pagan. It is here that the greatest achievements of western Mon art—a splendid profusion of architecture and decorative work—are probably to be found. After 1287, when Burma was sacked and garrisoned by the Mongols, new construction at Pagan was virtually abandoned.

Pagan

In Pagan (founded *c.* 849), architecture is the dominant art; except for the big brick icons, mostly ruined, sculpture and painting play a subordinate role. Pagan contains the largest surviving group of buildings in brick and plaster of the many thousands that once stood in various parts of South Asia. The remains at the site, all religious buildings of one kind or another that must once have been surrounded by dense building in perishable materials, are in varying states of preservation. The inscriptions they bear indicate that royal devotees often turned their palaces over to religious use; so it is likely that palace and monastic architecture were very close in style. A few structures still stand that belong to the period before Anawrahta, some of them inspired by Mahāyāna Buddhism and one—the Nat Hlaung Gyaung (*c.* 931)—by Hinduism. Flanking the Sarabha Gate is a pair of small *nat* shrines with pointed, open windows—the earliest in Burma, perhaps 9th century.

The library, built about 1058 to house the books of one of the Buddhist monasteries, is one of the most important buildings in Pagan. It is rectangular, with a series of five stepped-in, sloping stone roofs crowned by a rectangular tower finial. The concave contours of the roofs are characteristic of much Burmese architecture. The eaves and corners of all the tiers are adorned with the typical Pagan flame ornament, or antefix.

The *cetiya*

There are other buildings of the same general type among the ruins of Pagan. Far the most numerous and important, however, are the buildings—called *cetiyas*—that combine the attributes of stupa and shrine. These have a history and a line of evolution of their own, which can be traced from the Pyu stupa to the huge structural temple. The normal stupa, derived from the early medieval Indian form, is a tall structure consisting of a solid dome set on a tiered square plinth (often with miniature stupas at the corners) around which the faithful may perambulate. The dome is surmounted by a *harmikā,* which resembles the small railed enclosure found on the oldest Indian stupas. In Burmese stupas, however, the *harmikā* becomes a decorated cubical die, above which is a circular pointed spire; in memory of its distant origin in India, the spire is horizontally flanged (rimmed) with moldings in a series of honorific umbrellas of decreasing size. In later practice *harmikā* and umbrella spire become a single architectural unit. The Burmese stupa dome, based on the tall, cylindrical Pyu prototype, has a spreading concave foot resembling a bell rim. The Lokananda and Shwesandaw at Pagan are two well-known examples. Because in recent times they have been coated with plaster, the finely detailed brick carving characteristic of early Pagan architecture has been obscured. Such carving is beautifully exemplified in the Seinnyet temple at Myinpagan (11th century).

Anawrahta's type of *cetiya* followed the general form of the early Pyu stupa. The main point of evolution was in the progressive elaboration of the terraced plinths on which the dome stands. The plinths became virtually sacred mountains, with a series of staircases running from terrace to terrace up each of the four sides. Perhaps inspired by vanished work in contemporary late-11th-century India, the Burmese began to open up the interior of the terraced base of the stupas with wide corridors and porticos, converting it into a roofed temple. The cylinder of the stupa dome was carried down through this temple space to its floor. Four large Buddha icons were added to the lower part of the dome, facing the four directions. Once this conception had evolved, it was possible to create around the central stupa a broad circuit of roofed enclosures, which from the outside would still suggest the traditional pattern of the stupa standing on its raised terraces, while the interior could be used for ceremonial, as in a true temple. Sculpture and painting, decorating the internal halls, corridors, and doorways, recounted the life of the Buddha and presented the example of his previous virtuous incarnations. The most famous example of this type of *cetiya* is the great Ananda temple at Pagan (dedicated 1090). It is still in use, unlike most of the old temples there, and so is kept in repair; it is painted a blazing white with lime stucco—which has, of course, obscured the finer detail of its old architecture. Its plan is square, with a broad, four-pillared porch hall added to all of the four doors in the four faces of the square. Its tower is a curvilinear pyramid resembling eastern Indian Hindu temple towers, and its enormous brick mass is pierced with two circuits of vaulted corridors. The sloping, curved terrace roofs have an elegant overall concave profile and flame antefixes along all the eaves.

As time went on, Burmese brick and stucco architecture developed principally through the stiffening of masses into rectangular blocks and through the elaboration and often the coarsening of its ornament. The 13th-century Gawdawpalin temple at Pagan, for example, consists of a rectangular hall with a large closed entrance porch; the hall is surmounted by a tall but narrow second story whose decoration repeats that of the lower story; the whole building is crowned by a four-faced tower with a curved profile. Multiple moldings and decorative motifs are used as outlining elements and the doors are framed in elaborate upward-flaring hooded porches.

Until the Mongol conquest in 1287 much excellent work seems to have been done at Pagan. It is, however, impossible to form an adequate idea of the older styles of temple architecture at other sites in Burma, such as Rangoon or Mandalay. Whereas most of the temples of Pagan were abandoned early on, so that even though they may be ruined they show their original characteristics, temples in modern cities have been repeatedly and drastically restored. Old stupas may have as many as eight successive casings of brick and stucco; temple walls and doors are constantly torn down and rebuilt; and stucco surfaces may be renewed almost annually. Such attentions to a religious building are popularly regarded as acts of merit; thus, revered architectural monuments suffer continually from well-intentioned but disastrous renovation. At the big stupa sites huge numbers of pagodas are constantly falling into decay and new ones are being built at great speed. Among them are variants, whose evolution cannot at present be traced, on the basic pattern of the long tapering bell, with a variety of transverse moldings, standing perhaps on a recessed plinth. Many are covered quickly with extravagant and gross stucco ornament. Ornate flaring porches and flame finials are added to gates, wall ends, and eaves corners. A tapering slenderness is the outstanding characteristic of all the different types.

oon and
Iandalay

The monastic architecture—patterned on the hall, with its elaborate doors—that surrounds the great stupa sites of Rangoon and Mandalay is mainly in wood, built by simple pillar and architrave construction. The roofs are steeply gabled, with multiple gables riding over each other on immense carved pillars in the larger halls. The angles between pillar and architrave and the edges of roof gables, tiers, and terraces are filled with flamboyant cartouches (scroll-shaped ornaments) of pierced work, often lacquered and gilt; thus, the whole building may be smothered in repetitive ornamental curlicues. All this ornament has an otherworldly or spiritual significance. Other stupa sites in Burma, where less money has been spent and less ornament added to the buildings, may be more beautiful to the modern eye, with only a few flamboyant antefixes pointing the gables and punctuating the eaves. All over Burma similar buildings can be found; but, while many have been listed, they have been scantily surveyed, and no real study of their complex history has yet been attempted. There may well be a substantial Chinese influence in the construction of some of the wooden halls and pavilions.

Paintings and sculpture in Theravāda Burma do not seem to have reached the same heights of achievement as in other countries of Southeast Asia. They do not show the same originality and sense of life. The temples of Pagan contain the best examples, although even these are highly schematic, reminiscent in design of eastern Indian Buddhist manuscript styles. A number of early buildings at Pagan contain fragmentary terra-cotta (fired clay) reliefs or scraps of wall painting whose individual figures display some of the sensuous charm of their Indian prototypes (it is quite likely that Indian artists worked there). The 12th-century terra-cotta panels from the elaborate facings of the Ananda temple, however, show the beginnings of the petrifaction that overtook later Burmese figurative art. Both in reliefs and in wall paintings, the figure compositions are reduced to schematic groups of the minimum number of standard human and celestial types needed to tell a moral story, without any infrastructure of significant form and execution. The colossal Buddha images enshrined in the temples were usually built of brick and finished in stucco, gilded and ornamented. Such work is still done at high speed today. The technique is not a flexible one, and the emphasis of Theravāda Buddhism on the exact imitation of ancient Buddha images gave the Burmese no aesthetic incentive to develop the expression of their figures or compositions. The repeated heavy gilding and repainting of older icons has almost entirely destroyed any formal vitality they may once have had.

From about 1700 to 1850 Burma excelled in the decorative arts, whose forms continually recall those of Theravāda Ceylon. Burmese woven silks and embroideries are well-known. The carved wooden screens, panels, and brackets used inside temple halls, many devoted to representing the *nat*s and the population of the spirit world, have benefitted from being outside the strict canon of Theravāda Buddhist orthodoxy. The figure types follow fluid, slightly "boneless" conventions derived from classical Indianizing dance postures. The decorative goldwares and silverwares, which use much stereotyped decorative scrollwork, are also based on standard Indianizing iconography. Perhaps the most aesthetically satisfying works of the Burmese sculptors are the reliefs ornamenting the *sū-*

tra chests that were used in monasteries to store the sacred texts of Buddhism. The gilt gesso (paste used for making reliefs) facings of these chests carry the schematic style of relief sculpture beyond its normal aesthetic limits. This is accomplished by the way they are compelled to set off their figures as an intelligible scheme of thin raised lines and inlay against a plain ground. The forms of the fine lacquer bowls and boxes used in monasteries, decorated only superficially with painted ornament, show the underlying formal sense of the Burmese at its clearest.

Regional Burmese art

Interesting regional types of Burmese art are those of the Shan and Karen peoples, who live in the relatively remote northern hills. These areas have often produced extremely beautiful types of domestic and religious architecture, made of wood, on stone bases. They are a simpler and more austere version of the ancient pattern that underlies the halls and pavilions of the more sophisticated recent southern temple buildings, with their steep, gabled roofs. The peoples of the north also produce a variety of decorative arts. Notable among them are the textiles, which are characterized by banding, checkering, and triangular counterchanging of brilliant colours set off against black. The woven shoulder bags, particularly, are well-known in the West.

THAILAND AND LAOS

Dvaravati Mon kingdom: 6th to 11th century. Archaeology has recovered in central Thailand substantial glimpses of the magnificent early layer of Indianized culture, which includes a religious art that was produced between the 6th and 11th centuries by the eastern Mon kingdom of Dvaravati. The art was created predominantly to serve Theravāda Buddhism. Remains of Dvaravati architecture so far excavated include stupa bases: notable examples include the Wat Phra Meru in Nagara Pathama (Nakhon Pathom) and others at Ku Bua and U Thong, some of which have elephants supporting their bases, following a pattern that originated in Ceylon. The plinths of Buddhist assembly halls, which existed near the solid monumental structures, have also been discovered. Many terra-cotta and stucco fragments of decorative surface designs and celestial figures have also been found. The Wat Pra Meru, on a plan similar to that of the Ananda temple at Pagan in Burma (see above *Burma*), probably antedates the latter's foundation (*c.* 1090). It is likely that many other ancient monuments are encased in later stupas that are still being used for religious purposes, for it was probably customary not to destroy an old sacred monument but to encase it in a new shell, maybe several times over, and perhaps to construct a small external replica of the encased original alongside.

At many sites, especially Lop Buri, Ayutthaya, and U Thong, fine Dvaravati sculptures have been found among the architectural remains. Particularly important are the seated and standing Buddha figures in stone and bronze. Many of the faces have characteristic Mon features, with lips turned outward (everted) and downward-curved eyelids marked by double channels. Some of these Dvaravati images may well have furnished models for later Khmer art in Cambodia.

Dvaravati sculpture

Dvaravati sculpture shows close relations with several Indian styles, notably those of Amarāvatī, Gupta, post-Gupta, and Pāla Bihār. It also was probably influenced strongly by the art of the enigmatic kingdom of Śrivijaya in Sumatra, as well as by central Javanese types (see below *Indonesia*). One outstanding masterpiece from Chaiya, of Dvaravati date, may well be a work produced in Śrivijaya. It is a bronze torso and head of a *bodhisattva,* for which a mid-8th-century date is suggested. The body and face are modelled with a plastic and delicate sensuousness; and the elaborate necklaces, crowns, earrings, and armlets are beautifully chased (decoratively indented by hammering). The Śrivijaya origin is made more likely by stylistic reminiscences of the sculpture of contemporary Indonesia, which was also under Sumatran inspiration.

Khmer conquest and Tai immigration: 11th to 13th century. In the 11th century Dvaravati was captured by the Khmer of Cambodia and became a province of their empire. A number of Khmer shrines, probably intended as focuses of the Khmer Hindu dynastic cult, were built in Siam (Thailand). At Phimai (Bimaya) was the most important full-fledged Khmer temple, where one of the personal cult statues of the Khmer king Jayavarman II (see below *Cambodia and Vietnam*) has been found, together with bronze images, some of Tantric Buddhist deities. At Lop Buri the Phra Prang Sam Yot is perhaps the best surviving example in brick and stucco of Khmer provincial art in Thailand, its tall towers having complex rebated (blunted) corners and its porticoes high, flamboyant pediments (the triangular space used as decoration over porticoes, doors, and windows). Wat Kukut, at Lamphun, built by a Dvaravati Mon king *c.* 1130, represents an adaptation of the Khmer stepped-pyramid temple base as pattern for the temple itself. The niches on its terraces are filled with images in a deliberately archaistic revival of the old Mon style.

Domination by the Tai people

During the period when the Khmer were taking over the southern Mon region of Thailand, the northern region was falling under the domination of immigrant racially Tai peoples. The Tais were a branch of the migrating population who invaded Burma as the Burmese and of the Sinicized Vietnamese who were then pushing southward into what is now Vietnam. The Tais seem to have professed an animist nature religion, resembling the early form of the Burmese cult of the *nat*s (see above *Burma*). This whole group of peoples originated most probably as a tribal population in the region of Tongking and Canton. In the course of their southward migrations they probably played an important role, as yet unclear, in a kingdom called Nanchao, in what is now the Chinese province of Yunnan. The rulers of this kingdom seem to have followed a Mahāyāna form of Buddhism, including the cult of a *bodhisattva* as personal patron of the king. Several smallish bronze icons of a *bodhisattva* with a nude torso and a strap round the upper belly are known from Nanchao, in a style reminiscent of the later Pallava art of the east coast of peninsular India. The date of these images is still uncertain. Tai kingdoms were gradually established further and further south. Some of their tribes gained experience of administrative techniques by living within the boundaries of the Khmer Empire, with their own chieftains under Khmer officials. When the Khmer power was broken in the 13th century, the Tai moved into central and southern Siam, intermarrying with the Mon.

The Tai people normally built in perishable materials, wood and bamboo in particular. Their animist religion, which has no canonical group resembling the Burmese *nats*, is still very much alive today. The spirits of trees need to be pacified, and the ancestors can be powerful helpers. Shamans, in a state of trance, make contact with the spirit world to perform good or evil magic. In the wooden high-gabled houses of the northern Tai (Chiengmai province), even today, ornate lintels are carved with floral relief designs to sanctify and potentiate the inner domestic part of the house where the domestic spirits live. The animist religion gave ground partially to Buddhism, which was gradually assimilated among the people, and at some date, as yet uncertain, was adopted by the greater Tai kings as a dynastic religion. With the spread of Buddhism a special religious architecture in brick and stucco was established.

)ivision of iam

The Thai kingdom: 13th to 17th century. During most of its history, Thailand has been divided into two fairly distinct regions, a northern and a southern, the capital of the north at Chiang Mai, the capital of the south at Ayutthaya. Between the two lies the great trade-route city of Sukhothai, possession of which fluctuated between the north and the south. Sukhothai seems to have been the principal focus and source of Buddhist culture in Siam, for it retained direct touch with Ceylon, which, after the decline of Buddhism in India in the 12th century, became the principal home of Theravāda Buddhism. By the 15th century the difficult art of casting large-scale Buddha figures in bronze had been mastered in the north of Siam, as well as in the south.

Sculpture. The Thai kings made repeated attempts to "purify" their conservative Theravāda strain of Buddhism, importing patterns of art along with texts and learned monks from Ceylon and trying to wean their people from worship of the spirits. To retain the greatest spiritual potency, Buddha icons in Thai temples had to be as close in type as possible to a great original prototype that Buddhist tradition erroneously believed had been made during the lifetime of the Buddha; in practice, this meant the types the local craftsmen knew as the oldest and most authentic. There were at least three major successive efforts by Thai kings to establish and distribute an "authentic" canon for the Buddha icons, which were their prime artistic concern. Each type that became canonical and was known to be magically effective was imitated repeatedly. For it was regarded as an act of merit simply to multiply images of the Buddha, whether they were to be installed in temples or not; hence, in addition to icons, enormous numbers of small images—made of many materials, from bronze, silver, stone, and wood to terra-cotta—were kept in temple storehouses. The images followed canonical patterns established for the major temple icons.

Since their work had to be as similar as possible to the oldest sacred images of which they knew, the Buddhist sculptors in Siam adhered to strict formulas and diagrams; artistic development was never a part of their purpose, though of course gradual change did occur. There is no tradition in Theravāda Siam in any way resembling the traditions of Mahāyāna art in, say, Cambodia or Indonesia, which encouraged artists to explore the possibilities of their mediums to express developing religious conceptions. Thus, Thai Buddhist sculpture consisted almost entirely of careful repetitions of the standardized types, which tended naturally, despite the artist's desire to capture an authentic sense of style, to lose their older vitality. It also happened that the three main canonical patterns often lost their individuality, blending into each other. Perhaps the best works were made in the 15th century, but work of high quality was still being done in the 16th and early 17th centuries.

Canonical types of Buddha image

The first canonical types were the Sukhothai, which seem to have been evolved in the trade-route city of Sukhothai as an attempt to capture the quality of early-medieval Ceylonese images and elements from Dvaravati sculpture. The developed versions of these types are marked by an extremely smooth, rounded modelling of the body and face, without any clearly defined planes. The outlines of hair, eyebrows, lips, and fingers are elegantly recurved, or S-curved, and the head is crowned by a tall, pointed flame finial. The entire figure gives an impression of great elegance. Full-fledged Sukhothai images of the full-round walking Buddha—an original Sukhothai invention—emphasize a kind of swaying, sinuous, boneless grace in the execution of the legs and arms. One of the most impressive colossal images of the type is the brick and stucco icon at the Wat Mahathat, Sawankhalok, another Sukhothai technical forte, dating probably to the 14th century. This type of image remained the most popular in Siam; an enormous number of imitations, of all dates, are preserved, many in Western collections.

Perhaps the Buddha types most successful aesthetically were those called after U Thong. They were produced originally in the southern capital of Ayutthaya, which took over Sukhothai in 1349, and represent a fusion of the Sukhothai types with vestiges of Khmer and Theravāda Dvaravati traditions, whose Buddha types had been marked by a strong Mon sense of squared-off design and cubic volume. The latter may have been influential because they seemed to incorporate an older and more authentic tradition, since they were based upon patterns developed in eastern India, the true homeland of Buddhism. In the U Thong style the sinuous linear curves, loops, and dry ridges of the pure Sukhothai patterns are suppressed, and genuine modelling, with clearly defined planes and volumes, appears. In the northern kingdom a crude version of the Sukhothai type gained currency in the late 14th century. When, in the middle of the 15th century, King Tiloka of the northern kingdom reestablished contact with Ceylon, images seem to have been imported directly from that country. They must have shown clearly how far the Sukhothai types had departed from the type used in the Buddhist homeland, because the third Siamese icon pattern, known as the lion type, attempted to recapture the stern simplicity of the genuine Sinhalese images. Most of the best examples were made between 1470 and 1565. Limbs and bodies are given a massive cylindrical strength, and the Sukhothai elegance

is eliminated. It seems, however, that the native Thai genius is for the sinuous and unplastic curve, which may have expressed for them the same spiritual unworldliness as it did in Burmese ornament. Thus, in later examples reminiscent of the lion type, the curvilinear patterns of the Sukhothai style reassert themselves with more or less emphasis; and by the end of the 16th century the lion type had lost its distinguishing features and merged into the run of Sukhothai patterns.

Architecture and painting. There are as yet few results of authenticated research available concerning the history of architecture during the early period of Thai supremacy. Many monasteries contain stupas, or *cheddis,* that either originated or were renewed in this period; but most of the monasteries themselves have been repeatedly overworked. Building complexes seem to have developed by accretion, rather than by the studied working out of space articulations. The oldest building in Ayutthaya, dating from the early 13th century, is the Wat Bhuddai Svarya, a towered shrine, approached by a columned hall. From the late 14th century onward, Sukhothai influence seems to have predominated everywhere. The architectural types included a bell-shaped reliquary stupa with a circular flanged base and onion finials, reminiscent of combined Ceylonese and Burmese patterns; a stupa raised upon a cylindrical shrine as its drum; and a shrine with a plinth faced with images (usually later additions) above which rise one or more pyramidal towers reminiscent of the tower of the Mahābodhi temple at Buddh Gaya in Bihār, India. An example of the third architectural type is King Tiloka's late-15th-century Wat Chet Yot at Chiang Mai, which has one large and four smaller pyramids mounted on a main block.

14th-century architectural types

Wat Chet Yot, Chiang Mai, Thailand, late 15th century.

The Thai kings also adopted something of the personal funeral cult of Khmer Angkor (see below *Cambodia and Vietnam*), for a custom grew of building bell-shaped brick stupas—which had earlier been used only for the relics of Buddhist saints—as the kings' tombs, each approached by a colonnaded hall and surrounded by smaller stupas or shrines. In many of the brick and plaster or wooden monastic buildings of more recent centuries, such as the Wat Po in Bangkok, one can trace the distant influence of the Khmer styles of Angkor. Tall, gabled roofs, with steps and overlaps, the gables adorned with flame finials, are typical, exemplified by the Water Pavilion at Bang Pa-in.

Luc Bouchage—Rapho/Photo Researchers

Thai painting of the early period (13th–16th centuries) demands a great deal more research and study than it has yet received. Although it is, of course, devoted to the canonical iconography of the Theravāda, its fluent and relatively unschematic outline shows that it retained much of the original inspiration visible in the earlier work at Burmese Pagan (see above *Burma*). The oldest examples of Thai painting are the much-ruined frescoes in the Silpa cave, Yala, and some engraved panels from Wat Si Chum, Sukhothai, dated to 1287. Later paintings (dating to the 1420s) in the inner chambers of the Wat Rat Burana and Wat Mahathat at Ayutthaya show strong Chinese and perhaps Khmer influence in their high perspectives and landscape backgrounds with animals, combined with the native Thai clear outlines and bright, flat colours. By the 17th century at, for example, the Wat Yai Suwannaram at Phet Buri, large mural compositions—such as an elaborate scene of demons worshipping the Buddha—were being undertaken. In this later painting, theatrical stereotypes from the Thai dance-drama exerted a strong influence in the rendering of figures.

18th century to the present. In the 18th century the Burmese invaded and conquered Siam. The Burmese king—in expiation, it is said, of his war guilt—ordered the construction of many Buddhist buildings in the current Burmese style (see above *Burma*). These made their impact on Thai art, and the gaudy gilding and inlay characteristic of late Burmese ornament were widely adopted. When the capital was moved to the present Bangkok, in 1782, no substantial artistic development took place, though large pagodas were built and filled with rows of images, many in gilt wood. A highly ornate interpretation of older, airily flamboyant Burmese decorative styles, featuring curved "oxhorn" projections, blunted the edge of architectural and sculptural quality. Without exception, the new large-scale icons were dull and inferior works of art; and the monstrous guardian figures of spiritual beings and lions decorating the major shrines are fantastic rather than aesthetically valuable. In the painting of wooden panels, some of them votive, and of historical manuscripts, the Thai retained a good deal of their older vigour. The figures illustrating legend and history are based upon the unworldly stereotypes of the court dance.

Burmese influence on Thai art

In addition to the incorporation of European motives, many buildings and their ornamentation in Bangkok have a strongly Chinese flavour. This is attributable partly to the influence of the large expatriate Chinese population

Sawankhalok, Sukhothai, and Chiang Mai pottery

living there and partly to the influence of earlier expatriate Chinese craftsmen. The early 20th-century Pathamacetiya at Nagara Pathama (Nakhon Pathom), which is entirely orange, is a fine example of the many *cheddis*. Some tiles were certainly imported from China, but others were descendants of the fine pottery (of basically Chinese inspiration) that was produced at the kilns of Sawankhalok during the 14th and 15th centuries by expatriate Chinese craftsmen. This pottery imitated in its own materials Chinese Yüan dynasty (1279–1368) Tzu-chou and celadon wares (stonewares and porcelain with a glaze developed by the Chinese) with underglaze ornament and blue or brown painted decoration. Similar wares were made in the 15th century at kilns at Sukhothai and at Chiang Mai. Some of these pieces are, in their own idiom, as fine as native Chinese work. Later, during the 18th and 19th centuries, somewhat garish, flamboyant Ayutthaya figure designs in polychrome were applied to rice bowls and other vessels.

Laos. The kingdom of Lan Xang (Laos) was founded in the mid-14th century and ruled by Buddhist Thai. At the northern capital, Luang Prabang, the influence of the northern Thai city of Chiang Mai predominated; in the southern capital, Vientiane, a mixture of Ayutthaya and Khmer motives prevailed. In Laos there is no stone and little brick architecture. The most impressive single monument, the brick and stucco That Luang in Vientiane, founded in 1586 but much restored, is a stupa, shaped as a tall four-faced dome on a square plinth enclosed in a court; the dome is crowned with an ornate spire and encircled by a row of similarly shaped spires. The architecture of monastic halls also follows the Thai pattern; very steep multiple-gabled roofs, gently curved and overhung with long eaves, are carried on brick or wooden pillars and adorned with flame finials. Buddha figures, preserved in some of the monasteries, are based on northern Thai versions of Sukhothai types; some may be as early as the 17th century. The schematic paintings on monastery walls are in versions of the later Thai styles. In the northwest a strong influence from late Burmese art can be found in Buddhist images made to serve a religion that was far closer to the original Thai animism than to true Buddhism.

CAMBODIA AND VIETNAM

Paleolithic tools similar to types found in India have been found in Cambodia (Kampuchea) and Vietnam; and it is possible to trace the movement of population or culture groups, some of whom probably migrated onward by sea from Southeast Asia into the islands. The important group of speakers of Mon–Khmer languages may conceivably have been the people who produced the megalithic monuments in Cambodia and Laos, which include colossal stone burial urns, dolmens, and menhirs, perhaps associated with the many circular earth platforms as yet unexcavated (see above *General development of Southeast Asian art*). Probably contemporaneous, at least in part, with the Neolithic Mon–Khmer culture is the culture known by the name of its richest, most northerly site, Dong Son, on the coast of the Gulf of Tonkin in northern Vietnam. It seems probable that the chief influences on this culture came from southern China. Many sites, ranging in date from about the 4th to the 1st century BC, stretch southward from the coast of Vietnam, as far as northern New Guinea. The islands of Indonesia and parts of Malaya may have been the principal location of the Dong Son culture.

Bronze drums

The most impressive bronze objects produced by this culture are large drums, which seem sometimes to have been buried with the dead. Splendid examples have been found in Java and Bali (see below *Indonesia*). These and many other bronze objects, such as superb funeral urns with relief ornament based on squared hooks, lamp holders, dagger hilts in the form of human figures, and other weapons, are of extremely high quality. Their ornament was produced by the Chinese casting technique of incising the patterns into the negative mold that was to receive the molten bronze; much of it suggests a parallel version of contemporary Chinese ornament of the Ch'in period (221–206 BC). From the figures and objects represented in this bronze work, it seems that the Dong Son culture had much in common with that of some of the peoples of the Melanesian islands today. The culture knew large seagoing canoes, houses similar in structure to those still common among peoples of Melanesia, and ceremonies that the Melanesians might recognize. It is probable that one group of their descendants, which retained its identity, is known to the history of this region as the Cham (see below *Vietnam kingdom of Champa*).

Although many peoples isolated in the densely forested uplands also retained a tribal identity, by far the most important art was produced in the two Indianizing empires: Khmer, in Cambodia, with its linear predecessors the kingdoms of Funan and of Chenla (names they were given by Chinese historians), and the Cham, in Vietnam.

Cambodian kingdoms of Funan and Chenla: 1st to 9th century. Funan, which was in existence by the 1st century AD, was the earliest of the kingdoms that arose along the lower reaches of the Mekong River in response to Indian ideas. Its influence probably extended over long stretches of the coast of the Gulf of Siam, even as far as southern Burma, and corresponded with the range of the Mon peoples. Lying on the natural focus of land and sea routes linking eastern India and southern China to the islands of the South Seas, its geographical situation was ideal for a kingdom whose wealth was based on trade. At Funan sites even Roman, Ptolemaic Egyptian, and Sassanian Persian objects have been found, giving an idea of the extent of its trading interests.

The founder was probably a Brahmin trader from western India; for a local legend describes how the first king, a Brahmin, married the daughter of a local serpent deity, so establishing the ruling family. Serpents (*nāgas*) in Indian mythology are the spiritual patrons of water; and the basis this kingdom laid for later kingdoms in the same area was an elaborate system of waterworks, canals, and irrigation channels controlling and distributing the waters of the Mekong River. Contemporary Chinese accounts refer to cities with splendid wooden buildings, carved, painted, and gilded. But nothing remains, save a few foundation piles. Probably during the 6th century AD the kingdom called Chenla was established in the upper-middle reaches of the Mekong River, in what is now Laos. The kings who ruled in Chenla were descended from the kings of Funan and took over much of the Funan domain. It seems that disastrous floods had finally ruined Funan, which had previously suffered from Indonesian aggression, and that the shift of power to Chenla represented a recognition of temporarily insuperable geographical difficulties.

Stone sculptures

Culturally, Funan and Chenla are continuous. Their artists produced some of the world's greatest stone sculptures, most of which are large, freestanding icons, carved in sandstone. Intended to be installed in brick-built shrines, none of which survive, they usually represent the two major deities of Hinduism, Śiva and Vishnu. Sometimes both deities are combined into a single figure called Harihara; the right half of the body is characterized as Śiva, the left as Vishnu. A few examples of other figures are known, including some magnificent images of goddesses. The style of these sculptures is marked by an extremely smooth, continuously undulating surface, given strength by a system of clear, broad frontal planes and side recessions related to the foursquare block. Such images were meant to demonstrate the power and charm of a heavenly prototype to whom an earthly king appealed for his authority. The earliest images belong to the 6th century, and the series continues into the 9th.

In later Khmer times each king and sometimes each member of a royal house had statues of himself or herself in the guise of a patron deity set up in the family temple precinct. That the same custom prevailed in 6th-century India, particularly in the southeast, suggests that some of the early Funan and Chenla sculptures may have served the same function. A number of figures are Indian in style—some more markedly than others, which is probably more than a matter of date; for it is quite likely that Indian craftsmen occasionally travelled into this region to work. The style of the greatest of these early sculptures, however, is not Indian at all.

Sandstone lintels

Similarly non-Indian are the magnificent sandstone lintels made for the doorways of the vanished brick shrines. Although distantly related to Indian prototypes of the 1st and 2nd centuries AD, they appear as full-fledged Indochinese inventions and may well have been developed in combination with a native conception of the lintel as a special attribute of the spirit shrine (see above *Thailand and Laos*). They are carved in relief with designs based on a pair of monsters, one at each end, which are linked by an ornate arched or lobed beam. The beam is adorned with figures inside foliate plaques, a long sequence of elaborately carved swags of jewels hanging beneath them.

Among the Funan–Chenla sculptures are a few Buddhist icons executed in sandstone, markedly less sensuous than the Hindu figures and close to the styles of Dvaravati (see above *Thailand and Laos*), though a number of small Buddhist bronzes representing *bodhisattva*s approach the delicacy of the Hindu work.

Kingdom of Khmer: 9th to 13th century. Late in the 8th century the kingdom of Chenla declined politically, perhaps because of dynastic disputes with the rising power of Indonesian kings, who were themselves also descended from the original royal dynasty of Funan. It seems that the Indonesians gave some assistance in establishing a new kingdom in the northern part of what had been the territory of Funan. In 802 a Khmer king, who took the title of Jayavarman II, established his capital near Phnom Kulen, about 20 miles (30 kilometres) from Angkor. It was a rather unsuitable place for an administrative capital, but it was a mountain, and the peoples of Southeast Asia have always believed that gods and spirits dwell on mountaintops. The image of the sacred mountain thereafter remained the inspiration for all the later architecture of the Khmer around Angkor. Jayavarman, who built other temples in the vicinity, seems to have revived the Chenla style. A distinctively Khmer art, however, began to emerge under Indravarman I (877–889), who expanded the boundaries of the Khmer kingdom and finally settled its administration. Most important of all, he developed the initial plan of the colossal city of Angkor, whose mysterious ruins, lost in dense jungle until very recently, have tantalized Western travellers for three centuries.

Angkor was not only a city; more important, it was an immense technological achievement, from which the agricultural prosperity of the whole Cambodian plain derived. This plain was well watered naturally, but its rivers were subject to strong seasonal fluctuations. Controlled,

Plan of Angkor.

chno-
gical
nificance
Angkor

they were capable of producing an enormous increase in fertility. Angkor was thus essentially an elaborate system of artificial lakes, canals, and radiating irrigation channels that watered a huge acreage of rice paddy; and it was the basis for the strength and prosperity of the Khmer Empire. Since Angkor itself was the technical source of the life-giving agricultural water controlled by the king, it was regarded by the Khmer with religious reverence. Its temples and palaces were an expression of that reverence and at the same time an essential part of its supernatural mechanism. Royal intercession by numerous ceremonies, some of which re-enacted the primal marriage of Hindu divinity and native earth spirit on the pattern of ancient folk cult, ensured the continuing gift of the waters of heaven. The king, an earthly image of his god, was the intermediary who ensured that his kingdom would continue to receive divine benevolence in the form of water in controlled quantities. Courtiers played roles at once religious and administrative for the king, who believed that after his death he would be united with his patron deity. Dedicatory statues were often set up in his chief temple to commemorate his divinization.

In order to conform with mountain mythology, the Khmer kings built themselves a series of artificial mountains on the Cambodian plain at Angkor, each crowned by shrines containing images of gods and of themselves, their family, and their ancestors. The huge platforms of earth on which these buildings were founded probably consist of the soil excavated in forming the lakes, moats, and channels that not only divided up the city but also provided an easy means of transport. The temple mountains, like the city itself, are oriented east to west, the main gates facing east. Each king strove to outdo his predecessor in the height, size, and splendour of his temple mountain. The earlier ones, therefore, are relatively small, though beautiful, while the later ones, such as Angkor Wat and the Bayon, are of stupendous size.

ie basic
ittern of
e Khmer
mple
ountain

In the basic pattern of the Khmer temple mountain the principal overall enclosure, which is square or rectangular, is at ground level. Within it the artificial mountain rises through a series of terraces and at least one further enclosure wall toward a flat summit. On the summit stands either a single shrine or a group of shrines, often a quincunx—five shrines, one at each corner and one in the middle of a square. Arranged along the terraces or within the enclosures there may be further shrines, whose arched doorway pediments refer to the rainbow bridge between heaven and earth. There may be other long buildings, perhaps used as libraries or administrative offices. A principal staircase runs directly up from the east gate to the summit, and sometimes subsidiary staircases run up from other gates at the cardinal directions.

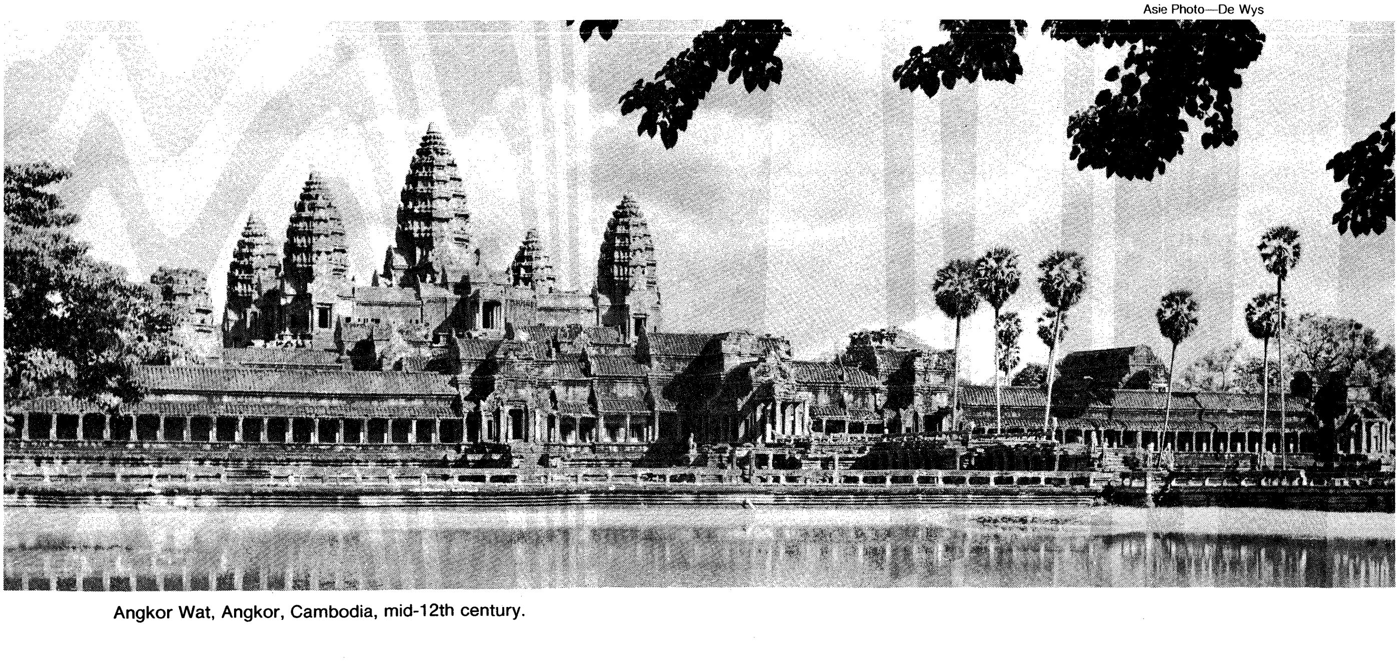
The architecture of the shrines themselves is relatively simple; it is based upon patterns invented in India, though the ornament of the shrines is often highly developed and characteristically Cambodian. Fundamentally, each shrine consists of a cell whose internal space is cubic and whose external walls are marked by moldings at top and bottom. The shrine is roofed by a pyramidal tower composed of a series of similar but diminishing tiers, each of them a compressed version of the exterior pattern of the main shrine volume. Depending on which Indian pattern is followed, the cell has one main door with an elaborately carved portal or, if the plan is cruciform, four entrances. The earlier shrines were built of brick, most commonly with stucco ornament and figures on the outside. The later shrines were built of stone, with all their ornament and figurative sculpture carved in relief. The moldings on the roofs of the shrines and the decoration of the roofs of many of the subsidiary buildings are extremely elaborate. There are long panels of dense foliate ornament, and the niches in which the sculptured relief figures of celestials are set are framed in flamboyant ogival (contoured like a pointed arch) moldings crowned by no less flamboyant foliate ornament; the smaller architectural features, such as niche pilasters, are elaborately carved and molded. The figures themselves wear gorgeous jewelry and chignons. The massive stone icons that survive in some of the shrines and on the terraces do not have the subtlety or strength of the Funan–Chenla sculptures. Instead, they have an inflated massiveness, intended, no doubt, to make them awe-inspiring. Among the lesser relief figures of celestials, which decorate the walls of the shrines, one finds a more sensuous touch; for many of these celestials represent *apsaras,* the celestial girls of Indian mythology.

Relief
panels

On some of the temple mountains there are also relief panels illustrating various aspects of the royal mythology. Episodic relief sculpture first appears on Banteay Srei (10th century). The relief revolves around a series of Indian legends dealing with the cosmic mountain Meru as the source of all creation and with the divine origin of water. The chief artistic achievement of its architecture is the way in which it conceives and coordinates the spaces between the walls of the enclosures, the faces of the terraces, and the volumes of the shrine buildings. A most sophisticated architecture of full and empty space, it seems to have been influenced by that of the Hindu Pallava dynasty in southeastern India.

The earliest more or less complete example of a shrine complex devoted to deifying the ancestors of a king is the Preah Ko at Roluos, near Angkor, completed in 879. The earliest surviving temple mountain at Angkor itself is the Bakong, probably finished in 881. In the central shrine at the summit was a *liṅga,* the phallic emblem sacred to

Asie Photo—De Wys



Angkor Wat, Angkor, Cambodia, mid-12th century.

Śiva. Around the base of the terraced pyramid stood eight large shrines inside the main enclosure, with a series of moats, causeways, and auxiliary sculptures guarding the approaches to the exterior. The Bakheng, begun in 893, had an enormous series of 108 tower shrines arranged on the terraces around the central pyramid, which was crowned by a quincunx of principal shrines. The whole was intended to illustrate a mystical conception of the cosmos, very much on the lines of the great temple mountain at Borobuḍur in Java (see below *Indonesia*). Pre Rup, dedicated in 961, was probably the first of the temple mountains intended as a permanent shrine for the divine spirit of a king after his death. It, too, has a quincunx of principal shrines, but it is distinguished by the large number of auxiliary pavilions arranged along both sides of the inner enclosure wall.

From about the same period is perhaps the most beautiful—and most beautifully preserved—of the early Khmer temples, Banteai Srei. This was actually a private foundation, built some 12 miles from Angkor by a Brahmin of royal descent. Its auxiliary buildings, all of sandstone, are adorned with a profusion of elaborate ornament and relief figure sculpture. The roof gables, in particular, are treated with antefixes of fantastic invention. Its principal icon, a huge sandstone sculpture of the god Śiva, seated with his wife Umā on his left knee, is perhaps the most impressive full-round sculpture from the whole Khmer epoch. It differs from 10th-century Khmer official sculpture, which began to take on a conventional and relatively insensitive massiveness.

The Baphuon temple mountain (1050–66) is unfortunately almost completely destroyed. It was a vast monument 480 yards (440 metres) long and 140 yards (130 metres) wide, approached by a 200-yard (180-metre) causeway raised on pillars. Its ground plan shows that it was no mere assemblage of buildings but a fully articulated structure. In this it must rank as the immediate prototype for the great Angkor Wat. Built by Suryavarman II in the early 12th century, Angkor Wat is the crowning work of Khmer architecture, the culmination of all the features of earlier styles.

Angkor Wat

The enormous structure of the Wat is some 1,700 yards (1,550 metres) long by 1,500 yards (1,400 metres) wide. Surrounded by a vast external cloister, it is approached from the west by a magnificent road, which is built on a causeway and lined with colossal balustrades carved in the likeness of the cosmic serpent, associated with the sources of life-giving water. The Wat rises in three concentric enclosures. The western gate complex itself is nearly as large as the complex of central shrines, and both are subdivided into smaller, beautifully decorated courts. Only five of the original nine towers still stand at the summit; although they follow the basic pattern of the Khmer roof tower composed of diminishing imitative stories, the contour of the towers is not rectilinear but curved, so as to suggest that the stories grow one out of another like a sprouting shoot. All the courtyards, with their molded plinths, staircases, porticoes, and eaves moldings, are perfectly articulated enclosed spaces. The symbolic meaning of the Wat is clear. Its central shrine indicates the hub of the universe, while its surroundings—the gate complex, the cloister, the city of Angkor itself, and, finally, the whole visible world—represent the successive outer envelopes of cosmic reality. That it is oriented toward the west—and not to the east, as was customary—indicates that its builder, Suryavarman II, intended it as his own mortuary shrine; for, according to Indochinese mythology, the west is the direction in which the dead depart.

The sculptors who worked at the Wat demonstrate little ability in carving in the full round. Such full-round figures as there are—the guardians on the terraces, for example—lack life. The relief sculpture, however, is magnificent and full of vitality. The open colonnaded gallery on the first story contains over a mile of relief carving six feet (two metres) high. Much of it was originally painted and gilded, which strongly suggests that there must have been a Khmer style of painting of which nothing is known. The subject matter of the carvings is taken principally from the Hindu epics, but there are also many scenes representing Suryavarman's earthly glory. Working in relief only about an inch deep, the sculptors were able to depict an extraordinary complex of scenes of figures in vigorous action, full of complex overlaps to suggest deep space. The solid bodies are created mainly out of groups of convex curves; and everywhere there is the typical regional feeling for decorative spirals. Perhaps the most interesting group of figures are the *apsaras*, carved in relief, either singly or in groups, on the plain walls of the courtyards. These celestial beauties, whom Indian tradition describes as rewarding with their charms the kings, heroes, and saints who attain heaven, are carved with sinuous sensuality; but the most important part of their charm is their elaborate clothing, jewelry, and hairdressing or ornate, towering, jewelled crowns. Apparently, deep, downward-drooping curves standing far out from the body represented the height of Khmer chic. Skirts, stoles, and the long sidelocks of the hair all follow these curves, laid out flat on the ground of the relief. Symbolizing the erotic joys that are essential attributes of heaven, the *apsaras* were natural possessions of the king.

Bas-relief of a battle scene, Angkor Wat, Angkor, Cambodia, early 12th century.

Holle Bildarchiv, Baden-Baden

The *apsaras*

In many senses the Wat was the end of the road for Khmer art. The effort demanded of the people in constructing this colossal stone monument, along with its four miles (six kilometres) of stone-lined moat 200 yards (180 metres) wide, appears to have been too great. The irrigation system itself may well have been neglected in favour not only of shifting the building stone—as much in quantity as there is in the Pyramid of Khafre in Egypt—but also of dressing, carving, and ornamenting it. After Suryavarman's death, the Cham, from the neighbouring kingdom of Champa (see below *Vietnam kingdom of Champa*), seized and sacked Angkor for the first time in its history (1177), thus shattering the confidence of the Khmer people in the protective powers of their Hindu deities. When Suryavarman's son, Jayavarman VII, came to the throne he inherited a ravaged kingdom. In 1181 he succeeded in driving out the Cham; he invaded their country and seized their capital, thereby making Champa a province of the Khmer. Then, over 60 years old, he embarked on a series of campaigns that extended the borders of the Khmer Empire further than ever before—into Malaya, Burma, and Annam.

The Bayon

The ruler of this empire naturally believed himself to be the greatest of the Khmers, and he set about demonstrating the truth of his belief by building his own city, Angkor Thom (*c.* 1200), and, at the centre of it, the biggest temple complex of them all—the Bayon (*c.* 1200). Breaking with all previous Khmer traditions, he took as his patron deity not one of the Hindu gods but one of the Buddhist *bodhisattvas*. Although Buddhism had flourished for several centuries in the whole of Indochina, it had not been adopted by the Khmer as an imperial cult. Now that the Hindu gods had been discredited by defeat, Jayavarman placed himself under the patronage of Mahāyāna Buddhism. The mythology according to which the Bayon was designed was thus another version of the old mythology of the celestial mountain and the divine origin of water. Only the central figure of his mythology, Lokeśvara, Lord of the World, was specifically Buddhist. The colossal masks that look out over the four directions of the world from the towers of the Bayon and from the gates of Angkor Thom are there to demonstrate the compassionate, all-seeing power of Lokeśvara and the king.

When Jayavarman VII set out to create Angkor Thom, he had to raze the fine older work of his predecessors, for the site at Angkor had become choked with nearly four centuries of grandiose temple building. Within Angkor Thom's ten miles (16 kilometres) of moats he constructed huge complexes of building and made his city the focus of a final system of canals and irrigation, with additional lakes.

Unfortunately, the innumerable new shrines that surround Angkor Thom, the towers that crowd the Bayon, and the vast stone terraces faced with relief that surround the royal palace are in general much inferior in execution to the work of the earlier kings. Thus, today Angkor is dominated by the overwhelming presence of Jayavarman's immense but relatively unrefined architecture. The King's ambition was satisfied by size and quantity rather than artistic quality. Because sculptors were obliged to produce such vast quantities of work so fast, their standards deteriorated, and the huge vistas of narrative relief show signs of haste and slipshod workmanship. The real achievement lay with Jayavarman's scholastic architects, who conceived and laid out a complex of mythical imagery in massive architectural symbols. Their stupendous overall plan illustrates the creation of the world, a cosmos spreading outward from the central mountain tower. The two roads leading from the tower are lined with mile-long rows of gigantic deities who are pulling on the body of the serpent *nāga*. According to Hindu legend, the gods use the magical mountain Meru, symbolized by the mountain tower, as a churning stick and the body of the cosmic serpent as a churning rope to churn the world out of the milk of nothingness. Lake-sized fountains represent the healing waters of the Buddhist paradise, and allegories of salvation are realized in carved architecture. Perhaps the most impressive works of art associated with this last period of Angkor are some stone icons, such as the famous "Leper King," in the Angkor Thom complex. Many excellent smaller bronze figures of deities have also been found among the ruins.

Decline of Angkor

13th century to the present. After the death of Jayavarman VII, *c.* 1215, possibly as late as 1219, Angkor declined. The Thai population of Siam gradually pushed the Khmer down toward the Mekong Delta. Theravāda Buddhism became the religion of the people, and the grandiose vision of a cultural unity based on sacred kingship disappeared. In the 15th century, Angkor was retaken from the Thai, and a few buildings were restored by the ancestors of the modern (now abdicated) Cambodian kings. Some of the buildings were used as monasteries, but the city, with its essential irrigation system, had fallen into ruin.

Vietnam kingdom of Champa: c. 2nd to 15th century. The kingdom of Champa existed alongside the Khmer kingdom, sometimes passing under its rule, sometimes maintaining a precarious independence. From the north it was continually subject to the pressure of the advancing Vietnamese, a people racially related to the Burmese and Thai, who were themselves under pressure from the Chinese. The Hinduizing dynasties who ruled Champa from the 6th century were obliged to pay heavy tribute to the Chinese Empire. After 980 they were forced by the Vietnamese to abandon their northern sacred capital, My Son; thereafter, except for a brief return to My Son in the 11th century, their southern capital at Vijaya (Binh Dinh) became their centre. Under such disruptive circumstances, it is perhaps surprising that the Cham succeeded in creating and maintaining a dynastic art of their own. It was, however, always on a relatively modest scale, devoted to a conception of divine kingship similar to but far less ambitious than the Khmer.

The evolution of Cham art falls naturally into two epochs, the first when the capital was in the north, the second when it was removed to the south.

Art of the northern capital: 4th to 11th century. The form of the earliest temple at My Son, built by King Bhadravarman in the late 4th century, is not known. The earliest surviving fragments of art come from the second half of the 7th century, when the king was a descendant of the royal house at Chenla. The remains of the many dynastic temples built in My Son up until 980 follow a common pattern with only minor variations. It is a relatively simple one, with no attempt at the elaborate architecture of space evolved by the Khmer. Each tower shrine is based upon the central rectangular volume of the cell. The faces are marked by central porticoes that are blind on all but the western face, where the entrance door is situated. The blind porticoes seem to have contained figures of deities—perhaps armed guardians standing in a threatening posture. The porticoes are set in a tall, narrow frame of pilasters (columns projecting a third of their width or less from the wall), crowned with horizontally molded capitals that step out upward. They support a tall, double-ogival blind arch, crowned by another stepped in behind it. The arches are based on an Indian pattern and are carved with a design of slowly undulating foliage springing from the mouth of a monster whose head forms the apex of the arch. The faces of the walls are formed of pilasters framing tall recesses. The pilasters are carved with foliate relief, and elaborate recessed and stepped-out horizontal moldings mark their bases. The height of the pilasters and recesses gives a strong vertical accent to the body of the shrine. The principal architrave is carried on stepped-out false capitals to the pilasters. The roof of the tower is composed of three diminishing, compressed stories, each marked by little pavilions on the faces above the main porticoes. Inside the tower is a high space created by a simple corbel vault with its stepped courses of masonry. The chief portico was extended to include a porch, and the whole structure stood upon a plinth whose faces bore molded dwarfed columns (small columns) and recesses.

Pedestal altars

These temples have one distinguishing internal feature: a pedestal altar within the cell, upon which statues were set, sometimes, it seems, in groups. The pedestals themselves are often beautifully adorned with reliefs, and some of the best Cham sculpture appears upon them. The subjects are usually based on Indian imagery of the celestial court. The fact that the pedestal altars carried their sculptures in the space of the cell, away from the wall, meant that the Cham sculptors could think in terms of three-dimensional plasticity as well as relief.

The glory of Cham art is the sculpture of the whole of the first period. Much of what survives consists of lesser figures that formed part of an architectural decor: heads of monsters, for example, which decorated the corners of architraves, and figures of lions, which supported bases and plinths. These figures reflect the heavy ornateness of the Cham decorative style at its most aggressive; and many of them effloresce into the solid, wormlike ornament that is the Cham version of Indo-Khmer foliage carving and carries strong reminiscences of Dong Son work. The remaining fragments of the large icons suggest a double origin for Cham art traditions. On many of the capitals and altar pedestals are series of figures carved in relief in a sensuous style, which is nevertheless strictly conceptualized. This sophisticated work is reminiscent both of late Chenla art (see above *Cambodia and Vietnam*) and of Indonesian decoration, especially during the 11th-century return. Other figures are more coarsely emphatic in style, with the crudely defined cubic volumes and the heavy faces of Melanesian sculpture. It is thus probable that artists trained in the sophisticated Cambodian tradition worked for the Cham kings at one time or another, while Champa's own native craftsmen emulated the work of the foreigners in their own fashion.

Apart from My Son there are one or two other sites in north and central Vietnam where Cham art was made in quantity. The most important of these is Dong Duong, in

Quang Nam. It is a ruined Buddhist monastery complex of the late 9th century, conceived on the most beautifully elaborated plan of structured space in Champa. The architectural detail is distinguished from the My Son work by its greater emphasis upon the plasticity of architectural elements such as angle pilasters and porticoes. The circuit wall was about half a mile (one kilometre) long and once contained many shrines dedicated to Buddhist deities. It is possible that, when this complex of brick courts, halls, and gate pavilions was intact, it may have resembled very closely the contemporary Buddhist monasteries of northeastern India.

Art of the southern capital: 11th to 15th century. After 980, when the northern provinces were taken over by the Vietnamese and the Cham capital established at Binh Dinh in 1069, the kings maintained a gradually diminishing splendour. After the Khmer attack of 1145 they could claim little in the way of royal glory.

Decline of shrine architecture

Although the Cham kings made a brief return to My Son from 1074 to 1080, most of their artistic effort was spent on shrines at Vijaya (Binh Dinh) and a few other sites in the south. The early 12th-century Silver Towers at Binh Dinh are simplified versions of the older northern towers, with corner pavilions added to the roofing stories and arches of pointed horseshoe shape. Throughout the 13th and early 14th centuries the architecture of successive shrines gradually declined. The plasticity of the old pilasters and architraves was suppressed into simple moldings, and the beauty of the buildings became largely a matter of proportion. By the mid-14th century even the temples erected at Binh Dinh amounted to little more than piles of crudely cut stones articulated only by reminiscences of the classic Cham style.

Sculpture shows a parallel decline. One or two reliefs at the Silver Towers do convey a sense of tranquillity and splendour, but an indigenous style of rigid cubical emphasis came progressively to dominate the iconic Hindu figures at southern sites. The curlicued design of earlier figures was gradually converted into a style of massive, scarcely carved blocks that convey, at their best, an impression of barbarous strength but without the refinement of first-class primitive art.

As was the case in Cambodia, this decline in art by the mid-14th century may be attributed to the people's loss of confidence in the concept—and, with it, the imagery—of divine kingship. Theravāda Buddhism, as a popular religion based upon numerous small, local monasteries, adopted probably from the Tai, was spreading all over the region. The northern Vietnamese, who had originally been organized in self-contained kingdoms without any concept of royal divinity, owing an intermittent administrative allegiance only to the distant Chinese emperor, found this ultimately suitable as a state religion after the final eclipse of Confucianism in the 17th century. They did incorporate echoes of older Hindu architecture, however, in details of the flamboyant ornament used on eaves and gables of their wooden monastery buildings.

Vietnam: 2nd–19th century. The great achievement of Vietnamese art, at least during the Le period (15th–18th centuries), seems to have been in architectural planning, incorporating Confucian, Taoist, or Buddhist temples into the landscape environment. The plans themselves include halls for a multitude of images in South Chinese vein and provision for a variety of rituals. There are no intact monuments of early Vietnamese architecture that are unrestored. Numerous fragments exist, however—either isolated stone bases, columns, stairways, and bridges or carved wooden members incorporated into later buildings—all of which are influenced to some degree by Chinese styles.

Tombs of the Chinese type

Tombs of generically Chinese type from the 2nd to 7th century contain bronze furnishings, in many of which, such as lampstands, the influence of the Dong Son style is clearly visible. There are no spirit images so typical of Six Dynasties (3rd–6th centuries) and T'ang (7th–10th centuries) Chinese tombs. The Chua Mot-cot, Hanoi, has vestiges of a stone shrine probably dated 1049. The only old paintings, on rock, at Tuyen Quang, (9th century) represent the Buddha, *bodhisattvas*, and donors. The Van-mieu at Hanoi (built 1070 but frequently restored) contains ritual bronzes in "barbaric" Chinese style.

Perhaps the most interesting early sculptures to survive are the stone fragments from the Van-phuc temple (9th–11th centuries), which are based on Chinese Buddhist imagery but in a style strongly Indianized, perhaps by Cham influence. The most important piece of old work still virtually intact is the portable octagonal wooden stupa kept in the hall of the But-thap, at Bac Ninh, east of Hanoi. It has wooden panels carved in a flamboyant 14th-century Chinese style; part of it bears a representation of the Buddhist paradise of Amitābha. Incorporated in many Buddhist temples of the Le period (15th–18th centuries), as well as in stone terraces, bridges, and gateways, is extremely elaborate carved and coloured woodwork in a style based upon the coiling dragon-and-cloud decoration of Ming (1368–1644) and Ch'ing (1644–1911) China, but with a characteristically Vietnamese exaggeration of weight and curve.

At Tho Ha there was a potters' village, where the glazed ceramic figures used on many types of Chinse temple were manufactured. The remains of many tombs, palaces, bridges, and Confucian and Taoist temples decorated in similar vein are known everywhere.

19th and 20th centuries. The beautiful imperial palace of Hue (final plan before 1810) contained vestiges of older architecture and many works of Sinicized art before its devastation in 1968. It consisted of a series of simple, rectangular, one-story pavilions, laid out among trees inside a group of courts. These buildings and their decoration were southern Chinese in basic conception.

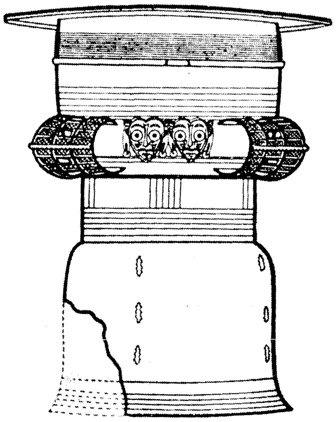
Elsewhere in Vietnam, both religious and secular buildings have been constructed in the 20th century in provincial versions of Chinese styles. There was little demand for the sculptor's art beyond the carving of stereotyped Buddha icons, monsters, and guardians. In modern times southern Vietnam has adopted a decorative style partly derived from the active traditions of Bangkok. Religious sects abound, with hybrid native European and Chinese elements used in their iconic and decorative art. Because of political turmoil, no clear and individual modern Vietnamese artistic tradition has been able to emerge.

INDONESIA

Megalithic monuments

The islands that at the present day compose Indonesia probably once shared in the complex Neolithic heritage of artistic tradition, which also spread further, into the islands of Melanesia and Micronesia. Beautifully ground Neolithic axes of semiprecious stone are treasured still in some countries. In many parts of Indonesia there are quantities of megalithic monuments—menhirs, dolmens, terraced burial mounds, stone skull troughs, and other objects. Some of these are undoubtedly of Neolithic date, but megaliths continued to be made in much more recent times. One stone sarcophagus in eastern Java, for example, is dated post-9th century. On Nias island, megaliths are still revered, and they are still being erected on Sumba and Flores islands. Thus, in Indonesia especially, different layers of Southeast Asian culture have existed side by side. The most impressive and important collection of megaliths is in the Pasemah region, in south Sumatra, where there are also many large stones roughly carved into the shape of animals, such as the buffalo and elephant, and human figures—some with swords, helmets, and ornaments and some apparently carrying drums.

These drums immediately suggest the drums characteristic of the mainland Southeast Asian Dong Son culture, which flourished *c.* 4th–1st centuries BC (see above *General development of Southeast Asian art*). This culture may well have helped to diffuse throughout the region styles related to Chinese Chou and pre-Han ornamental work. Certainly, the Dong Son influence is clear in many of the ceremonial axes, as well as many of the ornamented bronze drums, that have been found in the islands. The bronzes were cast by a cire perdue process resembling that used in parts of the Asian mainland. The largest and most famous drum is "the Moon of Bali," found on that island near Pedjeng. It has molded flanges, and cast onto its faces is extremely elaborate relief ornament consisting of stylized masks with ears pierced and lengthened by large earrings. Such drums were probably originally used in ritual—by the rainmaker, perhaps—and they may have been buried with the distinguished dead. No one knows the exact age of these bronzes; "the Moon of Bali," for example, could be anywhere between 1,000 and 2,000 years old. Similar small drums were used quite recently as bride prices; and many of the islands today produce textile designs and ceremonial bronzes that are strikingly reminiscent of Dong Son ornament.



"The Moon of Bali," bronze drum found near Pedjeng, Bali. In the Panataram Sasih temple, Pedjeng, Bali. Height 1.87 m, diameter 1.60 m.

From P. Rawson, *The Art of Southeast Asia*, Thames and Hudson Ltd., London

Central Javanese period: 7th to 13th century. Sometime between the 3rd and 6th centuries AD, Indianized principalities existed in Java. The chieftains who lived in their *kratons* (fortified villages) seem to have derived great inspiration, prestige, and practical assistance from the skills and ideas imported from India. In Sumatra there was the important but so far enigmatic Indianized kingdom of Śrivijaya, which, from its strategic position on the Strait of Malacca, exercised a powerful artistic influence in the whole region. Its great Buddhist centre, Palembang, might have had direct connections with the monasteries of southeastern India; for fine bronze Buddhas and *bodhisattvas* in a style reminiscent of Amarāvatī (2nd century AD) have been found in many regions where the influence of Śrivijaya might have been felt, including Mon Dvaravati (see above *Thailand and Laos*) and distant Celebes. Elsewhere among the islands were Indianized kingdoms still unknown to history.

The
Indianized
art of
Śrivijaya

The local dynasties of the *kratons* competed among themselves for power, and eventually the principal dynasties known to history came to the fore. The earliest major cultural assimilations from India took place probably during the 7th century, when the Hindu Pallava form of southeast Indian script was adopted for inscriptions in west Java. Thereafter, a central Javanese dynasty that worshipped Śiva made the oldest surviving artworks in stone. The last king of this dynasty retreated to east Java in the face of the rising power of another central Javanese dynasty, the Śailendra (AD 775–864.) The Śailendra were followers of Mahāyāna and Tantric forms of Buddhism, although Hinduism, as manifested in the worship of Śiva and Vishnu, was by no means eliminated. This dynasty created far the larger part of the immense wealth of first-class art known today in Java.

In Indonesia, the word *tjandi* refers to any religious structure based on an Indianized shrine with a pyramidal tower. This was the essential form on which virtually all the stone Indianizing architecture of Southeast Asia was originally based. The Javanese, like the Khmer, evolved an elaborate architecture of their own around the basic Indian prototype.

Central Javanese stone architecture did not use structural pillars, nor did its major stone monuments conceptualize hollow space in the way Khmer architecture did. Like Indian stonework, central Javanese stonework is fundamentally conceived as a solid mass, serving as a vehicle for figurative and symbolic sculpture. Its temples are centralized, with enclosures radiating around the central shrine. In eastern Java and Bali, however, the pattern of the shrine was influenced by older traditions and was usually conceived as an enclosure, the walled area of ground be-

ing the sacred element, while the buildings in it were of secondary importance. Old wooden buildings do not survive; but representations of wooden architecture in stone reliefs and the recent architecture of Bali show that eastern Indonesia was influenced by the ancient Southeast Asian tradition of constructing wooden pillared halls with tiered, sloping, and gabled roofs.

Hindu *tjandi*s

Because there are no inscriptions to supply dating points, the exact dates of the earliest Indonesian architectural monuments are not certain. The group of shrines generally believed to be the earliest is situated on the Dijeng Plateau. This is a high volcanic region, about 6,000 feet (2,000 metres) above sea level, where there are sulfur springs and lakes. The whole mountain seems to have been sacred to the Hindu deity Śiva, for all temples on the Dijeng are dedicated to him. There can be little doubt that during the 8th and 9th centuries the Javanese, who traditionally had interpreted the volcanic turbulence of their landscape as a manifestation of divine power, identified this power with the terrifying Śiva. On other Javanese volcanic mountains, also, groups of shrines are dedicated to him.

The temples on the Dijeng are single-cell shrines, roofed with diminishing stories. The exteriors of the temples are relatively plain; only around door frames and window frames are there distinctive passages of central Javanese ornament. Around the niches of Tjandi Puntadewa are perhaps the earliest surviving examples of the characteristic Javanese doorframe: across its lintel is carved a mask of the Indian Kāla monster, which represents time; and down the jambs, as if vomited from his open mouth, run string panels of foliage. The foot of each jamb terminates in an elaborately carved scrollwork cartouche, which is itself a *makara* (water monster) head seen in profile. This *tjandi,* like others on the Dijeng, has a single approach stairway rising between curved balusters. A few stone images of Śiva from these temples have been found. In broad, vigorous forms they express the dangerous power of the god.

Two of the very finest early Javanese sculptures—virtually in the full round—come from yet another Śiva temple, Chandi Banon, near Borobuḍur (see below). One, representing the god Vishnu (no stranger in syncretic Javanese temples of Śiva), has the extremely smooth, faintly amorphous suavity, the absolute convexity, and the lack of definition between planes characteristic of the classical central Javanese sculptural style; while the garment he wears, with its assortment of girdles, is closely reminiscent of late Pallava–early Cōḻa Hindu styles of southeast India. Another icon, sometimes called Agastya but more likely the third deity of the Hindu trinity, Brahmā, represents the god in the form of a bearded Brahmin sage. He has a large and, to Oriental eyes, splendid potbelly. This icon was indigenous to southeast India. The great depth of the side recessions of these figures, although perhaps not so clearly defined as in the great Funan–Chenla style (see above *Cambodia and Vietnam*), gives them a bland massiveness. The lack of movement in the figures and the regularity of the designs, the impassive faces, and the slowness of the lines must have been part of the central Javanese conception of transcendent glory.

Buddhist *tjandi*s

The Hindu temples of central Java are conceived simply as shrines to contain icons of deities for worship. The Mahāyāna and especially the Tantric Buddhist *tjandi*s, however, were called upon to do far more. They were designed to express complex metaphysical theories. The challenge this presented to the central Javanese architects was met in a series of splendid monuments, completely original in conception. The culminating work of the series, Borobuḍur, is a highly evolved architectural image, whose subtlety and refinement were never matched, even at Angkor in Cambodia.

The first work of this Buddhist series is Tjandi Ngawen, near Muntilan. This *tjandi* consists of five shrines facing east, 12 feet (four metres) apart in a row from north to south. Each shrine contained one of the five Buddhas who, according to Tantric Buddhist theory, presides over one of the five major psychological categories under which ultimate reality reveals itself. The shrines themselves are based on but more developed than those used for Hindu deities elsewhere in Java. Roughly square in plan and roofed with diminishing stories, they have pilastered projections on three faces and a portico on the east. Along the architrave are small triangular antefixes and reliefs of Kāla monsters vomiting floral scrolls hood the niches and portals.

The group of five Buddhas is familiar in the art of Tibet, Japan, and northeast India. Among them they compose what is called the *vajra-dhātu,* which means, roughly speaking, "the realm of total reality." According to the old Javanese theology, above this group is another, called the deities of the *garbha-dhātu. Garbha* means "womb" or "innermost secret," and its three deities personify the most esoteric realms of Buddhist speculation. At the centre of the group is the image of the single, undivided Buddha nature, which symbolizes the ultimate reality of the entire universe. From his right side emanates the *bodhisattva* Lokeśvara (Lord of the World), who is both compassionate and possessed of all power. From the left emanates the *bodhisattva* Vajrapāṇi, who is the personification of the most secret doctrines and practices of Tantric Buddhism. One of Java's greatest monuments, Tjandi Mendut, is a shrine expressly created to illustrate the combined doctrine of *garbha-dhātu* and *vajra-dhātu.*

Tjandi Mendut

Mendut dates from about 800 and is thus, generally speaking, contemporary with Borobuḍur. It is formed as a single large, square chamber, roofed with the usual diminishing stories, and mounted on a high, broad plinth,

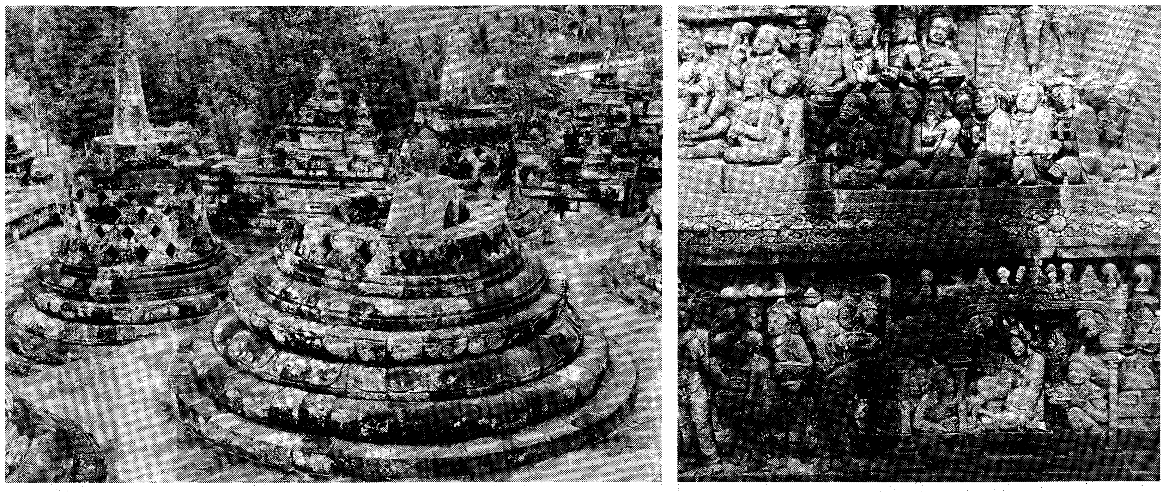
which is approached on its northwestern face by a staircase with recurved balustrades. The exterior is in every way more ornate than that of any shrine so far discussed. In addition to floral diaper (an allover pattern consisting of one or more small repeated units of design connecting with or growing out of one another) and scrolls, there are numerous figures in relief representing male and female deities, the subsidiary principles of the combined doctrine of *garbha-dhātu* and Vajrapāṇi. Cut into the fine ashlar (squared-stone) masonry are many relief panels with scenes from Buddhist literature, each panel self-contained and placed with consummate aesthetic judgment. Some represent mythical ideas, such as the wish-granting tree, others narratives from Buddhist legend.

The principal images were placed inside the cell chamber. Apparently, there were originally seven huge stone icons, but only three remain: the central Buddha, who also represented the ultimate Buddha nature of the *garbha-dhātu,* and his two emanations in the *garbha-dhātu,* Lokeśvara, and Vajrapāṇi. When complete, the interior of Mendut must have been an even more awe-inspiring and spiritually moving place than it is now. The three great statues are seated on elaborate thrones, backed against walls, but the figures are carved virtually in the full round. The inflated, gently inflected forms of the figures give them a majestic presence. The types and carving technique, as well as the monumental scale of the figures, are reminiscent of contemporary work in the cave temples of the western Deccan in India.

On the west–east road from Tjandi Mendut to Borobuḍur stands a small, relatively plain temple called Tjandi Pawon, dedicated to the god of wealth. Pawon was probably a kind of anteroom to Borobuḍur, catering to the more worldly interest of pilgrims. The outside has fine reliefs of female figures, and the roof bears towers of small stupas. On the reliefs are wish-granting trees surrounded by pots of money, and bearded dwarfs over the entrance pour out jewels from sacks.

Borobuḍur

Borobuḍur is one of the most impressive monuments ever created by man. It is both a temple and a complete exposition of doctrine, designed as a whole, and completed as it was designed, with only one major afterthought. It seems to have provided a pattern for Hindu temple mountains at Angkor (see above *Cambodia and Vietnam*), and in its own day it must have been one of the wonders of the Asian world. Built about 800, it probably fell into neglect by about 1000 and was overgrown. It was excavated and restored by the Dutch between 1907 and 1911. It now appears as a large, square plinth (the processional path) upon which stand five terraces gradually diminishing in size. The plans of the squares are stepped out twice to a central projection. Above the fifth terrace stands a series of three diminishing circular terraces carrying small stupas, crowned at the centre of the summit by a large, circular, bell-shaped stupa. Running up the centre of each face is a long staircase; all four are given equal importance. There are no internal cell shrines, and the terraces are solid; Borobuḍur is thus a Buddhist stupa in the Indian sense. Each of the square terraces is enclosed in a high wall with pavilions and niches along the whole perimeter, which prevents the visitor on one level from seeing into any of the other levels. All of these terraces are lined with relief sculptures, and the niches contain Buddha figures. The top three circular terraces are open and unwalled, and the 72 lesser, bell-shaped stupas they support are of open stone latticework; inside each was a huge stone Buddha figure. The convex contour of the whole monument is steepest near the ground, flattening as it reaches the summit. The bottom plinth, the processional path, was the major afterthought. It consists of a massive heap of stone pressed up against the original bottom story of the designed structure, so that it obscures an entire series of reliefs—a few of which have been uncovered in modern



Sculpture at Borobuḍur.

times. It was probably added to hold together the bottom story, which began to spread under the pressure of the immense weight of earth and stone accumulated above.

Symbolism of Borobuḍur

The whole building symbolizes a Buddhist transition from the lowest manifestations of reality at the base, through a series of regions representing psychological states, toward the ultimate condition of spiritual enlightenment at the summit. The unity of the monument effectively proclaims the unity of the cosmos permeated by the light of truth. The visitor was meant to be transformed as he climbed through the levels of Borobuḍur, encountering illustrations of progressively more profound doctrines the nearer he came to the summit. The topmost terrace, whose main stupa contained an unfinished image of Buddha that was hidden from the spectator's view, symbolized the indefinable ultimate spiritual state. The 72 openwork stupas on the circular terraces, with their barely visible internal Buddhas, symbolize incomplete states of enlightenment on the borders of manifestation. The usual way for a pilgrim to pay reverence to a Buddhist stupa is to walk around it, keeping it on his right hand. The vast series of reliefs about three feet (one metre) high on the exterior walls of the terraces would thus be read by the visitor in series from right to left. Between the reliefs are decorative scroll panels, and a hundred monster-head waterspouts carry off the tropical rainwater. The gates on the stairways between terraces are of the standard Indonesian type, with the face of the Kāla monster at the apex, vomiting his scrolls.

The reliefs of the lowest level illustrate scenes that show the causal workings of good and bad deeds through successive reincarnations. They show, for example, how those who hunt, kill, and cook living creatures such as tortoises and fish are themselves cooked in hells or die as children in their next life. They show how foolish people waste their time at entertainments. From these scenes of everyday life, one moves to the terraces above, where the subject matter becomes more profound and metaphysical. It illustrates important Mahāyāna texts dealing with the self-discovery and education of the *bodhisattva,* conceived as being possessed by compassion for and devoted wholly to the salvation of all creatures. The reliefs on the uppermost terraces gradually become more static. The sensuous roundness of the forms of the figures is not abated; but, in the design, great emphasis is laid upon horizontals and verticals and upon static, formal enclosures of repeated figures and gestures. At the summit all movement disappears, and the design is entirely subordinated to the circle enclosing the stupa.

The iconography of Borobuḍur suggests that the legend of the royal *bodhisattva* recounted in many of the reliefs was meant to "authenticate" some king or dynasty. Yet it hardly seems possible that Borobuḍur was the focus of a specific royal cult, as there is no provision at all for the performance of royal ritual. It must have been, then, in some sense a monument for the whole people, the focus for their religion and life, and a perpetual reminder of the doctrines of their religion.

A considerable number of bronzes, some small, some large, have been found in Indonesia in a style close to that of the sculptures of Borobuḍur and Mendut. One fine, large standing image comes from Kotabangun in Borneo; but some come from Java. Many small cult images of the Buddha and Buddhist deities exist. Some are close in type to the early Pāla images of Indian Bihār, the homeland of Buddhism, with which the Javanese must have maintained close touch. A few small but extremely fine gold figurines of undoubted Javanese workmanship have also turned up. For all their small size they must rate as first-class works of art. As well as images there are many beautiful bronze ceremonial objects, such as lamps, trays, and bells. These objects are decorated with the same kinds of ornament, although on a miniature scale, as the architectural monuments: scrolled leaves, swags, and bands of jewels.

Post-Borobuḍur *tjandi*s illustrate the Buddhist doctrine in different ways. Kalasan, for example, built in the second half of the 8th century, was a large, square shrine on a plinth, with projecting porticoes at the centre of each face. The roof was surmounted by a high circular stupa mounted on an octagonal drum, the faces of which bear reliefs of divinities. Topping each portico was a group of five small stupas, and another large stupa stood at each disengaged corner of the main shrine. The moldings were restrained and elegantly profiled. Each section of the exterior wall contains a niche meant for a figure sculpture. The decorative scroll carving is especially fine.

Another shrine from this period, Tjandi Sewu, consisted of a large cruciform shrine surrounded by smaller temples, only one of which has been restored. All of the temples seem to have had roofs in the form of tiered stupas, compressing the overall Borobuḍur scheme into the scope of a storied shrine tower. From Tjandi Plaosan came many beautiful sculptures, donor figures, and iconic images of *bodhisattva*s.

Tjandi Sa

Perhaps the most interesting of the post-Borobuḍur Buddhist shrines of the 9th century is Tjandi Sari. It is an outstanding architectural invention. From the outside it appears as a large, rectangular, three-storied block, with the main entrance piercing the centre of one of the longer sides. The third story stands above a substantial architrave with horizontal moldings and antefixes. Two windows on each short side, three on each long, open into each story, though at the rear they are blind. The windows are crowned by large antefix-like cartouches of ornamental carving based on curvilinear pavilions hung with strings of gems. The uppermost windows are hooded with the Kāla-monster motif. The roof bears rows of small stupas, and perhaps there was once a large central stupa. Inside, Tjandi Sari contains a processional corridor around three

interior shrines that were possibly intended for images of the *garbha-dhātu* deities, as at Tjandi Mendut.

The last great monument of the central Javanese period, Lara Jonggrang at Prambanan, is indeed a colossal work, rivalling Borobuḍur. It was probably built soon after 900. Not Buddhist but Hindu, the shrine represents the cosmic mountain. There were originally 232 temples incorporated into the design. The plan was centred on a square court with four gates containing the eight principal temples. Facing east, the central and largest temple, some 120 feet (40 metres) high, was devoted to the image of Śiva. To the north and south it is flanked by slightly smaller temples devoted to the two other members of the Hindu trinity, Vishnu and Brahmā. The smaller shrines contained many subsidiary images. The whole complex was enclosed, far off-centre, in an extremely large walled courtyard.

Although these are Hindu buildings, their high-terraced shrine roofs bear tiers of elongated and gadrooned stupas. The reliefs on these structures are especially beautiful. One series, representing the guardians of the directions, integrates the ornamental motifs with the plastic forms of the bodies in a most original way. The balustrades and inset panels abound with lively reliefs portraying various deities or scenes taken from the great Hindu classics, especially the *Rāmāyaṇa.*

East Javanese period: 927–16th century. During the east Javanese period a very large number of monuments were produced at the eastern end of the island (after 1222) and in Bali (after *c.* 1050). Few single structures, however, are as impressive and as comprehensively planned as are the monuments of Borobuḍur or Lara Jonggrang.

Around the strange natural mountain with tiered peaks cut and built in stone called Mount Penanggungan there are 81 structures (10th-century) of different kinds (now mostly in ruins). Prominent among these structures are bathing places. This mountain was identified by the people with the sacred Mount Meru, and its natural springs were believed to have a magical healing power and a mystical purifying capacity. Another such bathing place is Belahan (11th century). Made of brick, it, too, has extensive ruined temples. Belahan is supposed to have been the burial place of King Airlangga, who probably died about 1049. One of the greatest east Javanese icons formed the central figure against the back wall of the tank. Carved of red tufa (a porous rock), it shows the god Vishnu seated at peace on the back of his violently dramatic bird-vehicle, Garuḍa. It is said that the image represents the King himself in divine guise. Beside this image was a sculpture of a type associated with many of these sacred bathing sites. It is a relief of a four-armed goddess of abundance, her two lower hands holding jars pierced with holes, her two upper hands squeezing her breasts, which are also pierced; through the holes the sacred water flowed into the basin. There are many variants of this idea at the springs of Mount Penanggungan. On Bali the same kind of fountain sculpture appears at the Goa Gadjah, at Bedulu, in a spring-fed tank below a cave.

Four-armed goddess of abundance

In both Java and Bali there are many rock-face relief carvings from this period (there are no secure dates). Some represent legendary scenes; others represent *tjandis*; the shallow chambers of others are thought to be royal tombs.

The structure that gives the best ideas of what the typical east Javanese shrine of the mid-13th century was like is Tjandi Kidal. The nucleus of the building is a square cell, with slightly projecting porticoes each hooded by an enormous Kāla-monster head. But the cell itself is dwarfed both by the massive molded plinth upon which it stands and by the huge tower with which it is surmounted. The tower stands above an architrave stepped far out on tiered moldings. It is no longer composed of diminishing stories, as earlier towers were, but is conceived as a massive pyramidal obelisk made up of double bands of ornament spaced by stumpy pilasters and bands of recessed panels. The architectural projections and moldings distinguish Tjandi Kidal from earlier Javanese architecture, with its plain wall surfaces.

Many masterpieces of sculpture belong to the east Javanese period. Among them are some superb icons of Śiva and of a goddess of Buddhist wisdom from Singhasāri and a splendidly "primitivist" image of the elephant-headed god of wealth from Bara, Blitar.

From the late 13th century onward a whole series of *tjandi*s was created in eastern Java. As time went on the *tjandi*s lost their monumental scale and became simply shrines within a series of courtyards on a pre-Indian pattern. From Tjandi Djago through Tjandi Panataran at Blitar (14th century) and Tjandi Surawana it is possible to trace the line of descent of the modern Balinese temple enclosures.

Influence of shadow puppets on relief figures

By the end of the 14th century, the figures in the relief sculpture at these shrines had come more and more to resemble the shadow puppets of the popular *wayang* drama. They adopt the stiff profile stance that presents both shoulders, while the trees and houses resemble the stereotype silhouette leather and wood cutouts used as properties in the shadow plays. The art of carving in the near-full round, however, did not follow the same course of evolution as the reliefs. Such work did become softer and more delicate in style, with accretions of broad floral forms, but well into the 15th century the icons retain something of the strength of older sculptural conceptions. Another plastic tradition that seems to have escaped domination by the *wayang* formula resulted in the production of beautiful small terra-cotta figures as part of the revetment (stone facing sustaining the embankment) of the east Javanese capital city of Majapahit. Like the reliefs, the many small excavated bronzes of Hindu scenes are under the *wayang* influence, three-dimensional though they may be. Curlicues proliferate, and the plasticity of bodies is virtually ignored.

16th century to the present. When Islām arrived in Indonesia, it used the repertoire of traditional ornament for its mosques and tombs; but, in conformity to a puritan Muslim custom, the representation of living creatures was excluded on religious buildings. The gates of the 16th-century mosque at Sendangduwur, Badjanegara, show a splendid example of this adaptation. The wings of the old Hindu Garuḍa, a colossal bird-vehicle of the high god Vishnu, frame the gate; the body and head are suppressed. Above the lintel are abstract tree-clad mountain forms recalling the imagery of the cosmic Meru; and legendary snakes hood the jambs. The 16th-century mosque at Kudus even has a gate based on the split-*tjandi* pattern used in Bali (see below). Tombs such as that of Ratu Ibu at Airmata, on the island of Madura, add to their simple volumes elaborate but abstract variants of the scroll-filled antefixes of older architecture and of the petal-shaped aureoles of the larger east Javanese icons. In Sumatra the Muslim rulers encouraged a revival of the pre-Indian ancestor cult, along with its ancient and characteristic arts.

Bali. The rajas of eastern Java finally retreated before the Muslim invaders during the 16th century and departed to the island of Bali, where they remained. The old Javanese Indianized culture they brought with them survived and combined with animist folk elements. In Bali today that culture has bred a widespread popular art. There are now many hundreds of temples in Bali of varying age. Each family group has its own temple, dedicated to the ancestors; each village, too, has its temple, in which special attention is paid to a rich fertility goddess identified with the ancient Indian goddess of bounty, Śrī. Special temples dedicated to the goddess of death stand near the cremation ground. There are numerous major temples—many associated with volcanic peaks—dedicated to different deities and spirits; they range in size and importance from Besakih on Mount Agung (where a megalith is incorporated as a phallic Śiva-emblem) to Panataram Sasih of Pedjeng (where the bronze drum called "the Moon of Bali" is preserved).

Balinese temples

Balinese temples are conceived as multiple courts raised on terraces. The tall stone or brick and plaster gates are shaped like a *tjandi*-tower split down the centre; they are usually encrusted with ornament based upon deep multiple curlicues interspersed with simplified, two-dimensional relief figure sculpture. Fantastic three-dimensional guardians sometimes stand at the foot of the access staircase. Beyond the gates are one or two courts within which various ceremonies (including sacrifices and cockfights) may take place. The rearmost court backs onto the mountain, whence spirits descend temporarily when invoked. The court has no icons; at most, there is a seat for invisible deities. The structures in the court, mostly of wood and thatch, may be of many stories. (Such structures are called *merus*.) Sometimes the treasuries are ornamented with carving; and a few older stone *meru* towers in local shrines are carved with mythological figures.

Temple ceremonials, especially the cremation of distinguished people, evoked elaborate ritual art objects in precious metals, as well as in wood or fabric. All were characterized by exuberant and repetitive curvilinear floral ornament and by figures based on Indian legend, especially the *Rāmāyaṇa* and parts of the *Mahābhārata.* In the villages today, music, dance, sculpture, and painting are focussed on the shrines and are practiced with an intensity unknown elsewhere in the world. Art is woven intimately into the life of the people. The masks carved of wood for the dances are specially refined, sometimes ornate versions of the masks used in the animist rituals of other Southeast Asian peoples. In the 20th century there are numerous village sculptors and painters, who sell to tourists work based upon the old ceremonial arts. During the 1930s an outside impetus to develop their traditional legendary imagery in Western formats came from a German painter, Walter Spies, who lived on Bali. A landscape tradition was evolved, and the painters have been able to communicate something of the extravagant visual charm of their island, giving glimpses of luminous village and mountain landscape. The style of both sculptors and painters, however, is based upon gently undulating curves and is often highly ornamental, with repeated patterns. A repertoire of posture and gesture has been abstracted from the *wayang.* The work thus tends to prettiness rather than vigour; the sculptors create no truly intelligible volumes, and the painters fill their surfaces with naïvely structured shapes.

Indonesia painting

Java: 20th century. A conscious revival of traditional art has been attempted in the 20th century, especially in Java, the main territory of modern Indonesia. There has been government support for the resuscitation of old crafts—silverwork, for example. A number of artists have adapted Westernized figure drawing to their own decorative compositions. The best known painter of Indonesia is the Javanese Affandi. He has used oil paint to execute pictures of Indonesian subjects in a vividly coloured Expressionist impasto (thick application of pigment to the canvas). This European brushwork technique, however, contains a strong element of the sinuosity of Javanese tradition. As yet, Affandi is the only artist from Southeast Asia to have attained a personal worldwide reputation.

THE PHILIPPINES

The population of this island group contains a number of different ethnic strata, the oldest of which shares in the general folk culture and its associated folk arts of the islands of Southeast Asia (see above *Indonesia*), with an emphasis on geometric simplification. An element in the Tagalog (a people of central Luzon) is perhaps descended from the oldest level of immigrants with a Paleolithic background. The Moro are Muslims, converted to Islām during the 15th and 16th centuries. Today they produce a decorative art in which old Muslim geometric motifs are combined with strong Chinese decorative influences (from Sung times, Chinese ceramics and textiles were imported). The decoration is applied primarily to textiles, weapons, and containers to hold the betel nuts that are chewed throughout Southeast Asia.

Influence of Spain upon Philippine art

The most important departure in Philippine art was the result of the Spanish conquest of 1571. Thereafter, the bishopric of Manila and all of Luzon became the focus for an elaborate development of Spanish colonial art, primarily devoted to the construction and decoration of Roman Catholic churches in the current flamboyant, highly ornate, and colourful colonial style. There is good colonial architecture in other islands, including Bohol and Cebu. A large quantity of religious sculpture of the canonical Christian subjects was imported from Mexico and from Spain itself. Sculptors and missionary painters also immigrated, and a powerful local school developed under the direct influence of the 17th-century Spanish artists Murillo and Alonso Cano. Local arts were encouraged in 1785 by the remission of taxes for religious artists. Because of the close colonial ties, the stylistic developments corresponded

San Agustin church, Manila, the Philippines, 1599–1614.
Bruce Coleman

substantially with those elsewhere in the Spanish Empire, and European prints served as models for local artists. Of the major early churches for which this sculpture and painting was executed, only San Agustin (1599–1614), in Manila, still stands; it was designed by Fray Antonio de Herrera, son or nephew of the great Spanish architect Juan de Herrera. During the 19th century the neo-Gothic style was imported, mainly through the Philippine architect Felipe Roxas, who had travelled in Europe and England. San Sebastian in Manila is a notable example of this style. The Spaniard Hervas, Manila's municipal architect from 1887 to 1893, favoured neo-Byzantine forms; *e.g.,* Manila Cathedral (1878–79).

ɔdern ilippine hitects

It was only in the later 19th century that any secular art flourished at all. Schools of fine art modelled on the European schools were set up between 1815 and 1820, and a number of painters began to work in versions of European academic styles, painting landscapes, portraits, and classical subjects. The best known among them are Juan Luna, Felix Resurrección Hidalgo, Antonio Malantic, and the genre painter Fabian de la Rosa. After the transfer of rule to the United States in 1898, industrialization began in earnest; the methods of the art schools were adapted, as in Europe, to the needs of modern commercial society. In the 1930s a substantial modern experimental school of Philippine architects began the remodelling of the industrial environment in terms of 20th-century architectural and design conceptions. Prominent names are Pablo Antonio, Carlos Arguelles, and Cesar Concio. Beginning in the 1930s but especially after World War II, artists in Manila adopted the Abstract and Expressionist styles current in the United States. After the devastation wrought by that war, Manila and other cities and towns were rebuilt, virtually anew, in local variants of the international business style.

FOLK ARTS

The arts of many regions in Southeast Asia remained either untouched or only slightly influenced by the Indianized arts of other regions. Such influence is found especially in regions where the gold trade flourished. In Sarawak (Bonkisam), for example, the remains of buildings similar to late Tantric east Javanese *tjandi*s have been discovered. Among a few people (*e.g.,* the Meo of highland Vietnam), vestiges of Indian erotic temple imagery have been adapted to local fertility ceremonies, and most of the religious ideas of the region show at least faint traces of Indian influence.

Save for the megaliths and Dong Son bronzes, most of the known folk-art objects are relatively recent, although their inspiration and types belong to traditions far older and geographically more far-reaching than the Indianized traditions.

The two main non-Indian art styles in the whole region have been provisionally named the "monumental" and the "ornamental–fanciful." They coexist virtually everywhere, though they probably represent two evolutionary phases. The principal manifestations of the monumental style are the megalithic monuments, although there is great variety among the megalithic customs of the many different populations in Sumatra, Laos, Indonesia, Borneo, and the Philippines. The influence of the ornamental–fanciful style, which is characterized especially by the scrolled spiral, insinuates itself even into many of the decorative arts, particularly in the curvilinear and flamboyant inflection given to ornamental motives in the major Indianizing styles.

The squatting ancestor figure

The link between the two styles is probably the ubiquitous squatting ancestor figure, cocked knees supporting elbows, carved in soft wood or woven in cane or fibre. These figures may be either male or female. Under special social circumstances in recent times, very large wooden versions of the figure have been used as substitutes for more conventional, standing megalithic ancestral monuments (Sumatra and Sabah). The custom is probably an old one. There can be little doubt, for example, that the Theravāda Buddhist images of Burma, Thailand, and Laos were accepted as special modifications of the ancestor image. The transition from revering numinous ancestor images whose identity had been forgotten to worshipping an Indianizing icon was easy for the tribal populations.

The complex significance of the original squatting ancestor figure enabled it to be used in a variety of contexts. It might have combined associations of the fetus, the fetal burial position, and female birth and intercourse positions, as well as a ceremonial posture assumed by the living. It came to be used primarily in wooden sculpture on all scales, but also in woven textiles (*e.g.,* Iban), to represent the continuing power informing human existence, both in the purely ancestral sense of family continuity and identity and in the sense of the fertility of the land. Its earliest recorded appearance may be on Chinese Yang-shao painted pottery (*c.* 2000 BC); but it appears in essentially the same form over a range of territory including Sumatra, Nias and Sunda islands, Java, Borneo, New Guinea, Taiwan, the Philippines, and out into northern Australia and Melanesia. It may be used purely as an ancestral image in a family shrine house or as a motif added to any one of a variety of implements to potentiate them; for example, large bowls (Sumatra), kris or sword handles (Java, Sumatra, Borneo), spoons (Timor, the Philippines), musical instruments (Borneo), and magicians' staves (Borneo).

The treatment of such figures may be invested with more or less of the characteristics of the ornamental–fanciful style, in those regions where this style prevails (*e.g.,* Batak, Dayak). There are also special versions of the squatting figure that seem to belong especially to important magical crafts, such as the Javanese kris handle, on which miniature carvings can give an extraordinarily monumental effect. Sumatran Dayak hereditary magical staves may be carved with a "tower" or "tree" of such ancestor figures. On Nias, for example, along with the squatting figure, a standing figure in the bent-knee posture common in Polynesia also appears as a variant. In the Philippines similar variants are sometimes interpreted as vestiges from a remote Indian mythology, adopted probably for the sake of their cultural prestige. In southern Borneo the figure appears carved in the full round and as a pattern for woven textiles; it often has a protruding tongue and, sometimes, antlers—a combined motif known in the Ch'ang-sha art of southern China (*c.* 300 BC). Antlers also appear on certain Sumatran knifehilt figures. A variety of designs, some of them "abstract," are based on this figure. Among the Jarai of Vietnam, for example, a pattern of lozenges represents an abstraction from a group of these figures. Especially in the textiles of Sumba and other Indonesian islands, similar patterns, often referred to as decorated triangles, represent the same phenomenon. When, as in textiles, the anthropomorphic reference of the abstract pattern is lost, the male genitals may remain to assert the ancestor significance.

Cult of the skull

The association between the squatting figure and the widely practiced cult of the skull is manifested in the combined cult of ancestors, headhunting, and head worship. Among the Wa of Upper Burma, for example, the squatting figure in a lozenge abstraction decorates the chests in which the severed heads of enemies are stored. Virtually everywhere among the early farmers of Southeast Asia, such heads were regarded as repositories of great spiritual power. The cult of the skull has produced a version of the squatting figure that is commonly known by the Indonesian word *korvar;* it is a figure with an ancestral skull in place of a carved head. Such figures are especially common in the more easterly island cultures. The ghostly power of the deceased ancestor can thus become present and available to his descendants—to give oracular advice, for example. A related idea is incorporated in the masks used in a wide variety of rituals and dance-dramas throughout Southeast Asia; for example, among the Batak of Sumatra and the Dayak of Borneo, where especially fine examples are made. There can be little doubt that the same idea (blended with imagery from the imported Hindu epics) underlies the range of elaborate masks that were once used in the Javanese and now can be seen in the Balinese *wayang* dances. It is possible that the flamboyant flame skull protuberances and winglike flanges ornamenting the head in so much of the Buddhist art produced in Burma and Thailand reflect a persistent but submerged interest in the cult of the skull.

Another major motif is the snake, which (even in areas where direct Indianizing influence was not strong) is frequently combined with imagery derived from the cult of the powerful, magical Hindu *nāga;* often many-headed, this serpent is the patron and guardian of water and treasure, both material and spiritual. The snake motif has also been blended with images of the Chinese dragon, going back perhaps to Chinese Han ornamental designs. Outstanding examples are found on the elaborate relief-carved doors of Sumatran Batak houses; "flying" roof finials in many parts of Indonesia; and in much Borneo Dayak ornament, from tattoos to carved bamboos and bronze body ornaments. The snake is the magico-mythical creature that gives both its bodily shape (either straight or undulant) and its metaphysical power to the kris. Distributed from Malacca to Celebes, these swords (the earliest known dated 1342) reached their high point of artistic development in Java. A variety of other motifs originating on the mainland of Asia is found in many of the surviving folk arts of Indonesia. Among them are the "man in the embrace of an animal" (Dayak kris handles) and animals "stacked" one above the other (Timor, Indonesia).

Use of curves and spirals

The ornamental–fantastic style. The styles in which these variations on basic motifs are carried out vary principally according to the preponderance of the sinuous curves and spirals of the ornamental–fantastic style. This style serves as the basis for decoration and as a method of artistic phrasing. It may have made its way into Southeast Asia as late as the 1st millennium BC, being formally related to the spirals used in Chinese Neolithic, Shang, and Chou bronze art. (It should, perhaps, be mentioned that Chinese art, certainly until well into the Christian Era, was itself far more "tribal" than later Chinese tradition recognizes.) Probably connoting spirituality, the spiral imagery appears in Southeast Asian magical art at all levels, from the textiles of Java and the incised bamboo implements or carved doors of Dayak Borneo to the ornament on the costumes of sculptured dancers or deities at every major city site. Given a fiery upward inflection, it appears in the finials on major Indianized stone architecture and on the carved wooden gables of Burmese and Thai Buddhist halls. There is not always complete stylistic consistency within any one cultural group. For example, the fantastic snake-dragon creatures carved in deep relief on the housedoors of the Batak may be extravagantly sinuous, with many spirals, while their figure sculpture adheres to the sterner plastic idiom, virtually without any linear sinuosity. Among the Dayak of Borneo the fantastic style may be confined entirely to surface ornament. On Indonesian islands, ancestral figures may be relatively static and foursquare, while the decorative carving and textiles may display considerable linear fantasy. A special version of the ornamental–fantastic style characterizes the surviving Indianized arts of Bali and Java, intruding even into sculptural inventions derived from strongly three-dimensional medieval Indianizing patterns. Thus, the decoration on the *wayang* cutout leather puppets, with its somewhat stereotyped curlicues, has proliferated at the expense of the three-dimensional sense (see above *Indonesia*). Balinese *wayang* masks may be carved entirely out of curling surfaces and completed in paint with sinuous eyebrows and moustaches. In many parts of Southeast Asia, including Thailand, Vietnam, Burma, Sumatra, and Indonesia, designs originally based upon Indian flowering-scroll patterns can be found in architecture, textiles, theatre costumes, musical instruments, and wooden utensils, all efflorescing with extravagant curling ornament. It is unfortunately true that only in a few of its most serious manifestations does this kind of ornament display substantial artistic invention, with carefully varied, asymmetrical, complementary, and counterchanged curves. Usually, it degenerates into repetitive space filling, without variety or formal meaning.

Batik and *ikat*

Textiles. Perhaps the types of folk art best known in the West are the textiles, especially batik and *ikat.* Both names refer to techniques practiced by different groups of people, who must have learned it from each other. Essentially Javanese but known in other islands, batik may have resulted from the imitation with dyes of South Indian painted cloths, probably before 1700. The essence of the technique is that melted wax is poured from a small metal kettle onto areas of a plain cotton cloth, which is then dyed, only the unwaxed parts taking the colour. The process can be repeated with several different colours. The oldest basic colours are indigo and brown; red and yellow were used later. The possible patterns range from lozenges and circlets through a large repertoire of cursive animal and plant forms. The batik technique can produce sumptuous and complex designs that not even the most elaborate weaving techniques can duplicate. It was encouraged by the Muslim rulers as a major element of social expression in garments and hangings.

Ikat is known among the Batak, in Cambodia, and especially among the dispersed Dayak people. It, too, probably originated in India. The extraordinarily difficult *ikat* textiles (woven cotton and occasionally silk, especially in Cambodia) are made primarily for use in important ceremonials and were regarded by their makers as major works of art. Before being woven, the thread is tightly tied at carefully calculated points in the hank (coiled or looped bundle); this is then dyed, the tied parts not taking up dye. The process may be repeated for different colours. As a consequence of the predyeing, designs appear as the thread is woven. In most *ikat* only the warp (the series of yarns extended lengthwise in the loom and crossed by the weft) is so treated; but in southern Sumatra a tie-dyed floating weft is added to the plain weft. Naturally, *ikat* designs tend to be static and more or less rectilinear. In the finest *ikat,* however, birds and animals, spirits and houses, and, in Cambodia, a vestigial iconography of royal Buddhism may be formalized into extremely beautiful banded compositions. (P.S.R.)

(1964; Eng. trans., *The Indianized States of Southeast Asia,* 1968) and *Les Peuples de la péninsule indochinoise* (1962; Eng. trans., *The Making of Southeast Asia,* 1966), are standard works.

Literature: (*Burma*): MAUNG HTIN AUNG, *A History of Burma* (1967), contains a general survey of Burmese literature. The same author's *Burmese Folk-Tales* (1948), *Burmese Law Tales* (1962), *Burmese Monk's Tales* (1966); and MAUNG MYINT THEIN, *Burmese Folk-Songs* (1970), provide a good survey of Burmese oral literature. Dramatic literature is treated in MAUNG HTIN AUNG, *Burmese Drama* (1937). (*Thailand*): P. SCHWEISGUTH, *Étude sur la littérature siamoise* (1951), is the standard work on Thai literature. The *Journal of the Siam Society* (various issues) contains studies on Thai literature. (*The Philippines*): LEONARD CASPER, "The Philippine Literature: The Unexplored Potential," *Asia,* 9:80–87 (1967); ALBERT RAVENHOLT, *The Philippines: A Young Republic on the Move* (1962). (*Vietnam*): NGUYEN NGOC BICH (ed.), "The Poetry of Viet Nam," *Asia,* 14:69–91 (1969). (*Malaysia*): RICHARD WINSTEDT, *The Malays: A Cultural History,* 6th ed. (1961); and OLIVER RICE and ABDULLAH MAJID (eds.), *Modern Malay Verse, 1946–61* (1963), are important works to consult. (*Indonesia*): T.G.T. PIGEAUD, *Java in the 14th Century,* 5 vol. (1960–63), is a special study of Javanese literature in the Majapahit period. See also A. TEEUW, *Modern Indonesian Literature* (1967). TAKDIR ALISJAHBANA, *Indonesia in the Modern World* (1961), contains good accounts of modern Indonesian literature against the political, cultural, social, and historical background.

Music: WILLIAM P. MALM, *Music Cultures of the Pacific, the Near East, and Asia,* ch. 2 and 5 (1967), discusses the music of the Southeast Asian region; LAWRENCE PICKEN, "The Music of Far Eastern Asia and Other Countries," in *The New Oxford History of Music,* vol. 1, *Ancient and Oriental Music,* pp. 83–194 (1957), discusses intercultural and musical relationships between Far Eastern and Southeast Asian countries. See also D.R. WIDDESS and R.F. WOLPERT (eds.), *Music and Tradition* (1981), essays on Asian music. (*Burma*): U KHIN ZAW, "Burmese Music: A Preliminary Inquiry," *Journal of the Burma Research Society,* pp. 387–466 (December 1940), appends several pages of music notations to a discussion of music history and the structure of Burmese scales. (*Cambodia and Laos*): ALAIN DANIELOU, "La Musique du Cambodge et du Laos" (1957), is a brochure that discusses with the help of illustrations traditional musical instruments of both countries. (*Indonesia*): JAAP KUNST, *Music in Java,* 2 vol. (1949), an important work with a comprehensive bibliography including works of many Dutch scholars, treats matters regarding history, vocal and instrumental music, structure, notation, and tonal systems of the East-Central and the West-Javanese gamelan; MANTLE HOOD, *The Nuclear Theme As a Determinant of Patet in Javanese Music* (1954), modal structure of patet is analyzed according to basic elements in themes of several gamelan pieces of music; COLIN MCPHEE, *Music in Bali* (1966), gives detailed descriptions and specific musical examples of repertoire played in many gamelan ensembles; WALTER KAUDERN, "Musical Instruments in Celebes," in *Ethnological Studies in Celebes,* vol. 3 (1927), a detailed study with a long list of names of musical instruments, 130 figures, and 19 maps showing the geographical distribution of musical instruments; JAAP KUNST, *Music in Nias* (1939), describes both vocal and instrumental music, classifies musical instruments (Hornbostel-Sachs divisions), and illustrates their distribution in 7 maps; *Music in Flores* (1942), lists in a table the native names of 54 instruments of the five divisions of the archipelago; CHARLES S. MYERS, "A Study of Sarawak Music," *Sammelbände der Internationalen Musikgesellschaft,* 15:296–308 (1913–14), 13 gongs from different cultural groups and music of some instruments are analyzed with the help of musical examples; HENRY L. ROTH, *The Natives of Sarawak and British North Borneo,* 2 vol. (1896)—vol. 1, ch. 9 deals with feasts, festivals and dancing, while vol. 2, ch. 26 discusses music in general; EDWIN H. GOMES, *Seventeen Years Among the Sea Dyaks of Borneo* (1911), terms for songs and names of musical instruments that the author cites are still known in Sarawak; IVOR EVANS, *Among Primitive Peoples in Borneo,* ch. 14 (1922), devoted exclusively to a discussion of musical instruments, music, and dancing; JAAP KUNST, *Music in New Guinea* (Eng. trans. 1967), comprises three works first published in 1931 and 1950 that treat of vocal and instrumental music of the Papua in the north and the central range of mountains, of songs in the north and the West, and of music in the West Central range, Southwest, North and West coasts (many musical examples and a distribution map of musical instruments). (*The Philippines*): JOSE MACEDA, "The Music of the Magindanao in the Philippines," (1963, Ann Arbor University Microfilms), discusses instrumental and vocal music of the whole culture with copious musical examples and two long-playing records available at Folkways Records, New York; and "Drone and Melody in Philippine Musical Instruments," paper read at an International Conference on Traditional Drama and Music of Southeast Asia, Kuala Lumpur, August 27–31 (1969), discusses age, spread, and variety of combinations of drone and melody as a root structure. (*Thailand*): DAVID MORTON, "The Traditional Instrumental Music of Thailand," (1964, Ann Arbor University Microfilms), a study that covers both the historical and structural aspects of Thai music. (*Vietnam*): TRAN-VAN-KHE, *La Musique Vietnamienne traditionelle* (1962), detailed and important information about history, musical instruments, and musical theory (references abound with criticism of some works); and *Vietnam* (1967), a clear and concise presentation, containing valuable new historical material.

Dance and theatre: JAMES R. BRANDON, *Theatre in Southeast Asia* (1967), a general survey of major theatre forms, incorporating firsthand observation. (*Burma*): MAUNG HTIN AUNG, *Burmese Drama* (1937), a detailed history and translations of plays, four complete and eight in excerpts; KENNETH SEIN and J.A. WITHEY, *The Great Po Sein* (1965), a lively chronicle of the Burmese stage of the last century, cast in the first person narrative, by a famous contemporary actor; U POK NI, *Konmara Pya Zat* (1952), a complete English translation of a 19th-century play with interpretive notes. (*Cambodia*): JACQUES BRUNET, "Nang Sbek, Danced Shadow Theatre of Cambodia," *World of Music,* 11:18–37 (1969), a brief and excellent description and history of Cambodian shadow theatre; SAMDACH CHAUFEA THIOUNN, *Danses cambodgiennes,* 2nd ed. (1956), the most complete history and analysis of plays, music, and dance of female and male dance-drama. (*Indonesia*): BENEDICT R.O'G. ANDERSON, *Mythology and the Tolerance of the Javanese* (1965), major *wajang* characters are described and their significance as behavioral models is treated; JAMES R. BRANDON (ed.), *On Thrones of Gold: Three Javanese Shadow Plays* (1970), translations, with description of action, music indication, and photographs, of three *wajang kulit* plays; CLAIRE HOLT, *Art in Indonesia* (1967), excellent chapters on *wajang kulit,* dance, and dance-drama in all parts of Indonesia; JAMES L. PEACOCK, *Rites of Modernization* (1968), the plays, structure and content, of *ludruk* in Java as seen through the eyes of a modern anthropologist; W.H. RASSERS, *Pañji, the Culture Hero* (1959), a disputed but brilliant theoretical discussion of the origin and meaning of Indonesian theatre; H. ULBRICHT, *Wayang Purwa: Shadows of the Past* (1970), useful for its extended translations of synopses of Pandawa plays found in J. KATS's famous Dutch work *Het Javaansche tooneel,* vol. 1, *Wajang Poerwa* (1923); BERYL DE ZOETE and WALTER SPIES, *Dance and Drama in Bali* (1938), an authoritative and encyclopaedic pre-World War II description of Bali's performing arts. See also I MADÉ BANDEM and FREDERIK E. DEBOER, *Kaja and Kelod: Balinese Dance in Transition* (1982); and ANA DANIEL, *Bali: Behind the Mask* (1981). (*Malaysia*): JEANNE CUISINIER, *Le Théâtre d'Ombres à Kelantan,* 2nd ed. (1957), Malaysian shadow theatre described and illustrated, with a partial play translation; RICHARD WINSTEDT, *The Malays: A Cultural History,* 6th ed. (1961), contains background information on Malaysian drama, including translations of pre-performance invocations. (*The Philippines*): JEAN EDADES (ed.), *Short Plays of the Philippines* (1950), a collection of recent one-act plays in English; ALBERTO S. FLORENTINO, *Outstanding Filipino Short Plays* (1961), short plays with two appendixes on traditional and modern drama in the Philippines; FRANCISCA TOLENTINO, *Philippine National Dances* (1946), descriptions and brief histories of many folk dances. (*Thailand*): UBOL BHUKKANASUT (trans.), "Manohra," in *Traditional Asian Plays,* ed. by JAMES R. BRANDON (1972), a translation with stage directions of the *lakon jatri* play "Manohra"; H.H. BRIDHYAKORN, "The Nang," 3rd ed. (1956), a short booklet on *nang yai* shadow play; and with DHANIT YUPHO, "The Khon," 3rd ed, (1956), a short booklet on *khon* masked pantomime; DHANIT YUPHO, *Classical Siamese Theatre* (1952), 52 folk and classical dance sequences described and illustrated; and *The Khōn and Lakon* (1963), synopses, commentary, and illustrations for 32 classic dance plays as performed by the Bangkok Department of Fine Arts between 1947 and 1960. (*Vietnam*): SONG-BAN, *The Vietnamese Theatre* (1960), brief descriptions of theatre in Vietnam.

Visual arts: PHILIP S. RAWSON, *The Art of Southeast Asia: Cambodia, Vietnam, Thailand, Laos, Burma, Java, Bali* (1967),

a comprehensive survey with many illustrations and plans; BENJAMIN ROWLAND, *The Art and Architecture of India,* 3rd ed. rev. (1967), sets the art of the region in relation to South Asian, or Indian art; WIM SWAAN, *Lost Cities of Asia* (1966), a pictorial study of Ceylon, Pagan, and Angkor; detailed articles in the *Encyclopedia of World Art* (1960–67): GEORGE COEDES, "Burmese Art," "Khmer Art," and "Cham Art"; A.B. GRISWOLD, "Siamese Art"; MADELEINE HALLADE and ROBERT HEINE-GELDERN, "Indonesian Art"; LOUIS BEZACIER, "Vietnamese Art"; and J.M.R. RIVIERE, "Philippine Art"—all these articles have extensive bibliographies. (*Burma*): A.B. GRISWOLD, CHEWON KIM, and P.H. POTT, *Burma, Korea, Tibet* (U.S. title, *The Art of Burma, Korea, Tibet;* 1964), the only survey of Burmese art; BURMA RESEARCH SOCIETY, *Fiftieth Anniversary Publications,* vol. 2 (1960), source material including important articles in English by G.H. LUCE and W.B. SINCLAIR. (*Champa*): The basic studies are PHILIPPE STERN, *L'Art du Champa (ancien Annam) et son évolution* (1942); and LOUIS BEZACIER, *Relevé des monuments anciens du Nord Viêt-nam* (1959). (*Siam and Laos*): Three basic sources include SILPA BHIRASRI, *Thai-Mon Bronzes* (1957), and *The Origin and Evolution of Thai Murals* (1959); and L. BORIBAL BURIBHAND and A.B. GRISWOLD, "Sculpture of Peninsular Siam in the Ayuthya Period," *Journal of the Siam Society,* 38:1–60 (1951). PIERRE DUPONT, *L'Archéologie mône de Dvāravatī* (1959), is the most authoritative study of this topic so far. The chief illustrated source for dating Buddhist art is A.B. GRISWOLD, *Dated Buddha Images of Northern Siam* (1957). See also CAROL STRATTON and MIRIAM M. SCOTT, *The Art of Sukhothai: Thailand's Golden Age* (1981), covering the period between the mid-1200s and the mid-1600s. (*Indochina*): JEAN BOISSELIER, *La Statuaire khmère et son évolution,* 2 vol. (1955), an exhaustive study of the development of Khmer sculpture; GEORGE COEDES, "Le Culte de la Royauté divinisée . . . ," *Série Orientale,* conference vol. 5 (1952), a basic iconographic study; PIERRE DUPONT, *La Statuaire préangkorienne* (1955), the authoritative book on pre-Angkor sculpture; LOUIS FREDERIC, *Sud-Est Asiatique: ses temples, ses sculptures* (1964; Eng. trans., *The Temples and Sculptures of Southeast Asia* (U.S. title, *The Art of Southeast Asia: Temples and Sculpture;* 1965), a well-documented pictorial survey; BERNARD P. GROSLIER, *Indochine: carrefour des arts* (1961; Eng. trans., *Indochina: Art in the Melting Pot of Races,* 1962), the most comprehensive survey in English; and with JACQUES ARTHAUD, *Angkor, hommes et pierres* (1956; Eng. trans., *Angkor: Art and Civilization,* rev. ed., 1966), a thoroughly documented pictorial survey. (*Indonesia*): F.A. WAGNER, *Indonesia: The Art of an Island Group* (1959), a comprehensive survey of Indonesian art in English; A.J. BERNET KEMPERS, *Ancient Indonesian Art* (1959), a comprehensive illustrated book. Major works on Borobuḍur include T. VAN ERP, *Beschrijving van Barabudur,* vol. 2, *Bouwkundige beschrijving* (1931); N.J. KROM, *Barabudur: Archaeological Description,* 2 vol. (1927); and PAUL MUS, *Barabudur, esquisse d'une histoire du bouddhisme fondée sur la critique archéologique des textes* (1935), which covers the subject of the role of Indian philosophy and theology as a background to Borobuḍur.

Southern Africa

The subcontinent of southern Africa is a vast region that includes the countries of Angola, Botswana, Lesotho, Malaŵi, Mozambique, Namibia, Swaziland, Zambia, and Zimbabwe. The nation of South Africa, as well as the dependent states within its borders, is treated in a separate article. The region of southern Africa has been the background for continuous political struggle of European colonizers and the white elite of emerging nations with the diverse national groups seeking self-determination. (Ed.)

The article is divided into the following sections:

PHYSICAL AND HUMAN GEOGRAPHY

The land

RELIEF

ıree ajor cles of osion

Vast areas of southern Africa are characterized by uniformity and monotony of landform and natural vegetation. Level or slightly undulating surfaces occur widely and sometimes give the impression of being a lowland plain, even though lying at a considerable elevation above sea level. Much geomorphologic investigation remains to be done, and more precise correlation is needed between the surfaces recognized in different parts of the continent. There is a fair measure of agreement on the view that at least three major cycles of erosion have been completed and are represented by well-marked surfaces, certainly in southern Africa where most field study has so far been done. The oldest of these is a high-level erosion surface of Late Jurassic Age at between 7,000 and 8,500 feet (2,100 to 2,600 metres) above sea level. It has been recognized in the Cape ranges, the mountains of Lesotho, and, farther north, in the Nyika Plateau of Malaŵi. The second surface (of Miocene or mid-Tertiary Age) stands at about 4,500 feet and is best preserved where rivers like the Orange and Limpopo and, to the north, the Zambezi and Congo have carved out great valleys in troughs that were filled with easily erodable Karoo sedimentary rocks. The third well-developed surface, occurring at between 2,500 and 4,000 feet, is Pliocene or Late Tertiary and is most marked where the sedimentary rocks are weaker and in the Cretaceous beds of the Luangwa Valley and of the Lake Malaŵi Trough.

The East African Rift Valley extends into southern Africa. The edges are obvious enough to the south in Malaŵi, where a huge crusted block collapsed along the parallel faults that constitute the steeply rising slopes of Lake Malaŵi. The lake is 360 miles (579 kilometres) long but never more than 50 miles wide, and has a maximum depth of 1,226 feet. The rift then follows the line of the Shire Valley to reach the coast of the Indian Ocean near Beira, Mozambique. The western branch, or Western Rift Valley, extends from the northern end of Lake Malaŵi in a great arc.

DRAINAGE

The Zambezi is 2,200 miles long, and its basin covers 513,500 square miles (1,330,000 square kilometres). Its upper course drains a huge shallow alluvial basin more than 4,000 feet above sea level; many of its tributaries there are intermittent because of the highly seasonal nature of the rainfall and the intensity of evaporation. The falls and rapids are in its middle course, the most spectacular being the Victoria Falls, 355 feet high (*cf.* Niagara, 167 feet). Below the falls the river follows a narrow zigzag course developed along successive fault lines. Farther downstream the Kariba Dam has formed a huge lake in the section known by the Matabele (Ndebele) people as Gwembe. Nearer the Indian Ocean the river is more than five miles wide in places.

The Orange River, with only one important tributary, the Vaal, is 1,300 miles long with a basin of 329,000 square miles. It drains some of the higher parts of the South African plateau westward to the Atlantic; but it loses so much of its water through evaporation and, in recent years, through withdrawal for irrigation that in drought years it may even be dry. Much of the rainfall never reaches the main river but collects in shallow lakes (*vleis*) and is evaporated so that the lakes become salt-encrusted.

Also deserving individual mention is the great gray-green Limpopo River, all set about with fever trees, draining an area between the Zambezi and the Orange. (Ro.W.St.)

CLIMATE

A tropical climate is found in Zimbabwe, Zambia, Malaŵi, and Angola, and in part of Botswana. With the exception of the deep Zambezi Valley, the whole of this area lies above 3,000 feet, and in the east some of it is above 6,000 feet. Rainfall is moderate (30 to 50 inches [760 to 1,270 millimetres]), and the temperatures are lower than in the tropical region north of the Equator. The daily maximum temperature in summer at about 5,000 feet is approximately 80° to 85° F (27° to 29° C). The hottest areas are in the deep valleys of the Zambezi (Luangwa and Kafue), where temperatures of more than 100° F (38° C) are common, and the coolest are near the eastern mountains.

Zone of transition

To the south is a dry region forming a zone of transition from the savanna to the deserts. The northern Kalahari and southern Angola belong to this dry region. Rainfall is low (15 to 30 inches), and the rainy season lasts only three to five months. Temperatures are high throughout the year (mean October maximum: 95° F [35° C] at Maun, Botswana). The seasonal range of temperature is small (varying about 18° F [10° C] at Maun), and there is no real winter. The hot weather at the end of the long drought is uncomfortable, and, despite the rise in humidity, the arrival of the rains brings relief from the heat.

Desert climate. The Kalahari Desert in southern Africa extends from the Orange River to the Zambezi and has a summer rainfall varying from 10 inches in the south to more than 25 inches in the north. Practically the whole area supports a natural vegetation of some economic value. Normal summer maximum temperatures are close to 90° F (32° C), and days with temperatures as high as 106° F (41° C) can be expected only about once a month. The winter temperatures are more than 70° F (21° C) in the daytime with light frosts at night and occasional severe frosts at altitudes above 3,500 feet. The Namib and the southern end of the plateau in Namibia also belong to this region of desert climates. Although the rainfall (5 to 15 inches) is meagre, nearly half of it falls in winter, allowing for a vegetation of low scrub that provides grazing for sheep and goats. Summer temperatures are similar to the Kalahari, but winters are somewhat colder.

The coastal zone of the Namib is a narrow sandy desert, cool and almost rainless, stretching from Angola to Cape Province. True desert begins some distance south of Luanda where the mean annual rainfall is 13 inches; Moçâmedes (Mossâmedes) has only three inches of rain, and the coast of Namibia almost no rain at all. The upper air over the coast is warm, but the surface air is cooled by the Benguela Current, and the coast is liable to frequent low cloud and fog. Called *cacimbo* in Angola, it occurs mainly in the cool season, spreading inland from the sea in the early morning and dispersing a few hours later. In Namibia, however, it becomes a thick layer of stratus clouds about 1,000 feet high extending from the seaward limit of the cold water to about 30 miles inland. Almost every morning in summer and on many days in winter, the sky is overcast and a fine drizzle falls and wets the ground. Toward afternoon the sky clears, and a strong, almost violent sea breeze comes up to raise the loose sand of the desert into clouds of dust. The hottest days are in the winter months when the cool weather is occasionally disturbed by the berg winds of South Africa—hot dry winds from the direction of the interior of the plateau that make the temperatures on the cool coast rise to more than 90° F.

Humid subtropical. The plain in the southeast of Mozambique has a warm and humid climate, which is distinctly subtropical in the north but temperate in the south where it becomes cooler and merges into the region of year-round rainfall found on the southern coast. The extent of the region is restricted by altitude, losing its subtropical character above 2,000 feet. Rainfall occurs mainly in summer and varies from about 30 to 50 inches (Maputo averages 32 inches). The warm Mozambique Current exerts a strong influence on the temperature of the whole coastland of Mozambique and Natal, and daily maxima in summer vary between 80° and 90° F (27° and 32° C; the mean January maximum at Maputo is 86° F). These temperatures combined with a relative humidity of about 65 percent are uncomfortably warm, but in the winter the climate of this coast is the most genial in southern Africa (mean July maximum at Maputo: 75° F).

Rainy season

The rainy season in Mozambique (November to April) corresponds to the season of the northern monsoon, which is a southern extension of the Asian circulation into the Mozambique Channel. The southern monsoon, which blows in winter, is part of the trade-wind circulation of the Southern Hemisphere and does not usually bring rain.

Temperate plateau. The grassland plateau is the area from 3,000 to 6,000 feet in altitude and includes the highveld. The main features of the climate are low rainfall, cloudless skies, and large diurnal changes in weather. Local differences of rainfall and temperature are due to relief and exposure, and a number of isolated areas of wet, cool, and misty mountain climates are found on the prominent eastern escarpment. Seasons are sharply contrasted. Summer is warm, and the rains, which are mostly convectional, occur then; winter is cool and dry. Mean annual rainfall varies from about 20 to 40 inches decreasing from east to west.

Highland climate. Highland climates occur where the altitude exceeds 6,000 feet. The Lesotho highlands with their natural vegetation of mountain grass are the only region of southern Africa that can be considered in this category. The higher mountain slopes are cool, misty, and often wet; in the winter they are snow-covered and intensely cold. The population is therefore concentrated in the valleys where conditions are less severe. (Mokhotlong, Lesotho, at an altitude of 7,800 feet, has an average annual rainfall of 22 inches and a mean July maximum temperature of 28° F [−2° C].) (S.P.Jn.)

Traditional cultures

Grouping and distribution. The natives of southern Africa are conventionally classified into four major divisions, which are based primarily on language distinctions: San (Bushmen), Khoikhoin (Hottentots), Bergdama (Damara), and Bantu. The San, originally scattered throughout the region, are now found chiefly in the Kalahari Desert and adjacent areas to the north and west. The Khoikhoin are represented only by the Nama in the southern half of Namibia. Farther south and east there were formerly three other groups: Cape Hottentots, Eastern Hottentots, and Korana. These groups have disappeared almost completely, partly because of the effects of war and disease but mainly as a result of absorption into the Cape Coloured and other mixed-blood communities of which they were a basic element. The Bergdama live chiefly in the centre and north of Namibia, to which in historical times they have always been confined. The Bantu, far more numerous and widespread, consist of the following four subdivisions:

Divisions based on languages

Eastern. Located in the coastal regions east of the Drakensberg Mountains and south of the Sabi River, the eastern division comprises two main clusters, Nguni and Tsonga. The Nguni include the Cape Nguni of Ciskei and Transkei (Xhosa, Tembu or Thembu, Mpondo, and others, as well as the Mfengu, fugitive remnants of tribes broken up in Natal during the great intertribal wars at the beginning of the 19th century); Natal Nguni or Zulu of Natal and Zululand, with their offshoot the Ndebele (Tebele) of Zimbabwe; Swazi of Swaziland and eastern Transvaal; and Ndebele of central and northern Transvaal. The Tsonga, subdivided into Tsonga, Ronga, and Tswa, are found chiefly in Mozambique, with offshoots in eastern and northern Transvaal.

Central. This subdivision occupies most of the interior plateau north of the Orange River and west of the Drakensberg. It also comprises two main clusters: (1) Sotho, including the Southern Sotho of Lesotho (formerly Basutoland) and adjoining districts, Tswana (Thlaping [or Tlhaping], Rolong, Hurutshe, Kwena, Ngwaketse, Ngwato, Tawana, Kgatla, and others) of Botswana (formerly Bechuanaland) and western Transvaal and Northern Sotho (Pedi and many others) of central and northern Transvaal, and (2) Venda, a homogeneous cluster inhabiting the Soutpansberg district of northeastern Transvaal.

Shona peoples. These groups of Zimbabwe and Mozambique are subdivided linguistically into Zezuru, Manyika, Karanga, Kalanga, Korekore, and Ndau.

Western. The fourth group comprises the Ambo in northernmost Namibia and the Herero in central Namibia and northwestern Botswana. The Ambo consist of several distinct tribes, notably Ndonga, Kwanyama, and Kwambi; the Herero are customarily divided into Herero, Mbanderu, and Tjimba.

Major population movements. Because of the remote affinities of San (Bushman) languages with the Hadza and the Sandawe languages of Tanzania, it used to be held that the San had entered southern Africa from the northeast. Later research, however, indicates that they developed by local differentiation from some preexisting southern people and then spread north of the Zambezi. Although relating existing to prehistoric populations is largely guesswork, it is nevertheless possible that some of the Late Stone Age (about 8,000 years ago) inhabitants of southern Africa may have been the ancestors of the modern San. Relics of their much more recent ancestry (*e.g.*, stone artifacts, pictorial art, and place-names) are found throughout the region in areas where the San no longer live—notably Cape Province, Orange Free State, Lesotho, and Natal.

Relics of the San

An East African (and partly Hamitic) origin has also been claimed for the Khoikhoin, but this belief is now likewise largely rejected. Since some speakers of Khoi languages still practice hunting and gathering, one may suppose that this was perhaps the original means of livelihood of an indigenous Khoi population (also arising from local differentiation) and that sections of this population later received livestock from a source that remains uncertain.

The origins of the Bergdama are also problematic. If less importance is attached to their physical appearance, however, and more is attached to the fact that they speak a Khoi language, it may be possible to regard them as descendants of a section of the early Khoi population that did not acquire livestock.

Migration of the Bantu

The Bantu are universally held to have moved into South Africa from the north, although there is no certain evidence of their place of origin. They apparently came in many separate bodies and along diverse routes, each of their main groups representing a different series of migrations. Archaeological evidence, notably from the Great Zimbabwe and similar ruins, suggests that the ancestors of the Shona were already in what is now Zimbabwe by the 8th century AD. Other evidence indicates that the Nguni and Sotho had reached their present habitats by the 14th century, that the Venda migrated from Zimbabwe to the Soutpansberg about 1600, and that the Ambo and Herero entered what is now Namibia from the upper reaches of the Zambezi at about the same time. More cannot be said with much plausibility, and even the dates mentioned are hypothetical.

The impacts of different native peoples, upon one another, as well as the later advance of European settlers inland from the Cape, resulted in many local upheavals, during which various groups of San and Khoikhoin ceased to exist and the Bantu also were greatly affected. In particular, the wars of conquest initiated by the Zulu chief Shaka (1818–28) led to widespread devastation and enforced migration. One sequel was the creation of several other strong native states. Mzilikazi, after dominating central and western Transvaal (about 1821–37), went on to conquer the Shona in Rhodesia, where he established the Matabele (Ndebele) kingdom. Soshangane subjugated most of the Tsonga in Mozambique and founded the Gaza kingdom, while Zwangendaba and others founded Ngoni kingdoms north of the Zambezi. Mshweshwe (or Moshesh or Moshoeshoe), from the remnants of many scattered tribes, similarly created the modern Basuto nation in Basutoland (now Lesotho). Thulare and his son Sekwati brought many northern (Transvaal) Sotho tribes under the rule of the Pedi; Sebetwane, leading a horde of Sotho refugees from the south, established in far-off Barotseland (Zambia) the great Kololo kingdom. The wholesale destruction of life and dispersal of people resulting from these upheavals facilitated the subsequent extension of European settlement over the country. By the end of the 19th century, European armies had destroyed most of the new kingdoms, but such large tribal states as the southern Sotho (of Lesotho), Swazi, and Ngwato survived as examples of Bantu political development. (I.S./W.J.Ar.)

THE KHOISAN PEOPLES

The term Khoisan is a composite for Khoikhoi herders and San hunter-gatherers; it designates the indigenous southern African peoples once known, respectively, as Hottentots and Bushmen. The nature of the relationship between the two Khoisan groups has given rise to much discussion. They closely resemble each other in physical appearance and are markedly different from any of the other southern African populations. The prevailing view is that they are of the same genetic stock and differ only in their cultures, the Khoikhoin (Hottentots) being pastoral while the San (Bushmen) were formerly all hunter-gatherers. The Central San languages, Naro (Nharo), G/wi, and G//ana (/ and // represent click sounds), have such close lexical and structural resemblance to Khoi languages that all have been classified as belonging to the same language family.

hysical ppearance f the hoisan eoples

San and Khoikhoin are lightly built with thin limbs and wiry muscles. They are shorter in stature than most southern African peoples; San males average about five feet two inches (1.57 metres), women being an inch or so shorter, and Khoikhoin are perhaps two inches taller than San. Their skin colour at birth is coppery yellow, darkening to yellowish brown with exposure to the sun. Their dark-brown eyes are narrowed by the fullness of the upper lids and the pronounced epicanthic folds, a feature that has led some erroneously to link them with Mongoloid peoples. Facial and body hair are sparse, and few men develop beards before middle age.

The now-extinct San south of the Molopo River were smaller and lighter coloured than are the present-day San of Botswana, Namibia, and Angola. The latter are thought to have acquired Negroid characteristics from intermixing with Bantu-speaking peoples.

THE KHOIKHOIN, OR HOTTENTOTS

Origin of the name Hottentot

The origin of the name Hottentot is uncertain. The most plausible theory is that it was invented in 1647 by the survivors of a Dutch shipwreck who camped in the vicinity of present-day Cape Town for a year before being rescued. They established friendly relations with the local inhabitants but were quite unable to learn their language. One theory is that the Dutchmen took the refrain *autentou* from a ¾-time dance of the people and used it in friendly, joking reference to them. Another theory is that the Dutch formed the word in an attempt to imitate Khoi click sounds in Dutch. Whatever its origins, the form Hottentot was later adopted by the Europeans and subsequently by the Hottentots themselves. The original Hottentot self-designation had been Khoikhoi ("Men of Men" or "Proper People").

Knowledge of traditional Khoi culture is fragmentary and imprecise. The only records come from travellers and missionaries who were untrained observers and therefore strongly influenced by their own values and preconceptions. By the time capable and interested observers came to the southern African scene, war and disease had taken their toll, and only vestiges of the traditional cultures remained.

Subsistence and economics. The Khoikhoin were pastoral, grazing their fat-tailed sheep and long-horned cattle over much of the drier, western half of the subcontinent. The native sward and the meagre supplies of water were unsuited to sustained stock raising, and the Khoikhoin had periodically to trek their flocks and herds in search of new pasture and water. No crops were cultivated. The diet of milk and meat was supplemented by game and wild plants.

Their settlement pattern appears to have varied with the conditions of the locale, but a typical community may have consisted of 200 or 300 people, together owning upward of 1,000 head of stock. The temporary settlement was enclosed by a circular fence of thornbush, within which were the kraals (corrals) for lambs and calves. No special enclosures were made for adult beasts, which were driven into the main enclosure at night among the huts of their owners. These huts were hemispherical structures made by planting a ring of wands in the ground and bending the tops over, tying them together to form a dome that was covered with woven grass matting. Weatherproof and cool, the huts could be assembled or taken down in a few hours, loaded onto oxen, and carried to the next settlement site. The oxen were used as mounts as well as pack animals.

The hut was the property and domain of the wife; she had complete authority over it, to the extent of being able to exclude her husband if she wished. It appears that the Khoikhoi woman's status was equal or nearly so to that of the man; women could own stock and were economically important in their role as gatherers of plant food. The men were herders and hunters and, among some tribes, metalworkers. The principal weapons were arrows and spears tipped with bone or iron. An extensive trading network seems to have existed through which scattered settlements exchanged aromatic, medicinal, and narcotic herbs; pottery; and metalware such as iron and copper beads, arrowheads, and knife and spear blades. Some Khoikhoin, particularly in northeastern Botswana, had developed rather advanced mining techniques; the old shafts indicate a high order of geologic insight.

Religion of the Khoikhoin. The Khoi deity Tsuni-g//oab is celebrated in myths as the first of that people from which all others take their origin. A great chief and a powerful magician, he worked many wonders, including the creation of men and women. He died several times and was resurrected, eventually becoming a purely spiritual being. As such he was omniscient and omnipresent and the giver of life and of rain. Supplication was made to him in an elaborate ritual to persuade him to send the rain that was essential for survival of man and stock.

Another deity, Heitsi-eibib, was the hero of a cycle of myth. He could change his form and had died and been reborn many times. He was worshipped at his many graves scattered about Khoi country; the passerby would add a stone to the heap marking the grave and pray to Heitsi-eibib for prosperity and success.

G//aunab was a god with varying attributes who, with appropriate phonemic changes of his name to fit a particular language, appeared in the theologies of a number of Khoisan peoples. In the myths of the Khoikhoin he is the adversary of Tsuni-g//oab and the bringer of death, disease, and other misfortunes. In some accounts he appears as the personification of the malevolent spirits of the dead. Among those peoples exposed to Christianity, he has been equated with the devil.

The Khoikhoin are also said to have worshipped the Moon, although not much is known about this. Certainly the Moon figures in their very rich mythology.

The practice of magic does not seem to have been extensive. Curing and divination were the main activities of magicians, although they occasionally misused their powers for evil purposes. When they did, their influence could be negated by the application of cold water, either to the sorcerer or to his victim—an illustration of the high value placed on water by the Khoikhoin.

Khoi confederation of clans

Political organization. Khoi communities were linked by language and kinship into a loose confederation of clans that formed a nation. Several nations existed in the 17th century. Each had its own territory, its own name, and apparently its own dialect. (The dialectal differences must have been minor, as there was great similarity in the Khoi languages across their total range of nearly 2,000 miles from the eastern Cape Province in South Africa to the highlands of Namibia.) The clans comprising a nation were ranked in order of seniority, the chief of the nation being drawn from the senior clan. Marriage within the clan was strictly forbidden; the need to find spouses in other clans helped to keep the nation together. The nation as a whole had exclusive rights to grazing and hunting land, water holes, and mineral deposits. In the larger nations there seems to have been some apportionment of land among the clans.

Leadership, despite its clan basis, was not strong; it was persuasive rather than autocratic. Many instances are recorded of individual clans hiving off from the main body, attracting a following from other clans, and setting up as an independent nation with a new rank order of constituent clans. It has been suggested that this anarchistic tendency was reinforced by social and environmental pressures. Among a people lacking a strong and coercive political system and totally dependent on a scarce resource such as water, the use of that resource can be effectively controlled only if harmony prevails in the community. Harmony is threatened if the community reaches an unwieldy size and imposes too heavy a demand on the limited supply of water. The only solution then is for the community to divide. The "daughter" component must put sufficient distance between itself and the "parent" community to avoid predation by the latter. The effect is to limit the size of communities and to encourage their wide dispersal over habitable country.

Khoi nations did not develop great strength or solidarity. As nomadic pastoralists, they were forced to give ground before the incursions of more cohesively organized peoples: the Bantu who moved down the southeastern coastal areas (probably about the 10th century AD) and European settlers who began moving inland from Table Bay in the 17th century. By the 19th century some of the Khoi nations felt themselves desperately pressed. Strong leaders were able to unite fragments of clans and nations under them, and large groups moved across the Orange River out of Cape Colony into South West Africa, thus retracing the route that may have been taken by forebears, who are thought to have migrated into southern Africa from the central African lakes. In South West Africa some of the Khoikhoin had troubles with the Herero group of the Bantu, who were roving farther and farther south. Caught between the Europeans and the Bantu, the Khoikhoin fought for nearly 100 years, giving up the struggle only after the suppression of the uprising of the Bondelswarts in 1922.

Remnants of the Khoi culture

Little now remains of a distinctively Khoi culture, despite the efforts of missionaries and governments to soften the impact of alien cultures. The Nama and Garikwe communities retain their identities as Khoikhoin, and the former have kept their language and some of their customs. Many other communities live on reserves, where they make a living from their livestock, supplemented by jobs as unskilled or semiskilled labourers, but theirs is more the culture of poverty than that of the traditional Khoi people.

THE SAN (BUSHMEN)

The term Bushman is an Anglicization of the 17th-century Dutch *bosjesmans* ("bush dwellers"; *i.e.,* people without fixed abode). The historical evidence concerning San is incomplete and often unreliable. As hunters and gatherers, they were unobtrusive in their occupation of the land. Few early explorers took much interest in them, and fewer had the time and means to study the small, widely dispersed communities that shifted their encampments every few weeks. The San occupied most of the country south of the Zambezi River that was not in the hands of the Khoikhoin or Bantu. Skeletal and cultural remains, particularly rock paintings and engravings, indicate that they once ranged over the whole subcontinent.

Present-day San. The San population lives in Botswana (chiefly in the western Kalahari) and Namibia, and a small number in Angola. Some of the San move among Zambia, Zimbabwe, and Botswana. Two groups lived in the Republic of South Africa, one in the Kalahari Gemsbok National Park in Cape Province and the other, a very small community, near Lake Chrissie in the eastern Transvaal.

It is often stated that the surviving San migrated to their present inhospitable desert habitats in recent times after being driven out of other territories. There is, however, ample evidence that they occupied their present locations in the mid-19th century, when other San were still living in parts of southern Africa where they are now extinct. In addition, there is no evidence that the latter groups migrated into the desert areas; rather, it is clear that they remained where they were until they were either overwhelmed by war and disease or absorbed by intermixing with Europeans and Bantu. The distribution of dialects among the present-day San population is consistent with their having lived in their present locations over a very long period.

The majority of today's San have been dispossessed of their territories by European and Bantu cattle raisers. The intrusion of cattlemen has reduced the supply of game animals and esculent plants that constituted the greater part of their diet. Most San have therefore turned to livestock raising for their living, either by hiring themselves as labourers to ranchers or by entering into master–serf relationships with Bantu owners of cattle posts. A few of them still follow the traditional hunter-gatherer style of life.

Ranch labourers. On the marginal cattle ranches in the arid regions of southern Africa, San compete with the Bantu for available jobs. Because of their relative lack of strength and marketable skills and because most do not know any language other than their own, they get only the lowest-paid jobs. In addition, a person who finds employment often attracts a number of dependent kin and friends who come and live with him on the ranch. It is common, therefore, for ranchers to increase the labourer's issue of rations (the usual supplement to wages) to accommodate the train of dependents. Some ranchers give an annual bonus of small livestock, which are allowed to be kept on the ranch and multiply.

Ranch San, although retaining their languages and some aspects of social organization such as the kinship structure, have lost much of the rationale of their old culture.

In the traditional life-style, women had great economic importance as the gatherers of food plants, which constituted the main part of the diet. On the ranches, however, a labourer's wife may be something of a liability when he is competing with other men for a job. Deserted wives and children are numerous; they turn to already overburdened kinsmen for help or to prostitution and petty crime.

Hunting-gathering San. Independent San are confined mainly to the western part of Botswana. In the northwest are the !Kung (! represents a click sound), who inhabit an area with some permanent water holes and numerous esculent plants, including extensive groves of mugongo trees (*Ricinodendron rautanenii*), which bear pleasant-tasting and nutritious nuts. The !xõ (!xu) live in the west central part of Botswana, a region without natural supplies of permanent water but rich in game and esculent plants. In the central Kalahari region of Botswana are the G/wi, /aba, and G//ana groups. This region does not have the seasonal abundance of game that is seen farther west and is also waterless except during the wet season. Other hunter-gatherer San are found elsewhere in Botswana, Namibia, and Angola, but they are not independent and autonomous, and their way of life is therefore less representative of the traditional San cultures.

ıltural
riety
San

San are not culturally homogeneous, although the cultures of some of the groups resemble one another. The !Kung, !xõ, and G/wi, though all hunter-gatherers, live in rather different habitats containing different resources, and the three groups show marked differences in their technologies and their patterns of exploiting resources. Organizationally, these groups also exhibit marked contrasts. The lexical and structural differences among their languages are so great that they have been classed in three different language families. Generalizations about the San can therefore be made only at the level of a "southern African hunter-gatherer culture" and limited to such superficial common features as the use of bows and poisoned arrows in hunting; a low population density and small communities; generally diffuse and ephemeral leadership; egalitarian communities, the government of which is by consensus; an absence of the lineage principle in most, if not all, kinship systems; and a lack of formal legal and judicial systems. Both the breaking up and coalescence of communities are common. Violence and warfare, although frequently reported in the literature of now-extinct San, are not characteristic of the present-day hunting-gathering San peoples; on the contrary, their ethics stress cooperation. A detailed description of one of the San peoples follows.

The G/wi people of the Kalahari. The G/wi inhabit the western half of the Central Kalahari Game Reserve and the eastern fringe of the Ghanzi ranches. Fewer than 1,000 G/wi live on the ranches as labourers and their dependents, and another few hundred move into the ranching area during periods of drought. Sporadic trading visits are made at other times in order to exchange the desert produce of game-hide leather for tobacco and iron rods as well as for fencing wire, which is used in the manufacture of tools and weapons. The remaining G/wi people, however, are permanent desert dwellers who have only sporadic contact with Bantu and Europeans and have retained their traditional hunter-gatherer culture.

viron-
nt of
G/wi

The habitat. The G/wi country lies in the centre of the Kalahari Basin, a depression in the vast inland plateau of southern Africa. The basin is covered by a mantle of fine-grained sand, up to 400 feet deep, poor in plant nutrients and of a texture that renders it susceptible to wind erosion, leaching, and scorching. Rainfall is confined to 10 or 12 weeks after midsummer. The country responds with startling rapidity to the first good rains, and within four days the landscape is transformed by a luxuriant growth of grasses and herbs and by the flush of foliage on shrubs and trees.

Rain is the key to all life in the Kalahari. The extreme seasonal variations in rainfall, humidity, and temperature lead to corresponding seasonal contrasts in the amounts of plant and animal food available to hunter-gatherers. There are a few localities in which resources are sufficient to meet the year-round needs of the hunters and gatherers, and these are the areas that the G/wi communities occupy as their territories.

The G/wi world view. In G/wi theology the universe was created by N!adima. He is the owner of all that is and may dispose of it as he wishes. His actions are, however, bound by the natural systems he is believed to have ordained. Therefore, he cannot suspend or reverse their operation.

N!adima is remote from his creatures. They cannot communicate with him or influence his will to their own advantage or favour. G/wi therefore have no religious rites such as prayer, worship, or sacrifice and no priests. They stoically accept N!adima's occasional caprice—*e.g.,* when "he grows tired of a man's face" and sends a marauding lion or some other misfortune to kill him.

G//amama is a less powerful being than N!adima. He sporadically attempts to do harm to man and is often successful, but he can be frustrated by a number of means that N!adima created and man has been able to discover. Several herbal medicines have the power to counter G//amama's influence; certain communal dances also serve to exorcize the evil he is believed to send in the form of invisible, magical slivers of wood.

The logic of the G/wi worldview is that N!adima, having created man, intends him to survive and thus permits him to make use of what is available in the environment to that end, subject to the restriction that N!adima will be angered by wastefulness or greed on the part of those using his property. Man, at least G/wi man, must devise for himself the best means of survival that he can, including the regulation of interpersonal behaviour. Social usages and customs are therefore seen as man-made and not sacrosanct. The stability of behaviour and the predictability of others' actions require agreement by all concerned. Such agreement can be won only by persuasion and ensured by the fulfillment of obligation. It is therefore imperative that individuals and the community remain on good terms with everybody in the circle of social contact.

Social and political organization. The communities, or bands, usually have between 40 and 60 members, the extremes being 25 and 85. They are open communities, in the sense that there are no particular qualifications for membership, but members tend to stay with a group over long periods. Eventually, some catastrophe such as severe drought or epidemic disease (*e.g.,* the smallpox outbreak of 1950) may lead some bands to merge, in order to ensure their members' survival.

G/wi
kinship
and social
structure

The G/wi kinship system is partially classificatory (*i.e.,* it subsumes several different biological relationships under a smaller number of categories). There is also a high degree of equivalence among those classified by the same kinship term. These features allow the kinship system to be applied to persons other than actual kin, including the whole membership of the band. The kinship system can thus be used as the organizing principle of society and, by further extension, to govern relationships between people in different bands.

The kinship system permits not only extension but also truncation: groups can be enlarged by inclusion of new members and also easily split when necessary by substituting other members for those who have left. This is of great advantage to the G/wi. Not only are their bands subject to periodic disasters, but they also grow; in some cases they outgrow their territorial resources and need to be able to split up. The bands normally respond to the decreased density of food resources in winter and summer by reducing their population density. This is achieved by fragmenting into constituent households, each of which goes off into a separate part of the territory and remains there until the approach of the wet season, when food supplies increase again. The organization of the band must therefore compromise between making the community cohesive enough to hold the members together and keeping it loose enough to allow them to separate when necessity dictates.

The kinship system also provides sets of rules for appropriate behaviour. All kin of any individual are either his avoidance or his joking relatives. Behaviour between avoidance relatives is reserved and polite. The avoidance category includes those who are in a relationship involving submission to or exercise of authority—firstly, the parent–child relationship and, by extension, relationships between all those who are classificatorily equated with parents and children. Siblings of opposite sex are in the avoidance category and, by extension, all those whose classificatory relationship prohibits intermarriage. All other kin are joking relatives, among whom behaviour is much less restrained: possessions are freely shared; ribald, bawdy joking is in order; and pointed but friendly criticism of behaviour is permitted in public without offense.

The regular retreat into isolation requires that each household be capable of independent existence for three or four months of the year. This precludes the development of any centralized authoritarian political system either within the band or among bands. Leadership is diffuse and ephemeral, arising in response to specific situations. The function of a leader is to make proposals for action that are acceptable to the members, and he has little power to force agreement. Because of its lack of firm leadership and its equalitarianism, the band would have only tenuous solidarity were it not for the emphasis placed upon harmonious relationships and the fact that social relationships are structured so as virtually to exclude competition.

The G/wi economy. About 30 plant species provide the basis of G/wi subsistence. None is available the year round, the number available at one time varying from 29 in autumn to only four in early summer—of which only two are sufficiently plentiful to make a significant contribution to the diet. The work required in gathering food for a household therefore varies greatly with the season; the more species there are to be taken, the easier and shorter is the search and the greater the number of people able to subsist on the resources of a given area. It is for this reason that the band separates in winter, when the frosts blight the plants and sharply reduce the amount of plant food available. Dispersed in individual households, each exploiting a particular area, the relative load on the food resources is reduced, as is also the amount of work required to gather enough to eat. Just before the onset of the wet season the variety and amount of food plants increase; the band can again reform and resume its normal life as one community, shifting its encampment every three to five weeks to a new supply of plant food.

Means of subsistence

The work of gathering is done mainly by the women and girls. They range over a radius of up to five miles, picking fruits and berries and digging the roots and tubers that comprise about 80 percent of the G/wi diet. A three-foot stick sharpened at one end serves as digging tool and carver. An antelope-hide cloak, worn over the shoulders and fastened around the neck, does duty as a blanket at night. The lower points of the cloak are tied about the waist, forming a bag.

Hunting and trapping is the work of men. They use a light bow and flimsy, unfeathered arrows tipped with poison prepared from the pupae of the beetle *Diamphidia simplex.* Arrowheads were formerly of bone, but most are now made of fence wire hammered by stone into precise shape; the poison is applied just behind the cusps of the arrowhead. Careful stalking is necessary if the hunter is to get close enough to the antelope and small desert mammals to place his arrow effectively and inject a dose of poison. The poison requires between six and 96 hours to take effect, depending on the animal, during which time the animal must be tracked and followed; when killed, its meat has to be carried many miles back to the encampment.

The beetle grubs for making poison can be gathered only in summer, and, since by the middle of winter supplies are usually exhausted, recourse must be had to traps. These are snares, loaded by attaching the free end of the line to a bent-over sapling. The noose is held in place by a trigger, which, when stepped upon, releases the sapling and causes the noose to tighten around the leg of the antelope and hold it until the trapper returns, which he does about four times a day. The monthly intake of meat per person varies from about four pounds (two kilograms) in October, the end of winter, to 15 pounds (seven kilograms) in January, when fresh arrow poison is available and the antelope population is increased by the arrival of migrating herds.

The G/wi have drinking water only for about eight weeks of the year. They meet their fluid requirements at other times from the juices of plants and by drinking the blood and rumen liquor (squeezed-out cud) of antelope; they also drink the amniotic fluid of pregnant does.

Technology

Tools are light and multipurpose. The desert does not provide many raw materials, and migrations between campsites impose a need for easy portability. Iron rods obtained from the ranches are beaten out on stone anvils to make the heads and blades of spears, knives, adzes, and axes. Pestles and mortars are adzed out of wood. Bowls and other receptacles are also carved from wood. Tin cans and enamelware are imported and used as cooking pots, replacing the fragile pottery that was formerly obtained from the Boteti (Botletle) River area and has now become rare. Antelope hides, pegged out to dry in the sun, are scraped clean of fat and other waste and then tanned, using a mixture of plant juices, bone marrow, urine, and rotted brains. The leather of the steenbok and duiker is worked into a fine kid having the softness of cloth and is one of the main commodities of exchange with the bands nearer civilization. Other antelope hides are made into cloaks and skirts or sewn to make bags or sandals.

Shelters vary with the season. The dry-season structure is a roofless windbreak of shrubs, branches, and grass. The wet-season hut is of a beehive shape, made from a frame of branches thatched with clumps of grass. When a band migrates, the huts or shelters are abandoned and new ones set up within several hours after arrival at a new campsite.

(G.Si.)

HISTORY

Southern Africa to 1800

EARLY MAN AND THE STONE AGE

The story of mankind in southern Africa may go back 2,000,000–3,000,000 years. Hundreds of fossils and artifacts found in the dolomitic limestone caves of the Transvaal and northern Cape suggest that for hundreds of thousands of years southern Africa was in the forefront of human development and technological innovation. With East Africa, the subcontinent has seen the evolution of hominids into the beings who, deliberately fashioning tools to a regular and set purpose, are commonly defined as human.

The hominid way of life

For a long time small groups of manlike creatures roamed the open savanna lands of southern and Central Africa, collecting fruits and berries—and perhaps roots—and either scavenging or catching small animals to supplement their diet. During the Early Stone Age the hominids, using first pebble tools and, later, all-purpose stone axes and natural traps, gradually became more skilled as hunters. About 200,000 years ago, with the discovery of the controlled use of fire, the hunting bands were able to make their camps not only in the watercourses in the dry savanna and coastal areas to which they had been previously restricted but also in rock shelters and in the more heavily wooded country of what are now Zambia and Angola.

After hundreds of thousands of years of relatively undifferentiated tools came the experimentation, regional development, and diversification of the Middle Stone Age, dated in what is now South Africa to between 120,000 and 40,000 years ago, with regional variations. Larger, more mobile populations with more varied settlement and subsistence patterns were able to exploit their environment more effectively than before. Over most of the area in this period, the large, crude Acheulian hand axes of the Early Stone Age were replaced by more diverse tools, made by striking flakes off a core into flake-blades and flaked spear points, crescents, and scrapers. Specialized adzes, gouges, and machetes were developed in the forest zone of the Zambezi and Zaire river valleys.

The ever-increasing number of radiocarbon dates available for the Late Stone Age in southern Africa suggest that its new small-blade technology developed from ancestral Middle Stone Age industries between 40,000 and 15,000 BC. In Zambia bored stones for weighted digging sticks and grinding stones suggest a greater emphasis on food gathering, while faunal remains everywhere show that there was a move to the hunting of smaller woodland animals rather than the exploitation of the large gregarious creatures of Middle Stone Age times.

In what is now South Africa, a number of distinctive Late Stone Age industries have been identified. Initially, these industries were based on macrolithic scrapers and the hunting of larger herds of antelope and separated the microlithic cultures of the Middle Stone Age from the widespread microlithic Late Stone Age Wilton industry. From the 7th millennium BC the Wilton industrial complex emerged over a large part of southern Africa and was characterized by the predominance of small convex scrapers and backed microliths. Despite regional variation, it seems to represent a single culture, reflecting changing fashions and local adaptations rather than any cultural or ethnic distinctions among the toolmakers. It was followed during the 1st millennium BC or perhaps a little earlier by another phase of a large scraper-based industry in many parts of what is now Cape Province, Namibia, and perhaps Zimbabwe as well.

Though there is considerable dispute and terminological confusion over the nature of the Middle and Late Stone Age skeletal remains, the Late Stone Age populations of southern Africa encountered in historic times—the Pygmy, San, and Khoikhoi peoples—were basically genetic developments of an ancient African stock that had evolved in the subcontinent. Khoisan remains are associated with the Wilton culture over much of southern and eastern Africa. There is some slight evidence also of a small non-Khoisan population, which may be associated with the stone bowl cultures of East Africa and possibly with the origins of sheep pastoralism in the Cape.

During the Late Stone Age hunter-gatherers appear to have been organized in loosely knit bands, of which the family was the basic unit. By using bows and arrows, often tipped with poison, and a variety of snares and traps, they achieved greater dominance over their environment. With hooks, barbed spears, and wicker baskets, they were able to catch fish and exploit rivers, lakeshores, and seacoasts more effectively. Each group had its own territory, in which special importance was attached to natural resources, and in many instances bands moved from summer to winter camping sites, following the game and vegetation, as they were to do in historic times. It seems likely, too, that the sexual division of labour was much the same as in historic times, with men responsible for hunting, women for collecting plant foods and for domestic chores.

one
ge art

Associated with the Late Stone Age are magnificent cave paintings and engravings on rocky outcrops. Although most of the surviving rock paintings are probably comparatively recent, in Namibia some have been dated to a pre-Wilton industry, while on the southern coast similar paintings are associated with Wilton remains dated to the 6th and 4th millennia BC. Whereas the art in the northern woodlands is stylized and schematic, that of the savanna and coastlands is naturalistic, showing scenes of hunting and fishing and of ritual and celebration. An analysis of the symbolic structure of the paintings suggests their deep religious significance; they also vividly portray the way of life of the Late Stone Age. In the rock art also is the first hint of the new groups of herders and farmers who were to revolutionize the economies and societies of southern Africa.

At a number of sites along the Cape coast and the Orange River, dating from about 2,000 years ago, there is clear evidence of the presence of sheep associated with distinctive pointed base, lugged pottery. Although as yet no cattle bones have been discovered so early, one of the outstanding problems for Late Stone Age research is to elucidate the spread of cattle and sheep pastoralism among the Khoisan.

THE COMING OF THE IRON AGE

The coming of the Iron Age to southern Africa almost 2,000 years ago brought with it the food-producing revolution. Agriculture combined with pastoralism supported far larger settled communities than had been possible and enabled more complex social and political organization to develop; it is with the evolution of these Iron Age farming communities into present-day African societies that the precolonial history of the region is concerned.

The Early Iron Age. Though documentary sources and oral tradition go back at most only 500 years, archaeological, linguistic, anthropological, and ethnobotanical data suggest that the complex of Early Iron Age traits—agriculture, settled village life, ironworking, and pottery—entered the subcontinent in fully developed form in the first half of the 1st millennium AD. The 3rd- to 5th-century-AD dates for Early Iron Age sites deep into South Africa are remarkably close to the first Early Iron Age dates to the north and suggest the rapid spread of the new culture over a very wide area. Although the language of these early farmers is unknown, the chronology and scatter of the Iron Age sites is consistent with what is known of the spread of the closely related Bantu languages spoken in the region today. Thus these Early Iron Age sites probably represent the first settlements of Bantu speakers, the precursors of the majority of the region's contemporary population. (As noted above, despite its widespread misuse, the term Bantu refers solely to this language family.)

Expansion
of Iron Age
culture

This movement into southern Africa was part of a wider expansion of Iron Age culture. Penetrating to the woodlands south of the moist forest zone of Central Africa, Early Iron Age farmers settled in substantial villages in the savanna grasslands, along rivers and watercourses, searching out richer soils. Their economy was based on the cultivation of millet and sorghum, and they had herds of sheep and goats and small numbers of cattle. Thus they avoided both the dangerous tsetse fly belts on the east, and the more arid western half of the subcontinent, which was suited only to a specialized pastoral way of life. There the first Iron Age dates are later than those of the better watered easterly regions.

Most of the Early Iron Age communities in the subcontinent shared a common, if regionally diversified, culture, a phenomenon suggesting the rapid dispersion and proliferation of small trickles of people. As they spread they absorbed the sparser Stone Age peoples, leaving small remnant groups in the southern and western fringes of the subcontinent. In some areas hunter-gatherers may well have adopted the food-producing techniques and even the language and culture of the newcomers. Thus, today the Bantu-speaking peoples of southern Africa are neither racially nor genetically uniform. The old picture of invading hordes of Bantu speakers moving into southern Africa, brandishing iron weapons, and wiping out the earlier inhabitants is not supported by the evidence. In South Africa the close relationship between hunter-gatherers and farmers is manifest at a number of archaeological sites, where Iron- and Stone-using peoples seem to have lived together, and by the presence of "click" sounds from the Khoisan languages in the South Eastern Bantu languages.

From early times Iron Age farmers made use of metals, settled near mineral as well as salt deposits, and engaged in trade, often with Late Stone Age people. Iron implements, such as hoes, and possibly pottery as well, passed from hand to hand, as some communities became known for their specialist craftsmen or settled near exceptionally good iron or clay deposits.

The Later Iron Age. From about the turn of the 1st millennium AD, in some areas of what are now central Zambia, southeastern Zimbabwe, and parts of Malaŵi, the Transvaal, and Natal, changes in ceramic style were paralleled by a change in the location and nature of settlements and a far greater emphasis on cattle keeping and milking. More sophisticated techniques of metalworking, more extensive gold and copper working (perhaps in response to the development of trade with the east coast), and a great extension in stone building suggest the evolution of more complex state structures, increased social differentiation, and new religious and ritual ideas. These changes were, however, neither simultaneous nor evenly spread.

The transition from the Early to the Late Iron Age is still poorly understood. Although many scholars are convinced that the transition is marked by a sharp break, best explained by new arrivals, research on sites in central Botswana and elsewhere suggests that the natural buildup of herds in the Early Iron Age may have provided the catalyst for change.

Importance of cattle

Growing numbers of cattle allowed for the accumulation of wealth in societies where there were few other ways of storing a surplus, and this, in turn, may have led to increased stratification and social control. Historically, cattle have been the main form of bridewealth in much of southern Africa, so that control over cattle has meant control over women and their productive and reproductive capacities. More wives, and thus more children, increased a homestead's ability to expand its agricultural production and its following: this was particularly important in societies where wealth and power were measured in terms not of land but of people. Patrilineal and polygynous cattle keepers had immense advantages over Late Stone Age hunter-herders and over Early Iron Age farmers without the new forms of wealth and social organization.

Greater stratification and more complex social organization were also probably accelerated by the growth of long-distance trading. In the early centuries AD the northeast African coast was well known to the traders of the Greco-Roman world. These contacts diminished with the rise of Islām, and the east coast became part of the great Indian Ocean trading network. By the 8th century Arab traders began to visit more southerly harbours, and between the 11th and 15th centuries they founded some 37 new towns. Though these towns never united politically, they developed a common Afro-Arab, or Swahili, culture and a splendour that amazed the Portuguese when they encountered them at the end of the 15th century.

The Limpopo and Save rivers appear to have been early arteries of the trade to the southernmost Arab trading posts and settlements, with African intermediaries initially bringing ivory, and later copper and gold, to the coast.

Prehistoric mining

From the late 1st millennium AD, the mining of copper and gold had become part of Iron Age culture. In Zimbabwe alone there are more than 1,100 prehistoric gold mines and 150 copper mines, while in the Transvaal there are thousands of iron, copper, and gold mines. While most of these date from the 2nd millennium AD, at Phalaborwa in the eastern Transvaal iron was being mined by the 8th century, and a little later the area became a rich source of copper.

The move from ivory to gold and copper trading is perhaps reflected in the archaeological record with the shift in power from sites like Schroda and Bambandyanelo in the Limpopo Valley, where ivory seems to have been of major importance, to the most prosperous of the Late Iron Age sites known in southern Africa—Mapungubwe, Great Zimbabwe, and Ingombe Ilede, whose prosperity was based on the mining of gold and copper. Although they do not typify the Iron Age as a whole, these sites share certain broad cultural similarities. They appear to be the settlements of a wealthy and privileged trading elite who built with stone and could afford to be buried with gold and copper ornaments, exotic beads, fine Chinese pottery, and imported cloth. Their homes, diet, and ostentatious burials are in stark contrast to those of the common folk, whose dwellings cluster at the foot of the sites where they probably laboured.

Mapungubwe. Located atop a steep hill in the mid-Limpopo Valley in the northern Transvaal, Mapungubwe flourished in the 11th and 12th centuries AD—rather earlier than the more famous Great Zimbabwe, from which site it was long considered a subordinate offshoot. The walling could only have been built by bringing large quantities of stone to the top of the hill, which suggests the organization of considerable labour, while gold and copper came in trade or tribute from settlements about 100 miles away. Mapungubwe therefore represents a far more powerful class-based state than anything witnessed in the area before. Fierce controversy has raged around the racial identity of its occupants. Early excavators refused to accept that it could have been built by blacks. Subsequent work on the Iron Age in southern Africa, however, puts both the skeletal and cultural evidence in the same category as that from other Late Iron Age settlements on the subcontinent, and there is little reason to doubt its association with Bantu speakers.

Mapungubwe's heyday lasted until 1150, and it had all but disappeared 50 years later. By the early 1980s there had been no equivalent site excavated in South Africa, although it would seem that Manekweni in southwestern Mozambique, dated to the 12th and 13th centuries, and Great Zimbabwe, which flourished in the 14th and 15th centuries, represent similar accretions of power based on wealth in cattle, which in turn enabled a preferential access to the coastal trade.

Great Zimbabwe. With 60 acres (24 hectares) of imposing ruins, Great Zimbabwe has dominated the discussion of the Late Iron Age of southern Africa. Long the subject of mystery and romance, the Zimbabwe complex—Great Zimbabwe is the largest and most impressive of more than 150 similar ruins extending from southwestern Zimbabwe into Mozambique—has been clearly established as being of African origin and of medieval date. From about 1300 to 1450 prosperity at Great Zimbabwe led to the import of fine cloth and celadon china, Indian beads, and elegant ornaments. Although the names of the rulers of Great Zimbabwe, the precise extent of their power, and the identity of their people are unknown, they probably were, like the contemporary majority of Zimbabwe's population, speakers of the Shona language.

In the second half of the 15th century the kingdom came to an abrupt end. Its successor in the southwest was the Torwa state, with its centre at the stone-built site of Khami. The new culture that emerged at Khami developed both the stone-building techniques and the pottery styles found at Great Zimbabwe and seeded a number of smaller Khami-type sites over a wide region. The Torwa kingdom seems to have lasted until the end of the 17th century, when it was replaced by the Changamire dynasty of the Rozwi from the central plateau.

Ingombe Ilede. The decline of Great Zimbabwe may also have been associated with the rise of a new trading centre at Ingombe Ilede, in Zambia. It was located in a strategic position on the Urungwe plateau just to the north of the middle Zambezi, and its chief export appears to have been copper, which the local people wrought into finely made crosses and traded over a wide distance. Neither the local people nor their rulers were likely to have been Shona, but they probably drew their supplies of gold from south of the river, and may thus have limited the expansion of Great Zimbabwe.

Other kingdoms. During the heyday of Great Zimbabwe a considerable number of similar settlements on a smaller scale were built by expanding dynasties, probably related to the Karanga ruling group at Great Zimbabwe. As wealthy, polygynous cattle owners, they would have had both the means to expand at the expense of surrounding people and the impetus to send their scions in search of fresh pastures. Between the 13th and 16th centuries dynasties bearing Zimbabwe-type culture expanded in every direction, absorbing earlier non-Shona-speaking peoples. Of these states, most is known about the kingdom of Mutapa, and its offshoots in the eastern highlands of Zimbabwe, because of their encounter with the Portuguese.

Farming communities. If the stone buildings of Great Zimbabwe and its satellites are readily visible remains of state formation in southern Africa, the majority of farmers in southern Africa in the first half of the Late Iron Age were relatively unaffected by long-distance trade and the formation of larger states. Most Iron Age farmers lived in small-scale societies, based on kinship, in which political authority was exercised by a chief who claimed seniority by virtue of his royal genealogy, but who may have risen to power through his access to mineral resources, hunting, or ritual skills. By 1500, Iron Age farming communities had stabilized in roughly their present-day habitats, reaching their ecological frontier on the southern Highveld of South Africa, where rainfall averages 16 to 20 inches annually, and gradually clearing the forests of the southeast coast.

By the time the peoples of the coastlands were encountered by the first literate observers in the late 15th and early 16th centuries, they had acquired part of their contemporary cultural and ethnic identity. This does not mean, however, that these societies were static and unchanging. Within these frontiers there was considerable movement as population expanded and found available resources inadequate. Thus, between the 17th and 19th centuries there was migration of northern and eastern Shona speakers into the centre and south of the plateau, while in South Africa, too, there was colonization of new land by people and cattle. In some areas this inevitably led to conflict as the newcomers came up against settled communities; in others the slow process of absorbing Late Stone Age people was completed, while in yet others the colder, more arid mountain lands were colonized.

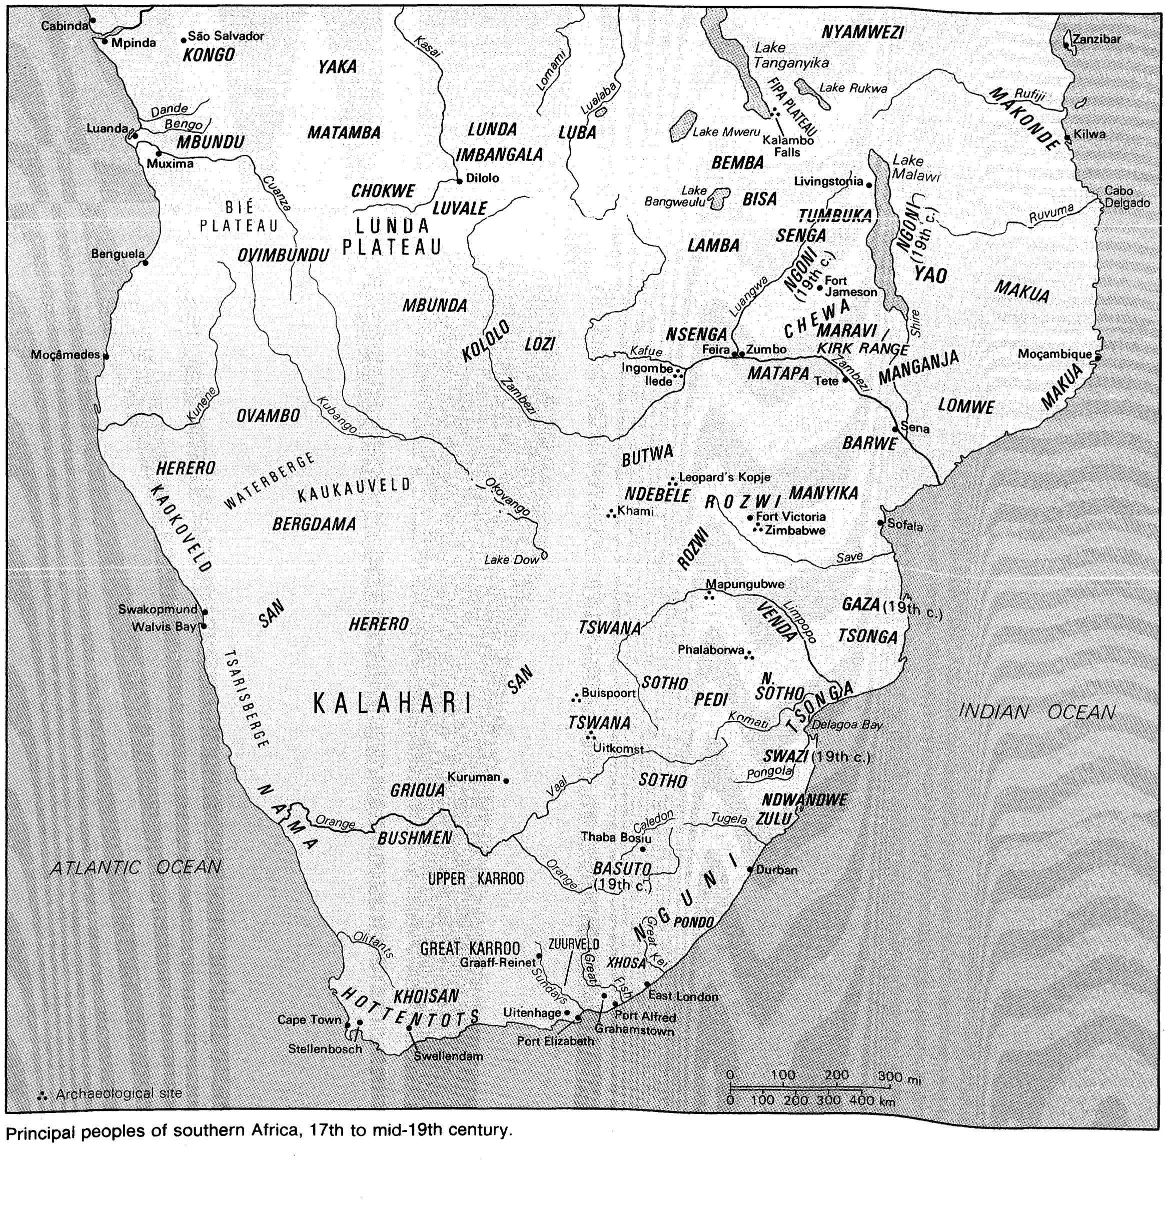
THE PORTUGUESE

In the hope of outflanking Islām, finding a sea route to the riches of India, and discovering additional sources of food, the Portuguese edged their way around the African coast from the 15th century onward. They reached the kingdom of the Kongo, to the north of present-day Angola, in 1482–83; early in 1488 Bartolomeu Dias rounded the tip of the continent; and just over a decade later Vasco da Gama sailed along the east coast of Africa before striking out to India. Within eight years of their arrival, the Portuguese had seized the divided if wealthy centres along the east coast, and by 1507 they had built a fortress and refreshment station on Mozambique Island, which soon became the key port of call for ships on the way to India.

The Portuguese in southeastern Africa. The Portuguese conquests led to the economic and cultural decline of the east coast cities. The Portuguese soon discovered that they were unable to control the vast area they had conquered. They faced resistance from the Swahili communities on the coast throughout the 16th century, and the profits they had expected from the gold trade failed to materialize. In an attempt to control the trade and to discover the precious minerals for themselves, the Portuguese, following in the tracks of Muslim traders from the coast, expanded into the Zambezi Valley. There they penetrated the Mutapa kingdom, with its heartland in the northeast between the Zambezi and Mazoe rivers.

Contrary to earlier historical opinion, there is little evidence to link the origins of Mutapa directly to Great Zimbabwe, nor did it reach the size suggested in some accounts. It was, nevertheless, a considerable kingdom by the beginning of the 16th century, the capital alone containing several thousand people. As at Great Zimbabwe, the gold trade was of great importance, although subsistence depended on agriculture and cattle. The Mutapa kingdom

In the 1530s the Portuguese dominated the trade exits from the coast and had established fortresses at Sena and Tete and trade fairs along the Zambezi River and on the plateau, where Africans came to exchange ivory and gold for beads and cloth. After 1541 Portuguese residents at



Principal peoples of southern Africa, 17th to mid-19th century.

The *prazo* warlords

these outposts elected representatives who were delegated certain powers by the Mwene (or ruler of) Mutapa. Individual Portuguese and Goans were also able to get land grants and judicial rights from local rulers, which enabled them to extract tribute from the local population. Out of these early grants grew the *prazo* system of landholding. Between the 17th and 19th centuries the *prazo* holders became immensely powerful and were able to interfere actively in local African politics and to resist attempts by the Portuguese crown at reform. By then an Afro-Portuguese society had been created in the lower Zambezi Valley independent of either African or Portuguese jurisdiction. Assisted by African and Portuguese soldiers known as the Chikunda, Afro-Portuguese warlords engaged in the slave and ivory trade, unsettling a wide area of east central Africa.

The effect on the Mutapa state of Portuguese traders along the Zambezi Valley was minimal until the late 16th century. The hold of the Portuguese over the Mutapa kingdom was strengthened in part, however, by the sudden irruption of Maravi peoples from north of the Zambezi. They were known as the Zimba, a term applied to any marauding group, and their migrations were probably set off by rivalries among chiefs in southern Malaŵi. They appeared along the Zambezi in the 1580s, attacking Sena and Tete between 1592 and 1593 and then the Portuguese settlements along the coast. By 1601 the Mwene Mutapa was forced to call on the Portuguese, while his attempts to expel the invaders also triggered a widespread and debilitating internal revolt.

In return for their assistance the Portuguese tried to control the Mwene Mutapa, and this proved increasingly disruptive. After an unsuccessful attempt by the reigning Mwene Mutapa to drive them from his domains in 1629, he was replaced by a rival from whom the Portuguese extracted extensive trading and mining privileges. Yet this appearance of Portuguese power and prestige was deceptive; the Portuguese never had the resources to control the interior. It was the Afro-Portuguese *prazo* holders who truly exploited the weakness of the Mwene Mutapa.

The Rozwi kingdom

The rise of the Rozwi kingdom under the Changamire dynasty also undermined the Portuguese presence in Mashonaland. By the late 17th century the Changamire, originally subject to the Mutapa, had expanded over much of central and southwestern Zimbabwe, and may even have had an eye on the Mutapa throne. In response to an appeal from the Mwene Mutapa, who was facing revived Portuguese pressure, the Rozwi swept up the Zambezi between 1693 and 1695 and forced a Portuguese retreat. Despite this, however, Rozwi intervention could not save the Mwene Mutapa from the civil wars that ensued and reduced the Mutapa state to a small chiefdom in the Zambezi Valley lowlands, where it maintained itself into the second half of the 19th century. Elsewhere, the hegemony of the Rozwi was probably recognized over a wide area. Heading a confederacy, which left a great deal of autonomy in the hands of local dynasties, the Changamire had both religious prestige and military power. Wealth was based on the agricultural and pastoral resources of the kingdom, internal tribute, and trade with African neighbours and coastal Arabs, Indians, and Portuguese.

The Maravi confederacy

In addition to gold, the Portuguese were interested in ivory and other mineral resources, particularly after 1700 when the goldfields on the plateau were exhausted. A search for silver mines first led them into Malaŵi in the 17th century, and from that point there is direct, albeit fragmentary, evidence of developments in the region. From Portuguese records it would appear that after a period of upheaval and migrations from the mid-16th century, during which newly arrived Maravi chiefs attacked Portuguese allies and attempted to cross the Zambezi, a single dominant Maravi chiefdom emerged. By about 1620, a single chief controlled the north bank of the Zambezi. During the 17th century Maravi Karonga chiefs of the Phiri dynasty formed a confederacy and exacted tribute from their neighbours. Like the Zimba, the Maravi attacked Sena and Tete and tried to conquer the Mutapa state during the civil wars of the 1620s. Frustrated in these efforts, they invaded Mozambique, where they traded with the Portuguese. By the end of the 17th century the rise of Yao traders to the east of Lake Nyasa (Lake Malaŵi) and of Bisa to the west contributed to the disintegration of the Maravi confederacy into several more or less autonomous fragments. To their north lived Tumbuka-speaking peoples, whose differentiation from the southern Maravi peoples probably dates to the mid-18th century, when new patrilineal migrants entered the region from the north and west.

By the early 18th century the Portuguese had also penetrated into present-day Zambia, establishing trading fairs at Zumbo in 1714 and at Feira in 1732. Though there were no highly organized broker kingdoms in the area, a number of different African peoples were trading with the Portuguese by that time.

From the beginning of the 17th century the Portuguese faced increasingly severe competition from Dutch and British ships in their colonial waters, while north of Cabo Delgado the Arabs also took advantage of Portuguese weakness. In 1631 a series of revolts began, which, by the beginning of the 18th century, had driven the Portuguese from the coast north of the Ruvuma River. The Portuguese then turned their trading interests southward. From the mid-16th century onward, they had been trading at Delagoa Bay with the local Tsonga inhabitants, and difficulties in the north and the decline in the gold trade reinforced this trend. In the late 18th century European competition over the ivory trade and the new market for foodstuffs significantly affected political relationships at Delagoa Bay and in its hinterland and transformed the nature of states as far south as northern Natal.

The Portuguese in west central Africa. Portuguese influence in west central Africa radiated over a far wider area and was far more permanent, dramatic, and destructive than on the east coast. Initially, however, it was on essentially peaceful links forged by the Portuguese crown and Jesuit missionaries with the kingdom of the Kongo, north of present-day Angola. Almost immediately, however, slave traders followed in the wake of priests and teachers, and west central Africa was tied to the demands of the São Tomé and transatlantic slave trade.

The Ndongo

Establishment of Portuguese power. Until 1560 the Kongo kings had an effective monopoly over trade with metropolitan Portugal; the vanguard of Portuguese expansion further south were the Afro-Portuguese traders and landowners who established themselves at São Tomé and in small numbers on the coast. When, in the 1520s, the Portuguese crown turned a cold shoulder to the overtures of the Ndongo kingdom further south, local Afro-Portuguese stepped into the breach. They relieved Ndongo of its war captives and supported the king in his military campaigns. With their assistance Ndongo, originally a small chiefdom among the agricultural Mbundu peoples under rulers called the *ngola,* became a major kingdom by mid-century. By 1556, when it threw off Kongo control, the kingdom extended over a wide area between the Dande, Lukala, and Kwanza (Cuanza) rivers.

By the last third of the 16th century, with the waning of its fortunes in the east and the diminishing return from its mines on the Guinea coast, the Portuguese crown began to take a more aggressive interest in its African possessions. The dispatch of Francisco Barreto in 1569 to discover the sources of gold in the Mutapa kingdom was paralleled in 1575 by the appointment of Paulo Dias de Novais as captain general, or governor, over an undefined area between the Dande and Kwanza rivers, which later became known as Angola. Basing himself at Luanda Bay, Novais soon found, however, that his plans for metropolitan development of the south were defeated by tropical disease, the mythical nature of the reputed silver mines, the unsuitability of the region for agriculture, and strenuous African resistance to settler encroachment.

Though the *ngola* held their own against Novais for a generation, within a few years of his arrival the first war of a century of almost constant warfare had begun. The wars soon resolved themselves into efforts to acquire slaves on Portuguese terms. After his death Novais was succeeded by a series of military governors, who found that they could not break into the existing Afro-Portuguese trading networks that depended on alliances with local rulers. Impelled by the increased demand for slaves for the plantations of Brazil, and relying on African mercenaries and allies, they initiated a policy of armed expansion. For the Ndongo kingdom the results were disastrous, as the political balance was overturned and rival factions turned on one another in an effort to secure the royal title.

Mbangala warbands and the kingdom of Kasanje

Civil violence was compounded by years of bitter drought, a recurrent feature of the local ecology. New warlords emerged at the head of bands of starving refugees, who from the late 16th until well into the 18th century swarmed down from the hills, fought one another, and devastated the settled kingdoms. By the end of the 16th century marauding cannibals in well-organized military bands, known as the Mbangala (Imbangala), began to appear along the coasts south of Luanda. In their anxiety to swell slave numbers in the second decade of the 17th century, Portuguese governors were ready to ally with these war bands, and together they dealt the final blow to the Ndongo kingdom by about 1622. By that time the Mbangala had retreated to the middle Kwango, where they established the kingdom of Kasanje. After the 1650s they reestablished their links with foreign slavers and became the chief slave-trading entrepôt between the coast and the Lunda kingdoms in the east over the next two centuries.

Queen Nzinga

As successful as the Mbangala warlords in surviving these turbulent times was Nzinga, half sister of the *ngola* of Ndongo, who created a new refugee-based state in the middle Kwango Valley based on trading slaves to the east. Nzinga dominated the politics of the region for nearly half a century. After the Mbangala–Portuguese victory of 1622, she attempted to use the Portuguese to secure her leadership in Mbundu politics. When this failed she moved eastward with her followers. Conquering the small Matamba polity, she developed it into a powerful slave-trading centre, with networks reaching north to the Kongo and Luanda and eastward to the Lunda.

Both Nzinga and the Mbangala kingdom welcomed the Dutch conquest of Luanda in 1641, but their relief was short-lived. By 1648 the Portuguese had reconquered Luanda and were thus free to reconsolidate their hold on their African possessions. Nzinga ended her days as a Roman Catholic, collaborating with the Portuguese in the slave trade; in 1681 her successor as *ngola* of Matamba was finally subjugated by the Portuguese, 10 years after the remnant Ndongo kingdom further west had been completely dismantled.

At the beginning of the 17th century, as they were penetrating inland from Luanda, the Portuguese also moved southward. In 1617 they established a colony at Benguela, which, like the Kongo kingdom, was annexed as part of Angola in the 19th century. Expansion inland from Benguela, however, like the initial expansion further north, was spearheaded by Afro-Portuguese slave traders, who used the southerly ports to outflank Portuguese control. As the slave frontier moved south, so the entire process of the construction and then dissolution of the slave-trading warrior kingdoms was repeated. By the 18th century the process had reached the Ovimbundu kingdoms on the lower Cuanza; these came to rival Kasanje as suppliers of slaves. By that time the slave trade from Benguela probably exceeded that from Luanda, with slave routes stretching as far as the Kunene River in the south.

Angola in the 18th century. Through the 18th and early 19th centuries the slave trade remained at the heart of Angola's economic existence, with Benguela replacing Luanda as the chief port. The expansion of plantations escalated the demand for slaves, which peaked in the last third of the 18th century. Routes stretched into the heart of Africa, with most of the trade in the hands of African and Afro-European traders. Rich chiefs and warlords still exchanged their captives for the luxury goods of Europe and for supplies of firearms; for the poor, mass-produced textiles, cheap guns, and the fiery Brazilian alcohol were of the essence.

Cheaper Dutch, British, French, and Brazilian manufactures increasingly undercut the Portuguese, and after 1763 the French became the chief traders on the southwest coast. Portuguese attempts to control the coastal trade and Ovimbundu resistance led in the 1770s to drastic Portuguese intervention in the Benguela hinterland in an attempt to install compliant rulers. By that time the Ovimbundu kingdoms, which probably originated in the late 16th and 17th centuries with the arrival of raiders and refugees from the Mbangala and Mbundu kingdoms, were formidable foes. Despite their military victory, the Portuguese were unable to control them effectively until more than a century later.

By the late 18th century Portuguese fortunes in both Mozambique and Angola were at a low ebb. Fewer than 1,000 settlers in each colony huddled on a number of estates around inland forts and along the Bengo and Dande rivers in Angola and along the lower Zambezi in Mozambique. Most of them had intermarried with local peoples and were independent of Portugal. The metropolitan Portuguese were unable to control either the coastal trade or the activities of merchants and warlords, who often acted in their name. In the absence of regular taxation or an effective system of customs and tariffs, the economies of the territories were poor, and their administrations weak and corrupt. Despite a mythology that held that the Portuguese did not differentiate according to race, from quite early times it is clear that whites had superior status and prestige, if not always greater power, in Angola as in Mozambique. Although both territories gained somewhat from the Napoleonic Wars, it was not until the end of the 19th century that the Portuguese regained anything of their initial colonizing energy.

Effect of the slave trade

It is not possible to compile an exact balance sheet of the devastation caused to west central Africa by the slave trade. In the 17th century some 10,000–12,000 slaves were exported annually from Luanda. Although this includes captives from the north as well as the south of the bay, it does not include those smuggled out in order to escape official taxation. The figure may indeed have represented a relatively small proportion of the total population of a vast area, but it was a significant proportion of the economically active young adults. Nor do these figures take account of the depopulation and social dislocation resulting from incessant warfare and banditry and from the famines whose effects were exacerbated by the withdrawal of productive labour.

The better watered regions were probably able to recoup their population losses within a couple of generations, and the introduction of new food crops, such as manioc and corn (maize), which the Portuguese imported from South America, supported larger populations. Nevertheless, the effect of the slave trade was, in social terms, incalculable. Accounts of Ndongo in the 16th century as rich and populous gave way to lamentations about its desolation in the 17th. And the processes of border raids, wars of conquest, and civil strife, which affected the Ndongo and then the Kwango Valley kingdoms in the 17th century, were repeated both to their south and east in the course of the 18th century as the slaving frontier expanded. The ending of the more overt violence as the slave frontier moved on left the weak—women, children, and the poor—vulnerable to innumerable personal acts of kidnapping and betrayal, a process exacerbated by the indebtedness of local traders to coastal merchants and their dependence on the transatlantic economy.

THE DUTCH AT THE CAPE

Apart from the enclaves of European settlement in Angola and Mozambique, the only other area of European settlement in southern Africa in the 17th and 18th centuries was the Dutch settlement at the Cape of Good Hope. In the late 16th century the Cape had become a regular port of call for the crews of European ships, who found the Khoikhoi (Hottentot) herders there ready to barter cattle in exchange for iron, copper, beads, tobacco, and brandy. By the mid-17th century Khoikhoi intermediaries traded far into the interior. These trade relationships profoundly affected the nature of contact between the Khoikhoi and the Dutch when, in 1652, the Dutch East India Company dispatched Comdr. Jan van Riebeeck and 125 men to set up a permanent station at the Cape.

Although initially intended as a refreshment station, the outpost soon grew into a colony of settlement. In 1657 a number of company servants were released as free burghers in order to cultivate land and herd cattle on its behalf; in the next year the first slaves were imported into the colony, mainly from the East Indies. In contrast to the Portuguese, the Dutch feared to imperil the cattle trade that was the raison d'être of the colony, and they prohibited the enslavement of the local population. At the Cape there was no indigenous slavery, and local chiefs had neither the people nor the power to engage in the trade. Nor did Late Stone Age peoples have the agricultural skills of Bantu-speaking farmers.

Dutch expansion and the trekboers. Although the Dutch settlers, called Boers (Dutch *boer*, "farmer") did not raid the local inhabitants for slaves, they soon undermined the loosely organized social structure of the Khoikhoi by their increasing demands for cattle and by encroachment on their grazing and hunting lands. As one Khoikhoi group became impoverished and reluctant to trade, another would take its place. Though the Khoikhoi offered considerable resistance to Dutch expansion, their small numbers enabled the colonists to move beyond their base at the coast far more easily than the Portuguese had been able to in Angola. Moreover, the Mediterranean climate of the Cape was well suited to European settlement. While the Portuguese in Angola and Mozambique were ravaged by disease, at the Cape the Khoisan were decimated by the epidemics brought by Europeans.

The greatest geographic barrier to Dutch expansion was the range of mountains inland from Cape Town. Once these were crossed, settlers relatively rapidly moved both east and north. There, in the arid scrubland, economic necessity and geography dictated a nomadic, pastoral way of life for the settlers, as it had for the indigenous peoples before them. Poor soil and inadequate rainfall could be compensated for by size, and 6,000-acre farms became the norm.

Apart from sporadic attempts, the Dutch East India Company made little effort to follow the cattle farmers, or trekboers, as they came to be known. The new districts of Stellenbosch (1685), Swellendam (1745), and Graaff-Reinet (1785) were large and unwieldy, and their centres far from the expanding colonists. Central governmental authority was even more remote, and the trekboers were left to their own defense, through the "commando" system. They became accustomed to handling emergencies on their own and to ruling over their slaves, servants, and clients as they saw fit.

European settlers at the Cape

The number of white settlers at the Cape initially grew slowly, then rose rapidly from about 1,000 at the end of the 17th century to about 15,000 by the end of the 18th. Despite their varied origins, company insistence that they all speak Dutch and conform to Calvinism, and their shared vicissitudes, led to a certain cultural uniformity. By the mid-18th century class divisions were marked between the affluent merchants and status-conscious company servants of Cape Town; the "gentry" of the southwest, who were engaged in the intensive production of wine and wheat for the world market, based on slave labour; and the trekboers of the interior, who—though always dependent on the market at the Cape to dispose of their cattle and animal products for arms and ammunition and luxuries—had evolved a semi-nomadic way of life that superficially resembled that of their African neighbours more than that of their kin in the western Cape.

As the settler population increased, so did the number of slaves. Experiments in the use of indentured European labour were unsuccessful, and in 1717 the governing Council of Policy decided overwhelmingly against its continuation. By the mid-18th century about half the free burghers at the Cape owned at least one slave, though relatively few owned more than 10. Slavery at the Cape is commonly regarded as a benign institution, but slave mortality rates were high and their fertility low. Manumission, baptism, and intermarriage rates were also extremely low, although a considerable number of newcomers and poorer burghers married slave women, and even, though more rarely, Khoi women. In the absence of white women, miscegenation with Khoi women was much more common, especially in frontier districts. Their children, however, took on the unprivileged status of their mothers, so that the practice did not affect the racially defined class society that was forming at the Cape. By the late 18th century the Cape society was closed and rigid; most blacks (though not all) were "servants" and most Europeans (though again not all) were "masters."

The existence of an enslaved labouring population affected the status and opportunities of the Khoisan once they lost their land and cattle and had to enter the labour market in increasing numbers. Although theoretically the indigenous inhabitants were "freemen," compulsion governed the relationship between master and servant or slave, and the legal status of the Khoisan increasingly approximated that of slaves. As they lost their cattle and grazing lands, they became virtual serfs on the settler farms, though some groups were able to escape beyond colonial borders. In the east they continued to be absorbed by the Xhosa, while on the Orange River, where they became known as the Koranna and Griqua, they established polities that strongly resembled the republics later established by Dutch settlers.

Khoisan resistance to the Dutch

Despite their ultimate subordination, Khoisan resistance to Dutch colonialism erupted into guerrilla war on three occasions in the 17th century; on the first, it almost destroyed the settlement. Cattle raids punctuated almost every decade of the 18th century, a continuation of this resistance. The raids and counter-raids mounted in violence as the Dutch expanded into the northeast; by the last quarter of the century the entire northern frontier was under arms and numbers of settlers were driven from their lands. The vigour of the Khoisan response to trekboer expansion, especially in the district of Graaff-Reinet, was probably related to the increased involvement of the Cape in the world market, as the demand for cattle by European ships led to more intensive exploitation of labour. The entire colonial order was challenged, and there were fears that the Khoisan would penetrate to the wine and wheat farms of the southwest. Those trekboers not ruined by the robberies were exhausted by constant military service; though they wore the Khoisan down through sheer bloodletting, further colonial expansion northward was prevented for some 30 years.

The Cape's eastern frontier. Settler expansion was simultaneously blocked in the east, where trekboers had come up against the populous and settled agricultural Xhosa people in the area of the Great Fish River. Although trading contact had existed between the colonists and the Xhosa from early in the 18th century, by the 1770s they competed over grazing, water, and the terms of the cattle trade. Demands for fresh meat at Cape Town increased during the Anglo-French wars and the American Revolution; Khoikhoi reserves of cattle had been exhausted, and the trekboers expanded to the edge of Xhosa settlement. Various attempts to draw a frontier between the colonists and the Xhosa were unavailing: when, in 1778, the Dutch decreed the Great Fish River the boundary between the colony and the Xhosa, there were Xhosa in the contested area known as the Zuurveld to the west and trekboers embedded in Xhosa society to the east.

The establishment of the district of Graaff-Reinet, with a full-time magistrate, hardly improved matters. The area of his jurisdiction was vast, and its inhabitants were ill-disposed to listen to a government that had left them alone for more than half a century. Before the 18th century was over, minor cattle raids had escalated into two frontier wars. They were the prelude to a struggle that lasted almost 100 years; the trekboers only expanded again after moving north and outflanking the Xhosa.

Despite the firearms of the Dutch, the two combatants were by no means unevenly matched, for the Xhosa were superior in numbers. Both sides suffered from internal divisions that complicated the struggle. Thus, the first two frontier wars ended in a stalemate.

Southern Africa, 1800–1910

In the 19th century new internal and external forces radically changed the demographic, economic, social, and political configurations established over the previous two centuries in much of southern Africa. Though certain areas remained unaffected by change until the late 19th century, for the area as a whole the first three-quarters of the century brought many new developments. Some, like the rise of the Zulu kingdom, appear to have had a largely internal dynamic; others, like the expansion of European settlement, trade, and missionary endeavour in the interior, were more directly a response to wider transformations in the international political and economic order.

THE MFECANE AND ITS EFFECTS

The first of these changes began toward the end of the 18th century in the area of present-day Zululand, where Zulu were one of numerous Bantu-speaking Nguni chiefdoms, closely related to the Xhosa on the Cape's eastern frontier. Their rise to power in the second decade of the 19th century profoundly altered demographic and political relationships in most of the subcontinent. Their expansion and its repercussions are known in the south as the Mfecane, or Difaqane—the "Crushing." Yet out of the Mfecane new polities were formed, and for those not destroyed by their advent, the invaders brought a challenge and an example of military and social organization they could use in resisting later intruders.

Shaka and the Zulu

Though it has been customary to attribute the warfare solely to the evil genius of Shaka, who became king of the Zulu in 1816, its pattern suggests that the pressure of people and cattle on Zululand's highly differentiated ecology at a time of reduced rainfall gave the rise of the Zulu empire its explosive force. Shaka's internal policies, which attempted to dramatically change existing social and economic relations through population control, lend force to these arguments.

The rise of the Zulu kingdom must also be put in the wider context of the rise of larger states in the region. From the middle of the 18th century the increased demand and price paid for ivory from Delagoa Bay had led to important political and social changes in those kingdoms supplying the market—both the result of attempts by chiefs to monopolize the trade and the increasingly centralized control that elephant hunting gave rulers over the military powers of young men. Out of this grew the *amabutho,* or age-graded regimental system, which became a key feature of warfare in the early 19th century. Access to traded luxuries and control over the *amabutho* enabled those chiefs closest to Delagoa Bay to greatly extend their authority. By the late 18th century a cattle market was established at the bay, and the *amabutho* began raiding their neighbours for cattle. This trend intensified during the severe drought of 1802–03. Whereas in the past population pressure and conflict had led to the colonization of new areas, this option was no longer open by the end of the 18th century. As the skirmishing increased, chiefdoms and fragments of chiefdoms were sent ricochetting off from the centre, only to dislodge their neighbours in turn and thereby increase the circle of disorder at the periphery.

While the opening stages of the Mfecane predated Shaka's accession to power, his military genius lay behind the rise of the Zulu. He used readily available military tactics with originality and within a few years had brought all the peoples from Delagoa Bay to the north and Pondoland to the south under his sway. Out of the numerous chiefdoms between the Tugela and Pongola rivers he welded a highly centralized military kingdom; to the south he created a buffer zone of havoc and destruction.

)rigins of he Swazi

The Ndwandwe under the leadership of Zwide were initially Shaka's most formidable rivals. In 1816 the Ndwandwe had already pushed the Ngwane people and their Dhlamini ruler, Sobhuza, to the north of the Pongola River, where the Dhlamini conquered and absorbed the local Nguni and Sotho chiefdoms and created the Swazi state. Under frequent attack from the Zulu, the Swazi withdrew northward and escaped the fate of those who remained within the Zulu orbit.

By 1820 Shaka had defeated Zwide's armies, which then broke into three groups. Zwide himself retired, but two of his commanders, Soshangane and Zwangendaba, fled northward, to be followed shortly thereafter by Nxaba, Msane, and Ngwane Maseko. Battles among Zwangendaba, Nxaba, and Soshangane on the middle Save River left the last victorious, and he built up the Zulu-type Gaza empire, which at its height stretched between the Zambezi and the Komati rivers; reduced both the Portuguese and the Shona to tributary status; and incorporated many of the peoples of southern Mozambique.

The Ngoni across the Zambezi

After their defeats both Zwangendaba and Nxaba moved to the highlands of Zimbabwe, fighting one another, disrupting the Mutapa and Rozwi kingdoms, and incorporating Karanga peoples. In 1835–36 Zwangendaba crossed the Zambezi, while Nxaba's followers who had joined up with the Maseko Ngoni split in two, one section remaining in what is now Zimbabwe, the other eventually settling in the Kirk Range in the 1860s. From there, they raided a wide area west of the Shire River and, after 1875, to the east of Lake Nyasa.

Across the Zambezi, Zwangendaba's followers raided into what is now Tanzania, Zambia, Malaŵi, and Mozambique, establishing tributary relations with many surrounding chiefdoms and incorporating many of the defenseless Cheŵa, Nsenga, and Tumbuka agriculturalists into their state. After Zwangendaba's death on the borderlands of Zambia and Tanzania in 1843, the Ngoni split into several groups. Two sections settled in Tanzania, and three of Zwangendaba's sons, including Mpezeni and Mbelwa (or Mombera), moved southwestward and southeastward. Having conquered the enfeebled Bisa, Mpezeni clashed fiercely with the Bemba, by then becoming one of the most powerful polities of northeastern Zambia; he finally reoccupied Nsenga country by the mid-1860s.

Mbelwa, with the largest fragment of Zwangendaba's following, moved back into Tumbuka country, where in 1855 he overthrew the local Kamanga chiefdoms, weakened by Swahili slave raiding. Ngoni movements were dictated by the need to avoid the more powerful African polities and to find new food resources after local cattle and crops had been exhausted through their raids. Though the Ngoni aristocracy retained political and social dominance through their monopolization of cattle, there were many tensions between the incorporated peoples and Ngoni commoners. They nevertheless retained their cohesion into colonial times.

Origin of the Mfengu

While the fragments of the Ndwandwe confederacy were making their way into east central Africa, chaos was being spread southward and westward by Shaka's campaigns against the chiefdoms of Zululand and Natal. The ever-widening circle of disorder reached the western Sotho and Tswana groups across the Vaal River, in Botswana, and in the northwestern Cape, as raiders and refugees moved off in all directions. Many went south to join fugitives making their way from Shaka's campaigns in Natal to the territory east of the Cape Colony. All these refugees, whose social structures had been disrupted by the years of warfare, became known as Mfengu (or Fingo). They rapidly emerged as a group of enterprising peasants, many of them converts to mission Christianity and ready to collaborate with the British (see below *British occupation of the Cape*).

Mshweshwe and Mzilikazi

Yet other shattered people scrambled to safety in the mountain fortresses of what is now Lesotho. There Mshweshwe, the Koena leader, built a new kingdom at Thaba Bosiu, based on his ability to provide his followers with raided cattle and protection and a series of shrewd diplomatic marriages. He invited missionaries in as advisers and was able, during his lifetime, to retain a precarious independence for his people.

Other dislodged Highveld peoples joined the Griqua polities along the Orange River or continued raiding along the Vaal and in the western Transvaal, where the disorders prepared the way for the coming of Mzilikazi. He moved out of Zululand in 1823 with 300 of his followers, known as the Ndebele (or Matabele), and over the next 15 years moved westward across the Transvaal in flight from the Zulu armies. Mzilikazi built up a 20,000-strong raiding kingdom by absorbing local Sotho peoples into his regiments. In 1837, after conflicts with the Zulu, with Griqua raiders from the Orange River, and with the expanding white farmers (or Voortrekkers) from the Cape, he led his followers across the Limpopo into what is now southwestern Zimbabwe.

Across the Limpopo, Mzilikazi found it easy to establish himself, for the Shona polities were ill-prepared for the new form of warfare and were weakened by drought. As in the Transvaal, Mzilikazi absorbed the local populace into his age-set regiments; a castelike society evolved, with the original Nguni nucleus on the top, the Sotho in the middle, and the Shona at the bottom. Beyond their immediate settlement, the Ndebele established relationships with surrounding peoples that ranged from exacting regular tribute to random raiding. Beyond the range of Mzilikazi's armies many Shona chiefdoms remained independent; by the 1870s they were trading firearms to resist Ndebele incursions.

The Kololo

Yet another group dislodged by the Mfecane, the composite Sotho group known as the Kololo, made their mark in west central Africa. Defeated in the warfare among the western Tswana, Sebetwane led his followers across the Zambezi, where in about 1840 they conquered the Lozi kingdom, which had been built up in the 18th century and then dominated what is now western Zambia. Weakened by a succession dispute and deserted by its tributaries, the ruling Lozi dynasty was swiftly crushed. Kololo triumph was short-lived, however; by 1864 the ravages of malaria, the accession of a weak and diseased king, and the revival of Lozi royal fortunes put an end to their hegemony. Nevertheless, a variant of Sotho is still the language of the region.

THE SLAVE AND IVORY TRADE NORTH OF THE ZAMBEZI

Long before the beginning of the 19th century, Central Africa was crisscrossed by trade routes to both the east and west coasts. By the second half of the 18th century there was probably a route all the way from Luanda in the west to Mozambique in the east. Until the mid-19th century the Luanda trade was mainly concerned with slaves. With the growing demand in Europe for ivory and the attempted legal abolition of the slave trade in Angola in 1836, however, ivory became the most important export, and Benguela replaced Luanda as the main outlet. At the same time, the Mbangala of Kasanje and the Portuguese traders on the coast were displaced as intermediaries by the Ovimbundu of the Bié Plateau, whose Chokwe neighbours were already renowned as elephant hunters. They penetrated deep into Central Africa, and with their firearms decimated the elephants in one region after another. By 1850 they were in Luvale and Lozi country and were reaching the southern Congo forests.

The ending of slave exports to the Americas did not end slavery in Africa, as local merchants, chiefs, and elders used slave labour to produce the tropical goods demanded by British merchants and to carry to the coast growing quantities of wax and ivory in the 1840s and '50s and rubber in the 1870s. By 1910 wild rubber accounted for 77 percent of Angola's exports by volume. Successful in the short term, the over-collection of wild rubber destroyed an irreplaceable natural resource, while new concentrations of population destroyed the ecology of a drought-prone environment.

Slaves and ivory in east central Africa

In east central Africa the ivory trade was more significant in the 18th century and remained so in the first half of the 19th. It greatly expanded the demand for slave carriers, however, as did the labour demands of the tropical plantations of Réunion, Mauritius, Pemba, and Zanzibar, and later of Cuba and Brazil, at the very time that the abolition movement was at its height. With the abolition of the trade north of the Equator in 1815 and 1817, slaving in east central Africa acquired enhanced significance, while the incursions of the Nguni greatly increased the numbers of slaves available. The Gaza and other Nguni offshoots engaged in the slave trade on a considerable scale, especially in the early years of raiding when they off-loaded their captives at the coast. By the 1830s Mozambique ports were supplying as many slaves as Angola, while the arrival of the Voortrekkers in the Transvaal opened up another outlet. The trade was further augmented by slaves captured by the Chikunda soldiers of the Zambezi warlords, whose rival armies were by the 1840s competing over the Zambezi Valley and over control of trade routes to Central Africa.

Failure of abolition

In both east central and west central Africa, British efforts to abolish the slave trade in 1836 and actual slavery some 20 years later were ineffective until the end of the century. In Angola the attempts led to widespread resistance, and to revolts in Luanda and Benguela. In Angola and Mozambique the external trade was simply replaced by increased internal exploitation of slaves and new ways of extracting forced labour from the African populace. On the east coast British pressure to ban the trade through the sultan of Zanzibar was easily circumvented and, though the abolition treaty forced on the Zanzibaris in 1873 was more effective, the reduced coastal demand for slaves led to even more ruthless methods in the interior of east central Africa, as slaves, no longer needed for export, were exploited locally.

East coast Arabs began to play a much more dynamic role in the interior. Though initially they worked through local chiefs, they came to exercise a wide military and political jurisdiction over the northern routes from their strategically placed commercial centres, many of which became plantations with their own slave labour forces.

The most important area of slave raiding appears to have been in present-day Malaŵi and northeastern Zambia, where predatory overlords, such as Msiri of the Nyamwezi and the Arab Tippu Tib, devastated a wide area from bases in the Congo. To the east of Lake Nyasa, the Yao—keen traders from the 17th century—moved from ivory trading to slave raiding, obtaining firearms from the Arabs, subjugating the Cheŵa agriculturalists, and building up powerful polities under new commercial and military leaders. Similarly, the Bemba were also able to increase their power through the slave and ivory trade, raiding the loosely organized Maravi peoples to the west of the lake from their stockaded villages on the infertile Zambian plateau. Although they never became large-scale slave traders, preferring to incorporate their captives, the Ngoni invaders also added to the dislocation and turmoil. Although the first European observers probably exaggerated the degree of depopulation, the political geography of the region was transformed and vast numbers of people were torn from their social settings.

Arrival of missionaries

It was into this fluid and turbulent world that European missionaries and traders, many of them inspired by David Livingstone, arrived in the 1870s. In 1875 the Free Church of Scotland established the Livingstonia Mission, while the Church of Scotland began work among the Yao at Blantyre. From Lake Nyasa the Scottish missions spread inland to northeastern Zambia, to be followed by a large number of representatives of other Christian denominations in the last decades of the century. In general, the missionaries found that while the weaker, raided peoples quickly adopted Christianity and the education that went with it, people whose livelihood depended on the slave trade were unenthusiastic.

In 1883 the Scottish missionaries and the African Lakes Company (a Scottish-financed firm set up to support the missionary endeavor and encourage "legitimate commerce") persuaded the British government to appoint a consul for Malaŵi and Mozambique, with a watching brief on the slave trade. The British government became increasingly embroiled in struggles with the Arab traders—which resulted in open warfare in 1887–88—and with the Portuguese. With the appointment of Harry (later Sir Harry) Johnstone as consul in 1889, they came to play a more aggressive imperial role in the region.

BRITISH OCCUPATION OF THE CAPE

By the beginning of the 19th century the small Dutch East India Company outpost at the Cape had grown into a sprawling settlement in which 22,000 whites dominated a labouring class of some 25,000 slaves and an indeterminate number of Khoisan peoples, many virtual serfs, as well as a growing number of Xhosa in the eastern districts. During the Napoleonic Wars the settlement passed first to the British (1795–1803), then to the Batavian Republic (1803–06), and then to the British again in 1806.

The substitution of British for Dutch rule at the Cape meant the supplanting of a mercantile company by an imperial state already undergoing the complex economic, social, and ideological changes of its industrial revolution. These developments in Britain had momentous effect at the Cape. Much of the colony's 19th-century history can be seen in terms of the transformation of a company outpost into a more fully capitalist state. The initial impulse behind Britain's annexation of the Cape was to protect its sea route to India. The demand, however, that the colony pay for its administration, produce raw materials for the metropole, and provide a market for its manufactures and a home for its unemployed locked the Cape into the world economy.

Constitutional developments

In its constitutional development the Cape Colony followed the pattern set by Britain's other settler colonies in the 19th century. It was initially a crown colony governed by an autocratic governor, whose more extreme powers were modified by the arrival of some 5,000 British settlers in 1820 and the presence at the Cape of an articulate middle class. After a decade of intense constitutional struggle, the colony was granted representative institutions in 1853. Elections were based on a colour-blind franchise that included Coloured voters (*i.e.,* voters of mixed racial descent) who, it was hoped, would support the British and counteract the influence of Dutch-speaking colonists.

In 1872 the Cape was granted full, responsible government. The colour-blind franchise was retained but came under increasing attack. As a strategy for incorporating the more prosperous black peasants and artisans, it was supported by white merchants, professionals, and officials. With the annexation of African territories and the creation of a mass black working class, however, it proved vulnerable (see below), and in 1887 and 1892 the franchise qualifications were changed in an effort to restrict the numbers of black voters.

Property and labour relations

From the outset, the Cape colonial state intervened to secure and extend existing property relations. Soon after their formal acquisition of the colony, the British attempted to reform the nature of Dutch landholding to immobilize the trekkers, provide the conditions for capital-intensive farming, and raise government revenue through the auction of crown lands. Later, land policy was geared toward fostering independent peasant production among Africans, though by the end of the century forms of individual tenure were encouraged mainly to force out labour.

Indeed, the most dramatic area of state intervention in the 19th century, as in the 20th, was in the creation and control of labour. By the 1820s and '30s the imposition of British notions of "free labour" had an explosive effect on the class relations of a colony dependent on both slaves and serfs. In 1807 the slave trade was abolished in the British Empire, and in 1834 slaves were emancipated. At the same time ordinances were passed attempting to regulate relations between "masters and servants," to ensure standards of treatment and equality before the law, and to transform the basis of the labour supply from serfdom to contracted wage labour. The most important of these measures was Ordinance 50 of 1828, which conferred a degree of civil liberty on the Khoisan while facilitating their movement into the labour market. The "modernizing" policies of the British government threatened the world of the Dutch farmers, and several thousand of them left the Cape Colony between 1834 and 1845 in the movement known as the Great Trek.

Labour and property relations were not simply a matter of internal policy, however. In the 19th century, as in the 18th, the expansion of commodity production led to the extension of colonial frontiers and the conquest and incorporation of the Bantu-speaking farmers to the north and east. By the mid-century the Cape's northern frontier was the Orange River, while in the east the frontier had moved from the Great Fish to the Kei River.

The eastern frontier

The British were also confronted by a series of interlocking crises in the eastern districts. In the space of eight years they were faced with three rebellions by the trekboers of Graaff-Reinet (1795, 1799, 1801) and the third war between settlers and Xhosa on the eastern frontier, which coincided with a mass uprising of the recently subordinated Khoisan of Graaff-Reinet, who deserted with their masters' horses and guns. The British managed to divide the African forces, but were unable to dislodge the Xhosa from Zuurveld.

Although the appearance of regular British troops on the frontier in 1811 pushed the Xhosa west of the Great Fish River and tilted the balance in favour of the settler, in 1819, 1834–35, and 1846 the almost constant unrest there exploded into war. Increasingly the object of the wars was not only African land and cattle but also labour. For most of the century the Cape was dependent on British troops for its defense and for the conquest of African territory. Each conflict pushed the Xhosa closer in on one another, and the tensions between Xhosa chiefdoms grew as the colony extended into the eastern Cape. By mid-century the Xhosa were formidable foes, using firearms and adopting guerrilla tactics. Thus the eighth war in 1851 was the most drawn-out and expensive of all. As in 1799, a simultaneous uprising of Khoisan–Coloured people at the Kat River settlement (established as a buffer for the colony in 1828) exacerbated the situation for the colonists.

In the end, it was not so much British arms or settler prowess that defeated the Xhosa as the internal tensions that had built up as a result of the expansion of traders, missionaries, and settlers. These pressures were increased by the expansion of commercial sheep farming and the arrival of the Mfengu refugees. During the 1834–35 war the Mfengu fought on the British side and were rewarded with Xhosa lands and cattle—a pattern that was to be repeated in each subsequent war. In 1857 the Xhosa—exhausted by years of attrition, in the midst of severe drought, and faced with the aggressive policies of Gov. Sir George Grey—turned to millenarian prophecies. In the belief that to do so would raise their ancestors from their graves to drive the whites into the sea, they slaughtered their cattle and destroyed their crops. When the awaited salvation failed to materialize, some 20,000–30,000 Xhosa streamed across the frontier to seek work in the colony. An equal number died of starvation in the Transkei. Although Xhosa fought the colonists again in 1877 and 1879, by then their lands were impoverished and eroded and many were forced to work in the colony. Thereafter, the annexation of the remaining African territories between the Cape and Natal proceeded peacefully, if piecemeal. The last of the independent kingdoms to pass into Cape hands was Pondoland, in 1895.

If the Cape's eastern frontier saw some of the fiercest and most prolonged resistance to colonial expansion anywhere in 19th-century Africa, it was also the scene of the closest black and white interaction. Trading relations in the frontier zone existed from the early 18th century, and by the 19th, with the coming of the British, trade was expanding rapidly. The terms of this trade were unequal: Africans exchanged their cattle and crops for beads and brandy; yet by the last third of the century, they were earning sufficient cash to purchase the plows, seed, and fertilizer that were transforming African agriculture. The advent of missionaries from the beginning of the century also encouraged the growth of peasant communities, cultivating for the colonial market.

Role of the missionaries

The first converts in the Cape were the Khoisan and mixed groups along the Orange River—the Griqua—and their example was followed early in the century by a number of southern Tswana people. In the eastern Cape, Mfengu refugees were soon the focus of mission activity. By the 1850s the Mfengu were regarded as the most progressive element in the eastern Cape. After the cattle killing of 1857, and even more after 1879, an increasing number of Xhosa also turned to Christianity and to new political techniques with which to confront colonialism. By the last quarter of the 19th century missionaries of almost every denomination were working among the people of southern Africa.

THE ORANGE FREE STATE AND LESOTHO

When the British withdrew from Transorangia in 1854, a far greater proportion of the small settler community was already tied into the world economy through wool production. Many of its burghers (citizens) had trekked across the Orange River before the Great Trek and wished to retain links with the Cape and British economies. After the British withdrawal they established a Volksraad, or parliament, and drew up a U.S.-style constitution. Of a population in 1875 of some 125,000, only the 26,000 whites had burgher status, but many European observers in the 1870s considered the Orange Free State a "model" republic. Despite the Dutch ancestry of the majority of the settlers, English was the language of commerce and education into the 20th century.

Even before the British withdrawal of 1854 there had been constant friction between the Sotho and the settlers over the land. To the east of the trekkers, Mshweshwe had built up a formidable mountain state, and by 1848 he had attracted some 80,000 followers. With the restoration of peace, many hoped to return to their homes, only to find that the Boers had settled their most fertile lands. Overcrowded, the Sotho spilled over onto Boer farms, as well as onto lands occupied by other African groups.

Despite Mshweshwe's attempts to keep the peace, cattle raiding from those of his subjects who saw no hope of recovering their land by negotiation, together with increasing demands for land and labour from the settler-sheep farmers, led to war in 1858 and again in 1865. On the first occasion, the Orange Free State was forced to sue for peace. On the second, Basutoland, starved of arms and torn by internal jealousies, was beaten. Some chiefs, especially in the north, offered their allegiance to the Boers and, with their followers, became labour tenants on their farms; others fled into the Transkei. In 1868, in response to repeated appeals from the Sotho, the governor of the Cape intervened to declare the Sotho British subjects and their land British territory—much to the anger of the Free Staters. Nevertheless, the Orange Free State gained in security and held the Caledon Valley. In 1869 the frontiers of Basutoland were delimited and shortly thereafter it was handed over to the Cape. In 1881, however, when the Cape government tried to disarm the Sotho, a war that the colony could not control broke out, and in 1884 the Cape returned the territory to Britain.

GOLD AND THE SCRAMBLE FOR SOUTHERN AFRICA

Even more important than the discovery of diamonds in transforming the subcontinent was the discovery of vast quantities of gold deep in the southern African interior. While the diamond discoveries had begun a series of social and economic changes, the discovery of gold—and especially the deep seams of gold of the Witwatersrand, or the Rand, in 1886—intensified and carried this revolution far beyond the Limpopo. From the late 1880s, gold outstripped diamonds as the region's most important export, and by 1898 the value of gold production had risen to £16,000,000, about one-fifth of world output.

When local capital resources from the Cape and the diamond mines proved inadequate, new funds flowed in from Britain, Germany, and France. The coastal colonies competed to control the lucrative trade. Immigration no longer needed official encouragement: in 1870 the total white population of southern Africa was probably under 250,000; by 1891 it had increased to more than 600,000; and by 1904 it was more than 1,000,000. Skilled miners were drawn from the mining frontiers of the world to the southern African interior by the lure of high wages.

Mineral discoveries led to economic development in almost every sphere. Roads, railways, and harbours had to be built. The need for coal led to the renewed exploitation of mines in the Cape and the opening of others in Natal and the Transvaal. Farming was commercialized. Manufacturing, though in its infancy, responded to the new markets, and land prices soared. The demand for labour was universal and insatiable. South of the Limpopo, the remaining independent African territories were annexed, and both within and outside the frontiers of the colonial states land, labour, and mineral concessionaires were spurred by prospects of further discoveries and the availability of speculative capital.

The Limpopo constituted no barrier to the flood of concessionaires, and between 1889 and 1895 all of the African territories up to the Congo were annexed. In Central Africa the British competed with the South African Republic, Portugal, Germany, and Belgium. In east central Africa, to the west and south of Lake Nyasa, the thrust from the south encountered the less powerful, but nonetheless still significant, antislavery missionary frontier from the east.

From the 1860s it was known that there were "ancient gold workings" between the Zambezi and the Limpopo. By the mid-1880s Lobengula, king of the Ndebele, was surrounded by concessions hunters. In 1887–88 alarm at possible Transvaal expansion across the Limpopo led the high commissioner at the Cape to declare the region a British sphere of interest. It was at this point that Cecil John Rhodes decided to enter the arena.

Cecil John Rhodes

The story of how Rhodes came to South Africa to repair his frail health and stayed to become a millionaire on the diamond fields before he was 30 is legendary. At Kimberley chaotic underground conditions—the result of the uncontrolled enterprise of individual miners and the unrestricted flow of diamonds to the world market—had led to monopolization. In 1880 Rhodes entered the Cape parliament to protect his interests, and he played a key role in securing the British annexation of Bechuanaland. Backed by international financiers, Rhodes bought out his rivals by 1888 and created the consortium of de Beers. By 1890 he had become the prime minister of the Cape Colony, by far the most powerful man in South Africa.

By 1888 Rhodes was looking to Central Africa to find a "second Rand," open a new area for exploitation, and outflank the increasingly powerful South African Republic. His agents secured exclusive mining rights in Lobengula's kingdom in 1888, and although the king soon regretted his concession, Rhodes immeasurably strengthened his hand by forming the British South Africa Company (BSAC). The company was granted a royal charter by the British government to exploit and extend administrative control over a vast area of southern and central Africa. An amalgamation of London financial interests, bedecked by an array of aristocratic shareholders, the BSAC represented the most naked exploitative enterprise.

British South Africa Company

Even before his charter was ratified, Rhodes was encouraged to stake his claims across the Zambezi, where the British were anxious to preempt their European rivals. In 1888–89 there was a flurry of treaty making by Rhodes's agents. These included Harry Johnston, who had been appointed British consul in Mozambique. A major objective was Msiri's kingdom in Shaba (Katanga), where the existence of rich copper deposits was already suspected, but Rhodes and Johnston were anxious to extend imperial hegemony over as wide an area of south central Africa as possible. None of Rhodes's agents persuaded Msiri to grant the BSAC concessions, and in the following year Shaba was forcibly annexed to the Congo Free State (now Zaire). Nevertheless, the whole of present-day Malaŵi and Zambia was staked out for crown and company.

The precise nature of the treaties and their dubious legality was of little importance. In general they secured mineral and sometimes land concessions for the BSAC, while the chiefs agreed to accept British jurisdiction over non-Africans in their domains and over external relations. But the frontiers of Africa were by then being decided in the chancelleries of Europe, and there the treaties provided useful bargaining counters. In 1890–91, British, Portuguese, and German conventions essentially established the frontiers of the modern states of Zimbabwe, Mozambique, Malaŵi, and Tanzania in the east and of Zambia, Angola, and South West Africa in the west.

For the British government the BSAC's great advantage was its promise to people Central Africa with white immigrants who would make British occupation effective against contending European powers and bring the necessary capitalist development to the interior at minimum cost. In 1890 Rhodes sent a "Pioneer Column," consisting of 200 white settlers and 150 blacks, backed by 500 police, into Mashonaland. From the outset, the real goal was the Ndebele kingdom. In 1893, to solve the company's financial problems, its resident commissioner, Leander Starr (later Sir Leander Starr) Jameson, deliberately provoked war with the Ndebele. The war was followed by a boom in BSAC shares and the flotation of several new speculative mining companies, with the BSAC receiving a half-share

Invasion of the Ndebele kingdom

in any profits. Yet, by the end of 1894, it was clear to Rhodes that the "second Rand" was not in Matabeleland, but on the Rand itself, where new deep-level mines were coming into operation. As their hopes of instant wealth through gold waned, so settlers and the BSAC turned to African cattle and land.

Settlers who participated in the war were granted farms on a lavish scale and in addition were rewarded with mineral claims, both of which soon passed into the hands of speculative syndicates. A land commission perfunctorily set aside two reserves for the Ndebele on poor soils. Vast quantities of African cattle were looted, and forced labour and taxation were prized out of both Shona and Ndebele communities by the newly formed Native Affairs Department and unpopular Ndebele police.

Ndebele
nd Shona
prisings

The Ndebele rose in March 1896 when an outbreak of rinderpest ravaged what was left of African cattle and the BSAC removed its police in anticipation of an attack on the South African Republic (see below *The South African War*). The Ndebele were joined in the middle of the year by a number of eastern Shona polities. Only the arrival of imperial troops and the collaboration of other Shona groups saved the company state. The Chimurenga, as the uprising was called by Africans, led to direct British government intervention in BSAC affairs for the first time with the appointment of a British resident commissioner in Bulawayo responsible to the imperial high commissioner in Cape Town.

Despite the hopes of the British government that the BSAC would effectively occupy the territory north of the Zambezi, these events left Rhodes little time, energy, or resources to spare until the late 1890s. Opposition from the missionaries and the African Lakes Company ensured that the region around Lake Nyasa and the Shire Valley was separated from the BSAC sphere; it was declared the British Central African Protectorate in 1891, with Johnston as commissioner. During the early years of the protectorate Johnston engaged in a spate of wars against the Swahili and Yao slave and ivory traders, who feared the loss of their livelihood. Given the ethnic fragmentation and social divisions of the region, he found little difficulty in implementing a policy of divide and rule. His antislavery wars had the advantage of releasing labour for European employment. His vision was not dissimilar to that of Rhodes: the protectorate's future development should be based on the marriage of white enterprise and black labour, assisted by Asian middlemen.

Lewanika
and the
Lozi

West of the protectorate Africans were more gradually drawn under colonial rule. Neither the BSAC nor Johnston had time to pay attention to the pleas from the Lozi king, Lewanika, that the British honour the treaty he had signed with Rhodes's agent in 1890, in which he had been promised technical and financial assistance in exchange for mineral concessions. Lewanika's "scramble for protection" in the 1890s was dictated from the same circumstances that initially led him to invite whites into his kingdom in the mid-1880s. The 20 years after the restoration of the Lozi monarchy, after the Kololo interregnum, had been filled with civil war and succession disputes. By inviting in the missionaries, and subsequently the BSAC, Lewanika hoped to bolster his internal position and gain the skills to enable him to deal with the intruders.

Finally, a BSAC administrator was sent to the Lozi kingdom (Bulozi) in 1897. Contrary to Lewanika's expectations, his arrival spelled the end of Lozi independence. Although his choice of manoeuvre and accommodation, rather than resistance, and the lack of minerals in his domains meant that he secured a protected status from the company, over the next decade the powers of king and aristocracy were whittled away. British insistence on the abolition of serfdom and slavery in 1906 undermined the cultivation of the floodplain on which Lozi agriculture depended, and Lewanika's hopes to retain control over the modernization of his state were in vain. Bulozi became a protectorate within a protectorate, tied to the southern African political economy.

In northeastern Zambia, too, the process of imposing colonial rule was later, but in the end swifter and less violent, than it had been to the south or west. A series of natural disasters in the 1890s weakened the ability of even the more powerful groups to resist, while for the others BSAC rule seemed a release from the raids and exactions of their Bemba, Ngoni, and Swahili overlords. Above all in this region, however, it was the lack of resources that spared people major confrontations with colonialism: in the one area where gold was believed to exist, among Mpeseni's Ngoni, the onslaught was as dramatic as in Zimbabwe and the expropriation as brutal.

THE SOUTH AFRICAN WAR

It was in the south that the most bitterly fought and costly colonial war of the period took place. By 1895, despite the progress of his plans all over southern Africa, Rhodes's hopes of gold in Matabeleland were disappointed and the development of his deep-level mines on the Witwatersrand were a heavy drain on capital. The South African Republic's inability to adequately create and coerce a labour force and its liquor, railway, and dynamite policies were irksome to the deep-level mine owners with their huge demand for labour, tight working costs, and great need for explosives. Making use of the largely fomented clamour of British immigrants in the Transvaal, known as Uitlanders ("aliens"; *i.e.,* non-Boers), over their lack of voting rights, and with the full knowledge of Joseph Chamberlain, the British colonial secretary, Rhodes plotted the armed overthrow of the republic by his lieutenant, Leander Starr Jameson.

The Jameson raid

The affair was a complete fiasco. The hoped-for uprising of Uitlanders failed to materialize, and Jameson was soon arrested by the Boers. Rhodes was forced to resign from the premiership of the Cape Colony, and the alliance he had constructed between the English and Afrikaners in the Cape was destroyed. Cape Afrikaners united behind the republican Pan-Afrikaner opposition to British imperialism. The dispatch of Sir Alfred Milner as British high commissioner to South Africa in 1897 exacerbated matters and Paul Kruger, president of the South African Republic, began to rearm. The war broke out in 1899 and lasted until 1902. In all, nearly 500,000 British troops were deployed against a Boer force of 60,000–65,000, at a cost to the British taxpayers of £222,000,000. Some 6,000 British soldiers died in action, another 16,000 of infectious diseases. The Boers lost some 14,000 in action and 26,000 in so-called concentration camps. The camps left a deep scar on Afrikaner consciousness and led the British Liberal leader, Sir Henry Campbell-Bannerman, to refer to his country's "methods of barbarism." The total number of African dead is unrecorded, although according to low official estimates more than 13,000 died in the camps. In the end, Britain's greater resources wore the Afrikaners down, and their leaders were forced to sue for peace, which was signed on May 31, 1902.

The clashes between Kruger and the representatives of British imperialism—Rhodes and Milner—are usually portrayed in personal terms, but the issues were essentially economic and political. The struggle was for supremacy over the richest gold mines in the world, and a leading role was played by the most important mining houses on the Rand. While strategic calculations played a role, essentially the Jameson raid and South African War (Boer War) were designed to eliminate the dangers of foreign intervention in the subcontinent and to substitute a state in the Transvaal that could fulfill the demands of the deep-level mining concerns.

Even before the war was over, Milner had appointed a group of young men from Oxford University to "reconstruct" the Boer states: the most serious grievances of the mine magnates were removed and an efficient bureaucracy was established. Central to Milner's plans was the smooth functioning of the mining industry for political and economic reasons. An acute shortage of African unskilled labour was resolved by the importation of 60,000 Chinese, despite the bitter opposition of white workers, and ambitious schemes were set on foot to reduce the cost of both black and white labour. Tax and pass laws were made more efficient and settler agriculture was improved. By 1906–07 the British were sufficiently confident of the new order they had established to grant self-governing institutions to the conquered territories. Although much British propaganda before and during the war had been concerned with the political rights of British subjects, regardless of colour, in neither of the colonies were these extended to blacks.

ANGOLA AND MOZAMBIQUE

The discovery of minerals in the southern African interior in the late 19th century was accompanied by a reassertion of Portuguese colonial ambitions, although a more active colonial policy predated the scramble for Africa by a few decades.

Attempts at plantation agriculture

From the mid-19th century attempts were made to foster plantation agriculture, and a certain amount of Portuguese capital began to enter the colony. Land grants were made in the Luanda hinterland, and planters experimented with coffee, cotton, cacao, and sugar, using the slaves who could no longer be exported. In the absence of an adequate administration or communications network, the plantations in Angola were never highly successful, although coffee cultivation spread among African peasant farmers in the region. The appropriation of land for plantations was resisted, and Portuguese attempts to expand their colonial nucleus led to a series of wars with African peoples, followed by famine and epidemics. The instability of the last decades of the 19th century paved the way of the colonial period to follow.

Portuguese attempts to develop Mozambique along capitalist lines met with even less success, given the lack of investment and the disorder that prevailed in the 19th century. This was exacerbated in the last decades of the century by the escaped slaves, soldiers, and porters who formed bandit bands in broken country in both Angola and Mozambique and attacked Portuguese settlements and African villages alike. In many areas domestic slavery underpinned the migration of young men to the labour markets of the south.

Liberal governments in Portugal from mid-century were anxious to outlaw the feudal aspects of the *prazo* system, but they were unsuccessful despite four military campaigns. The declaration in 1880 that the *prazos* were crown property brought little change. Until 1895 the Gaza kingdom controlled a wide area between the Komati and Limpopo rivers, while the Portuguese had little authority over Africans in the rest of the territory. The only bright spot in Portuguese fortunes in southeastern Africa was the growing prosperity of Delagoa Bay, as trade with the Transvaal increased. In 1875 Portuguese rights to the bay were formally recognized and, with the discovery of gold on the Witwatersrand, the bay acquired a new importance as its closest outlet. In 1888 Lourenço Marques became the capital of the territory, and the focus of Portuguese colonization shifted south.

Portugal's colonial aspiration

The late 19th-century scramble for African territories threatened even those territories the Portuguese considered theirs by historic right. The mineral discoveries, and knowledge that there was copper in Shaba, revived Portuguese dreams of linking their African territories. But

Portugal received short shrift from the other imperial powers. At the Berlin West Africa Conference of 1884–85, Portugal received the Cabinda exclave and a portion of the left bank of the Congo—considerably less than it had claimed. In 1886 the Portuguese ceded the Cunene–Okavango frontier between South West Africa and Angola, hoping to gain German diplomatic support for their colonial ambitions. Portugal fared even worse in the hinterland of Mozambique: with the declaration of the British Central African Protectorate and the expansion of the British South Africa Company in Southern Rhodesia, its economic hinterland was in the hands of the British. The instability of Portugal led the British and Germans to draw up a treaty to partition the Portuguese colonies between them should it be forced to give them up, and until World War I this remained a possibility.

Portugal nevertheless acquired about 800,000 square miles (2,000,000 square kilometres) of African territory, of which it controlled about one-tenth. In both territories "pacification" became a sine qua non of economic development, and there were military campaigns or police actions in almost every year between 1875 and 1924, a measure of Portugal's weakness as a colonial power. The greatest resistance came from those people with the longest experience of Portuguese rule and with the necessary firearms. In Angola the major campaigns were against the Kongo, Mbundu, and Ovambo peoples; in Mozambique, in the Zambezi Valley, and among the Islāmized Makua and Yao people. It was only the war against the already weakened Gaza kingdom in southern Mozambique that achieved rapid and dramatic success.

The majority of Portuguese troops in both territories were black, a situation that turned every campaign into a potential civil war. This, together with the fragmentation of political authority, the resistance of traditional elites who were threatened by colonial rule, and the precipitate introduction of tax and forced labour policies, made resistance in the Portuguese colonies the most prolonged in early 20th-century Africa.

The colonies were of particular importance as a market for Portugal's textiles and cheap wine, and tariff barriers were erected to protect Portuguese manufactures. Starved of capital and wracked by financial crises, Portugal planned to develop the colonies by attracting immigration and foreign capital. In both colonies, considerable tracts of land were granted to chartered companies with wide mining, agriculture, and commercial concessions. In Mozambique these companies, based on the old *prazos,* controlled more than half of the colony. None brought the anticipated level of development, and in both colonies it was the recruitment of migrant labour for South African, Rhodesian, and German enterprise that provided revenue for tax and trade.

THE GERMANS IN SOUTH WEST AFRICA

The Germans were the last imperial power to arrive in Africa, annexing South West Africa in 1884. An Anglo-German commission settled the frontiers of the new territory in 1890. The annexation signalled a change in Germany's colonial policies, accelerated the scramble for southern Africa, disturbed British hegemony in the region, and aroused fears of an alliance between Germany and the South African Republic.

nker frikaner

A vast, arid region, South West Africa was sparsely populated by pastoral Nama and Herero people in the south and centre and by the more densely concentrated agricultural Ovambo, who straddled the frontier with Angola in the north, as well as by scattered San and Bergdama (Damara) hunter-gatherers. Throughout the 19th century communities of Khoikhoi and Oorlam (mixed Khoikhoi-slave groups displaced from the Cape by colonial expansion) made their way into South West Africa, increasing the competition for water and grazing land. Initially, small groups of Oorlams settled peacefully on land granted them by the local populace, some of them establishing mission communities. Jonker Afrikaner, however, who brought his well-armed followers from the Orange River in the 1830s, significantly altered the political balance of power in the region. Responding to an appeal for assistance from the Nama, who were being pushed out of their grazing lands by Herero expansion, he settled at Windhoek. Gaining control over the all-important trade routes from Walvis Bay and the Cape Colony, he ensured Nama dominance over the Herero until his death in 1861.

Conflict between the Nama and Herero was exacerbated from the mid-19th century by the increasing tempo of the cattle and ivory trade from the south. As both sides acquired increasing numbers of guns, the conflict between them became even more destructive, and, apart from a breathing space between 1870 and 1880, it continued from 1863 to 1892, opening the way for German annexation and pacification.

Nor were the Ovambo to the north immune to the effects of the accelerated cattle and ivory trade. Initially trading in salt, copper, and iron from the Etosha Pan region to the north, and supplying hides and ivory to Portuguese traders, they had been largely able to stand outside the slave trade that ravaged their more populous neighbours. In the mid-19th century the volume of the ivory and cattle trade increased, only to collapse as the elephants were exterminated in the 1880s. With the firearms they had acquired through the trade, the Ovambo raided for cattle and people, and new warlords further destabilized the region.

Hendrik Witbooi

The Germans initially hoped to exploit the territory through a concession company, but it proved incapable of raising the necessary capital. The German government was increasingly forced to intervene, especially when settlers appropriated Herero cattle and grazing lands. The most formidable opponent of the Germans was Hendrik Witbooi, the Nama chief who tried unsuccessfully to unite the Herero and Nama against the Germans. He was defeated only in 1894, after a lengthy guerrilla war.

An outbreak of rinderpest that decimated African cattle, the alienation of the better watered highlands, unfair trading practices, and increasing indebtedness, together with the absence of legal redress, led in 1904–07 to an uprising of the Nama and Herero peoples. They were ruthlessly crushed: the Herero population was reduced from 70,000 to 16,000, many of them dying in the desert in an attempt to escape. The Nama were reduced by two-fifths. Although South West Africa was then open to European exploitation, the handful of settlers had to look for labour to the Ovambo in the north (only formally brought under colonial rule in 1915) and to the British territories. German rule lasted until World War I, when South West Africa was conquered by South African troops. After the war, South West Africa was transferred to South Africa as a mandate of the League of Nations.

The political economy of southern Africa, 1910–45

By the beginning of the 20th century new frontiers had been created that became the boundaries of modern states. The penetration of capital throughout the subcontinent wrought vast changes, though north of the Zambezi and in the Portuguese territories they were initially less dramatic. The exploitation of minerals, the capitalization of settler agriculture, and the establishment of manufacturing industries drew Africans into the world economy as workers and peasants, transforming old and creating new classes and political alignments.

Although everywhere the majority of Africans on the subcontinent lived by farming, south of the Limpopo the century-old battle over land had been won by settlers, though increasingly crowded pockets of land were reserved for Africans in the Transkei, Zululand, and the three protectorates that became High Commission Territories (Lesotho, Botswana, and Swaziland). In the reserves and protectorates government made use of African political organization, creating "tribes" where these did not exist and governing through compliant indigenous chiefs and headmen. The priority of every colonial administration was to raise taxation, which brought in revenue and pushed out labour, already a well-established expedient in South Africa. By 1910 Africans north of the Limpopo were all subject to taxation and inroads were being made on their lands.

Union of South Africa

In the south, where this process had gone furthest, settlers increased their hold through the unification of the South African colonies, creating, by 1945, the most highly industrialized state in Africa. The Union (later Republic) of South Africa, formed in 1910, has dominated its neighbours for much of the 20th century. International capitalist expansion northward was paralleled by vast labour migration to the mines and farms of South Africa.

In the early 20th century by far the most dramatic demand for labour came from the mines of South Africa, and it was there that much of the subsequent pattern of southern Africa's industrialization was established. In the 19th century a migrant labour system had evolved in the diamond and gold mines of South Africa, the result of struggles between traditional ruling groups and the new mine magnates over the labour power of young men. This was expensive so long as Africans had access to land and a state sufficiently powerful to create a proletariat and control desertion was lacking. By the end of the 19th century a nexus had grown up to control the work force through the compound system (first established to bring down labour costs at Kimberley between 1885 and 1887), pass laws, and masters' and servants' legislation. Similar institutions came to characterize the mining industries to the north, and the advantages of a work force of unorganized migrant labourers whose welfare and reproduction costs were borne in the reserves became more clear.

Demands for African labour on the Witwatersrand went far beyond the frontiers of South Africa. In 1889 the Chamber of Mines was formed in the Transvaal with the object of controlling African wages. It formed two major recruiting organizations to monopolize the labour supply, and by the early years of the 20th century its recruiters had spread north of the Zambezi.

In all the territories the economic exploitation of blacks was facilitated by the development of a racist ideology. Discriminatory policies were prompted by settlers' fears of the growth of African class consciousness and competition; they were lent respectability by anthropologists and paternalist administrators anxious to preserve African societies from rapid social change. Though "native policy" in the Portuguese territories was theoretically designed to assimilate Africans to a Portuguese way of life, obstacles to progress for the Afro-Portuguese and acculturated elite were enforced more in the 20th century than they had been in the 19th.

SOUTH OF THE LIMPOPO

With the granting by 1907 of self-governing institutions to the conquered Transvaal and Orange Free State, the way was open for the unification of the South African colonies. In 1910 the Union of South Africa was formed, dictated largely by the mineral revolution. Weak, with their economy dominated by foreign capital, 1,250,000 enfranchised whites nevertheless achieved political control over 4,250,000 Africans, 500,000 Coloureds, and 165,000 Indians.

High Commission Territories

There was talk of incorporating the landlocked High Commission Territories of Basutoland (now Lesotho), Bechuanaland (now Botswana), and Swaziland into the union. The opposition of their African inhabitants and of the humanitarian lobby, as well as Britain's desire to maintain a toehold in the region, however, prevented this. In a schedule to the Act of Union, conditions for their ultimate inclusion in the union were set out. This included the continued nonalienability of African lands, although in Swaziland in 1907 the British government confirmed the grant of one-third of the land to settlers and speculators on the basis of temporary concessions granted by the Swazi king in the late 19th century. Only Swaziland had a substantial number of white settlers.

Until the mid-20th century both Britain and South Africa assumed that the protectorates would ultimately become part of the union. Although this did not happen, the territories were fully locked into South Africa's regional economy through the migrant labour system and highly discriminatory tariff policies. All three territories, which had been grain and cattle exporters at the turn of the century, became increasingly dependent on the South African labour market, especially after measures were implemented by the South African state to protect white farmers. Administrators were often South African, and the form of indirect rule practiced left little room for political progress. This dual administration, as well as the dependent economies, was severely castigated by the Pim Commission of 1934–35, but despite modest reforms the territories remained poor and neglected.

Acquisitio of South West Africa

After World War I the union acquired South West Africa. Despite a League of Nations mandate that the territory be administered as a "sacred trust" for its indigenous inhabitants, white settlement was encouraged and subsidized, and the Africans never regained the land lost to the Germans. In 1922 the Nama and Herero were confined to reserves and subjected to police checks and pass laws. Although their reserves were large, they were located in the dry hinterland of the Kalahari or on sandy veld unsuited to man or beast. By the 1930s some 30,000 settlers (mainly from South Africa) controlled all of the potentially fertile, watered land, more than one-third of the total.

The main concern of the mandatory power was to foster international mining capital, which dominated the economy, and to subsidize white settlement. The Permanent Mandates Commission of the League of Nations constantly criticized the lack of economic and educational development for Africans and the violent confrontations between the South African government and the Africans. This had little effect and culminated in the withdrawal of the mandate by the United Nations in 1946, with even less effect.

White politics in the union

In the early 20th century international mining capital dominated the political economy of the union as well, though it had increasingly to come to terms with commercial farming and the growing manufacturing sector. The white population was divided by both class and ethnicity, and the years after union were turbulent, with major strikes by white workers on the Rand and a civil war between Afrikaners when South Africa joined Britain in World War I. Afrikaner nationalist feeling had been aroused in the aftermath of the South African War and was deliberately fostered in the years that followed by the Dutch Reformed Church and Afrikaner intellectuals. Poorer Afrikaner farmers and the northern petty bourgeoisie, as well as English-speaking workers, felt their interests were ignored by the South African Party (SAP), which held parliamentary power under the leadership of Louis Botha (1910–19) and Gen. Jan Smuts (1919–24). The SAP's essential aims were to promote capitalist farming and mining interests, maintain the imperial connection, and reconcile English and Afrikaans-speaking South Africans. In 1913–14, Gen. J.B.M. Hertzog broke away from the SAP to form the Afrikaner National Party.

Native Lands Act of 1913

For white farmers, mining capital, and industrialists, the crucial issue continued to be labour. In 1910 about 40 percent of the African population lived on reserves and about the same number lived on white-owned farms, either as labour- or rent-paying tenants or as sharecroppers. The mining industry wanted the reserves as the home base of migrant labour, while white farmers demanded the reserve lands for their own use, the elimination of competition from African peasant producers, and the reduction of various forms of tenancy to labour service. These objectives were reconciled in the Native Lands Act of 1913. Under this and the supplementary Native Land and Trust Act of 1936, about 12–13 percent of the land was scheduled for more than 4,000,000 Africans, while 87 percent was reserved for 1,250,000 whites. In the interests of the mining industry, the existing reserves were recognized, while Africans could only remain on white-owned land as labour tenants, subject to the masters' and servants' legislation. The land acts were part of a battery of legislation aimed at assisting and subsidizing settler agriculture at the expense of peasant production.

White working class

Maintaining the reserves and improving agricultural production was one way of reducing mining costs; another was by reducing the high wages of skilled white workers, who came increasingly to play a purely supervisory role over Africans, while the Africans replaced the whites at lower pay. In 1907, 1913, and most seriously in 1922, white miners struck work. In defense against their structural insecurity, they did not attempt to join hands with black workers, but demanded a colour bar that protected certain jobs for white workers only. Initially formulated by the Milner administration to reconcile white workers to the importation of Chinese labour, this was formally established under the Mines and Works Act of 1911 and its amendment in 1926. The years immediately after World War I saw a rising tide of worker militancy among both blacks and whites, the result of wartime inflation and postwar depression, with a series of strikes and the formation of the South African Communist Party in 1921. In 1922, at a time of falling gold profits—and, in part, in response to a massive strike of black mine workers in 1920—the Chamber of Mines challenged the job colour bar. White miners struck, martial law was declared, and a five-day battle between white workers and troops on the Witwatersrand ended with 230 dead and the ringleaders hanged.

The 1922 strike brought to a head growing disaffection with the South African Party, which had merged with the Unionists, the party of big capital, in 1920. In 1924 an alliance of Hertzog's Nationalists and the predominantly English-speaking Labour Party removed Smuts from office. Between 1924 and 1929 the "Pact" government made a number of concessions to white workers and incorporated them into the state through industrial conciliation machinery. This largely removed the political danger from white miners. Through raising tariffs and adding a nationalized Electricity Supply Commission to the state-run Iron and Steel Corporation established by Smuts, the Pact government promoted the interests of the manufacturing industry while attempting to resolve the problem of white unemployment.

For its nationalist constituency, Afrikaans was recognized as the second official language of South Africa (replacing Dutch), and a new flag and national anthem were established after great acrimony. At the same time, partly as a result of Hertzog's efforts, the nature of the connection with the British Commonwealth was redefined in 1926 and 1930.

Although the Nationalists won the 1929 elections, they were gravely weakened by the gold standard crisis in 1933. Hertzog formed a coalition government with Smuts and in 1934 their parties fused to form the United Party. South Africa's departure from the gold standard and the enormous rise in the price of gold enabled the new government to use the taxation from gold profits to foster secondary industrialization on an unprecedented scale, to subsidize white farming, and to largely resolve the "poor white" problem.

Poor
hites"

From the beginning of the 20th century the stream of black migrants making their way into the towns was paralleled by a stream of Afrikaners displaced from the land by capitalist agriculture. By 1930 one in five was classified as "poor white." Unskilled and semiliterate, they were in direct competition with Africans, some of whom had more industrial skills. Although their plight was frequently attributed to their refusal to do "Kaffir" work (a derogatory term for manual labour usually done by Africans), poor Afrikaners were at a double disadvantage in the towns. Unlike Africans who had some access to the land, they were totally dependent on their urban wage, while they lacked the skills of English-speaking workers.

The Pact government's "civilized labour" policy—which made government tenders to private industry dependent on the employment of white labour—had more effect in spurring capital-intensive manufacturing and the employment of cheaper, female Afrikaner operatives than in eliminating white poverty, though blacks were replaced by Afrikaner males in government services. A huge rise in gold tax revenues enabled social welfare services to be implemented for whites, while the expansion of manufacturing during World War II largely eliminated white poverty.

rban
acks

Urban blacks were not nearly so fortunate. By 1921 their numbers had risen to 500,000; they increased sharply to 1,250,000 by the late 1930s and to 2,000,000 by the end of World War II. Until the war years their welfare needs were largely ignored by the state, though poor health and the hazard this posed to the reproduction of the work force and to whites aroused concern. Through segregation and influx control the state hoped to restrain African urbanization and tie down farm labour. Increased manufacturing and the rapid development of unions among Africans improved African wages in the early 1940s, and there was talk of some form of stabilization and social reform. In general, however, wages remained low, and housing and health conditions appalling.

Purified
Nationalist
Party

The outbreak of World War II ruptured the fragile consensus of white political parties. As in World War I, Afrikaners were divided, and Hertzog resigned when the parliament voted by a narrow margin to join the Allies. Even before this, in 1934, a group of nationalists supported by the Broederbond—a secret society formed to advance Afrikaner economic interests and ultimately capture the South African state—had left the United Party to form the Purified Nationalist Party. Though their electoral support remained small in the 1930s, they built up their power through the establishment of extensive cultural, welfare, and economic subsidiary organizations directed, on the one hand, at promoting the interests of the Afrikaner petty bourgeoisie and, on the other, to winning over the Afrikaner poor from the predominantly Labour- and Communist-dominated trade unions.

During the war General Smuts, world statesman and for the second time a member of the British war cabinet, headed the government, supported by English-speaking whites. Divisions among Afrikaner nationalists and the adherence of certain factions of the party to fascist-type extra-parliamentary, paramilitary organizations masked the fact that the Purified Nationalists could potentially gain a parliamentary majority by mobilizing ethnic power.

NORTH OF THE LIMPOPO

Though the Union of South Africa had by far the most powerful and complex settler polity, in the first half of the 20th century settlers also acquired political control in Southern Rhodesia (now Zimbabwe). Even in Nyasaland (Malawi) and Northern Rhodesia (Zambia), it was accepted that settlers would provide the necessary economic development under the aegis of international capital, with Africans providing cheap labour.

Southern Rhodesia. The early years of the century saw intensified recruiting of African labour for the hundreds of small mines working scattered deposits. The Rhodesian Native Labour Recruiting Bureau drew in low-paid coerced labour from much of Northern Rhodesia, Mozambique, and Nyasaland to undercut local labour. The dubious profitability of mining in Southern Rhodesia meant that wages, food, housing, and health conditions were cut back ruthlessly and mortality and morbidity rates were exceptionally high.

After the South African War the British South Africa Company (BSAC) turned to the development of commercial corn (maize), tobacco, and cattle farming. Settlers replaced the speculative companies of the early days, and in 1907 they were granted an elective majority in the Legislative Council, first established in 1898. The settlers attacked competition from African producers and their continued access to the land that had been reserved for the Africans at imperial insistence after the uprisings. The colonial office, however, fearful of further disturbances, and the mining industry, with its interests in migrant labour, ensured the continuation of the reserves. By the mid-1920s, 31,000,000 acres of land in Southern Rhodesia were in the hands of about 11,000 whites, 22,500,000 acres had been reserved for the 676,000 Africans, and 45,500,000 acres remained open to purchase and occupation by people of any race.

Land
Apportionment Act
of 1930

The Land Apportionment Act of 1930, modelled in part on the Native Lands Act in South Africa, barred African land ownership outside the reserves, and a special freehold purchase area of 8,000,000 acres was set aside for "progressive farmers." These allocations soon proved wholly inadequate, as African "squatters" were displaced from the white farms and made their way to the increasingly congested reserves.

In 1922, when the BSAC handed over administrative control to the colonial office, the settlers in Southern Rhodesia opted for self-government rather than join the

Union of South Africa, as the company had hoped. The new constitution effectively excluded Africans (95 percent of the population) from the government, and provided an imperial veto, never openly exercised, over discriminatory legislation. Settlers controlled the police and armed forces. Between the 1920s and 1950s, the party of government generally remained closely allied to international capitalist interests, while the opposition represented settler farmers and workers in the face of African competition.

Thus, international capital's fears that self-government would jeopardize their interests proved unfounded. The BSAC continued to own the railways and coal mines, while other base and precious minerals were dominated by a handful of foreign-owned companies. The majority of small, undercapitalized, and struggling white farmers were also initially dominated by the interests of big capital. The Depression and the example of the Union of South Africa led to state assistance both for small mining companies and for white farmers through the establishment of subsidies, systems of control, and marketing boards. These policies had mixed results and were at the expense of the African peasantry and workers, although African corn production increased in the 1930s as rural stratification intensified and falling prices increased self-exploitation. It was only during World War II and immediately thereafter, with the tremendous boom in Rhodesian tobacco, that white farmers began to make money; in 1946 tobacco replaced gold as the most important export. Growing numbers of landless Africans meant that wages in the mines and agriculture fell sharply in the 1930s. White workers were protected by the Industrial Conciliation Act (1934), modelled on South African legislation, while black workers were tightly controlled.

Northern Rhodesia. Across the Zambezi the BSAC's territory of Northern Rhodesia was little more than an appendage of the south. In the northeast, administrative attempts to impose closer settlement and interference with local agricultural techniques interacted with the effects of the natural disasters of the 1890s to produce extremely high morbidity and mortality in the first decades of BSAC rule. These were exacerbated by the forced labour policies of the company. When the BSAC failed to find mineral wealth, Africans had to migrate in search of money for food and taxation to the mines in Shaba (Katanga), Southern Rhodesia, and South Africa. The absence of 270,000 young men recruited as porters during World War I further accelerated agricultural decline. Disease, malnutrition, and inflation followed in the wake of the war, so that by the time the BSAC handed over control to the British colonial office in 1924 the territory was no more than a massive labour reservoir.

Settlers were not initially encouraged in Northern Rhodesia, although a handful of white farmers and traders made their way to the territory. They were granted an Advisory Council in 1918, and in 1924 the BSAC handed over administrative control to the British government, while retaining its mineral rights. In an attempt to increase settler numbers, the colonial office threw open the colony's best lands for white farming, while reserves were drawn up for African occupation. Although extensive, the reserves' soils were poor and they rapidly became overcrowded with people and livestock.

Discovery of copper

It was, however, the discovery and exploitation of rich deposits of copper by U.S., South African, and British capital from the mid-1920s that transformed Northern Rhodesia's economy. Although copper mining was interrupted by the world depression, by the late 1930s Northern Rhodesia had joined the world's major producers, with nearly 90 percent of its export earnings coming from copper. Until 1947 the British government received 50 percent of the taxation on the mines, while the BSAC also exacted a royalty. Thus, despite the importance of the copper industry, the revenue accruing to the Northern Rhodesian government remained small until the boom in copper prices after 1949 and an agreement with the BSAC that gave the local government a share in the royalties. The BSAC's title to mineral royalties was eventually bought out by the Zambian government at the time of independence in 1964.

The inception of copper mining brought the number of white settlers up to 11,000 in 1930, largely skilled miners and farmers from South Africa. Their pressure—together with the reluctance of the British government to confront problems of African urbanization and proletarianization—led until the late 1940s to policies of indirect rule and segregation, with scant attention paid to the needs of urban Africans. The job colour bar, an enormous differential between black and white wages, and a variety of discriminatory practices characterized the Copperbelt in the 1930s and '40s, although by mid-century the development of a skilled and unionized African work force, the determination of the mine companies to cut costs, and the political weakness of the white working class enabled the companies to replace white miners with black.

Nyasaland. In Nyasaland, too, though the principle of African paramountcy was frequently proclaimed, British imperial and settler interests prevailed and led to the territory's depressed economy. In the early colonial period a three-sector economy developed: the ecologically marginal north soon came to act as a labour reserve; in the Shire Highlands an enclave plantation economy was established by settlers dependent on labour tenants; and in the south and centre a cash-cropping peasantry emerged.

In the north and centre, by the turn of the century the activities of missionaries and the growth of consumer demand, the violent imposition of taxation, and the need to replenish cattle herds decimated by the rinderpest epidemic meant that several thousand Africans left their homes each year in search of work on settler plantations or in neighbouring territories. Elsewhere the process was slower, and until the 1920s taxation, often brutally extorted, was necessary to break the autonomy of African societies and force out labour.

Nyasaland had no mineral wealth, transportation costs were high, and white plantation agriculture in the Shire Highlands remained poor and inefficient until the 1920s and '30s, when tobacco and then tea replaced the earlier unsuccessful efforts to grow coffee and cotton. In 1907 the planters were given membership in the Legislative Council, where they demanded state control over labour. With their appallingly low pay and working conditions the planters, even though they extracted labour from their tenants, were unable to compete with the mines in surrounding territories. It was only the influx of successive waves of Lomwe refugees from Mozambique that solved their labour shortages. Harshly exploitative conditions on the Shire Highlands estates led in 1915 to an uprising directed by John Chilembwe.

John Chilembw

From about 1910 the administration began to encourage African cotton production, notably in the Shire Valley and along the shore of Lake Nyasa, where rice was also grown. By the 1920s Africans in the south were also successfully producing tobacco. Yet a racial bias against African producers, and the poverty of the administration in the interwar period—the result of a massive railway debt, heavy freight rates, and the effect of the Great Depression—stultified peasant agriculture. By the 1930s, because of soil erosion and overpopulation, even areas where cash crops had previously provided an alternative were sending out increased numbers of migrants. And, whereas from 1913 the administration had banned official recruitment for the mines, the expansion of the South African and Southern Rhodesian economies in the later 1930s led to a renewal of systematic migrant labour, despite its destructive impact on village life.

ANGOLA AND MOZAMBIQUE

In Angola and Mozambique, too, the economy was sustained by labour migration, while forced cotton, coffee, and rice production increased the burdens on the African populace. To an even greater extent than in British Central Africa, and until considerably later, overt force was a central feature of colonial rule.

Labour migration

In the 1890s the Portugese government hoped to foster plantation agriculture in Mozambique, but the territory was already linked to the labour markets of South Africa. By 1897 more than half the workers on the Rand came from Mozambique. The Portuguese government controlled the flow, through conventions signed with the

South Africans in 1901, 1903, 1909, and 1928. Capitation brought revenue to the state, while deferred pay ensured the migrant's return, his tax, and his purchase of Portuguese manufactures. In exchange for black labour Mozambique received a set proportion of the Transvaal's railway traffic. In Angola this system had its counterpart in the contract labour sent to São Tomé: when this was terminated as a result of slavery scandals in 1908, the São Tomé planters turned to Mozambique for labour.

Most of the Mozambique labourers going south migrated from the region south of the Save River; in the north and centre of the territory were the concession companies that the Portuguese had allowed in the 1890s. In terms of productive capacity, the most important was the Sena sugar estate in the Zambezi Valley, established by British capital. The company totally controlled economic life in its zone of operations, and local Africans had little choice but to work on its plantations. The remaining companies were largely parasitic, extorting taxation and the crops Africans were already producing by force. Conditions were little short of slavery. The most lucrative export was manpower, with local food and cash-crop production falling on the women and children.

ettler
emands

Despite Portugal's schemes to settle immigrants in its colonies, their numbers remained minute. Many were illiterate and unskilled peasants who had little political power, which remained in the hands of the governor general, the highest colonial representative of the Portuguese government. The loosening of political authority in Portugal itself during the republican period (1910–26) was accompanied by a flurry of activity among settler political groups, some of them in alliance with Afro-Portuguese and with members of the creole elite who were angry at Portuguese maladministration, bureaucratic inefficiency, and corruption. A handful of planters dominated settler politics. They attacked migrant labour, demanded protection against African competition, and opposed the ban on distilling and the abolition of slavery without compensation. In Angola the collapse of rubber prices in 1913 added to settler problems, and many went bankrupt. In northern Mozambique campaigns against the Germans during World War I led to famine, forced labour, and high mortality both in combat and from disease. After the war, however, the colonies attracted new settlers as their economies recovered in response to the rise in world prices for tropical products. In Angola, diamond production in the northwest was an additional stimulus.

ntónio
alazar's
conomic
olicy

With the premiership (1932–68) of António de Oliveira Salazar of Portugal, however, immigration schemes were dropped and strict vigilance was exercised over all political and economic activity in the colonies. Minimal consultative institutions disappeared, and in 1940 there were only 27,400 whites in Mozambique and about 44,000 in Angola. Grand imperial rhetoric accompanied a return to protectionism in order to foster Portugal's needs for cheap raw materials and a closed market. Southern Mozambique was entrenched as a labour reserve for the Rand; elsewhere in the colony, from the mid-1930s, Africans had to produce fixed quotas of cotton. During the war years the demand for other tropical products led to a severe shortage of labour, and in both territories women were drafted to cultivate cotton and rice. Confiscations and assaults were legion, despite a plethora of protective legislation. By 1945 more than 80 percent of Portugal's raw cotton came from Mozambique and Angola.

THE AFRICAN RESPONSE

African peoples who had been drawn painfully into the capitalist-dominated economy of southern Africa and subjected to ever-increasing administrative, economic, and political control did not all experience their subjection in the same way. The 20th century witnessed the rise of new classes, with the emergence of an African petty bourgeoisie and working class in the towns and a considerable degree of stratification in the countryside. Migrant labour both undermined and strengthened the authority of the chiefs, especially in areas where the colonial state was anxious to retain traditional structures for purposes of social control. Side by side with the growth of nationalist movements among the new elite and trade union organization among workers, there was a continuation of royal family politics, a restructuring of ethnic identification, and a resort to millenarian solutions.

Royal family politics. In regions where large centralized states had existed at the time of the colonial takeover, royal politics continued to be of significance. In Barotseland, Swaziland, and Basutoland, where paramount chiefs were recognized by the British, the traditional aristocracy combined with the educated elite to protect their position and demand the redress of grievances. In both Matabeleland and Zululand, where the royal families had been militarily defeated, royalists combined to demand state recognition of the monarchy, while in Nyasaland in the 1930s there was an attempt to create a Tonga "paramountcy" and to restore the Ngoni king. In general, attempts to manipulate tradition were most successful in the climate of "indirect rule" of the 1930s and in areas where settlers were weakest.

South
African
Indian
Congress

Political organizations and trade unions. The experience of white rule for Africans has been longest and most intense south of the Limpopo, where the existence of substantial Coloured and Indian minorities gave an extra dimension to anti-colonialism. In South Africa, between 1906 and 1913, Mahatma Gandhi formed the South African Indian Congress and led the first large-scale nonviolent resistance campaign against anti-Indian legislation. He gained limited success, though restrictions on Indian movement and immigration to South Africa remained in force. After his departure in 1914, however, the militancy of the Indian Congress was lost until after World War II, when younger, more radical groups won power from the middle class that had dominated the organization.

The Coloureds of the Cape and Transvaal were never as successfully mobilized. Though the African Political (later African People's) Organization, founded in 1902, was the first black nationwide political organization, it was soon eclipsed by more vigorous African nationalist movements, and for most of the century the Coloured population was divided and relatively voiceless. The Non-European Unity Movement, founded predominantly by Coloureds in the 1940s, influenced African political thought, however, and numbers of Coloureds came to identify with the Black Consciousness Movement.

In 1912 educated Africans united the local associations that had developed in the late 19th and early 20th centuries into the South African Native National Congress, in 1917 renamed the African National Congress (ANC). It aimed to represent African grievances, overcome tribal divisions, and gain acceptance from whites through self-help, education, and the accumulation of property. Though demands for industrial education, individual land tenure, and representation in Parliament were accompanied by attacks on the pass laws, the colour bar, and the Native Lands Act of 1913, the ANC's methods remained strictly constitutional and appealed mainly to the black petty bourgeoisie.

Such associations had their counterpart in Central Africa, partly because many early nationalists either studied in the leading mission schools of the Union or had worked there. Thus, African National Congresses were established in Southern Rhodesia in 1934, in Nyasaland in 1944, and in Northern Rhodesia in 1949–51. Despite regional differences, the class composition and methods of struggle of these organizations were broadly similar until the 1950s, with South Africa leading the way.

Industrial
and Commercial
Worker's
Union

Despite the greatly increased numbers of Africans in South African industry by the end of World War I, African trade unions were hampered by the pass laws, lack of recognition, and police harassment; strikes were illegal and often were put down with violence. Nevertheless, the period 1918–22 saw a great deal of working-class militancy, and in 1920 Clements Kadalie, an immigrant from Nyasaland, founded the Industrial and Commercial Workers' Union (ICU). Based initially among dockworkers in Cape Town, it spread rapidly as a mass movement in towns and in the countryside, where the evicted responded with millenarian zeal to its message, arousing fear and hatred among white farmers. At its height it claimed 100,000 members and had branches in Southern Rhodesia South West Africa. Internal divisions, the mismanagement of finances, and the expulsion of its most active Communist members led to its disintegration by 1929. By that time the Communist Party was beginning to organize Africans in industrial unions; there were some 20,000 unionized Africans by the beginning of World War II and 158,000 in 1945. In the early years of the war the unions were able to win considerable gains for their members, but these were lost after the crushing of the African mine workers' strike of 1946 and the victory of the Afrikaner Nationalists in 1948.

From the early 1920s, to preempt political militancy, the South African government attempted to provide channels for the expression of African grievances through a variety of local consultative councils. This example was followed in Central Africa in the 1930s, where the authority of the chiefs was even stronger. Despite their powerlessness, educated Africans participated in them in the hope of gaining concessions from the state.

In Angola and Mozambique there were few political rights, apart from the republican period (1910–26), when political organizations, trade unions, and the press flourished. It seemed as if Africans and settlers in Angola would strive for similar reformist goals, but the Africans broke away to form organizations demanding limited welfare and educational benefits and to publicize black grievances, though they remained dominated by middle-class moderates. Crushed even before the advent of Salazar in 1932, they revived as ostensibly social and educational organizations in the 1930s and '40s. It was only in the 1950s that they returned to overtly political expression.

Role of Christianity. Even at their height, political organizations and trade unions never reached more than a fraction of the African population. By the beginning of the 20th century, however, parts of South Africa had experienced almost a century of Christian missionary presence. The Roman Catholic Church revived its presence in Angola and Mozambique, where it had a far longer history (it had largely disappeared by the late 19th century when Baptist and other Protestant missions had begun work there). In the early days of colonialism Christianity tended to advance rapidly among the disaffected and dispossessed, and it was usually only after a major disaster undermined the authority of traditional religion that considerable numbers turned to the new religion.

In general, the missionary heritage was ambiguous; by deliberately inculcating the individualism of laissez-faire capitalism and encouraging the stratification that was to lead so many of their converts onto the colonial labour markets, they simultaneously undermined African societies while championing them against more aggressive settler policies and enabling individuals to acquire the skills with which to survive in the white man's world. Frequently critical of settler colonialism, they also attacked much that was valuable in African tradition and developed an ideology to accompany colonial subordination.

Thus many Africans turned instead to the independent churches that first grew up in South Africa after the mineral discoveries and spread rapidly throughout the subcontinent. The churches ranged in size and structure from small family groups to vast organizations with links to black churches in the United States.

In the early years of the century Europeans in southern Africa interpreted the independent church movement as politically sinister and in some areas they sought to suppress it. By and large, however, it probably diffused African political energies. Though the initial break with a mission church betokened a desire for independence from whites, there were many motives for separatism. Independent churches and prophet movements drew on traditional religious and cultural beliefs, offering hope to a sorely pressed and poverty-stricken populace.

Southern Africa since 1945

When, after World War II, the imperial powers turned their attention to their African colonies, it was in the context of a changed world. Great Britain and France were weakened economically and under international pressure to decolonize. The founding of the United Nations, the Bandung Conference of African and Asian nations (1955), the liberation of South Asia, and events in West Africa led Britain to prepare for black independence.

The transfer of power in southern Africa to an African majority was greatly complicated by the presence of entrenched white settlers. Although Nyasaland (as Malaŵi), Northern Rhodesia (as Zambia), and the High Commission Territories (as Botswana, Lesotho, and Swaziland) moved to independence relatively peacefully, the 1960s and '70s saw escalating wars of liberation elsewhere in the subcontinent. By 1980 only South Africa and Namibia remained under minority rule. South Africa increasingly experienced violence and internal opposition; the dissident African National Congress, banned in South Africa from 1960 to 1990, carried on operations underground and outside of South African territory. In response to the transformed geopolitical situation, South Africa massively increased its defense expenditures and waged a war of destabilization against its neighbours. Namibia, however, gained its independence from South Africa in 1990.

South Africa and Namibia

The states of southern Africa remained, despite their political independence, embedded in a regional economy consisting of areas of high capital investment and rural areas of increasing impoverishment. The South African economy accounted for about 77 percent of gross regional production in the early 1980s. Attempts by surrounding states to break this dominance through, for example, the Southern African Development Coordination Conference, were strengthened by the end of the war in Zimbabwe (formerly Rhodesia) in 1979–80, though immense social, economic, and political problems remained.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* sections 945, 96/11, and 978, and the *Index.* (Sh.M./Ed.)

ANGOLA

Angola is situated on the southwest coast of Africa, with an area of 481,350 square miles (1,246,700 square kilometres) and 1,025 miles (1,650 kilometres) of Atlantic coastline, stretching from the Congo River estuary in the north to the Kunene (former Cunene) River estuary in the south, with a short stretch north of the Congo in the Cabinda enclave.

Independence

For 500 years a Portuguese colony, Angola became independent on November 11, 1975, as the People's Republic of Angola (República Popular de Angola), by proclamation of the Movimento Popular de Libertação de Angola (MPLA; People's Movement for the Liberation of Angola), one of three rival nationalist groups that had engaged in armed resistance since the early 1960s. The nation is bounded to the north and east by Zaire, to the southeast by Zambia, and to the south by Namibia.

Angola was recognized as a colony of Portugal at the Berlin West Africa Conference of 1884–85. The Cabinda enclave, which is 20 miles north of the Congo River and bounded by the People's Republic of the Congo to the north and Zaire to the east and south, was added to the colony by the Berlin conference and is an integral part of the People's Republic of Angola. The capital is the port city of Luanda.

The People's Republic of Angola became a member of the Organization of African Unity in February 1976 and of the United Nations in December.

Physical and human geography

THE LAND

Relief. The land rises from low coastal plains to an interior plateau. The Lunda Divide forms a watershed separating north- and south-flowing rivers.

The land may be divided into four zones, the flat coastal zone and three plateau zones. The principal plateau, the *planalto central,* lying from 3,500 to 4,500 feet (1,100 to 1,400 metres) above sea level, forms part of the great southwest African plateau and covers three-fifths of the total area of Angola. The higher tablelands (with altitudes up to 7,500 feet) include the Malanje (former Rand) Plateau in the north; the Benguela, Bié, Huíla, and Lunda Divide plateaus in the central regions; and the Humpata Highlands and Serra da Chela in the south. The uplands slope down to the coast in a series of escarpments joined by level areas. In the east they dip gradually toward the drainage systems of the Congo (Zaire) and Zambezi rivers. In the south, the Moçâmedes Desert stretches inland from the sea to the Serra da Chela, crossed by seasonal rivers that are dry for most of the year.

Soils. The coastal belt of Angola belongs to the partly Tertiary formation that follows the African coast from the Gulf of Guinea to the Cape of Good Hope. The southern zone generally consists of Recent superficial deposits of dunes and alluvia. The west of the *planalto central* has a crystalline bedrock, and mineral deposits lie close to the surface. The east, except for the Cassange Depression in the north, is mainly buried under relatively recent sand formations. In the coastal area are large concentrations of granite, crystalline limestones, and gneiss, as well as stretches of quartzite. The Zambezi and Congo areas display sandstone, schist, and quartzite and a wide variety of volcanic rocks. There are diamonds in the gravel and laterite in the Lunda area. In the coastal zone the soil is sandy, merging to desert in the south. Petroleum-bearing structures are found in Cabinda and in the Congo and Kwanza basins south to Benguela. There are limestone and sandstone cliffs as well as sandbars and spits. Alluvial soil along the riverbeds is fertile.

wanza
iver

Drainage. The principal rivers flow either from the plateau westward to the Atlantic or, in the eastern part of Angola, to the north and south. The Kwanza (former Cuanza), which flows into the sea some 40 miles south of Luanda, drains much of the central region. Other important rivers are the Kwando (Cuando) and Kubango (Cubango; the name in Angola of the Okavango), flowing through the southeast and into the Okavango Swamps of Botswana; the Zambezi in the east; and the Kunene (Cunene), which rises in the Bié Plateau and flows south and west for 587 miles inside Angola before reaching the Atlantic Ocean.

Climate. Angola has a tropical climate with two distinct seasons. In general, the average annual temperature decreases with distance from the Equator as well as with altitude; temperatures rise with proximity to the sea. To the south, the cool Benguela Current of the South Atlantic creates atmospheric conditions not conducive to rainfall. Soyo (former Santo Antônio do Zaire), in the north, has an average temperature of 79° F (26° C). In Huambo (former Nova Lisboa), in the *planalto central,* the average is 67° F (19° C). The rainy season lasts about seven months, from October to mid-May. The greatest amount of rainfall—about 70 inches (1,800 millimetres)—occurs in the Mayombe Forest in Cabinda, while the smallest amount—as little as two inches (50 millimetres)—falls on the coast. The northern coast near Luanda receives about 13 inches, Lobito 11 inches.

Plant and animal life. As far south as Benguela the coast is rich in oil palms and mangroves. In the north are dense forests, some of which, especially in Cabinda, contain valuable timber; in the south, toward the Kunene, are regions of dense thorn scrub. Rubber vines and trees are abundant but have been reduced by ruthless tapping; the commonest are various root rubbers, and species of *Landolphia* are also found. Coffee, cotton, and Guinea pepper are indigenous, and tobacco flourishes in several districts. Among timber trees are the *tacula* (*Pterocarpus tinctorius*), which grows to an immense size, its wood being blood red in colour, and Angola mahogany. The bark of the *musuemba* (*Albizia coriaria*) is used in tanning leather. A unique Angolan growth is the tumboa plant, (*Welwitschia mirabilis*), a primitive, low-growing plant of great botanical interest; described as a living fossil, it is peculiar to the Moçâmedes Desert.

The larger plant-eating animals include giant sable antelope, elephant, hippopotamus, white and black rhinoceros, giraffe, zebra, gazelle, and gorilla. Among the carnivores are lion, cheetah, and leopard. The land is rich in bird species and in a wide variety of reptiles, including crocodiles. Butterflies, poisonous spiders, white ants, and locusts are indigenous. Marine life includes the conger eel, the black (or southern) right whale, crustaceans such as lobster and giant prawns, tunny, and many temperate-water coastal fish such as mackerel, sardine, catfish, and mullet. Thirteen national parks and nature reserves have been created, the largest of which are the Parque Nacional do Iôna (about 6,000 square miles) and the Parque Nacional da Kameia (5,579 square miles).

Parks and
reserves

Settlement patterns. *Rural settlement.* The sparsely populated countryside of the north, east, and south contrasts with the more densely inhabited central part of the country. Eighty-five percent of the people are peasant subsistence farmers living in traditional and relatively small villages. In the southern desert, nomadic and seminomadic pastoralists live off their herds. European rural settlements in colonial times were concentrated in the rich coffee lands in the north and in the plateaus of Malanje, the central highlands, and the southern uplands around Lubango (former Sá da Bandeira), where the most fertile farmland is to be found. Since independence, these rural areas have become development poles for state and cooperative farming, as abandoned settler property has been taken over by the state.

Portuguese
colonists

Urban settlement. Urban settlements developed early in colonial history at ports and upriver along the Congo and Kwanza rivers as well as in the Bié Plateau on the trade route to Kasai, Katanga, and what is now Zimbabwe. Modern urban development, however, came after the start of armed struggle in 1961, when Portugal sent more than 40,000 troops to Angola and began a serious colonization program, sending unemployed or underemployed Portuguese families to Angola to populate rural development projects. Many drifted to the towns. A further rapid boom in urban development came in the 1970s after the Portuguese premier Marcelo Caetano opened Angola to foreign investors, ending Salazar's protectionism.

THE PEOPLE

Ethnic and linguistic groups. The largest ethnic group in Angola is the Ovimbundu of the central highlands, who speak Umbundu. The second largest group is the Mbundu, speaking Kimbundu, and spread over the coastal area north of Luanda down to N'gunza Kabolo (former Novo Redondo). The other major groups are the Kikongo-speaking northern Kongo; the Lunda–Chokwe from the east, speaking Chokwe and Lunda; the Nganguela, speaking Nganguela and spread over the east and southeast; the Nyaneka–Humbe from the south, speaking Nyaneka and Humbe; and the Ambo. Of non-Bantu ethnic origin are the San (Bushmen) and the Khoikhoin (Hottentots), speaking click languages. Other small separate groups are the Vatua and Xindonga. Only around one-tenth of Angolans speak Portuguese, and fewer still speak Portuguese as their mother tongue. It is the policy of the MPLA-Workers' Party to encourage development of the national languages, particularly in preliminary primary schooling and adult literacy teaching and later as part of the language course in secondary schools, while preserving Portuguese as the official language of the country. Statistics on the number of white Angolans and persons of mixed blood are not available.

Roman
Catholic
Church

Religion. The People's Republic of Angola is a lay state that guarantees, under its constitution, freedom of religion, conscience, and belief. Five hundred years of Portuguese rule had placed the Roman Catholic Church in a privileged position, constitutionally entrenched and part of the fabric of colonial government and administration. Protestant missions, concentrated in the north and in the central highlands and generally more sympathetic to Angolans' aspirations toward independence, were closely watched by the colonial government, and a number of them, suspected of harbouring subversive nationalist elements, were closed. After independence, the state took over administration of mission schools and hospitals in

accordance with constitutional provisions abolishing payment of fees and private education and health services; clergy employed in these activities became paid government employees. African Christian religions, such as the Kimbanguist Church, continue to flourish, and traditional religions based on worship of ancestral spirits still prevail in the rural environment, though less so in urban areas.

The role of churches and believers in a revolutionary state led by the principles of Marxism–Leninism has been debated. The Central Committee of the MPLA-Workers' Party stated at the first party congress that "the Party will base its policy on the assumption that the struggle for a free, scientific and materialist consciousness is an integral part of the struggle to build a society in which there will be no more exploitation of man by man, a struggle in which it is vital that both believers and atheists take part," and it concluded, "following the guiding principles of Marxism–Leninism, the Party and State of the People's Republic of Angola are not going to prohibit religion." Churches and religious organizations, however, must be registered and are subject to taxation, and in March 1978 the Jehovah's Witnesses were ordered to cease functioning. Formation of new religious organizations has been prohibited.

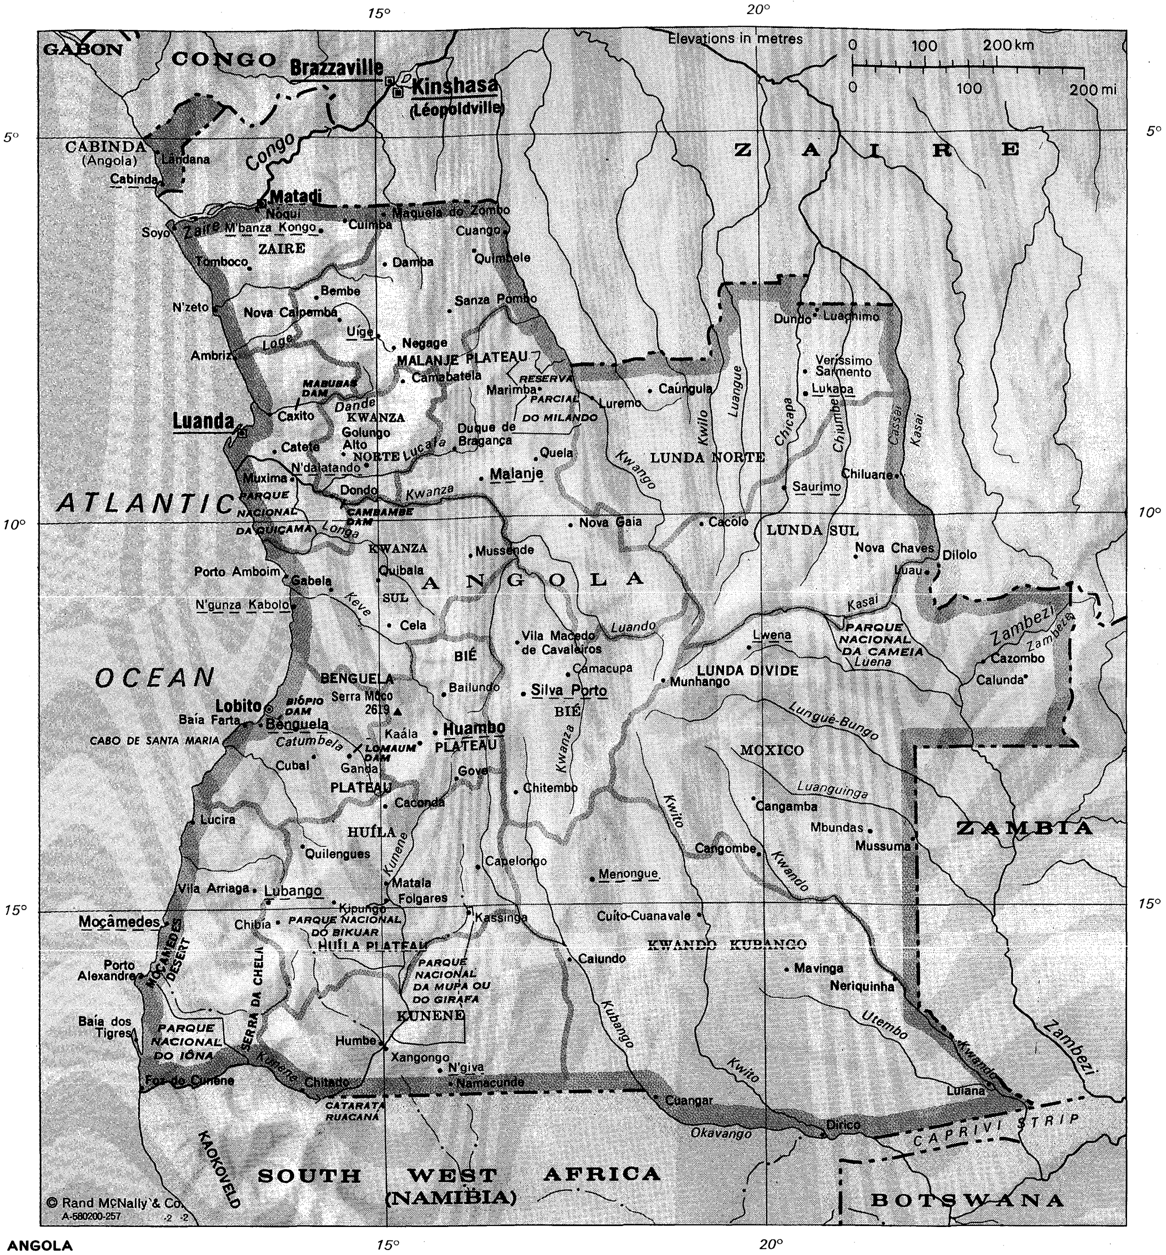
THE ECONOMY

Angola at independence found itself with a severely distorted economy, with only 12 percent of its gross national product (GNP) deriving from agriculture though 85 percent of its working population was engaged in it. The primary sector as a whole, including agriculture, forestry, and mining (prior to exploration of the Cabinda oil fields), in 1970 accounted for only 23 percent of the GNP. The secondary sector (industry and agro-industrial projects) accounted for a mere 14 percent, while the tertiary sector, mainly trade and services such as banking and insurance, accounted for a staggering 63 percent of the GNP—a typical settler-oriented economy. The country's enormous natural resources and soils and climate favourable for agriculture provide extremely promising conditions for development under an independent government. The retardant to economic growth will probably be the needed training and education of Angolans. At independence 90 percent of the population was illiterate.

Nevertheless, the large settler population and the buildup in the 1960s of the secondary and tertiary economic sectors to service it gave Angola at independence a more sophisticated economic structure than most African countries have yet achieved. Severe contrasts and imbalances that need to be corrected include the contrast between the eastern "badlands," where, in an area the size of Portugal itself, total colonial economic development (aside from the Benguela Railway line) consisted in some citrus fruit farms and a handful of sawmills, and Cabinda, where high technology petroleum industry drew industrial, commercial, and trading investments.

Angola is likely to become a leading African petroleum-producing country, along with Nigeria and Libya. Diamond extraction places Angola among the world's major producers.

Resources. Crude oil is the principal source of national income. A state oil company, Sonangol, created in 1977, derives revenues from joint ventures and production-sharing agreements with major international oil companies such as Gulf Oil in Cabinda and Petrofina and Texaco



ANGOLA

in the Congo and Kwanza fields. A law promulgated in 1978 provided for ownership of all crude oil resources by the state and set out broad guidelines for foreign participation in exploitation of oil, natural gas, and other hydrocarbons in partnership with Sonangol. Development of primarily off-shore oil fields has made Angola one of the major sub-Saharan oil producers. Recoverable reserves have been estimated at anywhere between 1,000,000,000 and 10,000,000,000 barrels. Approximately two-thirds of Angola's oil production is from the Cabinda enclave.

ıte
ʼnership

Agriculture, forestry, and fishing. Just under 3 percent of the total land area is arable and more than half of the economically active population works in agriculture. Before independence, even on more efficiently farmed plantations, use of fertilizers and irrigation was extremely rare, and intensive single-crop cultivation by the settler farmers was hard on soils.

After independence and the return to Portugal of the settler farmers, abandoned property reverted to the state and the agricultural sector was gradually restructured into large state farms or smaller cooperatives and peasant associations, formed voluntarily by subsistence farmers or former contract labourers. To improve nutrition, food crop production was extended in all provinces, and cooperative poultry and pig farming were introduced. Cash cropping presented an immediate structural problem: previously based on contract labour—wholly unacceptable in an independent state committed to raising living standards—cultivation of coffee, cotton, sisal, and bananas fell drastically in the years following independence. To compound the problem of restructuring, the infrastructure on the cash crop farms was entirely insufficient to house and provide health and education services for the families of any newly recruited labour force.

od
ɔps

Much of the essential work on the coffee plantations was carried out in the first years of independence by voluntary workers, organized through the MPLA and mass organizations into voluntary brigades from towns and cities nearby. In this way the coffee crop in 1977 reached around 70,000 metric tons. Angola produces more than enough cotton for its textile industry and exports the balance.

In the 1960s Portuguese settlers embarked on extensive ranching schemes, importing pedigreed cattle, sheep, and pigs (mainly from South Africa) and at times crossing them with local breeds to obtain better resistance to disease. Most of the country is free of the tsetse fly, and the southern part has been traditionally a livestock-raising area, particularly Kunene and Moçâmedes provinces, where Angolans live off the meat and sour milk from their cattle, cultivating small quantities of cereals as a dietary supplement. The livestock were decimated during the civil war after independence by indiscriminate slaughter and the driving of cattle over the borders into Zaire and Namibia. Rebuilding of the livestock and ranching industry is given economic priority, and government veterinary services were operating by 1977.

Timber, previously another major foreign exchange earner, was diverted wholly to fill national needs after independence. There are about 129,000 acres of forest in Angola, but the forestry industry depends mainly on Cabinda and the eastern Ganguela and Zambezi forests. Eucalyptus plantations along the Benguela Railway supply fuel for the steam locomotives. The Alto Catumbela forests provide raw material for a major paper pulp plant near Benguela.

Angola has a modern fishing industry, though it was severely affected by the war of 1975–76, when settlers sailed the majority of the fishing fleet back to Portugal or to Walvis Bay in Namibia. The refrigeration and fishmeal plants at Moçâmedes and Porto Alexandre were reactivated, and contracts were signed with foreign fishing fleets to land a proportion of their catch, while technical assistance agreements were made to build a new Angolan fleet and train Angolan crews; in 1976, however, the catch had fallen to only 10 percent of prewar figures. Before independence, industrial firms relying on modern refrigerated fishing vessels accounted for 86 percent of the catch. Main fishing centres are Moçâmedes–Porto Alexandre, Benguela–Baía Farta, Luanda–Cacuaco, and Porto Amboim–N'gunza Kabolo. Freshwater fishing is limited to traditional catching methods for home consumption. Both freshwater and saltwater fish are cured traditionally by drying or, in some areas, smoking.

Mining. Diamond mining is the principal mining activity in Angola. After a drop in production during 1975–77, during which time the state acquired a controlling 61 percent interest in Diamang, the British-dominated company that had had the monopoly on diamond mining (and Portugal retaliated by freezing assets of the company held in Lisbon), production regained the 1973 level of more than 2,100,000 carats during 1978. Black granite and fusing-grade quartz are also mined for export. Mining of manganese, copper, and iron ore had terminated by independence, after foreign mining companies had exhausted deposits that could be mined with profit. Evaluation of remaining lower grade iron ore deposits in Kassinga, however, is being carried on.

Industry. A small heavy industrial sector includes steelmaking, shipbuilding and repairs (at Lobito), paper pulp processing, and production of cement. Textile manufacture from Angolan cotton and imported synthetic fibres, tire manufacture, paints and plastics manufacture, sugar refining, and brewing and production of soft drinks are major industries, and sawmills and plywood mills process locally grown timber. The agro-industrial sector includes canning of fruit, vegetables, and meat, fish processing, production of edible oils, and production of biscuits and pasta from imported wheat, milled in local plants. Tobacco grown in the central regions supplies a cigarette industry. Following the civil war of 1975–76, the government gave priority to a national reconstruction program to recover sabotaged industrial plants, refit them, train Angolans for skilled industrial jobs previously reserved for settlers, and regain production levels of 1973.

Only a fraction of the country's population has running water or electricity at home, and a large rise in consumption is expected, entailing new investment in power generation. Angola's many rivers, as well as its domestic sources of fossil fuels, ensure plentiful supplies of cheap energy. The five most important hydroelectric plants are the Cambambe Dam on the Kwanza River near Dondo; Mabubas Dam, northeast of Luanda on the Dande; Lomaum Dam on the upper Catumbela; Biópio Dam on the Catumbela; and Matala Dam on the middle Kunene. The main Portuguese power company, Sonefe, is now under state control.

Hydroelectricity

Trade. At independence, a major aim was to diversify foreign trade, previously heavily weighted toward Portugal for all export cash crops and diamonds and for imports of general merchandise; and toward the United States, which took virtually all Angolan crude oil and most of the coffee. Sixty percent of exports of crude oil were in the hands of the state oil company, which thus had an opportunity to sell to new customers (though the low sulfur content of Angolan crude makes it ideal for the U.S. market); diamond sales had also been taken out of the hands of Portuguese company interests, though diamonds continued to be sold via the Central Selling Organisation ultimately. Coffee was sold by the state directly on the London commodity market rather than exported from Angola via private foreign brokers as it was formerly.

Imports came from a wide variety of sources. Capital equipment for existing industrial plants continued to come from Western countries.

Administration of the economy. *The public sector.* Economic management is directed by the MPLA-Workers' Party, which set out basic guidelines. Restructuring of the colonial economy proceeded rapidly, with a nationalization law, passed in March 1976, the major instrument for building a strong state-owned sector. Cooperatives were also being built up, principally in agriculture.

Long-term economic development, in the party view, must be based primarily on agriculture and the building up of heavy industry. Petroleum exploitation, building, and fishing have been singled out for development as sectors affording maximum short-term growth prospects. Medium-term objectives include investments in petrochemicals, mining, and phosphate production, the latter to provide fertilizers for agriculture.

Government revenue is derived from state-controlled enterprises and from exports, taxation, and stamp duties.

The private sector. Few non-Portuguese foreign firms were nationalized after independence, though a large number of joint ventures between the state and such firms has been established. Foreign multinational companies operating in Angola include the oil companies, banks, heavy-engineering firms, and computer, electronics, and telecommunications companies. Private manufacturers are concentrated in the clothing and food and beverage industries. The largest number of private entrepreneurs is found in the retail trade, mostly in small businesses, followed by the transport sector, with many small trucking firms.

Multinational companies

Taxation. After independence, a National Reconstruction stamp duty replaced colonial stamp duties. Direct taxation includes income tax, company tax, and building tax on property owners. Indirect taxation is under review, and one rise since independence has been in the indirect tax on gasoline. The constitution provides for progressive direct taxation.

Transportation. *Roads.* The major north–south road, built in colonial times, linked Luanda with South Africa, via South West Africa. A small stretch of unpaved road in South West Africa was the only break in a system that linked Luanda, Huambo, and Lubango (formerly Sá da Bandeira) with Windhoek (capital of Namibia), on to Cape Town in South Africa, and northward again as far as Beira in Mozambique. Coastal roads and major bridges across river estuaries were built by the Portuguese as part of the effort to control the country during the years of armed struggle between 1961 and 1974. They run from Soyo on the Congo estuary south to Luanda and on to N'gunza Kabolo, Benguela, and Lobito. Three main roads run from west to east: one from Luanda and one from Lobito to Luau (former Teixeira da Sousa) on the Zaire border and one from Moçâmedes to Luiana near the Zambian border.

Between July 1976 and July 1977 the state imported around 12,000 vehicles for state transport organizations. Private truck and bus companies continue to exist alongside the state-owned transport system. Municipal transport services, however, are all run by the state, and fares were lowered at independence for suburban areas, where the poorest people live.

Railways. The Benguela Railway, privately owned by a British company, runs 840 miles from Lobito on the Atlantic seaboard to the Zaire border at Luau, where it connects with the Zaire railway system and from there runs through to the Zambian Copperbelt. Both Zaire and

Zambia use the Benguela Railway for exports of copper and for vital imports. Other major railway lines also run east–west and were also built in colonial times for export of raw materials. The Luanda–Malanje line was built for export of cotton and coffee, the Gabela–Porto Amboim line for export of coffee, and the Moçâmedes–Menongue (former Serpa Pinto) line for export of iron ore from Kassinga.

Ports. The chief ports are Lobito, Luanda, and Moçâmedes, followed by Landana, Porto Amboim, Cabinda, Soyo, N'zeto (former Ambrizete), N'gunza Kabolo, Benguela, Porto Alexandre, and Baía dos Tigres.

Lobito has two L-shaped wharves as well as the only floating dock in Angola. The port is fully equipped with storehouses, railway lines and marshalling yards, depots for liquid fuel, and silos for grain. As terminus for the Benguela Railway, it handles Zairian and Zambian copper, Zairian manganese, agricultural products from the central highlands of Angola, and general imports for Angola, Zaire, and Zambia.

uanda
rbour

Luanda harbour is deep and easy of access, with about four square miles suitable for berthing ships. It is linked by rail with the main Luanda railway station and is equipped with up-to-date loading and unloading equipment. It is an outlet for coffee, cotton, timber, and cereals. Moçâmedes, railhead for the Moçâmedes railway, was the outlet for iron ore exports from Kassinga and has a special ore terminal. Moçâmedes harbour also serves an inland region potentially rich in agricultural and industrial products and has refrigeration plants to store meat from Huíla and Kunene. North of Lobito, Porto Amboim serves the coffee region around Gabela in Kwanza Sul province.

River traffic. Few Angolan rivers are navigable. The Kwanza can carry small craft upstream for about 140 miles. The Congo is navigable by oceangoing ships up to Noquí in Angola and to Matadi in Zaire. All Zaire-bound ships must use the Angolan territorial waters of the Congo River, which is not navigable at certain points inside the Zaire territorial water limits.

Air transport. The main international airport, at Luanda, is a port of call for airlines operating between Europe and central and southern Africa. An alternative landing site is Huambo. The Angolan state airline, Taag (Transportes Aéreas de Angola), links main cities and towns. There are airstrips for small planes. A state-owned charter company leases small aircraft and crews.

ADMINISTRATIVE AND SOCIAL CONDITIONS

Government. *Constitutional framework.* The constitution of the People's Republic of Angola, proclaimed on November 11, 1975, and amended in October 1976, provides for "construction of a prosperous and democratic state, totally free of all forms of exploitation of man by man." Leadership falls "to the MPLA-Workers' Party as the organized vanguard of the working class and a Marxist–Leninist party." State property and means of production are managed through central planning, while the right to private property and private activities is recognized in Article 10 "as long as these are useful to the country's economy and are in the interests of the Angolan people." Internationally, the constitution declares adherence to the charters of the United Nations and the Organization of African Unity and declares Angola's wish for relations of friendship and cooperation with all states on the basis of mutual respect and advantage. The highest organ of state power is the People's Assembly, which replaced, in 1980, the provisional Council of the Revolution.

ouncil of
inisters

The government executive is the Council of Ministers, presided over by the state president (who is also president of the MPLA-Workers' Party) as head of the government. Each member of the government is personally responsible for decisions and their execution. A permanent committee of the Council of Ministers acts as executive between meetings of the full assembly.

Local government. The country is divided into 18 provinces, broken down into smaller units of administration. A provincial commissioner coordinates activities of the branches of central government ministries in the provinces, under guidelines from the party. A party steering committee at provincial level, also headed by the provincial commissioner, is nominated by the Central Committee, pending elections once the new party has been fully constituted. The principle of "democratic centralism" governs relations between local government bodies and the central administration.

Foreign relations. Angola is one of the nonaligned countries, and its constitution prohibits membership in any international military organization and foreign military bases on Angolan soil. The constitution also expresses the wish for friendly relations with all countries on the basis of noninterference in each other's internal affairs, mutual respect, and mutual advantage. Angola is one of the five so-called front-line countries confronting domination by white minorities in southern Africa, and the constitution declares Angola's solidarity with peoples fighting for national independence.

The political process. The political struggle for independence from colonial rule was led by the MPLA, from its foundation in 1956. Among the several liberation movements, it alone succeeded in mobilizing a broad front of patriots from all parts of Angola and all social classes. The MPLA's national appeal was based on a conscious struggle against regionalism, tribalism, and racism. Although socialist principles were articulated in the liberation movement's program, it was not until the first party congress in December 1977 that the MPLA constituted itself into a Marxist–Leninist vanguard party of the working class (the Movimento Popular de Libertaçâo de Angola-Partido de Trabalho, or MPLA-PT, MPLA-Workers' Party) and launched a Movement of Rectification to clarify the party line and build new party cells. Members were selected through assemblies at workplaces at which all workers criticized and approved or rejected party candidates.

MPLA-
Workers'
Party

The first congress of the MPLA saw the election of a new Central Committee and Political Bureau, though provincial party committees were nominated rather than elected. The congress itself was elected from among MPLA militants, at grass roots committee level. An extraordinary congress met in 1980, after which regular congresses would be held every five years.

Mass participation in the process of party building was assured through the Movement of Rectification, involving all workers, in and outside the MPLA. As in other Communist countries, party-sponsored mass organizations have replaced former voluntary associations. The party youth organization and the women's mass organization, OMA (Organização da Mulher Angolana, or Organization of Angolan Women), involve young people and women in community organization, self-help schemes, literacy and health projects, and other mass campaigns. Local government issues are debated in mass meetings.

Justice. The Angolan judiciary is independent of the executive branch, according to article 50 of the constitution. A People's Supreme Court heads the judicial system. Collegiate courts administer justice through a system of professional judges and barristers and people's lay assistants. All private law practice has been abolished. A state public prosecutor is responsible for respect of the law by state organs, economic and social organizations and entities, and private citizens.

The colonial legal system is gradually being replaced by new laws, but colonial legislation is regarded as valid until repealed or contradicted. A law passed shortly after independence made divorce possible for the first time. Customary law is still administered in the countryside.

Education. Free education is guaranteed to all citizens under the constitution, though compulsory education extends only to primary schoolchildren.

State
aims in
education

Thorough renovation of the educational system is underway, its aims being to narrow the social gap between intellectual and manual work (by introducing practical manual work into the system), to rid the schools of colonial history and geography, to reinvigorate national cultural values, and to build a classless society. Parallel to the children's educational system, a system of adult education is being built to end illiteracy. Costs were kept low by use of volunteer teachers. The major problem facing the Ministry of Education is a shortage of teaching staff.

Foreign teachers, mainly from Cuba and Portugal, were enrolled and are both teaching in schools and centres of higher education and training Angolan teachers.

Health and welfare. A law passed in December 1975 established free medical care and a National Health Service. In 1977 all private, fee-paying medical services were abolished. Church mission hospitals are now administered by the National Health Service. Many hospitals had to be almost entirely reequipped after the devastation of 1975–76. Training of Angolans as medical and paramedical staff is under way, and foreign technical assistants, mainly from Cuba, are helping train hospital staff.

Widespread malnutrition and lack of sanitary education are principal causes of disease in both town and country. Preventive medicine is the main aim of the National Health Service, and mass immunization campaigns have been undertaken against endemic tropical and other common diseases. A high rate of infant mortality was being attacked after independence by education of pregnant and nursing mothers and establishment of mother and child care centres. African traditional medicine is still widely practiced and is being studied for its continuing values in use of herbs and other natural cures.

Housing. Most Angolans live in traditional wattle and clay or timber houses with separate kitchen buildings and outhouses for storage of food. In the towns there is sharp contrast between the modern villas and apartment and office buildings of the formerly white city centres and the sprawling peripheral shanty towns, or *musseques,* "cities of sand." A national housing program, with priority for rural areas, involves government construction of low-cost housing and a government-run self-help program, with building plans and materials made available to individual home builders.

Cities of sand

Wages and the cost of living. The wage structure inherited from colonial times was entirely reviewed after independence, and top government salaries were cut and a higher minimum guaranteed wage was established. Differences were then gradually narrowed. At the same time, privileges that under colonial rule had accrued to the civil service were either swept away or were extended to all workers (the family allowance is an example of the latter). The principle of "from each according to his ability, to each according to his work" is enshrined in the constitution, as is the right and duty of all Angolans to work. High unemployment in Luanda, a result of the flight from rural areas and the upheavals of war, was attacked by recruiting for rural jobs. To reduce the inflationary price trends that had accompanied the war and the general shortages of food and consumer goods, government price controls on essential food items and consumer goods were imposed, on the principle of a national price system.

Social and economic divisions. The overwhelming majority of Angolans are illiterate, poverty-stricken peasants. Urban workers and the privileged urban elite together represent no more than 15 percent of the entire population. The MPLA-Workers' Party has set about narrowing both social and economic divisions through national programs for literacy, education, health, and employment. A small class of private Angolan entrepreneurs, based in Luanda, Benguela, Huambo, and Lubango, has no significant influence on the national social or economic structures.

CULTURAL LIFE

A National Council for Culture is working to revive and rediscover Angolan indigenous culture while encouraging new creative forms proper to the revolutionary post-independence era. While literature and journalism were instruments of resistance to colonialism (as were music and dancing), traditional sculpture, pottery, weaving, and crafts in general declined in the final years of Portuguese rule. Suppression of Angolan culture was a general objective of the settler regime, which saw in it a threat to Portuguese hegemony and a magnet for nationalist aspirations. After independence a National Museum Directorate established an Anthropology Museum, an Archaeology Museum, a Slavery Museum, and a War Museum and breathed new life into scattered provincial museums, with greater emphasis on anthropology and Angolan history and culture. Popular music has revived, dance bands and traditional music players tour the country, and in 1978 the Luanda and Lobito *carnaval* was revived and taken to many other parts of the country.

The arts. Angolan sculpture of wood, clay, and stone is found in Lunda, Bailundo (former Teixeira da Silva), Kwango, Bié, and Cabinda. Pottery with incised designs and geometrical decoration, as well as woven textiles with geometric patterns and richly decorated basketry are seen particularly in the provinces of Lunda, Bié, and Cabinda.

Most famous is the art of the Lunda–Chokwe peoples, embracing sculpture and pottery and other objects of use, including richly carved furniture. In remote areas, shell necklaces and bracelets, tattooing, and elaborately dressed hair styles, adopted by both men and women, indicate region and tribe as well as social and economic status.

Music

Music has evolved to accompany work and recreation and, like dancing, marks principal events in the year and life cycle. Percussion instruments set the pace, and stringed and woodwind instruments, the portable finger piano or the much larger xylophone, as well as bamboo tubes accompany and provide the melody.

Literature and history are overwhelmingly oral traditions, though a school of modern Angolan writers, growing from the last part of the 19th century, became a focal part of the nationalist struggle as the Angolan intellectuals joined the MPLA in the 1950s. The first president, Agostinho Neto, was a poet of distinction in the Portuguese language.

Cultural institutions. The National Council for Culture has overall responsibility for cultural activities. The national Museum Board supervises museums and took over the most famous museum of the colonial period, a private institution run by the Diamang mining company in Lunda province; many of its treasures were transferred to the capital. The Union of Angolan Authors, formed after independence, publishes works by many Angolan writers and poets, and the National Union of Artists includes graphic artists, painters, and sculptors. Many theatre groups are being encouraged, with a view to both researching theatrical history and presenting new forms and revolutionary theatre. A National Library is based in Luanda. Cinemas exist in all towns, and a mobile cinema unit tours the provinces, under the party Department of Revolutionary Orientation, projecting films outdoors, on whitewashed house walls or other surfaces, in remote areas. Major sports include football, volleyball, basketball, swimming, gymnastics, athletics, and judo.

For statistical data on the land and people of Angola, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL. (Ja.Be.)

History

In the late Stone Age the northern part of Angola was populated by groups of hunters and gatherers who left a variety of stone tools. Later, during the 1st millennium AD, these early inhabitants were gradually absorbed by new, Bantu-speaking immigrants who introduced the revolutionary concepts of metalworking and agriculture. The Bantu communities in Angola remained for the most part small and isolated; the main exception to this was in the northwest where the Bakongo people developed a large, well-governed kingdom.

THE PORTUGUESE

About 1483 Portuguese seafarers began to arrive on the coast. They came to trade but soon discovered that Angola had no gold or other precious metals with which to pay for the new luxuries they brought. The only salable commodity was labour, and so within a few years an export trade in slaves developed. These slaves were mainly used to establish sugar plantations on the island of São Tomé and in Brazil.

Slave trade

The slave trade soon dominated events in Angola. At first it increased the wealth and power of the rulers who controlled it. In particular the king of Ndongo (Angola) greatly expanded his territory in the early 16th century. Later the trade caused internal divisions and rivalries that decayed the political fabric of the participating states and invited outside interference and conquest. In this manner in 1568 Kongo fell prey to the depredations of a warrior nation from Central Africa called the Jaga. Although the kingdom was later restored with the help of Portuguese troops it never recovered its former greatness and Portuguese interest and activity passed to Ndongo. Ndongo, however, soon clashed with the Portuguese.

For nearly a century the Portuguese who followed Diogo Cão and other explorers down the African coast were more interested in commerce than in colonial dominion. They took with them missionaries, who taught European concepts and values to their trading partners, but not soldiers. When the Kongo kingdom began to crumble, however, the Portuguese changed their policy and decided to establish in Angola a conquest colony similar to those of the Spaniards in Mexico and Peru. Luanda became their military base, and from 1576, under the leadership of Paulo Dias de Novais, they set out to subjugate the kingdom of Ndongo. In the ensuing wars the contestants proved fairly evenly matched and only after 100 years of intermittent fighting did the Portuguese prove successful. By 1680 their colony consisted of half a dozen forts in the lower Kwanza (Cuanza) Valley and the small outlying territory of Benguela on the southern coast.

Meanwhile, the slave trade continued to flourish, carrying off to the Americas more than 1,000,000 men, women, and children and killing countless others in the process. From the early 17th century, Portuguese traders were joined by those of Holland, England, and France; and during the 18th century in particular these western Europeans heightened the devastation that the slave trade was causing in Angola. The only attempt to relieve the country's decay was made by Dom Francisco de Souza Coutinho who, while governor of Luanda, unsuccessfully tried to diversify the Angolan economy.

The 19th century did not usher in a new era in Angola. The export of labour continued as before until British pressure forced the gradual suspension of the Brazilian slave trade in the 1850s. Thereafter the labourers, no longer called slaves but recruited in the same manner, were diverted to the cocoa estates of São Tomé, Portugal's original plantation island. By the end of the century Angola had suffered from four centuries of continuous slave trading and was as impoverished and underpopulated as any country in Africa.

esistance
the
ortuguese

When the colonial powers turned their attention to the partition of Africa in the 19th century the Portuguese were allotted the vast area comprising Angola and at once set about gaining possession of it on the ground. Their endeavour was fiercely resisted by the inhabitants, and sporadic wars of conquest lasted for 30 years. The first campaign was fought in the south where the Cuanhama and other pastoralists fought a long but losing battle to resist both the Portuguese from the coast and the Boers (Dutch colonists) from South Africa. The most decisive campaign was the Bailundo War of 1902 in which the Portuguese finally broke the power of the Ovimbundu kingdoms and captured the Bié Plateau, thus enabling European entrepreneurs to build the Benguela Railway and establish white settlers on the highlands.

The trials and experiments of the first 30 years of colonial rule in Angola were often hindered by political changes and unrest in Portugal. The main development projects such as the railways and diamond mines were launched with foreign capital and initiative. When in the 1930s stability returned to Portugal, new emphasis was placed on colonial planning. Progress, however, was long delayed, first by the depression of the 1930s and the conservative economic policies and then by World War II. Not until the 1950s did progress begin to take place in education, harbour and airport construction, road building, and plantation work. (D.Bi./M.A.Sa.)

INDEPENDENCE

Angolan
war of
liberation

The origins of the Angolan war of liberation lie in a series of apparently unconnected uprisings. They began in January 1961 with a revolt by the Mbundu in central Angola against forced cotton production at a time of dropping prices. Although they were bombed into submission, the Mbundu remained at the heart of Angolan resistance. The uprising was followed in February by an attempted coup in Luanda by the Movimento Popular de Libertação de Angola (MPLA), which emerged as the most important of the nationalist groups. The attempted coup ended in white hysteria, a massacre of blacks, and the suppression of the MPLA by the secret police.

Most important was the outbreak in March 1961 of violence among the poverty-stricken Kongo in the north. There the coffee boom of the 1950s had led to an influx of white settlers. Africans lost their land and were turned into wage labourers, while forced contract workers were brought in from central Angola. A dispute over wages led to the killing of several hundred settlers and contract workers and was followed by massive retaliation that spread the violence across northern Angola. Although at this stage the Kongo struggle failed to spread, the war of attrition continued for more than a dozen years. The Kongo were led by Holden Roberto's Frente Nacional de Libertação de Angola (FNLA).

By the mid-1960s warfare had also erupted in eastern Angola with the MPLA, which moved its base from the Congo to Zambia in 1965. Under its poet-president, Agostinho Neto, the MPLA also resuscitated urban political activity in Luanda. Although the MPLA was not able to extend its hold to the southern highlands, where the Ovimbundu joined Jonas Savimbi's União Nacional para a Independência Total de Angola (UNITA), the situation there, too, was tense as land was lost to white cattle ranchers. (Sh.M./Ed.)

The transition to independence in Angola was highly complex, with three nationalist movements vying for control. Their rivalries were greatly exacerbated by the involvement of Zaire, South Africa, the United States, and the Soviet Union. After Portugal recognized Angola's right to independence in 1974 the three nationalist groups made several unsuccessful attempts to form a coalition government. The exodus of Portuguese settlers left the country with a crippled infrastructure and without effective government. When independence was declared in November 1975, the MPLA and an allied FNLA-UNITA proclaimed two rival republics, and the country was plunged into civil war. The Soviet Union supported the MPLA's People's Republic of Angola, and South Africa and the United States aided the People's Democratic Republic of Angola proclaimed by FNLA-UNITA. Although the MPLA eventually established control of the government, intense factionalism continued, supported by the foreign powers. The government was unable to stabilize the country's economy and pursue its long-term objectives.

For later developments in the history of Angola, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL. (Ed.)

BOTSWANA

Botswana is a landlocked republic in southern Africa with an area of about 224,600 square miles (581,700 square kilometres). The greater part of the country is covered by the Kalahari. It is bounded by South Africa to the southeast and south, Namibia to the west and northwest, Zambia to the north, and Zimbabwe to the northeast and east. The actual border with Zambia along the Zambezi River, at the east end of the thin finger of Namibian territory known as the Caprivi Strip, is only several hundred yards long. The Caprivi Strip has not been established by international treaty and has been a source of controversy among the countries of Botswana, Namibia, Zimbabwe, and South Africa (the latter having acted as trustee for Namibia until 1990).

Before its independence in 1966, Botswana was a British protectorate known as Bechuanaland; one of the first acts of the nation was to move the capital from Mafeking in South Africa (since 1980 Mafikeng, Bophuthatswana) to Gaborone (formerly Gaberones). The country is named after its chief ethnic group, the Tswana, or Batswana. The language is Tswana (Setswana or Siswana).

Botswana is a member of the United Nations, the Commonwealth, and the Organization of African Unity (OAU), and it is a signatory of the Lomé Convention. It maintains economic links with South Africa as well as diplomatic ties with black states to the north and east, including Zimbabwe, Zambia, and Mozambique. Lacking adequate water and having a small population, Botswana was once primarily a stock-raising country. Large-scale mining of substantial diamond, copper, and nickel deposits and of other less important minerals began in the 1970s, diversifying and improving the economy.

Physical and human geography

THE LAND

The plateau

Relief and drainage. Botswana extends from the Chobe River (which drains into the Zambezi) in the north, to the Molopo River, a tributary of the Orange River, in the south. Most of the nation's territory lies within the Kalahari, a semidesert in the west. A plateau, with an altitude of about 4,000 feet (1,200 metres), divides the country into two distinctive regions, each with its own drainage system. After forming the watershed between the Molopo just to the south and the Notwani River to the southeast, the plateau extends northward from a point approximately 20 miles west of Kanye, a town in the southeast, to the border of Zimbabwe in the northeast. The area that lies to the east of the plateau is crossed by ephemeral streams that flow latitudinally into the Marico, Limpopo, and Notwani rivers; the western system, which once drained the tableland into the Makgadikgadi Pans, is now covered with deep sand.

The country has a mean altitude of 3,300 feet and is almost entirely flat or gently undulating, with Kalahari sands overlying Precambrian rock (from 570,000,000 to 4,600,000,000 years old). The greater part of the south has no surface drainage, and the rest of the country's drainage, except for the Limpopo and Chobe rivers on the borders, does not reach the sea.

The main drainage system is provided by the Okavango River, which, after flowing southeastward for 90 miles from the Angola border in the northwest, drains into a vast depression to form the approximately 4,000-square-mile Okavango Swamp, as well as Lake Ngami, a 70-square-mile pan, or basin. This system seasonally drains eastward along the Boteti River to Lake Xau (Dow), which is located near the centre of the country, and finally flows into the Makgadikgadi Pans farther east. The Molopo and Ramatlabama, which form the southern boundary, are both tiny streams.

The Kalahari is a "thirstland," rather than a true desert, being covered with grass and acacia thorn scrub; its tsama melons (a species of watermelon) help to sustain the San who live there. In areas where underground water is close to the surface, the Kalahari resembles parkland. The only typical desert occurs in the southwestern corner, where there are sand dunes.

Climate. Temperatures vary from temperate to subtropical. In summer (which lasts from October to March), temperatures rise to 100° F (38° C); in winter (which lasts from April to September), there is frequent frost, and temperatures fall below 32° F (0° C). Hot August winds carry sand from the Kalahari across the entire country. The average annual rainfall is 18 inches (460 millimetres), representing a variation from 25 inches in the north to five inches or less in the southwest. Most rain falls in heavy downpours between December and the end of April. Cyclical droughts, often lasting several years, are calamitous for both crops and cattle. One such drought occurred in 1965–66.

Plant and animal life. Woodland savanna (grassy parkland), in which species of acacia predominate, covers much of the country. In the northeast the most characteristic vegetation cover consists of mopane (African ironwood), mogonono (country almond), and mokusi (Rhodesian teak), while morukuru (*Spirostachys africanus*) frequently occurs in the central Kalahari. In the abundant grazing areas the several varieties of grasses include love grass, panicum, crabgrass, and bristle grass. True forest, which occurs only on the banks of the Chobe River, consists mainly of mokwa (bloodwood) mokusi, and monato (Rhodesian ash).

The game reserves

Herds of wild game teem on the plains, and the national parks and game reserves are well stocked. National parks include the Chobe, Nxai Pan, and Gemsbok; other wildlife areas are the Okavango delta and Lake Ngami, the Moremi Wildlife Reserve, and the Makgadikgadi Pans, Khutse, Mabuasehube, and Central Kalahari game reserves. Besides many species of large and small antelopes, there are lions, elephants, leopards, hippopotamuses, giraffes, buffaloes, and crocodiles. Poisonous snakes, among them the cobra and puff adder, abound; and there are many varieties of scorpions, spiders (including tarantulas), and termites. Bird life is prolific and includes ostriches, pelicans, and bustards. The principal fish, especially in the Okavango and Chobe rivers, are tilapia, tiger fish, and catfish.

Settlement patterns. The Tswana people are divided into eight principal tribal groups, each of which occupies its own separate territory with its own traditional chiefs and retains a communal ownership over its tribal lands that is inalienable. Associated with each of the dominant tribes are smaller related or formerly subject tribes. Only the nomadic San of the Kalahari, the few thousand Europeans, and some Tswana who have moved to the urban areas are not included in this traditional system. The largest tribe is the Ngwato (Bamangwato), which comprises about one-fourth of the total population and owns one-fifth of all the land; its territory lies in the eastern part of the nation. The Ngwato capital, Serowe, is spread out beneath rocky hills and is a large circular village consisting mostly of thatched huts. The next two largest tribes are the Kwena (Bakwena) and the Ngwaketse (Bangwaketse), who live in the southeast, near Gaborone. The other smaller tribes include the Kgatla (Bakgatla), the Bamalete, and the Tlokwa (Batlokwa), all of whom live in the southeast; the Rolong (Barolong), who spill over into South Africa; and the Tawana (Batawana), who live on the South West African border.

In the 19th century, several large blocks of land were transferred from African to European ownership around Lobatse, Gaborone, and Tuli in the southeast; Ghanzi in the west; and on the banks of the Molopo River in the south. The former Tati Concession in the Francistown District (now part of North East District), for example, gave a private company the right in 1869 to exploit a potentially rich mining region having an area of more than 2,000 square miles.

The Tswana way of lif

Unlike most Africans, the Tswana have a tradition of living in large villages, which are, in effect, capital centres for each tribe but are often located at great distances from their grazing lands. Cattle posts provide shelters for herdsmen and watering places for cattle. Richer cattle farmers have a large number of cattle posts, which are sometimes spread out at distances of 100 miles or more from each other. The farmers' practice is to spend several days of each week at their cattle posts, returning to their central village and families for long weekends.

Each village has its subchief, headmen, and *kgotla* or *lekhotlo,* a court and public meeting place situated near the chief's house, usually under a large tree and always beside the communal cattle enclosures, or kraals. The *kgotla* remains the centre of daily social life, at which disputes are settled in public and matters of local importance are discussed. Most villages have a school, a store, and sometimes a dispensary. Villages, small or large, are always divided into wards comprising the extended family, each part of which lives within its own compound. In the larger villages each ward tries to have its own borehole for water. Water carrying still forms a large part of the daily routine of women and girls throughout Botswana, just as cattle herding occupies the lives of boys, often conflicting with their schooling. The outlying villages are related closely

to their tribal capital, which is the seat of the paramount chief and the royal *kgotla.* This system of village democracy has, to a great extent, survived the politicizing of the nation and forms an integral part of the contemporary political structure.

Cattle, land, and rain are the most important factors in the lives of the people. Because the lives of people and cattle both depend on an unpredictable climate, rain (*pula*) is of particular significance. *Pula* is the people's familiar greeting on meeting each other and is the name of Botswana's currency.

There is considerable underemployment in Botswana, and many thousands of young people seek temporary work each year in South Africa. Outside the small tribal villages, employment within the country is mostly found in the half-dozen villages and towns along the railway line in the east—which links Botswana with South Africa and Zimbabwe—and at Selebi-Pikwe, the fast-growing centre of the copper- and nickel-mining industries. In such areas modern Tswana often break free of tribal constraints to form nationally integrated social and political groups.

Major cities

Gaborone, the capital city, has grown at the fastest rate. During the 1970s it passed Serowe, the largest of the tribal villages, in population. Francistown, the former centre of the Tati Concession area in the northeast, is the home of most of the European population. Mochudi and Lobatse have become commercial centres on the railroad line in the southeast.

THE PEOPLE

Ethnic groups. The original inhabitants were the San (known locally as the Sarwa or Masarwa), some of whom follow a nomadic way of life in the Kalahari, moving across the border of Namibia; they belong to the Naron, Auen, !Kung, and Heikum groups. Those of the San who have abandoned nomadism are mainly employed in servile positions by the dominant tribes or by the government. The Tswana group is composed of a cluster of tribes that are closely related in culture and language to the western Sotho.

The European population, mainly from South Africa, is small; it consists of farmers, traders, public officials, missionaries, and teachers. Most of these people live in European agricultural zones and in the towns along the railroad. Also living in Botswana are a few thousand Eurafricans, who are of mixed descent, and several hundred Asians.

The two official languages are Tswana and English. English is spoken only among the educated Africans or those who have worked for some time in South Africa. Afrikaans is spoken only by sections of the white community. Approximately one-third of the population is literate in Tswana and one-fourth in English.

Religious groups. The majority of people are Christians, although only a minority are active churchgoers; many are only nominal Christians in the sense that they still show some attachment to traditional religion, which is based on ancestor worship. The majority of practicing Christians are Anglicans, Congregationalists, Methodists, and Presbyterians; these four groups have united to worship as a single congregation. There are also smaller communities of the Dutch Reformed, African Methodist Episcopal, and Roman Catholic churches.

THE ECONOMY

Distribution of wealth

Most Tswana live by raising cattle. Mining, however, overtook the beef industry during the 1970s as the basis of the country's most important exports, and the mining of diamonds became the fastest growing source of revenue. A series of national economic plans after independence has given particular attention to energy needs, mining development, beef exports, and crop production. The economy has grown rapidly, but the distribution of this increased wealth has been disproportionate; wage-earning urban dwellers and large-scale livestock farmers have benefitted, while the rural majority of the population has experienced little or no gain.

Agriculture. Botswana's cattle are important to the country's economy. The animals are mostly crossbreeds; attempts have been made to introduce quality cattle based on imported herds. Except for European farming, there are few cash crops; most agriculture is grown on a subsistence basis. Periodic droughts and disease necessitate the importation of food and wreak havoc among the cattle population.

Mining. Diamond mines at Orapa, with a 50 percent share held by the government, began production in 1971; a second mine at nearby Lethakane began production in 1977. Since then diamonds have become the single most important export. A major new diamond pipe was discovered at Jwaneng in the late 1970s, and mining began there in the early 1980s.

The fastest growing area of Botswana, however, has been around Selebi-Pikwe, the location of the Shashi Project, which includes nickel and copper mines and water and power projects. Nickel and copper mining, begun in 1974, was initially hampered by technical problems but has come to play an increasingly important role in the economy of the country. There are substantial reserves of coal at Morupule and near Serowe. Prospecting for other minerals has continued, and legislation in 1977 vested all mineral rights in the state.

Industry. Almost all of Botswana's industries are associated with mining and agriculture, and there is virtually no manufacturing. The Botswana Development Corporation has assisted in the establishment of some industrial and commercial enterprises. Many of the smaller projects have been built in rural areas in an effort to decentralize employment.

Administration of the economy. The government is the largest employer of wage-earning labour and is active in promoting cooperative societies and water-development projects. In regard to private enterprise, the bulk of import and export trade is in European hands.

Transportation. During the 1970s the government began taking over the country's principal railway, which is managed by The National Railways of Zimbabwe. A main north–south road was completed in 1980, giving Botswana an all-weather road that runs the entire length of the country. Botswana has, in addition, several thousand miles of gravel and dirt roads. Air Botswana maintains domestic service and, with other airlines, provides international connections for travellers.

ADMINISTRATIVE AND SOCIAL CONDITIONS

Government. Legislative power is vested in the Parliament, which consists of the president and the National Assembly of 32 members elected by adult suffrage, four specially chosen members, and the attorney general. The president is the executive head of government; he is a member of and presides over the Cabinet, consisting of the vice president and other ministers drawn from the National Assembly. Elections for the presidency and National

Assembly are held every five years. The House of Chiefs advises the government; no legislation affecting tribal affairs may be passed without reference to this House. A code of human rights is enforceable by the High Court. A nonpolitical public service commission controls all matters relating to the public service. The local government system operates through nine district councils, as well as four town councils located in Gaborone, Francistown, Selebi-Pikwe, and Lobatse.

There are three nationalist parties, which represent more militant ideas than the ruling Botswana Democratic Party; they are the Botswana People's Party, the Botswana Independence Party, and the Botswana National Front. All four parties are national in the sense of having multitribal members; they usually attract both modern and tradition-minded supporters.

Justice. The High Court, consisting of a chief justice and puisne (associate) judges, exercises jurisdiction over all criminal and civil cases. The Court of Appeals deals with matters emanating from the High Court. There are subordinate magistrates' courts and African courts with limited jurisdiction in the local administrative districts.

Education. There are primary and secondary schools, some of which are run by mission societies and some by the government. Only a small number of pupils receive secondary education. Higher education is provided by the University College of Botswana, in Gaborone, and at teacher-training colleges. Technical training is also provided throughout the country.

Health and welfare. The most prevalent sicknesses are tuberculosis, gastroenteritis, pneumonia, and food deficiency diseases. Malaria is endemic in Chobe and Ngamiland, which is also infected by sleeping sickness. Bilharzia (a parasitic disease) occurs in the eastern area and in the Okavango Basin. There are hospitals and several health centres, dispensaries, and clinics. Care for mothers and children has been emphasized, and dental treatment was introduced in the 1970s.

CULTURAL LIFE

The life of the majority of the people is still strongly influenced by tribal institutions and cultures; there is a rich tradition of folklore, music, and dancing. The only strongly competitive cultural institutions are those provided by the churches and by some of the schools; Swaneng Hills School, an imaginative institution started by a South African expatriate, Patrick van Rensberg, may be especially mentioned. While not much vernacular literature of exceptional quality exists as yet, there are the beginnings of a modern vernacular literary tradition.

For statistical data on the land and people of Botswana, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL. (Co.L./Ed.)

History

Sotho peoples arrived in southern Africa at the time of the Bantu migrations; *i.e.,* mainly by 1600 or 1700. Some of the Tswana people only recently occupied their present homes.

EARLY EXPLORATION

A European expedition headed by J. Trüter and W. Somerville visited the Thlaping (or Tlhaping) of southern Botswana in 1801. These early visitors were followed by the traveller Martin Heinrich (Henry) Lichtenstein and the naturalist W.J. Burchell. John Campbell, having in 1813 been invited by the chief of the Thlaping to "send instructors," the London Missionary Society established a mission on the Kuruman (properly Kudumane) River. Under Robert Moffat, who took charge in 1821, Kuruman became one of the foremost Protestant missions of southern Africa. About this time the rise of the Zulu power had set up a chain of destructive movement across the continent. Thousands of refugees, fleeing from Shaka's Zulu armies, roamed the countryside pillaging and plundering and in their turn starting fresh waves of migration. In 1823 the Thlaping, threatened by one such horde, were saved only by Moffat's enlisting the help of Griqua mounted riflemen. In the same year Sebetwane started from the Vaal River and, after fighting his way through Botswana, founded the powerful but short-lived empire of the Makololo in the Zambezi Valley.

About 1826 Mzilikazi (Umsilikazi, Mosilikatze), son of Machobane, one of Shaka's captains, after breaking away from the Zulu king, settled with his people, the Ndebele, in what is now the western Transvaal. From there he raided extensively into Botswana. These depredations continued even when the Ndebele, after their defeat by the Boers in 1837, had moved to the north. The Great Trek of the Boers from the Cape Colony (1835 and after) brought the Voortrekkers across the Vaal River to the frontiers of Botswana. The Boers disliked the proximity of powerful, independent chiefs; thought that the penetration of Botswana by the missionaries of the London Missionary Society and by British traders and hunters would curb Boer expansion northward; and claimed a western boundary that included the "missionaries' road" (which ran through Botswana), the highroad from the Cape to the interior. They came sharply into conflict with David Livingstone, who had landed in Africa in 1841 and had settled among the Kwena, a senior Tswana tribe, whose chief, Sechele (Setshele), became a Christian. Livingstone sided with the Africans in their resistance to the various demands of the Boers, who further suspected him of supplying Sechele with firearms. In 1852 a raid was made on Sechele's town of Dimawe. During the raid Livingstone's mission at Kolobeng, near Dimawe, was ransacked, though by whom was never conclusively proved. The widely publicized raid on Dimawe was only one incident in a struggle that lasted for many years.

The Boers
and David
Livingstone

GOLDFIELDS

In 1867 gold was discovered near the Tati River, in country claimed both by the Ngwato and by the Ndebele. Pres. Marthinus Pretorius of the Transvaal in 1868 proclaimed the annexation of a huge area including the goldfields, but the British government refused to recognize this. At the same time Macheng (Matsheng), chief of the Ngwato, sought without success to persuade the British to occupy the goldfields. In the south the arbitration award of R.W. Keate, lieutenant governor of Natal, in 1871, purporting to define a boundary between the Rolong and the Transvaal, did nothing to abate Boer encroachment. Disorders among the tribes in 1878, quickly suppressed, led to the occupation of southern Botswana by a small police force. On the withdrawal of this force in 1881 the country relapsed into anarchy.

The Pretoria Convention of 1881 defined the boundaries of the Transvaal on all sides for the first time but still did not curb Boer encroachment. The chiefs relied on European supporters (not all of them Boers), to whom they promised land and cattle. These so-called volunteers then set up the two little republics of Stellaland and Goshen, threatening the missionaries' road. In 1883 Pres. S.J.P. Kruger of the Transvaal led a deputation to London to seek a revision of the Pretoria Convention. The London Convention of 1884 conceded to the Boers, among other things, small alterations in the western frontier; but Kruger failed to get the missionaries' road, though he tried hard to do so. About this time, moreover, German colonization in South West Africa was causing concern to the British. Humanitarians, inspired by John Mackenzie, a successor of Moffat at Kuruman and a vehement campaigner for African rights, were opposing the extension of Boer authority and advocating that the country should be taken under British protection. Cecil Rhodes meanwhile threw all his weight into a campaign for the annexation of Botswana to the Cape Colony. The British government then decided to establish a protectorate over the territory that later became British Bechuanaland and sent John Mackenzie as the first deputy commissioner. Mackenzie, without men or money, was unable to make much headway against the prevailing anarchy. He was soon superseded by Rhodes, who did no better.

Freebooters from Goshen attacked Mafeking; Kruger annexed the country of the Rolong; the republican flag was hoisted at Mafeking; and the freebooters proceeded to carve up the adjacent African-held lands. The British government, prompted by these aggressions, sent a strong force under Sir Charles Warren to set matters in order (which Warren was able to do without firing a shot) and then extended the protectorate northward to the 22nd parallel of south latitude and westward to the 20th degree of east longitude (March 1885). The territory south of the Molopo River was constituted as the crown colony of British Bechuanaland (September 1885; annexed to the Cape Colony, 1895). In 1892 another proclamation considerably enlarged the protectorate by adding to it the territory between the Shashi and Motloutsi rivers; the Tati district; those territories north of latitude 22° that were claimed by Khama (Kgama) III, chief of the Ngwato since 1875; and some vast ill-defined areas lying north and west of Khama's country.

MAINTAINING THE PROTECTORATE

In the early 1890s the protectorate, as Rhodes had intended, became the springboard for the British South Africa Company's colonization of Southern Rhodesia. But in 1895 a plan to hand the administration of the protectorate over to the company was frustrated by the action of the three chiefs Khama, Sebele, and Bathoen, who, supported by the missionaries, travelled to London and wrung from Joseph Chamberlain an assurance that their people would remain under the protection of the crown. In exchange they had to surrender strips of land on the east side of their countries for the construction of a railway. The Jameson Raid at the end of 1895 completed the ruin of any plans for the company's administration of the protectorate.

South Africa often expressed the wish that the administration of Botswana (with Lesotho [Basutoland] and Swaziland) should be handed over to it. The British government's position was made public on June 20, 1935; no transfer was to take place until the inhabitants had been consulted and until Parliament had expressed its opinion. On several occasions subsequent British governments confirmed that there had been no change in this policy.

In 1948 Seretse (later Sir Seretse Khama, who was knighted just before independence), son of Khama's son Sekgoma II and heir to the Ngwato chieftainship, married an Englishwoman, Ruth Williams, while he was studying in Britain. The British government, it is thought because of pressure from South Africa (Khama was declared a prohibited immigrant in that country), refused to recognize him as chief and he was banished from Botswana.

Until 1961 the country was administered by a resident commissioner under the direction of the British high commissioner in South Africa and with the assistance of an advisory council of chiefs. In 1961 executive and legislative councils, the latter with an unofficial majority, were introduced. In 1965 a constitution granting internal self-government was introduced, and at the first general election the Bechuanaland (later Botswana) Democratic Party (BDP) formed the government that led the new state to independence. The BDP was headed by Seretse Khama, who had been permitted to return as a private citizen in 1956. In an 80 percent poll the BDP received 113,177 votes and 28 of the Legislative Assembly's 31 seats. The Botswana People's Party received 19,664 votes and the remaining three seats.

INDEPENDENCE

The Republic of Botswana became an independent member of the Commonwealth of Nations on September 30, 1966. It was also admitted to the United Nations in that year. By terms of the constitution, the prime minister (Sir Seretse Khama) became the first president and the Legislative Assembly elected in 1965 became the first National Assembly. (Ay.Sy./S.Tr.)

Relations with Soutl Africa

South Africa changed its previous attitude to the former high commission territories (Bechuanaland, Basutoland, and Swaziland). In 1965 the prohibition on Khama's entering South Africa had been lifted. South African Prime Minister B.J. Vorster later stated that Botswana's becoming independent was not a development that caused concern and that it was in keeping with South Africa's own policy. Sir Seretse Khama, however, dismissed a suggestion, coming from unofficial quarters, that Botswana should join a southern African federation. This, he said, would prevent Botswana from having ties with black Africa and from acting as a bridge between north and south. Moreover, this would make Botswana a "Bantustan," which could not be permitted.

Sir Seretse Khama and his government therefore attempted to maintain a delicate balance between Botswana's "front-line" neighbours—the majority-ruled states bordering on South Africa—and South Africa itself. Botswana retained its close trade and transport links with South Africa, but in 1980 it also was among the founding members of the Southern African Development Coordination Conference, an economic and political union formed to increase regional cooperation and decrease the member nations' dependence on South Africa.

Botswana harboured refugees from Rhodesia, during the struggle there for majority rule, and from South Africa and was accused by South Africa of supporting guerrillas of the outlawed African National Congress (ANC) as well. The country was thus exposed to incursions by South African forces seeking to rout ANC guerrillas and supporters. At the time of independence Botswana had chosen not to establish an army but to rely on an efficient police force instead, but in 1977 a permanent defense force was created to patrol the borders and maintain order.

Sir Seretse Kharma was sworn in for his second term as president; he held office until his death on July 13, 1980, and was succeeded by the vice president, Quett Masire. The Botswana Democratic Party retained its majority representation in the national government, although some local support was lost to opposition parties in elections held in 1984.

For later development in the history of Botswana, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL. (Ay.Sy./S.Tr./Ed.)

LESOTHO

The Kingdom of Lesotho in southern Africa has an area of 11,720 square miles (30,355 square kilometres). It is one of only two independent states in the world (the other is the Republic of San Marino in western Europe) completely encircled by a single country on whom it must depend exclusively for access to the outside world. It forms an enclave within the Republic of South Africa, bordering on three of the latter's provinces—Natal, the Orange Free State, and Cape Province. This physical dependence on its neighbour is further accentuated by Lesotho's own grave lack of resources, which makes it necessary for between one-fourth and one-half of the labour force to live and work, mainly as migrants, in South Africa. For this reason, it is sometimes described as a "hostage state." It is a member of the Commonwealth and of the Organization of African Unity, and it is a signatory of the Lomé Convention. Before its independence on October 4, 1966, it was one of the three British High Commission Territories—the other two being Bechuanaland (now Botswana) and Swaziland.

Lesotho is the name of the country and Sotho (or Basotho or Basuto) is the name of the people; a single individual is referred to as a Mosotho. Sotho (or Sesotho) is the language. The capital is Maseru.

Physical and human geography

THE LAND

Relief. Two-thirds of the country consists of mountains; the highest peak, Thabana Ntlenyana, is 11,425 feet (3,482 metres) above sea level. The Drakensberg Range forms the eastern boundary with Natal. The Maloti spurs,

he
ateau

running north and south, join the main range in the north, where they form a plateau between 9,000 and 10,500 feet in altitude. This plateau is the source of South Africa's two largest rivers—the eastward-flowing Tugela and the westward-flowing Orange, as well as tributaries of the Caledon. The foothills, which have average altitudes of between 6,000 and 7,000 feet, descend in undulating slopes to the west, where the lowlands bordering on the Orange Free State average 5,000 to 6,000 feet in altitude.

The mountain soils are of basaltic origin and are shallow but rich. The soils of the lowlands derive mainly from the underlying sandstone. Extensive erosion has severely damaged soils all over the country.

Climate. The rainfall, brought by the prevailing winds, occurs mostly between October and April; it is variable, averaging about 28 inches (711 millimetres) a year throughout most of the country. Although droughts are rare, their periodic occurrence is devastating. Temperatures in the lowlands vary from 90° F (32° C) in the summer to 20° F (−7° C) in the winter. In the highlands the temperature range is much wider, and readings below 0° F (−18° C) are not unusual. Frost occurs widely in the winter, when the Maloti are usually snowcapped. Hail is a frequent summer hazard.

Plant and animal life. The grasslands of the highlands are mainly covered by *Themeda triandra* or red grass. Indigenous trees and shrubs have survived only in the more remote and sheltered valleys. The most common types are wild olives, wild garlic, wild willow, brushwood, thatching grass (*Hyparrhenia hirta*), hypoxis, and aloes. Wildlife has become almost extinct, except for occasional small antelopes, hares, and reptiles.

Settlement patterns. Although not permanently inhabited, the mountain grasslands on the slopes of the high plateau as well as in the valleys provide excellent grazing for sheep and cattle, which are tended by herdsmen in isolated cattle posts. Some of the deep valleys, like the Senqunyane, produce good crops of wheat, peas, and beans. About one-third of the population lives in the highlands; another one-fifth lives in the foothills, which good grazing and cultivation have made the most productive region. One-half of the population lives in the lowlands, which form a narrow corridor, averaging only 25 miles (40 kilometres) in width, along the Caledon River.

ɔour

The Sotho combine modern and traditional ways to an unusual degree; this provides stability in a society that, possibly more than any other, is disrupted by a permanent system of migratory labour. Traditional authority is still firmly exercised through a system of chieftaincy extending from the paramount chief (the king) and his court, down through senior chiefs and subchiefs, to headmen and subheadmen at the village level. Their authority now rests largely on the fact that they are responsible for the working and distribution of all land that belongs to the nation, with the king acting as trustee.

Social cohesion is strengthened by the persistence of clan and family loyalties. Families and clans still cluster together as units in the numerous small rural villages. There are no large towns in the country. The villages range in size from one large to four or five extended families, with an average of from 30 to 50 immediate families. The villages are often picturesque, offering fine views of the rocky highlands; on the plains they are often surrounded by aloes and trees, and the walls and doors of many houses are covered with patterned designs. The villages themselves consist of clusters of circular or rectangular huts solidly built of turf, Kimberley brick (unburned clay), or dressed stone, mostly with thatched roofs; more recently, however, corrugated iron has become a popular roofing material.

The average household usually has two or three huts, the larger one being used as a living and dining area and as the parents' bedroom; the smaller ones are used for kitchen and storage purposes and as sleeping quarters for the children. The hut of the chief, or headman, is usually in the centre of the village, flanked by that of the principal wife and ringed by those of the junior wives. The *lekhotla* (open court) is in front of the chief's hut; beside it are the kraals (enclosures) for the cattle and stables for horses. Village life centres largely on the fields, the chief's court, the kraals, the school, the church, and the initiation lodge. Circumcision forms an integral part of the ritualized initiation ceremonies that train boys to take their place as full members of the family, clan, and nation—the three centres of social cohesion. Young boys still spend a large part of their lives as herdsmen, while women and young girls do much of the hard work in the fields, a practical necessity because the able men are usually absent, although they contrive to return home briefly for the plowing or the harvest.

Initiation
ceremonies

Two distinctive features of social life are the people's love for horses and for blankets. The small, sturdy Sotho pony is renowned for its surefootedness in rough country; it is often the only means of rural transport. Because of the sharp variations in climate, both men and women invariably wear blankets, which they use as cloaks; a great deal of care is taken in choosing a blanket, which, especially for the men, is usually multicoloured. Men and women also wear the typical Sotho hat, which is woven from reed into conical shapes, with an unusual topknot.

Maseru, the capital, in the northwest on the banks of the Caledon River, is a small rural town with civil servants, professional people, and traders. On most days of the week, however, it is a bustling town crowded with people who are either in from the surrounding lowlands or down from the mountains, or with migratory workers passing to and from South Africa.

THE PEOPLE

Ethnic groups. The Sotho comprise a cluster of tribes of the Southern Sotho linguistic stock, who are united by a common loyalty to the royal house of Mshweshwe (or Moshesh or Moshoeshoe). The group that formed the nucleus of the nation is that of the Kwena, who are made up of the Molibeli, Monaheng, Hlakwana, Kxwakxwa, and Fokeng tribes. They still regard themselves as the true nation and tend to look down on the other two main groups that were politically absorbed into their society but were not always culturally assimilated, although they speak the same language. The first of these groups is formed by the Natal (North) Nguni, who include the Phetla, Polane, and Phuti; they are largely indistinguishable from the Kwena. The second group comprises the Mahlape tribe of the Natal Nguni and the Cape (South) Nguni (Thembu).

There are a few thousand Europeans, Asians, and Coloureds (of mixed racial origin). The Europeans are mainly traders, businessmen, technicians, government officials, missionaries, and teachers, while the Asians are mainly professionals or traders.

Emigration

Because the country is severely overpopulated, both temporary and permanent emigration has taken place. No exact figures exist for the number of Sotho working or living in South Africa. The great majority of the migrant workers are men under the age of 40.

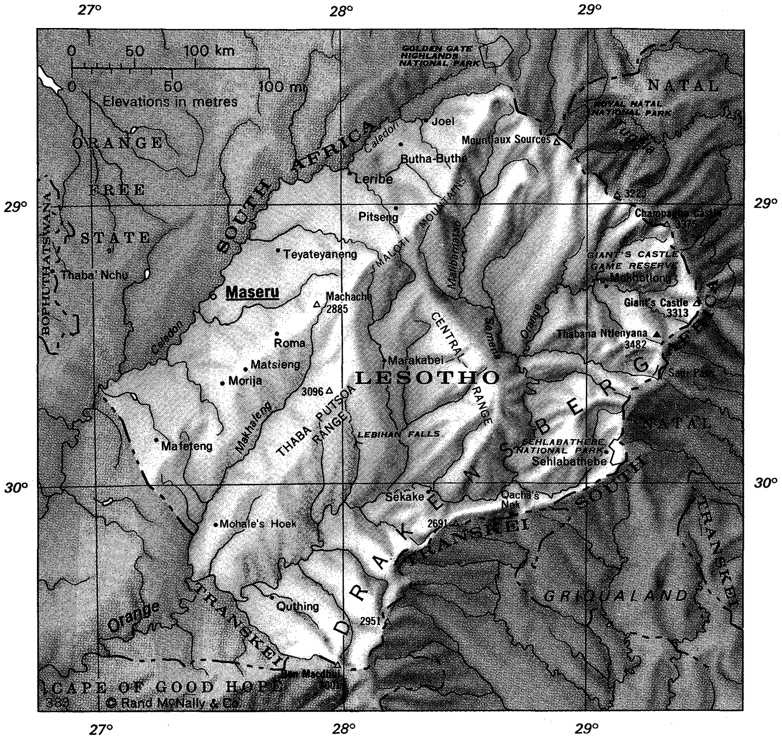
Religious groups. Christianity and traditional religions (which are based on a belief in ancestral spirits) coexist uneasily in a country where the great majority of people are active members of Christian churches. The Christians are about evenly divided between Roman Catholics and Protestants (mainly French Protestants, Anglicans, Baptists, and members of the Dutch Reformed Church).

THE ECONOMY

Economic
links to
South
Africa

Lesotho is a poor country with few natural resources; these are certainly insufficient to sustain even the present population. Its economy could not be sustained at all without such benefits as it derives from South Africa, with which Lesotho forms part of a customs union and shares an integrated communications system. Lesotho also depends wholly on South Africa for the export of its surplus working population.

Agriculture. Only about one-tenth of the land is arable; this amounts to less than one acre (one-half hectare) per head of the resident population. Agriculture provides about one-third of the gross domestic product. The crop yields are low; subsistence crops such as corn (maize), sorghum, wheat, peas, beans, and barley are the most important. A large percentage of the cattle die each year, and so the cattle herds have little commercial value. By



LESOTHO

contrast, the sheep and goat herds are valuable assets. Wool is exported, and Lesotho is one of the world's largest mohair producers.

Industry. Geological surveys have so far shown little promise of mineral wealth, although small quantities of diamonds have been found. Other minerals discovered, such as iron ore, gypsum, quartz, and calcite (limestone chalk), are commercially uneconomic.

Secondary industry is of recent growth and is confined to such small-scale manufacturing as milling, brickmaking, and furniture making.

Tourism. Tourism is promising for a country that has justifiably been called the Switzerland of southern Africa. Modern hotels have been built, mountain roads and pony trails developed, and trout streams stocked with fish. There are casinos and large hotels in Maseru and a ski resort at Oxbow.

Trade. Lesotho has a large and growing trade deficit. Most trade is with South Africa. The large deficit is made up by the remittances of Lesotho's migrant workers, by external aid, and by receipts from the Customs Union in agreement with South Africa, Swaziland, and Botswana.

Administration of the economy. The government is the largest employer of labour in the country, more than one-third of its annual budget being made up of payments to its public employees. Three forms of direct taxation are levied: a basic tax on all adult males; a graded tax on all income earners; and an income tax.

Transportation. A main road runs along the western and southern boundary, and a mountain road from Maseru reaches into the interior. These two main arteries are served by short-distance feeder roads. Villages in the mountains are served by bridle paths. A one-mile railway line links the capital to the South African transport network.

Although considerable use is made of light aircraft for passengers and for transporting mail and freight to the interior, only Maseru has a regular airport suitable for commercial planes. There are also rough airstrips. A national airline was formed in 1977.

ADMINISTRATIVE AND SOCIAL CONDITIONS

The country's constitution provides for a bicameral parliamentary system with the king as hereditary head of state. Under the constitution the National Assembly has 60 members, each elected by universal adult suffrage to represent a single constituency; the Senate has 33 members, of whom 22 are principal chiefs and 11 are appointed.

The constitution was suspended following the contested results of the 1970 general election, in which the opposition claimed to have defeated the ruling Basotho National Party (BNP). The legislature was replaced by an appointed 93-member interim assembly that included the 33 members of the Senate. In 1973 a new National Assembly, consisting of the 22 principal chiefs and 71 members from the BNP and other parties, was appointed, but the assembly was dissolved in 1986.

Justice. The legal system is based on Roman and Dutch law. There are magistrates' courts, a Court of Appeals, and a High Court. Appeals of certain cases of a constitutional nature may be taken to the Privy Council in the United Kingdom.

Literacy

Education. The country has one of the highest literacy rates in Africa. More girls than boys attend school, due to the latter's employment as herdsmen. Although about nine-tenths of all school-age children are in primary schools, fewer than one-tenth attend beyond the lower primary level, and fewer than a third of these attend secondary schools. Most of the schools are run by the Christian churches. There are primary and secondary schools, one agricultural school, and teacher-training colleges. The National University of Lesotho is based at Roma, 22 miles from Maseru.

Health and welfare. The country's healthy climate contributes largely to the comparatively low rate of sickness. The main incidence of ill health is the result of food-deficiency diseases, venereal disease, chronic rheumatism, infections of the respiratory tract, and dyspepsia. There are several hospitals, about half of which are operated by the government, and a number of clinics for maternity, child health, and venereal diseases, as well as a few health centres and dispensaries.

The country offers few opportunities for earning a salary. Some teachers and corporate employees are paid by the state. Of those working outside the agricultural sector, most are employed by the government, by schools or missions, in commerce, or by cooperative societies.

CULTURAL LIFE

Traditional institutions remain strong despite the modernization and politicizing of Sotho society. The paramount chief and the system of chieftaincy remain a strong focus

nportance
'the
ieftains

of loyalty, especially since some of its more venal aspects were reformed in the 1960s; there still is, however, considerable criticism of the power of chiefs and headmen, especially of their manner of administering the distribution of land and of the proliferation of officeholders within the chieftaincy system. Historical traditions and the philosophy of the founder of the nation, Mshweshwe (who was born at the end of the 18th century and died in 1870), exercise a profound influence in sustaining the Sotho nation's sense of independence and national pride. There is a strong literary tradition, which has been stimulated by modern education. Folklore flourishes, both in oral and written forms.

The initiation schools continue to play an important role in the villages and are a source of keeping alive a sense of the traditional values of the clans and the nation.

Village crafts, such as the decoration of walls, woodwork, clay making, weaving, and basketwork, flourish. Choir singing is popular.

For statistical data on the land and people of Lesotho, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL. (Co.L./Ed.)

History

The San (Bushmen) were the earliest inhabitants of what is now Lesotho, but they died out many years ago. The first Bantu were Nguni (Zulu-speaking) tribes who crossed the Drakensberg in the 18th century and settled along the banks of the Caledon River. Later they were joined by Sotho-speaking tribes. They all lived at peace, disturbed only by intermittent cattle raids, until early in the 19th century, when that part of Africa was set in turmoil by the Zulu Shaka. Many tribes fled over the Drakensberg, pursued by his regiments until the social fabric of the people was almost destroyed. Eventually a young chief, Mshweshwe (also Moshoeshoe or Moshesh), born about 1786, gathered the remnants of the tribes about him and, using impregnable mountain fortresses such as Thaba Bosiu as his bases, beat back the invaders, and established his people securely against the Zulus.

No sooner was the Zulu menace from the east contained than the Basuto people had to face the Europeans who were trekking up from the south. With the unerring skill of a diplomat, Mshweshwe played off the rulers of the Boer states and the colonial government of the Cape Colony against each other. He welcomed missionaries and traders to Lesotho, but with both he showed himself well able to hold his own. As tension increased between the Basuto and the Boers, who were passing through or settling in his country in increasing numbers, Mshweshwe's conviction grew that the only hope of "existence and peace" lay in British protection. He laboured incessantly to make this hope a reality, and with the help of Sir George Napier, governor of the Cape Colony, he achieved it.

Protection was first granted in 1843. Then in 1848 British sovereignty was proclaimed over the Orange River country, and in 1849 the boundaries of Mshweshwe's territory were reduced. But in 1854 the British renounced sovereignty over the Boers north of the Orange, and Mshweshwe was left to battle on through repeated disappointments and almost continuous strife with his Bantu, Boer, and British neighbours, until at last, in 1868, Lesotho was proclaimed British territory. The Boers, who had overrun practically the whole country up to the foothills, protested in vain against this interference and had to be content with a 30-mile strip of "conquered territory" along the Caledon. Mshweshwe died two years later, happy that his people had at last become British subjects. The Basuto owe their existence as a nation to the genius of Mshweshwe, who must be regarded as one of the dominant figures of South African history in the 19th century.

ınex-
on to
pe
lony

In 1871, without adequate consultation, Lesotho was annexed to the Cape Colony and a small administrative staff established. Then tactless attempts at direct rule, ignoring Basuto customs and loyalties, coupled with precipitate doubling of the hut tax, led to minor revolts and increasing restlessness. This finally flared into open revolt (the Gun War, 1880) when the government attempted to disarm the people. Peace was reestablished in 1883. The Cape Colony, weary of attempting to administer Lesotho, asked the British government to be relieved of the responsibility, while the Basuto chiefs for their part preferred British protection to the possibility of renewed encroachment from the Free State. In 1884 Lesotho ceased to be a portion of the Cape Colony and became a crown colony.

The new governor's agent was instructed that "nothing more should be attempted at first than the protection of life and property and the maintenance of order on the border," and that the Basuto "were to be encouraged to establish internal self-government sufficient to suppress crimes and settle intertribal disputes." These instructions were faithfully obeyed. The chiefs were left to rule their people according to traditional law and custom, and the authority of Mshweshwe's senior son and of his son Lerotholi after him was supported. By 1898, after a few bloody affrays, Lerotholi enjoyed undisputed supremacy, and British control was accepted. Credit for this was due to the early resident commissioners, Sir Marshall Clarke (1884), Sir Godfrey Lagden (1893), and Sir Herbert Sloley (1902), and to Lerotholi, who was paramount chief from 1891 to 1905 during the difficult transitional period. In 1905 Lerotholi died, and the national council with the imperial government concurring elected his son Letsie chief.

Basuto fears for their future were never entirely allayed, however. During the South African War, they were uneasily neutral. In 1906 the extension of the South African railway system to Maseru, indicative of the growing importance of the country's agriculture, trade, and labour supplies, was strenuously opposed by the younger chiefs as a potential threat to their independence, although only one mile of the new line lay inside the border. These fears were revived again in 1909 by the unification of the four South African colonies and discussion about the transfer of the administration of the High Commission Territories to the government of the new Union of South Africa. A deputation petitioned the king, asking that the country remain "outside [the Union] as far as possible, independent as it is now" and was reassured.

Thereafter the matter remained quiescent until 1933, when informal discussions were opened between the Union and British governments. In 1935 an *aide-mémoire* recalled the pledges made by the British government both to the British Parliament during the passage of the South Africa Act (1909) and to the inhabitants of the Territories, and recorded that the two governments now agreed that in the ensuing years their policies toward Africans "should be directed to bringing about a situation in which if transfer were to become a matter of practical politics it could be effected with the full acquiescence of the populations concerned." The South African government continued until 1955 to assume that it would ultimately incorporate Lesotho. The Basuto, however, never expressed anything but hostility to this assumption, and their determination not to be taken over by South Africa was strengthened in mid-20th century by the rise of a nationalist movement seeking independence and by the support given the movement by member states of the United Nations and the Organization of African Unity. The South African government initially showed great anxiety about the possibility of an independent African state in its heartland, but after the electoral victory in 1965 of the conservative and traditionalist Basotho National Party, led by Chief Leabua Jonathan, it agreed to its small and completely dependent neighbour's mapping out its own political future.

Nationalist
movement

After discussions in September 1966 Hendrik Verwoerd, prime minister of the Republic of South Africa, and Chief Jonathan issued a statement outlining their objectives. These were "to establish how good neighbourly relations and cooperation could be arranged. . . . There is no desire for our states to interfere in one another's domestic affairs, but that friendly relations between these two independent neighbouring states will be preserved." (S.Tr.)

Lesotho became an independent kingdom within the Commonwealth of Nations on October 4, 1966. The first head of state was the paramount chief (Motlotlehi) Moshoeshoe II; Chief Jonathan was the first prime minister. Moshoeshoe's demand for powers wider than those of a constitutional monarch was denied. In January 1970, following elections in which the opposition Basotho Congress Party claimed to have gained a majority, Chief Jonathan proclaimed a state of emergency, suspended the constitution, and placed the King under house arrest. Moshoeshoe was later allowed to go to The Netherlands. A reconciliation was effected between Chief Jonathan and the King, who returned to Lesotho in December 1970 to again become head of state, with the understanding that he would take no part in politics. (S.Tr./Ed.)

Lesotho's relations with South Africa fluctuated under Chief Jonathan and deteriorated in the early 1980s. Seeking friendship and aid elsewhere, Chief Jonathan opened diplomatic relations with China, North Korea, and the Soviet Union. Within Lesotho, political opposition to Chief Jonathan's Basotho National Party increased. In January 1986 troops of the country's paramilitary forces overthrew the government. A six-man military council dissolved the National Assembly and returned executive and legislative powers to the King, who was to act on the advice of the council.

For later developments in the history of Lesotho, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL. (Ed.)

MALAŴI

A landlocked southeast African country of dramatic highlands and extensive lakes, the Republic of Malaŵi occupies a narrow, curving strip of land along the East African Rift Valley. Stretching about 520 miles (837 kilometres) from north to south, it has a width varying from five to 100 miles and is bordered by Tanzania to the north, Mozambique to the east and south, and Zambia to the west. Its total area of 45,747 square miles (118,484 square kilometres) includes some 9,400 square miles of lake surface dominated by the 8,900 square miles of Lake Nyasa (known in Malaŵi as Lake Malaŵi). In 1975, the capital was moved from Zomba to Lilongwe, in the Central Region, and the new capital city became the focal point of the nation's development.

Most of Malaŵi's population engages in cash-crop and subsistence agriculture. The country's exports consist of the produce of both small landholdings and large tea and tobacco estates. Malaŵi has successfully attracted capital investment and has made great strides in the exploitation of its natural resources. The country is almost totally dependent upon Mozambique for access to the sea.

Physical and human geography

THE LAND

The four basic regions

Relief. While Malaŵi's landscape is highly varied, there are four basic regions—the East African (or Great) Rift Valley, the central plateaus, the highlands, and the isolated mountains. The Great Rift Valley—by far the dominant feature of the country—is a gigantic troughlike depression running throughout the country from north to south and containing Lake Nyasa and the Shire River valley. The lake's littoral, situated along the western and southern shores and ranging from 5 to 15 miles in width, covers about 8 percent of the total land area and is spotted with swamps and lagoons. The Shire Valley stretches some 250 miles from the southern end of Lake Nyasa at Mangochi to Nsanje at the Mozambique border and contains Lake Malombe at its northern end. The Central Region plateaus rise to an altitude of between 2,500 and 4,500 feet (760 and 1,370 metres) and lie beyond the littoral to the west; the plateaus cover about three-quarters of the total land area. The highland areas are mainly isolated tracts that rise as much as 8,000 feet above sea level. They comprise the Nyika, Viphya, and Dowa highlands and Dedza-Kirk Mountain range in the north and west and the Shire Highlands in the south. The isolated massifs of Mulanje (10,000 feet) and Zomba (7,000 feet) represent the fourth physical region. Surmounting the Shire Highlands, they fall away in the east, running down to the Lake Chilwa–Phalombe Plains.

Drainage and soils. The major drainage system is that of Lake Nyasa, which covers some 11,430 square miles and extends beyond the Malaŵi border. It is fed by the North and South Rukuru, Dwangwa, Lilongwe, and Bua rivers. The Shire River, the lake's only outlet, flows through adjacent Lake Malombe and receives several tributaries before joining the Zambezi River in Mozambique. A second drainage system is that of Lake Chilwa, the rivers of which flow from the Lake Chilwa–Phalombe Plains and the adjacent highlands.

Soils, composed primarily of red earths, with brown soils and yellow gritty clays on the plateaus, are distributed in a complex pattern. Alluvial soils occur on the lakeshores and in the Shire Valley, while other soil types include hydromorphic (excessively moist) soils, black clays, and sandy dunes on the lakeshore.

Climate. There are two main seasons—the dry season from May to October and the wet season from November to April. Altitude has an important effect upon temperature. Nsanje (Port Herald), in the Shire River plain, has a mean July temperature of 69° F (21° C) and an October mean of 84° F (29° C), while Dedza, which lies at an altitude of more than 5,000 feet, has a July mean of 57° F (14° C) and an October mean of almost 69° F (21° C). On the Nyika Plateau and on the upper levels of the Mulanje Massif, frosts are not uncommon in July. Annual rainfall is highest over parts of the northern highlands and on the Sapitwa peak of Mulanje Mountain, where it is about 90 inches (2,300 millimetres); it is lowest in the lower Shire Valley, where it ranges from 25 to 35 inches (650 to 900 millimetres).

Diversity of vegetation

Plant and animal life. The natural vegetation pattern reflects diversities in altitude, soils, and climate. Savanna (grassy parkland) occurs in the dry lowland areas. Open woodland with bark cloth trees, or *miombo* (leguminous trees unsuitable for timber), is widespread on the infertile plateaus and escarpments. Woodland, with species of acacia tree, covers isolated, fertile plateau sites and river margins; grass-covered, broad depressions, called *madambo* (singular, *dambo*), dot the plateaus; grassland and evergreen forest are found in conjunction on the highlands and on the Mulanje and Zomba massifs. Swamp vegetation is, however, being greatly altered by human settlement. Much of the original woodland has been cleared, and, at the same time, forests of softwoods are being planted in the highland areas. High population density and intensive cultivation of the Shire Highlands hinder the natural regeneration process; wells have been sunk and rivers dammed to irrigate the dry grasslands for agriculture.

Game animals abound only in the game reserves, where antelope, buffalo, elephants, leopards, lions, rhinoceroses, and zebras occur; hippopotamuses live in Lake Nyasa. The lakes and rivers contain more than 200 species and 13 families of fish. The most common and commercially significant fish include the endemic tilapia, or *chambo* (nest-building freshwater fish); catfish, or *mlamba;* and minnows, or *matemba.*

Settlement patterns. A rural village—called a *mudzi*—is usually small. Organized around the extended family, it is limited by the amount of water and arable land available in the vicinity. On the plateaus, which support the bulk of the population, the most common village sites are at the margins of *madambo,* which are usually contiguous with streams or rivers and are characterized by woodland, grassland, and fertile alluvial soils. In highland areas, scattered villages are located near perennial mountain streams and pockets of thin but arable land. The larger settlements of the Lake Nyasa littoral originated in the 19th century as collection points for slaves and later developed as lakeside ports. Improvements in communication and the sinking of wells in semi-arid areas have permitted the establishment of new settlements in previously uninhabited areas. Architecture is also changing; the traditional round, mud-

walled, grass-roofed hut is yielding its place to rectangular brick buildings with corrugated iron roofs.

Urban development began in the colonial era, with the arrival of missionaries, traders, and administrators, and was further stimulated by the construction of the railway. The only true urban centres are Blantyre-Limbe, Zomba, Mzuzu, and Lilongwe. Although some district centres and missionary stations have an urban appearance, they are closely associated with the rural settlements surrounding them. Blantyre, Malaŵi's industrial and commercial centre, is situated in a depression on the Shire Highlands at an altitude of about 3,400 feet. Zomba, seat of the University of Malaŵi, lies at the foot of Zomba Mountain and is purely of administrative origin. Farther north is Lilongwe, Malaŵi's new capital, which is developing agricultural industries.

THE PEOPLE

edomi-
ınt
ıguages

Nine main groups are historically associated with modern Malaŵi—the Chewa, Nyanja, Lomwe, Yao, Tumbuka, Sena, Tonga, Ngoni, and Ngonde (Nkonde). All the African languages spoken belong to the Bantu language family. Although Chichewa and English are the official languages, English was understood in 1966 by less than one-fifth of the population, while Chichewa was spoken by more than half and understood by about three-quarters. Other important languages are Chilomwe, Chiyao, and Chitumbuka.

The major religious groups are traditionalist, Christian, and Muslim. Although these groups appear to be about equal in number, their exact distribution is not known.

The establishment of new rural and urban growth centres, and the opening up of previously inaccessible fertile agricultural areas, has resulted in a significant reversal of emigration. The majority of persons who were working in other parts of southern Africa in 1966 had returned by 1977.

THE ECONOMY

The backbone of the Malaŵi economy is agriculture. The most significant evidence of Malaŵi's economic performance after independence was that the government recurrent budget moved from a significant deficit to a small annual surplus in the 1970s.

Resources. Most of Malaŵi's mineral deposits are neither extensive enough for commercial exploitation nor easily accessible. Exploration and assessment studies continue, however, on minerals such as apatite, located south of Lake Chilwa; bauxite, on the Mulanje Massif; kyanite, on the Dedza-Kirk range; coal, in Karonga District; vermiculite, in Ntcheu District; and rare-earth minerals at Kangankunde Hill in Machinga District.

More than half of Malaŵi's total land area is suitable for cultivation. Some 3,400,000 acres (1,400,000 hectares) are under field crops, with a further 1,600,000 acres (640,000 hectares) lying fallow and about the same area potentially arable. Forests and woodlands cover nearly 9,000 square miles, of which almost 4,000 square miles are state-controlled forest reserves.

The lakes and rivers of Malaŵi provide a rich harvest of fish.

Malaŵi has a vast water supply potential, although some areas have an inadequate amount of water. Treated water for the major cities of Blantyre and Lilongwe is supplied by the Walker's Ferry Scheme and the Kamuzu Dam, respectively. Most of the rivers are seasonal, but a few large ones, particularly the Shire River, have a considerable irrigation and generating potential. The total hydroelectric potential of the country is about 1,200 megawatts, of which more than 500 megawatts can be generated on the Shire River alone. Present power demands, which represent about 8 percent of potential capacity, are met by the Nkula Falls and Tedzani Falls hydroelectric schemes and diesel plants.

Agriculture, fishing, and forestry. The most important agricultural export products are tobacco, tea, sugar, and peanuts (groundnuts). Tea is grown on plantations on the Shire Highlands by the largest proportion of the country's salaried labour force. Tobacco is raised largely on the Central Region plateau. Other important crops are corn (maize; the major staple food), cotton, cassava, coffee, and rice. Between 1966 and 1978, the contribution of cash crops to the gross domestic product averaged about 15 percent a year, while that of subsistence agriculture averaged about 33 percent. The principal cash crops are marketed by the Agricultural Development and Marketing Corporation; a few cooperative societies purchase and market produce.

The amount of fish landed—mainly from Lake Nyasa—is likely to increase with the recent rise in the water level of Lake Chilwa, which had previously shown signs of drying up. Sales of softwood forestry products greatly increased, and Malaŵi is no longer a net importer of wood and wood products. Sawn poles, posts, and manufactured wooden items are produced largely for the domestic market, and some forest products are exported.

Industry. Malaŵi now satisfies its domestic need for products such as cotton textiles, canned foodstuffs, beer, edible oils, soaps, sugar, radios, hoes, and shoes, all of which previously had to be imported. The main demand for electric power is in the industrial areas of the Southern Region, where electricity consumption more than trebled after 1964; the industrial area of Lilongwe; the vast sugar estates of Sucoma and Dwangwa; and the pulpwood scheme of Vipya.

Manufacturing—together with mining and quarrying of clay, granite, limestone, and marble for building and construction—contributes about 6 percent of the annual gross domestic product. Mining may expand as a result of surveys of the bauxite deposits on the Mulanje Massif and of other minerals in promising areas. Exploitation of bauxite will depend on an increased hydroelectric capacity to meet the demand of bauxite smelting for abundant cheap electric power. In addition, it is expected that the Vipya pulpwood afforestation scheme will form the basis for a pulp and paper industry.

Trade and finance. About 95 percent of Malaŵi's exports are derived from agriculture. In the 1970s, however, exports of manufactured products to some neighbouring countries began to increase.

There are two commercial banks—the National Bank of Malaŵi and the Commercial Bank of Malaŵi. The Reserve Bank of Malaŵi is the central bank of the country. Other financial institutions include the Post Office Savings Bank, the New Building Society, and finance houses. Among the several insurance companies, only one is locally based.

The public and private sectors. In the early 1970s the government's economic policy was anti-inflationary, arising from the need to reduce the deficit in public expenditure and to maintain the level of foreign-exchange reserves. In budgetary policies maximum restraint, consistent with development needs and planned reduction of grants-in-aid from the United Kingdom, was exercised.

The main emphasis continues to be directed toward agricultural export production and the completion of investment projects, while at the same time maintaining a satisfactory external balance. The Malaŵi development program is concerned with the public sector only insofar as it does not interfere with the private sector. Priority is given to transport, agriculture, education, and housing.

Taxation, trade unions, and employer associations. A minimum annual tax of kwacha (K) 3.50 is payable by all men over 18 years of age unless they are liable to other taxes. Employed men and women who earn up to K 900 a year pay a graduated tax, and those with higher incomes pay an income tax. Local companies pay taxes at the rate of 40 percent of chargeable income, and companies incorporated outside of Malaŵi pay an additional 5 percent.

There is no sizable industrial labour force. Some 20 trade unions and employer associations are connected with such enterprises as the tea plantations, the building and construction industry, road transport, and railways. The Ministry of Labour plays a significant role in maintaining good relations between employers and employees.

Promoting higher crop yields

Administration of the economy. The government seeks to strengthen the agricultural sector by encouraging integrated land use, higher crop yields, and irrigation schemes. In pursuit of these goals, four large-scale integrated rural development programs, covering one-fifth of the country's land area, were in operation by 1980. They were the Shire Valley Agricultural Development Project, the Lilongwe Land Development Project, the Central Region Lakeshore Development Project, and the Karonga Rural Development Project. These projects include extension services; credit and marketing facilities; physical infrastructures such as roads, buildings, water supplies, health centres, afforestation units, and crop storage and protection facilities. Outside the main program areas, advisory services and educational programs are available and the Malaŵi Young Pioneers, a national youth movement, trains over 2,000 young men and women yearly in techniques of rural development.

Both higher incomes in the rural areas and continued public expenditure are likely to increase the purchasing power of the public as a whole, thus providing a stimulus for further industrial development. The government continues to promote the establishment of manufacturing industries, thus reducing reliance on expensive imported goods, and so strengthening the balance of payments situation, at the same time increasing employment opportunities.

Transportation. *Road and rail network.* Malaŵi has road connections to Chipata on the Zambian border; to Harare (formerly Salisbury), Zimbabwe, via Mwanza and Tete; and to several points on the Mozambique border. The backbone of the road system is represented by a road running from Blantyre in the south to Lilongwe in the west. A lakeshore highway runs roughly parallel to the inland highway from Mangochi to Karonga.

Of Malaŵi's two railway links to the sea, the first stretches more than 570 miles from Lilongwe eastward to the port of Beira on the Mozambique coast; an extension from Lilongwe to Mchinji, on the Zambia border was completed in 1980. The second railroad joins the Salima–Blantyre line at Nkaya Junction to the south of Balaka and travels due east to link with the Mozambique Railways system at Cuamba, from where it continues to the port of Nacala.

Lake transport. Of the rivers, only the Shire is partially navigable, all other streams being broken by rapids and cataracts. Lake Nyasa has long been used as a means of inexpensive transportation. A passenger and cargo service that operates on the lake is linked to Chipoka railway junction about 17 miles south of Salima. The main ports on the lake are Monkey Bay, Nkhotakota, Nkhata Bay, and Likoma Island.

Air services. Air Malaŵi, the national airline, operates services from the main airport at Chileka, 11 miles from Blantyre, to several foreign countries and neighbouring African capitals.

ADMINISTRATIVE AND SOCIAL CONDITIONS

Under the republican constitution of Malaŵi promulgated in July 1966, Parliament is composed of a president, who is head of state and government and of the National Assembly. The cabinet is appointed by the president. The original number of 50 elected members of the assembly was raised to 60 in 1969 and 87 in 1979. In addition, the president can appoint no more than 15 nominated members.

The country is divided into 24 administrative districts. The local government system consists of district councils, the city councils of Blantyre and Lilongwe, the municipality of Zomba, and seven town councils.

Malaŵi was a de facto one-party state from August 1961, when the first general elections were held, until 1966, when the constitution formally recognized the Malaŵi

Congress Party—led by Pres. H. Kamuzu Banda—as the sole political organization. According to the constitution, elections for the presidency and the assembly are to be held every five years; general elections, however, have been held only in 1971 and 1978. The presidential candidate was nominated by an electoral college composed of party officials at the national, regional, and district levels; the League of Malaŵi Women; the League of Malaŵi Youth; members of Parliament; recognized chiefs; and all chairmen of district councils. In 1971, Banda was elected president for life. Candidates for the National Assembly may stand for election only after their nomination by the district party conferences.

:lections

Justice. The judiciary is based upon the system prevailing in the British colonial era and Malaŵi traditional law. It consists of a Supreme Court of Appeal, a High Court, magistrates' courts, and traditional courts. Since 1969, criminal cases involving witchcraft or local superstition, for which the death penalty can be imposed, have been tried in the traditional courts instead of the High Court. The minister of justice has the power to direct a particular case or group of cases to a particular court; cases tried in the traditional courts can be appealed to the National Traditional Court of Appeal.

Health and welfare. Health facilities include one central hospital, general hospitals, district hospitals and clinics, Zomba Mental Hospital and Kochira Leprosarium. The most common diseases are malaria, bilharzia, and trachoma. The main emphasis of the health services is unavoidably on curative medicine.

An acute shortage of housing has existed for several years in urban areas. The Malaŵi Housing Corporation has, however, launched several projects to build houses and develop traditional housing areas.

ducation

Education. Elementary education in the primary schools is provided by local education authorities. Post-primary education comprises a four-year secondary school course that can lead to a university education. There are also institutions for teacher training and for technical and vocational training. Because of limited resources, only about a third of the school-age population is enrolled in schools. The Malaŵi Correspondence College is available to many students. The Kamuzu Academy at Mtunthama is a secondary school for gifted children. The University of Malaŵi, founded in 1965, has three constituent colleges.

CULTURAL LIFE

Though under the impact of modernization, Malaŵi's traditional culture is characterized by continuity as well as change, and the traditional life of the village has remained largely intact. One of the most distinctive features of Malaŵi culture is the enormous variety of traditional songs and dances that use the drum as the major musical instrument. Among the most notable of these dances are *ingoma* and *gule wa mkulu* for men, and *chimtali* and *visekese* for women. There are various traditional arts and crafts, including sculpture in wood and ivory. There are two museums—the Museum of Malaŵi in Blantyre and a smaller one in Mangochi. While various cultural activities are organized by the Ministry of Youth and Culture, the University of Malaŵi Travelling Theatre, and other groups in Blantyre, the radio from Zomba and Lilongwe has proved to be the most effective means of bringing traditional and modern plays to the rural population.

For statistical data on the land and people of Malaŵi, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL. (Z.D.K.)

History

The paleontological record of human cultural artifacts in Malaŵi dates back more than 50,000 years, although known fossil remains of early *Homo sapiens* belong to the period between 8000 and 2000 BC. These prehistoric forebears have affinities to the San (Bushmen) of southern Africa and were probably ancestral to the Twa and Fula, whom Bantu-speaking peoples claimed to have found when they invaded the Malaŵi region between the 1st and 4th centuries AD. From then to about AD 1200, Bantu settlement patterns spread, as did ironworking and the slash-and-burn method of cultivation. The identity of these early Bantu-speaking inhabitants is uncertain. According to oral tradition, names such as Kalimanjira, Katanga, and Zimba are associated with them.

With the arrival of another wave of Bantu-speaking peoples between the 13th and 15th centuries AD, the recorded history of the Malaŵi region began. These peoples migrated into the region from the north and they interacted with and assimilated the earlier pre-Bantu and Bantu inhabitants. The descendants of these peoples maintained a rich oral history, and from 1500 written records were kept in Portuguese and English.

Early political units

Among the notable accomplishments of the last group of Bantu immigrants was the creation of political states or the introduction of centralized systems of government. They established the Maravi Confederacy around 1480. During the 16th century, the confederacy encompassed the greater part of what is now central and southern Malaŵi, and, at the height of its influence in the 17th century, its system of government affected peoples in the adjacent areas of modern Zambia and Mozambique. North of the Maravi territory, the Ngonde founded a kingdom around 1600; in the 18th century, a group of immigrants from the eastern side of Lake Nyasa created the Chikulamayembe state to the south of the Ngonde.

The pre-colonial period witnessed other important developments. In the 18th and 19th centuries, better and more productive agricultural practices were adopted. In some parts of the Malaŵi region, shifting cultivation of indigenous varieties of millet and sorghum began to give way to more intensive cultivation of crops with a higher carbohydrate content, such as corn (maize), cassava, and rice.

The independent growth of indigenous governments and improved economic systems was severely disturbed by the development of the slave trade in the late 18th century and by the arrival of foreign intruders in the late 19th century. The slave trade in Malaŵi increased dramatically between 1790 and 1860 because of the growing demand for slaves on Africa's east coast. Swahili-speaking people from the east coast and the Ngoni and Yao peoples entered the Malaŵi region between 1830 and 1860 as traders or as armed refugees fleeing the Zulu Empire to the south. All of them eventually created spheres of influence within which they became the dominant ruling class. The Swahili speakers and the Yao also played a major role in the slave trade.

Islām and Christianity

Islām spread into Malaŵi from the east coast. It was first introduced at Nkhotakota by the ruling Swahili-speaking slave trader, the Jumbe, in the 1860s. Traders returning from the coast in the 1870s and 1880s brought Islām to the Yao of the Shire Highlands. Christianity was introduced in the 1860s by David Livingstone and by other Scottish missionaries who came to Malaŵi after his death in 1873. Missionaries of the Dutch Reformed Church of South Africa and the White Fathers of the Roman Catholic Church arrived in the 1880s and 1890s.

Christianity owed its success to the protection given to the missionaries by the colonial government, which the British established after occupying the Malaŵi region in the 1880s and 1890s. British colonial authority was welcomed by the missionaries and some African societies, but was strongly resisted by the Yao, Chewa, and others. In 1891 the British established the Nyasaland Districts Protectorate, which was called the British Central Africa Protectorate from 1893 and Nyasaland from 1907.

Many changes for the better took place under the colonial regime. Roads and railways were built, the cultivation of cash crops by European settlers was introduced, and inhumane practices were suppressed. On the other hand, the colonial administration did little to enhance the welfare of the African majority because of its commitment to the interests of the European settlers. It failed to develop African agriculture, and many able-bodied men migrated to neighbouring countries to seek employment. Furthermore, between 1951 and 1953 the colonial government decided to join the colonies of Southern and Northern Rhodesia and Nyasaland into a federation, against bitter opposition from their African inhabitants.

These negative features of colonial rule prompted the rise of a nationalist movement. From its humble beginnings during the period between the world wars, African nationalism gathered momentum in the early 1950s. Of special impetus was the imposition of the federation, which nationalists feared as an extension of colonial power. The full force of nationalism as an instrument of change became evident after 1958 under the leadership of Hastings Kamuzu Banda. The federation was dissolved in 1963 and Malaŵi became independent as a member of the Commonwealth of Nations on July 6, 1964. (Z.D.K./K.M.G.P.)

Soon after independence, a serious dispute arose between Banda, the prime minister, and other ministers. In September 1964 three ministers were dismissed and three others resigned in sympathy. Henry Chipembere, one of the dismissed ministers, escaped from house arrest and defied attempts to recapture him, becoming thenceforth the focus for antigovernment opinion. On July 6, 1966, Malaŵi became a republic, and Banda was elected president. He was made president for life in 1971.

In external relations Banda pursued a policy at variance with that of most of the recently independent countries of tropical Africa. He accused the Organization of African Unity (OAU) of adopting attitudes that it was powerless to support, established friendly trading relations with the Republic of South Africa, and appealed to other African leaders to be more realistic in their attitude toward racial problems. (J.C.Mi./K.In./Ed.)

Malaŵi joined the Southern African Development Coordination Conference, a union of majority-ruled nations neighbouring South Africa, in 1980 but refused to sever its formal diplomatic links with South Africa.

For later developments in the history of Malaŵi, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL. (Ed.)

MOZAMBIQUE

The People's Republic of Mozambique is located on the southeastern coast of Africa between latitudes 10°27′ and 26°52′ south. Its elongated territory of 308,642 square miles (799,380 square kilometres) has an Indian Ocean coastline of 1,737 miles (2,795 kilometres). Mozambique is bounded on the north by Tanzania, on the west by Malaŵi, Zambia, Zimbabwe, and the Transvaal province of South Africa, and on the south by Swaziland and the Natal province of South Africa. To the east lies the Mozambique Channel, which separates the African mainland from the island-state of Madagascar (formerly Malagasy). The capital of Mozambique is Maputo (formerly Lourenço Marques).

Physical and human geography

THE LAND

Plain, plateau, mountains

Relief. Mozambique occupies southern Africa's largest coastal plain; nearly half of the total area lies below 750 feet (230 metres). This coastal lowland is widest in the south, where it covers virtually the entire width of the territory, but northward it becomes narrower. In central and northern Mozambique an interior plateau develops, with elevations ranging from 500 to 2,000 feet. Toward the western boundaries with Malaŵi, Zambia, and Zimbabwe, this plateau rises still higher, and mountainous terrain occurs. Highest elevations along the Zambia–Malaŵi border range from 5,741 feet extreme north, near Lake Nyasa (Malaŵi) in Niassa Province, to 7,241 feet in the northwest, near the intersection of the Zambia–Malaŵi boundary in Tete Province.

The lengthy coastline is marked by several distinct features. In the extreme south lies Delagoa Bay, the best natural harbour on the East African coast, and on its shore the capital of Mozambique, Maputo, has grown. Northward, from Delagoa Bay to the delta of the Zambezi River, the coast is sandy and swampy, with mangroves and offshore bars. North of the Zambezi Delta, however, sandy stretches of coast are interrupted by rocky cliffs and headlands, as well as islands, many of which are of coral formation. In addition to the Zambezi, some 50 other rivers reach the coast of Mozambique, including the Limpopo, the Save, the Búzi, the Lúrio, and the Messalo. In the far north the Rovuma River forms the boundary between Mozambique and Tanzania.

The Zambezi River

The pivotal geographical feature of Mozambique is the Zambezi River. Almost all the higher and more rugged terrain lies to the north of the river, while to the south the gently undulating coastal lowland prevails. Apart from the higher elevations near the Rhodesian Plateau, there is only one marked feature of positive relief located south of the Zambezi: the Serra da Gorongosa in Sofala Province. Elsewhere, southern Mozambique presents a gently rolling, rather featureless landscape, with an occasional group of low hills, broken by the wide alluvial valleys of the rivers.

Drainage. Mozambique's topography generally declines in elevation from west to east, so that, from the Rovuma River in the north to the Limpopo in the south, streams have an eastward orientation. The higher parts of the territory are sustained by the crystalline rocks of the ancient African basement complex, or shield. In the Zambezi Basin and on the coastal plain, dipping toward the Mozambique Channel, lie more recent sedimentary rocks deposited during the Triassic Period (about 260,000,000 to 200,000,000 years ago). Still more recent sediments, of Late Cretaceous and Eocene age, lie in the eastern parts of the coastal plain. A notable feature is the rhyolite-sustained Lebombo Mountains, which coincide with the political boundary between Mozambique and Swaziland and also extend northward along the Transvaal border.

With the exception of northern Mozambique east of Lake Nyasa, Mozambique's major rivers rise to the west of the territory, on the African Highveld. The headwaters of the Limpopo lie on the margins of the Kalahari; the Save River rises on the Great Dyke of Zimbabwe, and the Zambezi rises in the Angola–Zambia borderland. Since the interior plateaus receive moderate rainfall at best, with marked seasonal variation, water levels alter considerably. The largest drainage basin is that of the Zambezi, which, with its Shire tributary (the outlet of Lake Nyasa), drains most of the centrally situated provinces of Tete, Manica, Sofala, and Zambézia.

Soils. Good soils are the exception rather than the rule in Mozambique. The soils of the plateau areas, derived from underlying granites, gneisses, and schists, are leached and rich in iron and aluminum and are generally rather infertile. In the dry interior to the north of the Limpopo Valley, sandy, iron-bearing soils prevail, their high permeability increasing the area's dryness. Along the coastal plain there are waterlogged organic soils, with some poorly developed alluvials. In the alluvial lowlands of several of the river basins, and in the *machongas* (patches of humus-rich, moist lowland between the dunes of the coastal plain) lie Mozambique's most productive soils.

Rainfall

Climate. As Mozambique lies on the tropical East African coast, apparently in the path of the southeast trade winds, and as the warm Mozambique Current flows southward offshore, a prevailingly rainy, moist climate would be expected, especially since the mountains of the interior cause air currents to rise, increasing the probability of rain. Much of Mozambique, however, is subhumid, and drought is common in many areas. Maputo, for example, receives a mere 30 inches (750 millimetres) of rain in an average year, Inhambane 36, Beira 60, Angoche 42, and Tete 23. With the prevailing tropical temperatures (Maputo has an annual average of 73° F [23° C], while Quelimane's warmest month averages 86° F [30° C] and its coolest month 68° F [20° C]), much of this rainfall is lost by evaporation or by plant transpiration. Mozambique north of the Zambezi is a region of greater moisture and lesser drought incidence (although the Zambezi Basin around Tete is itself deficient in moisture); the south suf-

fers from drought and low rainfall, except along the littoral and against the Rhodesian Plateau slopes. Only north central and northwestern Mozambique generally maintain a favourable moisture balance. (H.J. de B./A.C.G.B.)

There is a distinct rainy season from October (or November) until April. The dry season usually lasts from April into September. It is altitude that moderates temperatures. Although Maputo lies nearly 1,000 miles south of Pemba, its annual average temperature is only slightly lower and its annual range only slightly greater. Chillier nights and cooler winter months are recorded in the higher zones along the western borders.

Palm trees

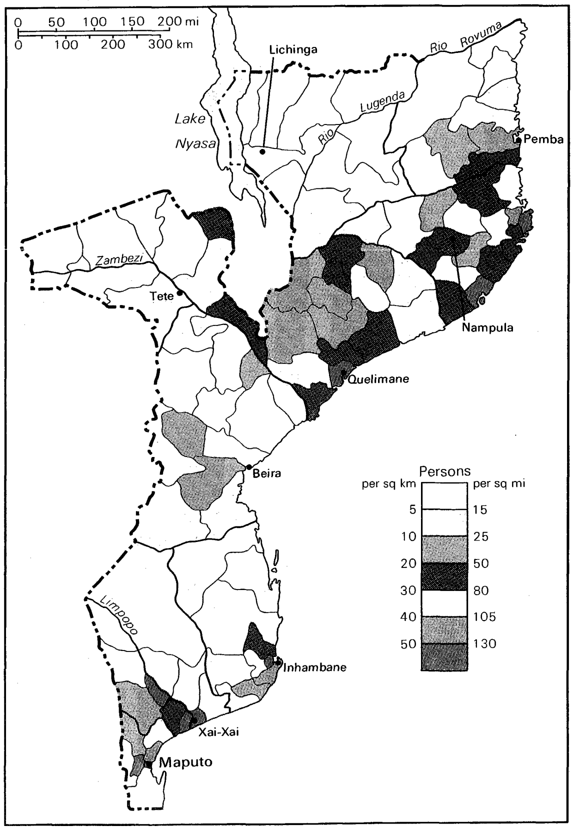
Plant and animal life. Mozambique's vegetation is mostly tropical forest and savanna. Along the coast, especially between 17° and 20° south, the coconut palm is common. Several other types of palm, including the date palm, also occur. Patches of forest, which include stands of ironwood and ebony, are generally found on better drained slopes amid savanna country. In the narrow ravines, tree growth is dense, including the large Senegal khaya, resembling mahogany and used for timber. Along the upper reaches of the major rivers, notably the Zambezi and the Limpopo, the mopani tree—a type of ironwood producing hard, durable timber—prevails on the savanna, where the baobab is also a characteristic feature. Areas of mangrove exist along the coast, especially in the Zambezi Delta. Bamboo and spear grass occur abundantly along the river banks and in the marshy areas.

Despite excessive hunting, Mozambique still has a rich fauna. Lions are numerous. The cheetah, spotted hyena, jackal, serval, civet, mongoose, and wild dog occur in several areas. The elephant is common, as is the black rhinoceros; the white rhinoceros occurs, although more rarely. The lower courses of many of Mozambique's rivers are inhabited by the hippopotamus. Among the herd animals, antelope, buffalo, and zebra are often seen. Giraffes, warthogs, and monkeys are common, as are snakes, especially the python, cobra, puff adder, and viper. Crocodiles abound in the rivers.

Mozambique's birdlife is varied. Flamingoes inhabit the northeast, and species of cranes, storks, herons, pelicans, and ibises occur. The eagle, buzzard, vulture, and crow are omnipresent. Guinea fowl, partridge, bustard, quail, wild goose, and wild duck are all found in large numbers. (H.J. de B./A.C.G.B./Ed.)

Settlement patterns. The Zambezi River forms a significant dividing line between northern and southern Mozambique. South of the river the colonial influence is stronger: there Portugal established its most profitable agricultural settlements, which yielded cash crops whose primary markets lay in Europe. There also Portugal invested most heavily in roads and railroads to link the coastal ports of Maputo (then Lourenço Marques) and Beira with the prosperous mines, cities, and farms of South Africa and what was then Rhodesia. It was from southern Mozambique that tens of thousands of African workers were recruited each year to supply South Africa's mines and farms with labour under a system that was tantamount to involuntary servitude to the state.

Whereas southern Mozambique contained the majority



Population density of Mozambique.

of the approximately 250,000 Europeans just before independence, some of the country's most densely settled African regions were in the north. The northern provinces of Nampula and Zambêzia together contain more than 40 percent of the country's total population. With its larger African population, its remoteness from the capital, its rudimentary transport system, and its lengthy boundary with Tanzania, northern Mozambique became the staging ground for the revolutionary struggle against Portuguese colonialism. There are other factors that distinguish the north from the south, among them the lack of economic opportunity inland, where Malaŵi and Zambia generate far less employment and trade than South Africa and Zimbabwe do, the scarcity of alternatives to subsistence agriculture, the imprint of Islām on some of the African peoples, and the generally stronger resistance to change.

Rural population

Approximately nine-tenths of Mozambique's population is rural, the vast majority of the people living in dispersed homesteads or small hamlets or villages. Most villages comprise clusters of houses grouped around either a cattle kraal or a central meeting place such as a school or agricultural cooperative building. Around each village are the cultivated lands, which by tradition were at the disposal of the community and after independence became the property of the state, which encouraged the peasantry to farm collectively. Manioc is the main food staple, especially along the coastal plains, while corn (maize) is widely grown. Yields of both crops tend to be low and the annual production highly variable. Famine remains a local threat.

Much of rural Mozambique is thinly populated bush country, but pressure on the land occurs in the coastal areas of Nampula and Zambêzia provinces and between Inhambane and Maputo. Because of past slave raiding, endemic sleeping sickness, and low soil fertility, Niassa Province in the north remains the country's area of lowest population density.

Considerable agglomerations of people exist in the hinterlands of the coastal towns, as a result of both greater soil fertility and the drawing power of the towns and cities such as Maputo, Xai-Xai (former João Belo), Inhambane, Beira, Quelimane, Angoche (former António Enes), and Lumbo, near Nampula. In these areas the traditional rural homesteads or hamlets are replaced by more intensive vegetable farms, fields of rice and maize, and some sugar and citrus plantations. The plantations and large-scale agricultural schemes, established during the colonial era, were nationalized as state farms in 1977.

Maputo nd Beira

Mozambique's largest cities are Maputo and Beira. Both are modern, attractive, and well-planned cities, with wide avenues, terraced public gardens, elaborate public buildings, and large apartment buildings. In the suburbs are villas and smaller houses in the characteristic Portuguese style. Many apartments—abandoned by the Portuguese when the government nationalized housing, abolished private rents, and prohibited individual ownership of more than two homes—were taken over by squatters who had lived in the crowded ghettos on the outskirts of the cities. The shanty towns continue to grow, swollen by Mozambicans in search of urban opportunities.

THE PEOPLE

Ethnic groups. Three major historical events shaped the peopling of Mozambique: the great Bantu migration from the north and west; the northward movement that followed the rise of the Zulu Empire in Natal to the south; and the penetration of Arabs, Persians, Portuguese, and other non-Africans from the east. The result is an ethnically distinct north and south, the Zambezi River being the boundary. North of the river the people are predominantly matrilineal in reckoning descent and are accustomed to a pattern of shifting agriculture; south of the Zambezi the people are predominantly sedentary farmers and pastoralists who trace their origins patrilineally.

frican thnic roups

Almost all of Mozambique's population is African. The balance is composed of Europeans, Asians, and persons of mixed racial origin. The Makua–Lomwe is the largest of Mozambique's 10 major ethnic groups. Makua and Lomwe are presently concentrated between Malaŵi and the east coast, having migrated there from the mountainous upper reaches of the Zambezi River two centuries ago. Most are subsistence farmers, although some produce cash crops and others are coastal fishermen. North of them and extending across the Rovuma River into Tanzania are the Yao and Makonde peoples. The Makonde are traditionally conservative and have resisted the Islāmization that is common among the coastal peoples. Makonde art, especially wooden masks and statuary, is acknowledged to be the finest in eastern Africa. The Yao, an Islāmized agricultural people who live in the remote northwest corner of the country, were the principal intermediaries in the slave and ivory trade between Arabs and interior African tribes during the 18th and 19th centuries. The Zambezi Valley is settled by many small fragmented groups.

Southern Mozambique is inhabited by the Tsonga, Karanga, Shona, Chopi, and Nguni people, who belong to the East African cattle-raising complex. For them, cattle traditionally symbolized wealth and prestige. The Tsonga, Mozambique's second largest population group, live between the Save (Sabi) River and Delagoa Bay. They repeatedly were the largest component of Mozambique's migrant labour force to South Africa. The Karanga Shona peoples, living between the Save and Zambezi rivers, are descendants of the Mwene Matapa Empire that thrived in Mozambique and adjoining Zimbabwe five centuries ago.

Europeans

Mozambique's Europeans, Asians, and mestizos are few but economically influential. In 1930 the territory had only some 17,000 whites (mainly Portuguese) and in 1950 about 48,000. During the 1950s, the European population nearly doubled, and on the eve of independence it had reached an estimated 250,000. In late 1978, fewer than 15,000 Portuguese remained. White immigration was encouraged by colonial Portugal in order to exploit the agricultural and mineral resources and to gain more effective control over the black population. Portuguese settlers had been offered land and loans by the colonial authorities, and elaborate settlement schemes were promoted in the valleys of the Limpopo, Revué, Zambezi, and other rivers.

Most Portuguese, however, were urban dwellers; almost half of them resided in and around the capital. They held a virtual monopoly not only of professional and skilled but also of semiskilled jobs. Their sudden withdrawal in 1974–75, accompanied by the willful destruction of property and equipment, threw Mozambique's economy into chaos.

In addition to the European minority, there are Euro-Africans and persons of Chinese, Goan, and Pakistani origin. Almost all of them are urban dwellers, employed in commerce and light industry.

Languages. Several distinct Bantu languages are spoken: Yao and Makua predominate in the north, Tsonga in the south, and Nyanja in the Zambezi Valley. None is spoken widely enough to be adopted as the national language. Swahili comes closest to serving as a lingua franca; it is spoken in the towns and villages along the coast, especially north of the Zambezi. Portuguese is the official language, but it is rarely used beyond government circles, the urban areas, and places where Portugal's influence was strongest. Less than one-tenth of the population is literate.

Swahili

Religion. A similar variation occurs in religious affiliations. In the north, especially among the Yao of Niassa Province, Islāmic traditions are superimposed on essentially animist societies. One-tenth of the entire population may be Muslim. In the south, Christianity, especially Roman Catholicism, has made deeper inroads. The constitution "guarantees the freedom of citizens to practice or not to practice a religion."

Society. During the colonial era, Mozambique's society was highly stratified. In 1927 the population was divided by law into two categories: *indígenas* (indigenous or unassimilated Africans) and *nao indígenas* (Europeans, Asians, *mestiços,* and *assimilados,* or "assimilated" Africans). The *indígena* had few rights, was required to pay taxes and to carry a passbook, and was subject to labour regulations and curfews. He could be conscripted into labour gangs for both public and private enterprise or to farm as directed by the authorities. The *nao indígena* enjoyed full rights of Portuguese citizenship.

Africans could become *assimilados* if they met stringent standards: they had to speak Portuguese, abandon their traditional way of life, be legally employed in commerce or industry, be financially solvent, and supply testimonials of their good character to the authorities. Failure to maintain these "responsibilities" could mean the revocation of the privilege. In 1961 the *indígena* system was abolished, and full citizenship was granted to all Mozambicans.

Mozambique's Frelimo (Frente de Libertação de Moçambique) government is committed to building a nonracist and nontribal socialist society. Frelimo's leadership is explicitly atheist and hostile to the Roman Catholic Church, which it considers to have been a bulwark of the colonial regime. Given the polyglot nature of the people, the institutional diversity, the traditionalism that prevails in many regions, and the paucity of both transport and communications, the government's goals have been difficult to achieve. Fundamental to the indoctrination of socialism is the establishment of "dynamizing groups" (*grupos dinamizadores*) in the communal villages, collective farms, and reorganized businesses and industries. These groups are the basic political links between the people and the Frelimo party. Their function is to involve all the people in discussion of national and local policy issues and programs and of possible solutions to the country's social and economic problems.

There has always been considerable internal migration in Mozambique in addition to large outmigrations from the southern provinces to South Africa and Zimbabwe. Domestic labour shortages created by these international movements were often filled by recruits from the north, especially from Zambézia and Nampula provinces. A pattern of male migration gave the cities an overly male and ethnically heterogeneous character. Like most cities in the Third World, those of Mozambique have a high degree of unemployment and inadequate housing, schools, and social services for the poor.

During the revolutionary war of independence, tens of thousands of Mozambicans fled across the borders to Tanzania, Malaŵi, and Zambia. Between late 1974 and mid-1976 the office of the UN High Commissioner for Refugees assisted in the repatriation of about 35,000 Mozambican refugees from Malaŵi and Zimbabwe and another 80,000 from Tanzania.

THE ECONOMY

Economic policy pursued during the colonial era neglected domestic development, notably in the rural African sector, and it denied most Africans access to technical skills and managerial experience. To protect manufacturing interests in Portugal, industrial development was discouraged. Little was done to exploit the country's mineral resources or to create an infrastructure that would support a self-sufficient, integrated, and growing economic system. The transport system, especially that of railroads, was designed for transit trade with South Africa and Rhodesia more than for developing the local economy and peoples.

Cash crops

Agriculture. Cash crops, primarily cashew nuts, cotton, sugar, tea, copra, and sisal, represented a critical sector of the colonial economy. Agricultural products during the last two decades of colonial rule accounted for at least three-quarters of Mozambique's foreign trade. To stimulate production, the colonial regime introduced a labour system known as *shibalo*, a word derived from the Swahili word *shiba,* meaning "serf," by which African peasants were compelled to cultivate specific cash crops. In the northern areas, for example, more than 500,000 peasants were forced to grow cotton instead of staple food crops. Local famines frequently occurred. Those who refused to cooperate were beaten, imprisoned, or otherwise punished by the local authorities.

Colonial Portugal was more interested in aiding European settlers than in promoting African-based agriculture. It offered choice tracts of land, technical assistance, long-term, low-interest loans, and cash bonuses to those Europeans willing to settle the land. One of the largest settlement projects (*colonatos*) was the Limpopo Valley Scheme, where 250,000 acres (100,000 hectares) were designated for irrigation and occupation by 10,000 families. In the hinterland of Beira another major scheme, involving 75,000 acres, was laid out.

In 1965 the colonial government relaxed its investment policy and permitted multinational agricultural firms, such as the largely British-owned Sena Sugar Estates, Ltd., to expand their operations. By the late 1960s, almost half of Mozambique's cultivated land belonged to these estates, representing less than 1 percent of all farming units, while the other half was cultivated by subsistence farmers.

Mining. Before independence, mining and minerals contributed only a very small proportion of the gross domestic product. The coal mine at Moatize, near Tete, was the only significant mining operation, and its production was directed to the domestic railroads, cement plants, sugar estates, and local shipping lines. Total reserves are estimated at 700,000,000 tons, minimally. Other minerals mined in small quantities include tantalite (Mozambique reportedly possesses the world's largest deposit of this rare mineral) at Murrua in the north, gold at Bragança, and manganese and asbestos in Catuane in the southwest corner of the country. Even smaller amounts of graphite, ilmenite, mica, and bismuth have been mined.

Coal

Natural gas was tapped near Moamba (northwest of Maputo) and near Pande (60 miles south of Beira). Just before independence, some potentially significant mineral discoveries were made. Near Namapa in Nampula Province, for example, an iron ore deposit was found with sufficient promise to attract Japanese capital for development.

Industry. Industrial activity during the colonial era was largely restricted to processing agricultural raw materials such as sugar, cashew nuts, and tobacco and was oriented either to the small local market (mainly European) or to distant Portugal and foreign markets. Manufacturing, long discouraged by Portugal and adversely affected by the close proximity of South Africa and Zimbabwe (Rhodesia), did not really begin in earnest until the mid-1960s. Most manufactures were consumer items and substituted for imports; they included textiles, clothing, beer, bicycles, soap, and pharmaceuticals. The largest capital-intensive projects operating before independence were the oil refinery, fertilizer factory, and chemical plants in greater Maputo and the steel works at Beira.

Migrant labour. Mozambique has supplied thousands of migrant workers to South Africa each year, beginning with the discovery of gold on the Witwatersrand in 1886. Migrant labour soon became one of Mozambique's major sources of revenue. The flow of labour was initially regulated by the Witwatersrand Native Labour Association, formed in 1901 by South African mine owners. Agreements were subsequently signed that provided between 100,000 and 150,000 contract workers each year. Apart from taxation on the earned income, withheld and paid directly to the Portuguese administration in Mozambique, South Africa paid the administration a fee for every worker who entered South Africa for contract work. Under these labour agreements, Mozambique received 60 percent of the miners' wages in gold at the official gold rate. It then resold the gold at much higher free market prices, thus making substantial profits that helped balance the foreign exchange position. In 1975, for example, some $150,000,000 was earned this way on a labour pool of 103,000 workers.

The right to recruit workers in Mozambique was linked by the Mozambique conventions (1909 and 1928) to the right of the Mozambique railroads to handle 47.5 percent of the southern Transvaal's transit traffic. Thus Maputo became the single most important outlet for the Witwatersrand, and through separate agreements Beira became the chief outlet for Rhodesia and Malaŵi. Transit trade often accounted for 30 percent of Mozambique's foreign exchange earnings.

Transit trade

Tourism. Tourism was another important source of foreign exchange for colonial Mozambique. Tourists, primarily from South Africa and Rhodesia, came to enjoy the "continental" atmosphere of Maputo and Beira, the beaches, and the Gorongosa National Park, famous for its lions. Tourism fell during the final years of Mozambique's struggle for independence and after the closure of the Mozambique–Rhodesia border in 1976.

Throughout the colonial period, Portugal and South Africa were Mozambique's principal trading partners.

During the 1960s Portugal bought, on average, about 35 percent of the territory's exports (cotton, sugar, vegetable oils, tea, and other agricultural products) and supplied more than a third of its imports (primarily machinery, metals, and textiles). South Africa's share of imports and exports just before independence averaged about 20 and 10 percent, respectively.

Administration of the economy. Mozambique experienced an acute economic crisis for the first three years of its independence. Several factors caused this crisis: the mass and rapid departure of skilled European workers with their capital, technology, administrative expertise, and consumer demands; the deliberate and widespread destruction of property, machinery, and equipment by the departing white settlers; the closure of the border with Rhodesia (1976) and the inadequacy of international compensatory assistance; the fall in foreign exchange earnings under the Mozambique Convention and a drastic cut in the number of Mozambican workers in the South African mines; a further drop in foreign exchange because of severe cuts in world sugar prices; a large drop in the production of agricultural export crops caused by the white exodus, droughts in the north, and floods in the south; a complete halt to the tourist industry since 1974; the inexperience of the new government in handling and reorganizing the economic system; and the high cost of rehabilitating war-torn areas in the north.

Marxist–Leninist program

When Mozambique's independent government came to power, it adopted a Marxist–Leninist program of development in which special emphasis was given to developing the country's industrial base as well as its agricultural sector. Agriculture is viewed as the base of development, industry as the driving force. Economic development is seen as inseparable from the building of a socialist society.

The first national plan for economic recovery and development stressed the need to establish a network of communal villages and state farms to increase agricultural production. The first stage emphasized increased food production and the need to restore the country's agricultural exports. The second phase stressed the growth of industrial production.

State ownership

Under the constitution, Mozambique's land and subsoil resources are the property of the state, which is to determine their development and use. Although private property is still recognized and guaranteed by the constitution, and foreign capital will be encouraged (especially in industry), the state-owned sector is considered paramount. Private property will eventually be replaced by collective, socialist ownership. By the end of 1978 the large plantations, settlement schemes, coal industry, oil refinery, some metal industries, rental properties, and banking and insurance had been nationalized, as were all private banks except one; their assets and liabilities were transferred to the Bank of Mozambique and a newly created state-owned People's Development Bank. Education and health services and the Cabora Bassa Hydroelectric Project also were nationalized.

Despite its commitment to the establishment of a Marxist state, Frelimo has adopted a pragmatic approach to solving its economic difficulties. Foreign-owned businesses are allowed to operate provided they contribute to the well-being of the country and do not exploit its workers. The country relies heavily upon foreign aid in the form of cash grants, pledges, loans, technical assistance, and supplies of food, medicines, and other goods.

Transportation. Transport is insufficiently developed, having been constructed more to serve the transit trade of South Africa and Zimbabwe than the country's own needs. Both roads and railroads focus on three ports: Maputo, Beira, and Nacala.

Maputo–Witwatersrand line

Railways. There are three main systems. The Maputo system serves the Witwatersrand of South Africa, Swaziland via a short line through Goba, and the Limpopo Valley as far as Chicualacuala (former Malvêrnia) on the Zimbabwe border. The Beira system was built to serve Zimbabwe, Malaŵi, and Zambia. It is V-shaped, the western line running to Zimbabwe and the northern lines serving Tete and Malaŵi. The Nacala system extends due west to Malaŵi, with a branch line to Lichinga. Three secondary rail systems focussing on Quelimane, Inhambane, and Xai-Xai serve small agricultural areas near the coast.

Roads. The major all-weather roads are between Maputo and Ressano Garcia on the Transvaal border; Beira and Umtali in Zimbabwe; and Chimoio and Tete and the borders of Malaŵi and Zambia. There is also a coastal road from Maputo through Inhambane to Beira, which has been extended to Quelimane, Lumbo, Nacala, Pemba, and Mocímboa da Praia in the far north. During the 1960s the road network was improved and expanded, mainly for military purposes, but vast areas of the country are still virtually without roads.

Seaports. Mozambique's major ports are Maputo, Beira, and Nacala. The deepwater port of Maputo, situated on the well-protected Delagoa Bay, has special coal- and ore-loading facilities. It can accommodate 20 ocean-going vessels at a time and handle more than 16,000,000 tons of goods each year. Four miles away, at Matola, are a petroleum refinery, lumber wharves, and a mechanical loader for iron ore from Swaziland.

Beira, located at the confluence of the Púngoè and Búzi rivers, 15 miles from the open sea, is less favoured. Its harbour is shallow, sand and silt accumulations necessitate constant dredging, and a sandbar constricts the mouth of the Púngoè River. Its capacity is about half that of Maputo. Nacala, the principal port in the north, has a sheltered, modern harbour, one of the finest in East Africa. Other smaller ports include Mocímboa da Praia, Pemba, Lumbo, Angoche, Quelimane, Chinde, and Inhambane.

Air transport. Domestic air transport is operated by the state-owned DETA (Direção e Exploração dos Transportes Aêreas), which also has service to Portugal, South Africa, and Tanzania. There are international airports (Maputo, Beira, and Nampula), smaller domestic airports, and numerous landing strips in isolated regions.

Cabora Bassa dam

Power. Mozambique possesses a large hydroelectric potential and has many small and medium-sized power stations, mainly thermal, burning coal, wood, diesel oil, and gasoline. Several large dams are in operation, the largest of which is Cabora Bassa, located on the Zambezi River about 80 miles upstream from Tete. Begun in 1969 and built and financed by an international consortium of companies including South African, Cabora Bassa became operational (sending some electricity to South Africa) in 1976–77. During the war of independence, Frelimo forces repeatedly tried to destroy the dam.

Cabora Bassa's principal markets lie in South Africa, but there are plans to use its energy to develop mineral resources in Tete, Zambézia, and Nampula provinces; to irrigate parts of the Zambezi Valley; and to promote forestry, the livestock industry, and general manufacturing. River transport is now possible between the dam site and Tete. Backed up behind the dam, and extending 150 miles (240 kilometres) west, is a 600-square-mile lake that is being stocked with fish. The new lake required the resettlement of about 25,000 people.

ADMINISTRATIVE AND SOCIAL CONDITIONS

At independence, Mozambique's constitution (1975) created a single-party state in which all power was vested in the leadership of Frelimo. It declared the president of Frelimo to be president of the state, and it provided for the creation of the People's Assembly (later Popular Assembly) as the supreme legislative organ of the state. Samora Moïsés Machel, leader of Frelimo, became the first president.

Political Committee

At its third national congress, held in February 1977, Frelimo was officially converted into a party of the Marxist–Leninist ideological elite, which is committed to the destruction of capitalism and racism and to the creation of a truly revolutionary socialist (*i.e.*, Communist) state. The most powerful body is the 10-member Political Committee, which is composed of the President and his Cabinet (Council of Ministers). Frelimo insists on a very strong degree of centralization. Open discussion and criticism are encouraged at the lower levels of government provided they do not question the party line. At all levels, decisions rest with a very small inner group. Outside the organ of Frelimo, no political discussion is tolerated. Most members of the first Cabinet and the Political Committee were southerners and non-black Africans, a situation resented by the northerners, who provided the vanguard of the independence struggle.

For administrative purposes, Mozambique is divided into 10 provinces, about 94 districts, many town and city districts, and localities, or *localidades*. Each level has assemblies, but election to membership is not by direct universal suffrage. Above the *localidade* level, elections are indirect, each tier of assemblies electing those in the tier above. Mozambique's first general elections were completed in December 1977.

Police

Justice. Local law and order is in the hands of the Mozambique Police Corps and the National Service of Popular Security, which is responsible for the detection and combat of subversion and sabotage. The criminal code inherited from the Portuguese has been modified; the justice system suffers from lack of facilities and experienced administrators. Vigilance groups have been formed to counter reactionary activities and to fight alcoholism. Rehabilitation camps instead of prisons deal with minor criminals, prostitutes, and alcoholics.

Health and welfare. Health services collapsed with the flight of medical personnel at the end of colonial rule. In 1975 Frelimo nationalized all private clinics and prohibited private medical practice. It also introduced a program to train paramedics and began a vaccination campaign against smallpox and measles. The campaign began in the northern provinces of Cabo Delgado, Niassa, and Tete. Fragmentary data suggest that malaria, tuberculosis, bacterial and amoebic dysentery and other gastroenteric infections, plus pneumonia, measles, and infectious hepatitis are the most common diseases.

Rural health clinics are being expanded, and most medical care is free; preventive medicine is emphasized. The Maputo Central Hospital is the country's largest.

Education. Education was also nationalized in 1975, and in the next two years primary school enrollment rose. Primary education is now obligatory, and the government is attempting to encourage all young girls to attend school. Adult literacy classes are also available. Education is closely linked to the requirements of economic development and emphasizes reading, vocational training, and political education. Collective work in the fields is an integral part of the education process.

Housing. Under Frelimo's socialist–collectivist directives, the state largely controls the development and construction of housing. Large-scale urban renewal is underway in the major cities, in an attempt to house the thousands of Mozambicans who lived in the crowded shantytowns and slums. Rental properties belong to the state, which sets rental prices according to family income, family size, and type of residence. In the fully developed communal villages, there are nurseries, schools, health stations, and consumer cooperatives.

CULTURAL LIFE

During the colonial era there was no attempt to systematically introduce the Africans to Portuguese language and culture. In contemporary Mozambique, the state is trying to preserve and promote those indigenous values and customs that strengthen the socialist cause. Cultural centres have been established in urban neighbourhoods and communal villages throughout the country by the National Institute of Culture, which aims to collect indigenous literature, music, crafts, and mythology. During the revolutionary years, much of the poetry and literature had an immediate emotional and ideological purpose.

Cultural centres

For statistical data on the land and people of Mozambique, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL. (A.C.G.B.)

History

EARLY EXPLORATION AND TRADE

Between the 11th and the 15th centuries the Mozambique coast as far south as Sofala was linked politically and commercially to the coastal city-states north of Cape Delgado. Arab and Swahili traders penetrated inland from Sofala and up the Zambezi into what later became Manica e Sofala District. This was the situation the Portuguese found when Vasco da Gama put in at Mozambique Island early in March 1498. Just before this he had discovered and landed at what he called the Rio do Cobre (the Inharrime) and the Rio dos Bons Sinais (the Quelimane, the northern outlet of the Zambezi). Da Gama left Mozambique for India at the end of March, accompanied by a pilot lent by the sultan. In July 1500 Pedro Álvares Cabral, on his way to India, saw Sofala, and on his return it was visited by a squadron of his ships under Sancho de Toar, who made inquiries about its legendary gold trade. Between 1500 and 1502 either Cabral or João da Nova visited Lourenço Marques Bay. A Portuguese settlement was made at Sofala to exploit the fabled gold trade from the empire of Mwene Matapa, which was centred in what is now Zimbabwe but extended into Mozambique. The Portuguese in 1507 occupied Mozambique Island to serve as a way station to India.

Portuguese settlement at Sofala

Attempts to reach the Mwene Matapa were disappointing, though a convict named António Fernandes explored much of his territory before 1514. The Portuguese soon realized that they could not control the trade of the interior from Sofala alone, as Arab and Swahili merchants were making increasing use of the Zambezi route. Accordingly, after 1531 the Portuguese established settlements on the Zambezi banks at Sena and Tete, respectively 160 miles and 260 miles upstream. In 1544 a post was founded at Quelimane to guard the river delta. Simultaneously, the Portuguese began to trade at Inhambane and Lourenço Marques Bay, though no permanent settlement was set up at either place for some time. Portuguese efforts at Mozambique centred on the gold of the Mwene Matapa; it was only there that they involved themselves seriously in African affairs. In 1561 the Jesuit Gonçalo da Silveira reached the head village of the Mwene Matapa, whom he baptized. The Arabs and Swahili, seeing their commercial position threatened by the Portuguese, convinced the chief that Silveira's intentions were evil, and he had the Jesuit strangled.

The death of Silveira was followed by the dispatch (1569) of an expedition from Lisbon to seize the Mwene Matapa's mines. The expedition ended unsuccessfully in 1575, but despite this setback the Zambezi Valley and the Mwene Matapa's country remained the focus of Portuguese attention until the late 19th century. Elsewhere, the Portuguese limited themselves, or were limited by African opposition, to scattered settlements along the coast. Nevertheless, the arrival of the Portuguese in East Africa had a vital impact on African trade to the north of the Zambezi.

Taking advantage of factional strife the Portuguese in 1629 negotiated a vassalage treaty with Mwene Matapa Mavura, who thereby recognized Portuguese sovereignty over his kingdom. Portuguese ascendancy was short-lived, however, and at the end of the 17th century the expansion of the Rozvi kingdom of Guruhuswa, ruled by Changamire, eclipsed the power of both the Mwene Matapa and the Portuguese to the south of the Zambezi.

In 1752 Mozambique, after being subordinated to the Portuguese administration at Goa in India, was separated and given an independent governor. In the 18th century the slave trade became an important factor in Mozambique for the first time. The demand came first from French slavers from the Mascarene Islands and later from the Brazilians. Slave trading by Europeans continued into the 1850s, and an active slave trade to Madagascar was carried on by Arabs and Swahili for several decades more.

COLONIZATION

Until the mid-19th century the most serious attempt to colonize Mozambique was through the *prazo* system. This system of crown grant estates, which had its roots in the late 16th century, was formalized by the Portuguese government in the middle of the 17th. It failed as a colonization scheme, because the estate holders (*prazeros*) amassed large personal fiefdoms. In the 19th century a series of wars was waged by the government against these virtually autonomous rulers. A similar though less ambitious attempt was made to colonize the Kerimba Islands, which extend from Cape Delgado almost to Porto Amélia. There, too, the estate holders became independent lords.

No further colonization plans were contemplated until the 20th century. Several pilot projects failed in the 1930s and '40s, but since the 1950s an attempt to settle immigrant Portuguese peasant cultivators, either in cooperatives or on small individual family holdings, was pursued in the south. The most ambitious of these was centred in the lower Limpopo Valley, another was proposed for the upper reaches of the Revué River. The Mozambique government, unlike its counterpart in Angola, kept to a minimum the influx of poor unskilled white immigrants.

Portugal and other European powers in Africa. At the beginning of the 17th century the Portuguese beat off three attempts by the Dutch to seize the port of Mozambique. The Austrians seized Lourenço Marques in 1777, but Portuguese sovereignty was reestablished in 1782. During the Napoleonic Wars the French attacked Lourenço Marques, Inhambane, Mozambique, and the Kerimba Islands. During the same period these islands suffered more seriously at the hands of Sakalava raiders from Madagascar.

In the 19th-century partition of Africa among the European powers, Portugal maintained rights based on the discovery of most of the African coast, in the face of the doctrine of effective occupation. Until the Berlin Conference (1884) Portugal hoped to preserve a continuous belt of territory from coast to coast, uniting modern Angola with Mozambique. The acquisition of British rights in the area frustrated this design. The Portuguese proposed to submit the question to arbitration, but Britain refused and delivered an ultimatum to Lisbon (1890). A treaty in 1891 defined British and Portuguese possessions.

Colonial rule. The establishment of effective colonial rule in the interior began in the 1890s and was not completed in the northwest until 1912. The Makombe Rebellion (1917), which embraced much of the country south of the Zambezi, was the last traditional manifestation of African opposition to Portuguese rule.

The Companhia de Moçambique was incorporated by royal charter in 1891 for a term of 50 years. Much of its capital was foreign, and it exercised sovereign rights over the territories of Manica and Sofala until they were entrusted to direct Portuguese administration in 1942. The Companhia do Niassa acquired a charter for the administration of lands north of the Lurio River in 1894. Development was comparatively slow, and in 1929 the Portuguese government took over administration of the area.

Under the Treaty of Versailles (1919) the German East African territory between the mouth of the Ruvuma River and Cape Delgado was added to Mozambique.

Economic expansion

Railway building led to a rapid expansion of Mozambique's economy, and conventions with the countries of the hinterland were signed covering the question of transit trade and the recruitment of Africans from Mozambique to work in the South African mines. In 1901 a modus vivendi governing these matters was concluded with the Transvaal government. This was replaced by the Transvaal-Mozambique Convention in 1909, which lapsed in 1923 and was replaced in 1934 by a new treaty, which ran until 1939; it was then prolonged for five years and later remained in force subject to 12 months' notice of termination by either party.

A measure of autonomy was granted to the colony under the Portuguese republic, and this was extended in 1920. After the Portuguese revolution of 1926 this system was brought to an end, and within the provisions of the Colonial Act (1930) a much more centralized system was adopted. Mozambique was designated an overseas province of Portugal in 1951. (A.A.G.P./E.A.A.)

NATIONALISM AND INDEPENDENCE

Nationalist organizations became active in the 1950s, for the most part among the educated urban elite. In 1960 some 500 Makonde peasants were shot during a peaceful demonstration against forced cotton growing, and several thousand fled into Tanzania; there they were joined by a group of urban exiles committed to national revolution and led by Eduardo Mondlane. In 1962 they formed the Frente de Libertação de Moçambique (Frelimo) as an underground political and military movement. Within three years they claimed to have an 8,000-strong army and to have established their own administrative, educational, and marketing networks in Cabo Delgado and Niassa districts. Despite the assassination of Mondlane in 1969, a new phase of the war opened in 1971 in Tete province, under the leadership of Samora Machel. By 1974 Frelimo had won victories in central Mozambique.

Portugal's initial response to the outbreak of revolt was all-out war; by the mid-1960s there were some 70,000 Portuguese troops in each territory. Large numbers of black troops were recruited, and villagers supporting the guerrillas were subjected to savage reprisals, as at Wiriyamu in Mozambique in December 1972, where hundreds of people were burned to death. In 1963, in a bid to attract international support, Portugal opened the colonies to foreign investment, and the building of the Cabora Bassa Dam was partly designed with the same object. By the late 1960s the regime also turned to economic and educational reform, in part to meet the rising demands for a semiskilled work force, in part to preempt the nationalists. But the reforms were too few and too late, and in April 1974 the sheer cost of the wars—together with rising dissatisfaction with the government in Portugal—led to a revolt of Portuguese army officers.

Independence

The collapse of the regime in Portugal led directly to Mozambique's independence in June 1975 under a Frelimo government headed by Machel. The flight of skilled expatriates and Mozambique's geopolitical relationship to South Africa and Rhodesia were the immediate problems confronting the new government. Machel's Frelimo movement was restructured as a self-proclaimed Marxist-Leninist party and set about revising the constitution, providing for a system of elections, reforming the military, and reviving the shattered economy. At the same time, Mozambique was constantly raided by Rhodesian and South African air and land commandos in reprisal for obeying UN sanctions against Rhodesia and for providing a guerrilla base for the Zimbabwe African National Union (ZANU). (Sh.M./Ed.)

Mozambique was a founding member of the Southern African Development Coordination Conference, and Machel made diplomatic visits to several Western nations as well as to Mozambique's traditional allies, the Soviet Union and East Germany. South Africa continued to finance and support the dissident Mozambique National Resistance Movement (known as Renamo, or MNR), and Mozambique continued to harbour supporters of the African National Congress. In 1984 the two nations signed the Nkomati Accord, which promised mutual nonaggression, but each side later accused the other of violating the treaty.

For later developments in the history of Mozambique, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL. (Ed.)

NAMIBIA

The Republic of Namibia, formerly known as South West Africa, lies on the Atlantic coast of Africa between latitudes 17° and 29° south. In the north it is bounded by the Kunene and Okavango rivers, which separate it from Angola. Here a narrow strip of land—the Caprivi Strip (Caprivi Zipfel)—extends eastward for nearly 300 miles (485 kilometres), bringing the territory to the borders of Zambia. In the south the Orange River marks the boundary with South Africa. In the east Namibia adjoins both Botswana and South Africa. Extending inland some 600 miles in the north, without the Caprivi Strip, and about 220 miles in the south, the total area of Namibia, including the Walvis Bay enclave (administered by South Africa), is about 318,000 square miles (824,000 square kilometres).

Physical and human geography

THE LAND

Relief. Namibia may be described as a highland between two desert areas. Three main topographical regions may be distinguished—the Namib coastal belt, the Central Highland of the Central Plateau, and the northern and eastern parts of the plateau known as the Kalahari Belt. The Namib Desert extends from the Atlantic coast in the west until, at an altitude of 3,000 to 3,500 feet (900 to 1,100 metres), it meets the foot of the plateau edge, or Great Escarpment, in the east. A desolate strip of sand desert, high shifting dunes, salt pans, and bare rock outcrops, the desert is bounded by the Kunene River in the north and by the Orange River in the south; for much of its length it is less than 100 miles wide. To the north it becomes more mountainous, with spectacular granite masses rising abruptly from the plain. The Brandberg, with an altitude of 8,461 feet (2,579 metres), is the highest point in Namibia. The Namib constitutes about one-seventh of the total area of the territory.

East of the Great Escarpment lies the Central Plateau, which has two major surface divisions—the plateau hardveld (or rocky plain), known as the Central Highland, and the Kalahari sandveld (desert). The Central Highland extends from the southern to the northern frontier and varies in altitude from 3,200 to 6,500 feet. Its diverse surface characteristics include broken veld, rugged mountains, sand-filled valleys, gentle plains, and isolated peaks. A mountainous central part in the vicinity of Windhoek divides the Central Highland naturally into Damaraland to the north and Great Namaland to the south. Comprising such ranges as the Khomas Highland, the Auasberge (where the Moltkeblick at 8,143 feet is the second highest peak), and the Eros and Onyati to the east, it forms the territory's highest mountain tract, constituting a central watershed from which the various headwaters drain north, south, east, and west.

The Kalahari sandveld extends along the whole of the eastern frontier of Namibia northward to the Okavango River. Its thick layers of terrestrial sands and limestone vary in depth from more than 1,000 feet to a thin covering at the hardveld edge. The width of the sandveld varies from 50 miles in the south, where it covers most of the Nossob-Auob Basin, to 250 miles in the north, where it comprises part of the Etosha Basin and the middle Okavango Basin. It has a level, sandy surface, which may rise to as much as 300 feet. In the south the sandveld is crossed by long sand dunes and grass and is covered with thorn trees.

The scarcity of water

The water shortage, or the uncertainty of obtaining water, touches all aspects of life and of development. Of the larger rivers only the Orange, Kunene, and Okavango are perennial, and they constitute boundaries of the territory. All rise outside Namibia and—as with the Okavango—the Kwando and the Zambezi in the north flow only through small sections of the territory. The potential of these rivers for irrigation, however vital, is thus limited to the southern and northern margins. The remaining rivers, whether the large westward-flowing deep-channel streams such as the Swakop and the Kuiseb or the eastward-flowing shallow watercourses (*omuramba*s) such as the Epukiro and the Omuramba Omatako, usually run only intermittently. They rarely contain surface water, except after rains or floods, although they constitute storage places for groundwater. Surface water collects mainly in shallow clay or limestone pans, especially in the sandveld region—the most famous of which is the giant Etosha Pan measuring some 68 by 31 miles—as well as in small lakes. There are also a number of springs. The general scarcity of water thus makes the well and the borehole the basis for land utilization. The conservation of floodwater through the construction of dams is, however, also of importance. It is estimated that there are some 10,000 dams, with a total storage capacity of 875,000,000 cubic yards (670,000,000 cubic metres). The largest of these is the Hardap Dam on the southward-flowing Fish River, located northwest of Mariental.

Climate. The climate is generally hot and dry. The territory is partly situated in the tropical high pressure belt of the Southern Hemisphere, located between latitudes 25° and 35° south, which governs the wind system of the plateau. The coastal region, however, experiences the air circulation that occurs as a result of the interaction between the eastern sector of the South Atlantic High pressure system, and the upwelling of the cold Benguela Current offshore. The mean temperature is, as a result, lower than the latitude might suggest. The temperature varies from 66° to 72° F (19° to 22° C) in the Central Highland to about 60° F (16° C) on the coast. During the summer months it may reach as high as 100° F (38° C) in the north and 120° F (49° C) in the Namib and the south. In July, which is usually the coldest month of the year, frost may occur, although only lightly in the north. In the south, however, temperatures have been known to drop to 20° F (−7° C) or lower.

Variations in temperature

Rainfall in the territory increases from south to north. In the arid Namib and the Orange River Valley, the mean annual rainfall is less than four inches (100 millimetres); in the north, and along the Caprivi Strip, the rainfall increases to between 24 and 26 inches. The mean annual rainfall for the territory as a whole is about 10 inches. Most rainfall occurs in the summer months (December to February). Only the extreme southwest receives any rain (up to one-half inch) in winter. The territory is occasionally subject not only to periods of flood, when the precipitation may be more than double the normal expectation, but also to periods of drought. The rains are the most reliable in the wet northeast, and the most variable in the dry south.

Plant and animal life. There are two categories of vegetation. In the west is found the desert and semidesert type, with its desert grasses and shrub; in the northeast the woodland savanna type, with its grasses, bushes, and trees. In the Namib Desert region there is little vegetation except for succulents and the narra, the nut of a gourdlike plant. Farther inland, and in the south, there are varieties of grasses, of succulents, such as the large aloe, of euphorbias, and of dwarf trees such as those belonging to the *Acacia* and *Boscia* genera. From south to north the veld changes to grass country, increasingly studded with thorn trees, of which most are acacia. Many others are also found, however, such as raffirboom, witgat, bush willow, and wild olive. Farther north the annual grasses become more abundant, the "bush" vegetation and acacia scrub grows thicker, and the variety of thorn trees increases. This pattern is not, however, uniform. The areas to the east and west of the palm-tree belt in southern Ovamboland are, for example, sparsely wooded. In the north the growing density of the trees, the appearance of the palm-tree belt, and, to the west, the baobab tree, all are signs marking the proximity of the well-wooded northern forest region, which stretches from the Kaokoveld across Ovamboland in the west to the greater part of the Okavango and Caprivi Strip areas in the east. It is in this region that most of the indigenous timber trees of the territory are found—including Rhodesian teak and mahogany, mopane, marula, manketti, and kiaat among others. In the west, however, as one approaches the dry steppe of the Kaokoveld, the trees and the bushes thin out; in this region the grass spreads more abundantly, and the mopane trees and bushes diminish in size.

The northern forest region

Big game is relatively abundant and is found in many parts of the territory. The wildlife includes lion, elephant, rhinoceros, giraffe, leopard, buffalo, eland, oryx, hartebeest, kudu, and zebra, as well as many smaller species of game and of predatory animals. The most renowned of the game reserves is the Etosha National Park, which covers an area of 8,500 square miles and is one of the largest game parks in the world.

Settlement patterns. The ecological relationship between man and environment is a complex one. Among the elements affecting it are frequent drought, the low protein and low phosphorous content of grasses, and the high salt content and humus deficiency of the soil. The best grazing and the most groundwater are found in the plateau hardveld region, most of which is now available to all inhabitants of the region since the repeal of apartheid laws in the late 1970s. Despite this, however, the white-owned farms have continued to predominate.

The many factors affecting the land settlement include the large, uninhabitable desert regions, the German wars against the Herero and Nama, the encouragement of white settlement by South Africa, the setting aside of the Northern Sector for the blacks living there, and the allocation of additional Reserves in the Southern Sector.

Windhoek is the administrative centre and principal town of Namibia. Walvis Bay, administered by South Africa, is Namibia's chief port and only natural deep harbour. The other port, Lüderitz, is shallow and used mainly by small

coastal craft or lighters. Tsumeb, the principal copper and lead-mining centre, is some 250 miles north of Windhoek.

THE PEOPLE

Linguistic groups

Of the white population approximately two-thirds are Afrikaans speaking, one-quarter German speaking, and one-tenth English speaking. The nonwhite population may be divided into two main types, the Southwestern Bantu and the Khoisan types. The San (Bushman) and Nama peoples belong to the Khoisan peoples, and their language contains the characteristic Khoisan clicks. The Bergdama (Damara), a black African people of unknown origin, have adopted the Khoisan language. The Hereros, who speak their own language, belong to the Bantu language family, as do the Ovambo, the Okavango, and the Kaokovelders. The latter are closely related to the Hereros in origin, language, and culture. The East Caprivians also belong to the Bantu-speaking peoples but are related to the Lozi and Makololo groups of Barotseland (western Zambia), rather than to the Bantu of Namibia. The Tswana and other groups include a few thousand people originally from Angola. They are mostly Bantu-speaking but are not related to the other ethnic groups in the territory. Apart from the established group of Tswana, who are related to the Tswana of Botswana, most of these peoples are dispersed throughout the rural and urban areas of the territory. The Basters of Rehoboth (or Rehobothers) are of mixed origin, being descended in part from unions between Afrikaner trekkers and Nama women. They moved from the Cape Colony in the 1860s and settled at Rehoboth. Their language, like that of the Coloured people, is predominantly Afrikaans, and their way of life is Western. The Coloured people, more recent immigrants, were originally a part of the Cape Coloured population of South Africa.

THE ECONOMY

Namibia's economy is determined, in part, by the harsh and arid environment. Its three key industries—mining, farming, and fishing—together account for a large portion of the gross domestic product (GDP). Its internal market is small; traditional subsistence farming persists over large areas, and its economic dependence upon South Africa is virtually complete. Cattle and sheep (mostly Karakul) account for most of the total gross output of commercial agriculture. Namibia obtains its fruits and vegetables, as well as the bulk of its grains for the Southern Sector, from South Africa. In bad seasons, the Northern Sector, too, must rely on South Africa for these commodities. Mining of diamonds and base metals contributes more than one-fourth of the GDP. Manufacturing is severely restricted by high costs and by a low aggregate demand from a small, poor, and widely scattered population. Mineral products account for more than four-fifths of the total value of exports, and fishery products for most of the remainder.

The transportation network primarily serves the Southern Sector. Transport development has been aided by capital and loan funds from the South African government. Tarred roads link Windhoek to Tsumeb in the north, to Keetmanshoop in the south, and to Swakopmund and Walvis Bay in the west—all of which are in the Southern Sector. A road construction program for the Northern Sector is still in a rudimentary phase.

The railroad system

Namibia's railway system was amalgamated with that of the South African Railways and Harbours Administration, and the track and sidings are all in the Southern Sector. The railroad runs from South Africa to Windhoek and north to Tsumeb. This north–south central spine is linked, via east–west lines, with the two ports of Walvis Bay and Lüderitz. Another line links Windhoek with Gobabis.

The high cost of road building adds importance to air services. Windhoek has an international airport, and there are a number of other airfields and landing strips. There are flights from Cape Town and Johannesburg to Windhoek. South West Airways, a subsidized private airline, maintains internal services. (R.B.Ba.)

ADMINISTRATIVE AND SOCIAL CONDITIONS

Administration. Prior to its independence in 1990, Namibia was administered by the South African government, which gained possession of the territory in 1915. Namibia's constitution, which took effect on March 21, 1990, establishes a multiparty system, outlaws the practice of apartheid that had been imposed by the South African government, explicitly protects a large number of civil rights, including freedom of speech, and abolishes the death penalty. It provides for a president, who is the head of state and who, along with the cabinet, has broad executive powers; a bicameral Parliament; and an independent judiciary, which rules on the constitutionality of legislation.

The president is directly elected and limited to two five-year terms. The cabinet, headed by the president, directs the ministries of government and is composed of the prime minister and other members of the National Assembly appointed by the president. The president has the power to declare martial law and to dissolve the National Assembly.

The National Assembly, the lower house of Parliament, is composed of 72 directly elected members and no more than six nonvoting members appointed by the president because of special expertise. Legislation may be passed by a simple majority, but the constitution requires a two-thirds majority for legislation to become law without both the assent of the president and the confirmation of the National Council, the upper house of Parliament. The National Council is also responsible for recommending legislation concerning regional matters; its members are elected by the regional councils, discussed below, each of which choose two from among their members. A two-thirds majority in both the National Assembly and the National Council is required to impeach the president.

Appointments to the Supreme Court and to the High Court are made by the president. Decisions by the Supreme Court, which rules on appeals brought from the High Court, are binding on all Namibian courts. The High Court hears civil disputes and criminal prosecutions, as well as appeals from the Lower Courts, which are established and regulated by the National Assembly.

The boundaries for local and regional governments are delimited by a national commission. The constitution requires that each regional and local government have a freely elected council as its principal governing body.

Education. About one-quarter of adults in Namibia are illiterate. The 1990 constitution, however, requires all children under 16 who have not completed their primary education to attend school. There is no university in the territory; Namibians who attend university usually do so in South Africa.

Health and Welfare. While Namibia has one of the highest per capita incomes in Africa, a great majority of the nonwhite population is extremely poor. Many Namibians live in overcrowded housing and have a water supply that is either inadequate or unclean. Health problems linked to poor sanitation, such as tuberculosis and gastrointestinal diseases, are common, as is malnutrition. Much of the population lacks even basic health care services.

For statistical data on the land and people of Namibia, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL. (Ed.)

History

As a geographically defined area, South West Africa came into being during the last two decades of the 19th century. It was the result of agreements and boundary settlements between Britain, Portugal, and Germany following Germany's decision in 1884 to acquire a colony in southwestern Africa. One important enclave, however, did not become part of the German acquisition. The largest port, Walvis Bay, and a coastal strip comprising in all an enclave of 434 square miles had already been annexed by Britain in 1878 and became a part of Cape Colony in 1884. At the time of the formation of the Union of South Africa in 1910, it became South African property.

Apart from this enclave, South West Africa remained under German rule until shortly after the outbreak of World War I, when it was successfully invaded by troops from South Africa. The colony was then placed under South African military administration until January 1, 1921, when it became a Class C mandated territory, administered by South Africa on behalf of the League of Nations.

The Class C mandates explicitly authorized the administering governments to exercise full powers over the territories as integral parts of their own states, subject to the international supervisory authority of the Council of the League of Nations. Upon the formal dissolution of the League in April 1946, South Africa, after unsuccessfully seeking UN approval for the incorporation of the territory, refused to place it under the UN trusteeship system, and a dispute between South Africa and the United Nations began on the status of South West Africa. The position of successive South African governments was essentially that, with the demise of the League and its supervisory machinery, all of their international obligations concerning the mandate, save one, had lapsed. The acknowledged exception was the clause providing that the territory should be administered as a "sacred trust of civilization." The initial position of the United Nations was that the mandate was still in force, that the supervisory authority of the League was to be exercised by the United Nations, and that, both by its refusal to sign a trusteeship agreement for South West Africa and by the conduct of its administration, South Africa had violated the mandate. (R.B.Ba.)

)ispute
etween
outh
ıfrica and
ıe UN

The nature of South African rule came before the United Nations annually, and in 1966 the UN terminated the mandate and called for complete South African withdrawal. This was upheld in an advisory opinion from the International Court of Justice at The Hague in 1971. In 1973 the United Nations appointed its own commissioner for Namibia (as the territory became known in the 1970s).

In 1958 a mass-based nationalist organization, the Ovamboland People's Organization, was formed to protest against South Africa's policies. In 1960 it became the South West Africa People's Organization (SWAPO), which came to represent the opposition of all sectors of the population to political incorporation by South Africa, the alienation of African land, the contract labour system, grossly inadequate education, the proposed introduction of black states (formerly called Bantu Homelands), and racial inequalities even more glaring than in the republic.

.rmed
:ruggle
nd the
'urnhalle
'onference

After years of unsuccessful peaceful tactics, SWAPO decided on armed struggle, and in 1966 a major conflict at Ongulumbashe led to the replacement of the police with the South African Defence Force. With the independence of Angola in 1975, the war in the northern part of the country intensified. In the light of this and pressure from the United Nations and the Western powers in the UN Security Council, South Africa initiated the Turnhalle Conference, held in 1976 at Windhoek. It was unrepresentative, and its constitutional proposals called for the division of the country into 11 semiautonomous ethnic governments. SWAPO refused to attend the conference and, along with the United Nations and the Organization of African Unity, denounced its proposals. In 1977 a South African administrator general was appointed to carry out a form of decolonization, and a constituent assembly was formed in 1978 in accordance with the Turnhalle plans; neither gained international recognition. (Sh.M./Ed.)

Protracted negotiations among South Africa, SWAPO, the United Nations, and several Western powers broke down in the early 1980s over the implementation of the UN Security Council's Resolution 435, which contained a settlement plan that had been conditionally accepted in 1978 by both Namibia and South Africa. The plan involved a UN-supervised election for a national assembly that would draft Namibia's constitution. With the support of the United States, South Africa made acceptance of the plan contingent upon Cuban troop withdrawal from Angola.

South Africa renewed direct control over Namibia in 1983. Under the auspices of the interim administration, several Namibian political parties formed the Multi-Party Conference (MPC), denounced by SWAPO as an instrument of South Africa's interests. The South African government accepted the MPC's proposals in 1985 for a "transitional government of national unity," which was established to the condemnation of SWAPO and the United Nations.

In 1988 Cuba for the first time negotiated with South Africa and Angola on its presence in the region. Mediated by the United States, the talks resulted in a timetable for the withdrawal of South African and Cuban troops from Angola, as well as for the implementation of UN Security Council Resolution 435, which began on April 1, 1989. In November, elections for the new National Assembly gave SWAPO 57 percent of the vote, far short of the two-thirds required to control the passage of the constitution. Therefore, SWAPO was forced to work with other parties in writing the constitution, passed in February 1990, which established a multiparty system and a directly elected executive president. The assembly, which gave itself the power to elect the first president, unanimously chose the veteran SWAPO leader Sam Nujoma, who took office on March 21, the day of Namibia's independence.

For later developments in the history of Namibia, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL. (Ed.)

SWAZILAND

Swaziland is a landlocked, independent kingdom wedged between South Africa to the north, west, and south and Mozambique to the east. It has a total area of 6,704 square miles (17,364 square kilometres). Small and compact, the oval-shaped country is about 110 miles from north to south and about 85 miles from east to west. It is named for the Swazi nation, which comprises almost all of the country's people. The national capital is at Mbabane.

Formerly a British High Commission Territory, Swaziland gained its independence in 1968 under the leadership of its king, Sobhuza II. The small black nation is faced with delicate problems of economic development. It is rich in agricultural land and mineral resources, but its mines are controlled by foreign interests, and its commercial agricultural operations remain in the hands of Europeans. Economic progress has, however, been steady.

Physical and human geography

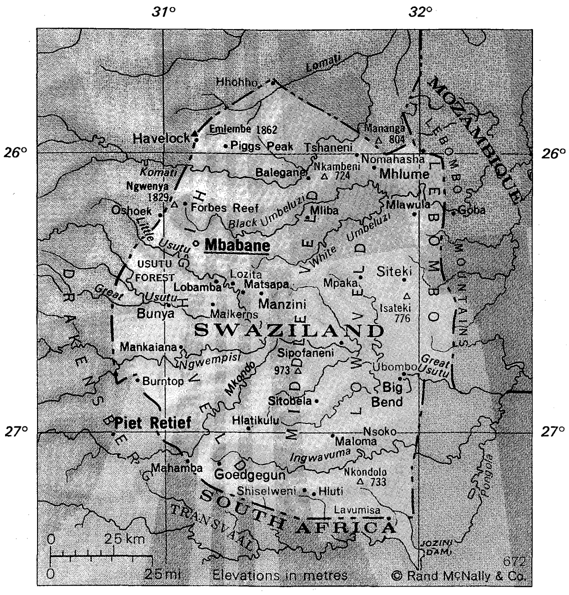
THE LAND

Relief and soils. Despite its small size, Swaziland has a rich variety of relief features and soils. There are four well-defined topographical regions, extending longitudinally from north to south in roughly parallel belts. From west to east they are Highveld, the Middle Veld, and Lowveld, and the Lebombo (Lubombo) escarpment.

The Highveld, which covers an area of 2,000 square miles, is a continuation of the Drakensberg range of South Africa. Locally known as Inkangala (meaning "a cold treeless place"), it is a granite massif (mountainous mass) with quartzite ridges that are broken up into rugged terrain. The average elevation is between 3,500 and 4,500 feet (1,100 and 1,400 metres); the highest elevations are the summits of Emlembe (6,100 feet) and Ngwenya (6,000 feet). The rocks on gentle gradients are covered by deep red, orange, and yellow acidic soils of medium texture.

The Middle Veld covers an area of 1,900 square miles and has an average altitude of 2,000 to 2,500 feet. It is a region of hilly country and well-watered valleys. Its foundation is mainly dolomite (limestone rich in magnesium carbonate) and gneiss (coarse-grained rocks containing ponds of minerals). Dolerite (coarse basalts) and quartzite also occur. The principal soils are deep and friable red and clay loams; gray-brown sands and sandy loams rest on mottled, sandy clay or iron concretions.

The Lowveld, or Bushveld (locally known as Lihlanze, a Swazi name meaning " a warm place with trees") covers 2,200 square miles. It is a gently undulating region with hills that rise from an average of 500 to 1,000 feet to a height of 2,300 feet reached by the isolated hill of Nkambeni and the isolated ridge of Nkondolo. The complex geology of the region ranges from the acidic rocks of the



SWAZILAND

west to the basalt and dolerite of the east. The soils are similar to those of the Middle Veld.

The Lebombo, covering 600 square miles, is an escarpment along the eastern fringe of the Lowveld. It rises from an average height of 2,000 feet to the two highest points of Isateki hill (2,500 feet) and Mt. Mananga, known as the Mananga Beacon (2,640 feet), which is on the border with South Africa. The scarp is intersected by the gorges of the Ingwavuma, Usutu, and Black Umbeluzi rivers. The plateau's foundations are composed of acidic and intermediate volcanic lavas, such as rhyolite, lava-formed granite. Soil is virtually absent in some areas, while in others it is fairly deep, reddish, and medium to heavy in texture.

The rivers

Drainage. The country is one of the best watered in southern Africa; major rivers flow through all four regions. From the Highveld the Lomati, Komati, Black Umbeluzi, Usushwane (Little Usutu), Usutu, Ngwempisi, and Mkhondvo rivers flow in a generally easterly direction toward the Indian Ocean. The Usutu, which carries the greatest volume of water, flows into the Pongola to form the Maputo River of Mozambique.

Climate. The climate varies from almost tropical and subhumid conditions in the Lowveld, where the average annual rainfall amounts to between 20 and 35 inches, to the humid, near temperate climate in the Highveld, which receives between 40 and 90 inches of rainfall. The Middle Veld and Lebombo region are subtropical and drier, receiving only 30 to 50 inches of rain. Rains occur during the summer from October to March. The mean annual temperature is 59° F (15° C) in the Highveld and 72° F (22° C) in the Lowveld.

Plant and animal life. More than 2,600 species of ferns and flowering plants have been recorded. Among these are 25 species of aloe (members of the lily family), arum lilies, Cape primroses, begonias, gladioli, and a rich variety of orchids. Cape heath (*Erica*), a large sturdy shrub, with red, pink, green, yellow, and white flowers, grows in the mountains. Trees include the crimson-flowered Hottentot's bean, the scarlet-flowered umsini, umvangata or kiaat (a leguminous tree that yields durable wood), and umbrella trees.

Although the animal population has been greatly reduced (earlier by hunting, but now by the expansion of agriculture), there are still numbers of hippopotamus, blue wildebeest, zebra, and antelope (including the kudu, impala, reedbuck, duiker, klipspringer, and waterbuck). Lions, baboons, monkeys, and galagos (small African lemurs known as bush babies) are less numerous. There are crocodiles in the Lowveld rivers. Birdlife is abundant and includes a few rare species with northern affinities, such as the European stork, the sacred ibis and hadedah. Other more conspicuous species are the hammerhead, the gray heron, the lisakabuli (widow bird), the hornbill, and the lilac-breasted roller.

Settlement patterns. Nine-tenths of all Swazis live in villages that are divided into family homesteads, or *umuti.* Each village is led by a headman, who is the village patriarch. A unique feature of Swazi life is the role of the headman's mother, who acts as village "mother" and is in control of everything affecting the homestead. Each such homestead, at the minimum, consists of a great hut, the cattle kraal (enclosure), and the bachelors' quarters. Flask-shaped pits for storing grain are built into the wooded palisades surrounding the kraal.

Rural life

The pattern of village life is strictly set by the seasons. With the onset of the rains in spring (August to October), women plant small gardens along the riverbanks; later when the heavy rains come in summer (November to January), with some help from the men, they hoe and sow corn (maize) and millet in larger fields; at this time all able women and children abandon their homesteads for the fields, and the men also join in the planting and weeding. The summer months are, on the whole, the hungry months.

Autumn (February to March) is the time of harvest; in winter (April to July) the last of the crops are brought in. Activity then moves to the homesteads, where women and men thresh the grain, the best of which is stored and the remainder consumed at once. Winter is a time for relaxation; the men hunt and entertain from their full food bins and the women visit their parents.

The central points of Swazi political life are the royal villages of the king at Lozita, and the queen mother at Lobamba. The two principal commercial centres are Mbabane and Manzini. Mbanane, attractively situated on wooded hills, contains both modern and colonial-style buildings. It is the country's largest town. Manzini is a growing industrial and agricultural service centre.

THE PEOPLE

The Swazi nation

The Swazi nation is composed of more than 70 clans, of which 70 percent are Nguni and 30 percent Sotho. The Dlamini, which is the dominant clan, forms the nucleus of the nation and constitutes the royal family. Its customs, laws of property and person, and its dialect, known as Siswati, prevail in all matters.

The Swazis compose about nine-tenths of the total population. Other Africans, mainly Shangane from Mozambique, Europeans, largely English- and Afrikaans-speaking South Africans, Eurafricans (persons of mixed European and African descent), and Asians make up the rest of the population. Eurafricans and Asians are mainly in commerce and industry as shopkeepers, clerks, and artisans. Most Europeans are either large-scale farmers, miners, technicians, teachers, public officials, or traders. The majority of the Europeans speak English, which is one of the official languages, together with Siswati.

A majority of Swazis are Christians. The remainder hold strongly to their traditional animist religious beliefs.

THE ECONOMY

Swaziland is principally an agricultural country, with nine-tenths of the population engaged in subsistence agriculture. Mixed farming is carried out on the Middle Veld, where rice and fruits, such as bananas and citrus, are grown under irrigation; corn, cotton, beans, tobacco, and pineapples are raised on dry lands. The Lowveld is ideally suited to cattle raising, which is little developed commercially; this region is under irrigation, and there is intensive cultivation of cash crops such as sugarcane, rice, tobacco, and citrus fruits, which are mainly grown by European farmers for export.

Resources. The nation's main export wealth derives from forestry and mining. The largest man-made forest, the Usutu afforestation estate, covers 100,000 acres of pine and eucalyptus trees planted in the Highveld. It supplies the wood pulp factory, near the town of Bunya, the products of which are a major export earner. Although not extensive, mineral resources are rich. Iron ore and asbestos deposits are located in the Highveld region, and there are also important coal deposits near Mpaka.

Mining operations

The most important mine is the iron-ore mine at Ngwenya, owned by the Swaziland Iron Ore Development Corporation and controlled by South African and British interests. The British-owned Havelock Asbestos Mine exports asbestos fibre. Third in importance are the Mpaka coal mines, mainly owned by a South African firm. Smaller mines, also foreign owned, produce kaolin, barite, and pyrophyllite.

Industry. Industry is mainly confined to the processing of agricultural products and to providing small-scale services. Manufactured products include clothing, edible oils, soap, canned fruit, and ginned cotton. There are also a slaughterhouse and a small engineering industry. Handmade woven and wooden articles are also produced.

Less than one-third of the working population is engaged in paid employment. Of this group, more than a third is employed in agriculture and related services. It was formerly traditional for Swazi labourers to engage in migratory labour in South Africa's mines and farms, but by the early 1970s the proportion that still did so had dwindled to about one-quarter of all male workers.

Trade. The bulk of all wholesale and retail trade is traditionally controlled by white South Africans. All commercial banking is foreign owned.

Swaziland depends on foreign aid—mostly from the United Kingdom—for capital and development needs. Imports of machinery, fertilizers, clothing, fuel, and vehicles largely come from South Africa. Exports—including iron ore, sugar, wood pulp, asbestos, and agricultural products—are sold to the United Kingdom, Japan, and South Africa.

The main sources of national income are taxes, mining royalties, and customs revenues. Income tax is payable on all incomes derived inside the country. A personal tax is paid by all non-Swazi adult males, and Swazi adult males pay a graduated tax based on the number of their wives. Company taxes are paid at a fixed rate, and mining taxes are on a variable scale.

Transportation. Good all-weather roads link the main population centres. The transterritorial highway runs from Oshoek, on the western frontier, to Nomahash, on the eastern border.

A railway line running from Kadake to the port of Maputo, in Mozambique, is linked to the Mozambique Railways network at Goba across Swaziland's northeast border. There is no rail link with South Africa.

The only airport is at Matsapa, five miles from Manzini. South African Airways operates scheduled services to Johannesburg and Durban, and Mozambique Airways flies to Maputo. There are also small landing strips.

ADMINISTRATIVE AND SOCIAL CONDITIONS

he overnmental ructure

Executive authority is vested in the king and exercised through a cabinet, which is presided over by the prime minister, who is appointed by the king. The cabinet advises the king and is responsible to a bicameral parliament. The House of Assembly is composed of 50 members—40 of whom are elected by an electoral college and 10 appointed by the king. There is universal franchise for all men and women over the age of 21 who are citizens of Swaziland and who are not insane and who have not been convicted of serious crimes. The Senate has 20 members, 10 elected by an electoral college and 10 nominated by the king. The civil service is controlled by a public service commission appointed by the king on the advice of the Judicial Service Commission.

Local urban government operates through town councils and urban area advisory committees. A majority of the council and committee members are elected and a minority appointed by the Minister of Local Administration. Rural administration is conducted in the four districts of Shiselweni, Lebombo, Manzini, and Hhohho by district commissioners responsible to the Minister of Local Administration.

Justice. The judicial system comprises a court of appeal, a high court, subordinate courts, and Swazi (traditional) courts. The court of appeal comprises a judge president and three justices of appeal appointed by the king. The high court, presided over by the chief justice, hears appeals in civil and criminal matters from subordinate courts and the Higher Swazi Court of Appeal. Subordinate courts, presided over by magistrates, have wide criminal jurisdiction but not over murder, sedition, or treason. There are 14 Swazi courts, two courts of appeal, and the Higher Swazi Appeal Court; these may hear cases only if all those involved are Africans and if the charges fall within a restricted list of criminal and civil offenses.

Land ownership is the most sensitive issue in Swazi national life. Under the British colonial administration about 44 percent of the land was either sold as concessions to Europeans or alienated by the government. Traditionally, however, all land is vested in trust in the king as Swazi national land, and all Swazis are entitled to a share, which is allocated by the king through the chiefs. The Swazi National Council adopted a policy in 1946 of repurchasing for the nation as much as possible of the 1,873,000 acres still held out of communal ownership by Europeans.

Educational services

Education. Half of the school-age children attend primary schools, of which most are mission (primarily Protestant) schools. A small proportion also attend secondary schools. Schooling is free except at the Waterford School at Mbabane, which is a multiracial institution for pupils from all over southern Africa. There are two teacher-training colleges. Higher education is provided at the Swaziland campus of the University of Botswana and Swaziland.

Health and welfare. Medical services are provided by the government, missions, industrial concerns, and private practitioners. The country has hospitals and rural clinics. Chief causes of illness are schistosomiasis (a parasitic infestation of the bladder or intestines), food-deficiency diseases, typhoid and paratyphoid, and respiratory diseases. Malaria has been virtually eliminated.

CULTURAL LIFE

Major national celebrations

Traditional ceremonies and music play an important part in Swazi social life. The two major cultural events are the *Incwala* (National Ceremony) held in December or January, and the reed dance (*umhlanga*) held in June or July, both at the royal village of Lobamba. The *Incwala*, the most sacred of the ceremonies, represents the king as the source of fertility and the symbol of power and unity. It lasts for six days and is a highly ritualized festival of song, dance, folklore, and martial display. The reed dance, which lasts for one week, encourages girls of the same age group to work in harmony under discipline and to preserve their virginity.

Traditional music accompanies the Swazi from birth to death, beginning with the first lullaby. There are songs for children and adults; for courting, weddings, and mourning; for working; for specific tribes and clans; and for insult. The main musical instruments are rattles, which are tied to the wrists or ankles or shaken by hand. The shield is used for percussion; buckhorn whistles and long reed flutes are the principal wind instruments.

For statistical data on the land and people of Swaziland, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL. (Co.L.)

History

According to the traditional account of the origin of the Swazi, when in the 16th century the main Bantu tribes were moving gradually southward along the coast of what is now Mozambique, a group diverged and crossed the Lebombo Range into the area that lies between the Pongola and Great Usutu rivers. Under pressure from the Zulus, the group moved northward to the Little Usutu River. Further attacks by the Zulus took place from time to time, and when King Sobhuza I died in 1836 his successor, Mswazi (Mswati) II, who reputedly gave his name to the tribe, moved farther north to the Pigg's Peak area. By that time, the Swazi had a well-trained army and conquered the tribes to the north, but in 1846 their ruler ceded any claims that he had to the country north of the Crocodile River in favour of the Lydenburg Republic. It was at that time also that Mswazi was compelled to seek British aid against the Zulus.

During the 1880s large numbers of Europeans visited the

Swazi king Mbandzeni in search of concessions. It may be said that these concessions were only intended to allow the concessionaires to share the use of the concession property with the Swazi.

In 1888 a charter of self-government was granted to the Europeans. Two years later, under a convention between the British government and the South African republic, a provisional government consisting of representatives of the two powers and a representative of the Swazi people was set up with the consent of the latter. In 1893 the British government signed a new convention permitting the South African republic to negotiate with the Swazi regent and her council for a proclamation allowing it to assume powers of jurisdiction, legislation, and administration, without incorporation in the republic. The Swazi refused to sign the proclamation, but in 1894 another convention was signed by the two powers, virtually giving effect to its terms. After the conquest of the Transvaal all rights and powers of the republic passed to Great Britain, and in June 1903 by an order in council under the Foreign Jurisdiction Act the governor of the Transvaal was empowered to administer Swaziland and to legislate by proclamation. In 1906 these powers were transferred to the high commissioner for Basutoland, Bechuanaland, and Swaziland. A commission was appointed in 1907 to deal with the problem of the concessions, and as a result of its report, land and grazing concessions were reduced by one-third. The regent did not accept this settlement, and a deputation of protest was sent to London in 1908, but it achieved little.

In 1963 the office of resident commissioner was replaced by that of Her Majesty's commissioner (equal in status to governor); in 1964 the office of high commissioner was abolished. A constitution providing limited self-government was promulgated in 1963. In 1967, under the new constitution of that year, the country became a protected state under the name of the Kingdom of Swaziland, and in the following year another and greater change took place when Swaziland became fully independent. (Jo.W.H.)

King Sobhuza II of Swaziland celebrated his diamond jubilee on September 4, 1981. Born on July 22, 1899, he was installed as the *ngwenyama* of the Swazi nation in 1921. Although he received a modern education at the Zombodze National School and at South Africa's famous missionary-run Lovedale College, the King jealously cherished and preserved Swazi traditions. Five years after Swaziland became independent in 1968, the King tore up the constitution designed by the British and restored the more ancient system of government in which all effective power remains in the royal capital, while a system of village government, known as the *tinkundlu,* operates at the grass roots. His one concession to modern government was to establish a Cabinet system and a prime minister, but all ministers were chosen by the King himself.

With a kingdom wedged between white supremacist South Africa and Marxist Mozambique, Sobhuza trod a careful path to maintain good relations with both his neighbours. He was a strong supporter of the Organization of African Unity but refused to allow Swaziland to be used as a base for guerrilla attacks against South Africa. Vehemently anti-Communist, the King maintained his strong Western ties. His was among the very few African countries that maintained close diplomatic and economic ties with Israel and Taiwan. (Co.L.)

Under the King's firm rule, Swaziland enjoyed a remarkable degree of stability and a measure of economic growth. Swaziland joined the Southern African Development Coordination Conference but maintained close diplomatic and economic ties with South Africa.

The King's death in 1982 was followed by a power struggle. The queen mother, Dzeliwe, who had assumed the regency, and her prime minister and advisory council were unseated by a faction loyal to the teenage heir, Prince Makhosetive. The Prince's mother, Queen Ntombi, was made regent in 1983, and in April 1986 the Prince was crowned King Mswati III.

For later developments in the history of Swaziland, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL. (Ed.)

ZAMBIA

Zambia is a landlocked republic in south central Africa. It has an area of 290,586 square miles (752,614 square kilometres). One of the largest producers of copper in the world, Zambia is one of the richest black-controlled states on the continent. It is bordered to the west by Angola; to the northwest by Zaire; to the northeast by Tanzania; to the east by Malaŵi; to the southeast by Mozambique; to the south by Zimbabwe and a small, ill-defined border with Botswana; and to the southwest by a thin strip of South West African territory called the Caprivi Strip. A wedge of Zaire territory—known as the Pedicle—thrusts so deeply into Zambia that the northern and eastern parts of the country are united to the western and central region only by a narrow corridor about 120 miles wide. The name Zambia is derived from the Zambezi River, which forms a common border with Zimbabwe. The capital is Lusaka.

Physical and human geography

THE LAND

Relief. The greater part of Zambia forms a plateau 3,000 to 5,000 feet above sea level. The landscape has a flat or gently undulating surface, resulting from long and uninterrupted erosion of the underlying crystalline rocks. The plateau occasionally retains remnants of earlier surfaces, and there are isolated hills and ranges. In the north, the general level rises toward the Muchinga Mountains, which form the Congo–Zambezi watershed, and toward the plateau at Mbala, near the Tanzanian border, which is 5,000 to 6,000 feet (1,500 to 1,800 metres) high. In the east, toward the Malaŵian edge of the East African Rift Valley, the Nyika Plateau is generally over 6,000 feet high, rising to about 7,000 feet in the Mufinga Hills in the northeast.

From the Congo–Zambezi divide in the north, the elevation falls southward toward the Zambezi Valley. The lowest point in the country, about 1,200 feet (360 metres) above sea level, is near the confluence of the Zambezi and Luangwa rivers. Most of the country consequently drains south and east to the Indian Ocean. Only in the Luapula River area does drainage flow to the west.

Several rift valleys are wholly or partly located within Zambia. The southern tip of Lake Tanganyika, where it intrudes into Zambia's northern border, is some 2,000 feet below the plateau. Nearby, the Kalambo River, which forms part of the border with Tanzania, flows into the lake through a narrow gorge cut by the Kalambo Falls (726 feet), the highest in the country. Lake Mweru, on the Zambia–Zaire border, lies in a rift about 1,500 feet below the plateau. The largest of the rifts, however, is the valley of the Luangwa River, extending more than 350 miles (560 kilometres) from the northeastern tip of Zambia to the Luangwa's confluence with the Zambezi in the south and constituting a serious barrier to communication. In the northwest region of the plateau lies Bangweulu, a shallow depression containing the lake of the same name and the Bangweulu Swamp, approximately 4,000 square miles (10,360 square kilometres) in area and one of the largest inland swamps in the world. Bangweulu is fed by the Chambeshi River and drained by the Luapula. The Luapula joins Lake Mweru, which in turn is drained by the Luvua, one of the headstreams of the Congo. Mweru Swamp, east of Lake Mweru, is another shallow lake in a swampy region. Extensive floodplains surround the Bangweulu area, the Chambeshi and Kafue rivers, and the Barotse Plain.

The Bangweulu region

Soils. Geologically, Zambia is dominated by a basement complex of ancient sediments and widespread volcanic flows that have been folded, distorted, and metamorphosed by granitic intrusions. The oldest rocks, found along the Kafue River near Kapiri Mposhi, are about 2,600,000,000 years old. It is in the Katanga sediments (550,000,000 to 620,000,000 years old), deposited on the basement rocks, that all the minerals of economic importance so far discovered have been found. To the west is part of the Kalahari region, consisting of a blanket of unconsolidated windblown sand and gravel partly derived from, and possibly overlying, the younger sedimentary rocks of the Karroo System. These Karroo rocks, between 200,000,000 and 300,000,000 years old, have largely disappeared elsewhere in the country, except in the Luangwa and Middle Zambezi valleys.

The porous Kalahari sands contrast with the generally well-watered plateau areas. The plateaus are drained by numerous seasonal streams, as well as by *dambos,* spongy, grass-covered depressions that act as water reservoirs. The commonest soil types in Zambia are the sand to sandy clay soils of the plateau, which are generally acid, low in humus, and underlain by laterite (red, leached, iron-bearing soil). These soils form the so-called sandveld, which is of indifferent agricultural value. The soils below the main plateau, being less acid and lacking the laterite layer, are more fertile. In the bottoms of the river valleys there are areas of highly fertile alluviums, and the lake basin soils, such as occur in the Chambeshi–Bangweulu area, are similarly fertile.

Climate. Although Zambia lies within the tropics, its altitude ensures a climate that, varying widely in both season and location, is generally favourable to both human settlement and comfort. There are four seasons.

The cool season. This season lasts from May to August. Temperatures tend to decline during May, and the weather is fair to fine, with occasional ground frosts on calm nights in wind-sheltered areas. Invasions of cold air from the south or southeast may bring overcast conditions. Instability in the upper air leads occasionally to light rain or showers. A rapid increase of temperature begins about the middle of August.

The hot season. This season, from August to October, consists of rising temperatures that continue through September, interrupted by occasional invasions of cold air. Rain is unlikely. In October, temperatures rise more slowly, reaching the highest levels of the year in mid-month, after which there is a tendency for cooler oceanic air to move in, increasing humidity and cloud formation. On the northwestern border, moist air from the Atlantic often causes thunderstorms. Storms often occur in early November, but rains are frequently scattered and are undependable.

The rainy season. The rainy season lasts from November to April. A westerly airstream flowing in from the Atlantic converges with the southeast trade winds (which usually cross Zambia as northeast winds), giving rise to the Congo air boundary that moves into Zambia from the northwest in November, bringing the first rains. The intertropical convergence zone (continental hot, dry air coming southeast from the Sahara to meet maritime moist, relatively cool air coming northeast) moves down from the north, entering Zambia in early December to bring the main rains as it proceeds south. In January or February there is a temporary decrease of rainfall in the north and northwest, followed by an increase as the intertropical convergence zone passes back to the north.

The post-rainy season. This season falls in April and May. In this transitional period, the air is still fairly moist, and clouds form daily. Showers occur occasionally in April and exceptionally in May. In April, day temperatures tend to rise and night temperatures to fall as cloud cover decreases, while in May both day and night temperatures are falling. Since out-of-season rainfall in Zambia is negligible, the mean annual rainfall is virtually identical with the seasonal average and ranges from about 58 inches (1,475 millimetres) in the north to about 28 inches in the south. Places with an average annual rainfall of 35 inches may expect rain to fall on half the days from November to March. The highest daily rainfalls do not usually exceed four to five inches. The highest daily rainfall on record is 12.11 inches.

empera- re ranges

Temperatures are generally moderate, due partly to the altitude and partly to the cooling effect of showers and of cloud shade during what would otherwise be the hottest time of the year. The extremes of temperature recorded are 111° F (44° C) in the Luangwa Valley in the east, at 1,230 feet above sea level; and 19° F (−7° C) at Sesheke in the southwest, at 3,120 feet. Throughout most of the country, however, extreme temperatures seldom exceed the range of 30° to 100° F (−1° to 38° C).

Average annual hours of sunshine range from over 3,000 in the southwest to under 2,500 on the eastern border. Relative humidity ranges from under 40 percent in the dry season to over 80 percent in the rainy season.

Plant and animal life. The plateau vegetation is dominated by wooded savanna (grassy parkland). These woodlands consist mostly of small leguminous trees of the *Brachystegia, Isoberlinia,* and *Julbernardia* species. Since they rarely form a dense leaf canopy, they permit the growth of tall perennial grasses or herbs. These grasses readily catch fire in the dry season, causing the trees to develop a corky, fire-resistant bark.

Low regions, such as the Zambezi and Luangwa valleys, are dominated by the mopane tree and short-lived annual grasses and by a few perennial herbs. In the sandy Kalahari area of the southwest, there are economically valuable forests of evergreens, notably Rhodesian teak. Few other specific species are commercially exploited, though mukwa (*Pterocarpus angolensis*), a good furniture timber, is found in the Bangweulu Depression. The ordinary woodlands, nevertheless, provide mining timber, cordwood, charcoal, building material, forage, and supplementary foods. More than 8 percent of the country has been set aside as forest reserve or protected forest area.

There are extensive areas of poor drainage that do not support tree growth; some of the largest of these are found in the major swamps and floodplains. These grasslands support livestock as well as wildlife. The resumption of the traditional practice of burning off the vegetation after crops have been harvested has led to an increase in the area of secondary grassland and has tended to increase the danger of soil erosion, as well as to lower the productivity of the land.

The mammals of Zambia are more notable for their variety than for their numbers. The predominant woodlands have never supported many large animals, though large concentrations occur on the major floodplains. While no species is in danger of extinction, a depletion of wildlife has occurred because of hunting, the increasing use of land for agriculture as a result of population increase, and the elimination of game as a measure to help eradicate tsetse flies.

About one-third of Zambia is either infested by tsetse flies or consists of marginal lands. A number of areas unsuitable for human settlement are game reserves. These include the Kafue National Park (8,650 square miles) and the Luangwa Valley game management areas (5,040 square miles).

Elephants are numerous; other animals found in Zambia include the genet, a small carnivorous animal related to the civet cat; hyena; wild dog; jackal; and ratel, a nocturnal animal resembling a badger; and such cats as the serval, leopard, cheetah, and lion. Hoofed animals include black rhinoceros, zebra, hippopotamus, warthog, bush pig, giraffe, buffalo, and several species of antelope. Two species of baboon, four species of monkey, and two species of galago (known as bush babies) are also found. There are many smaller mammals.

Bird life is varied and numerous; about 700 species have been recorded. These include shoebills, secretary birds, wood hoopoes, and guinea fowl—families unique to Africa—as well as many other tropical species. Lochinvar National Park on the Kafue Flats is the best bird-viewing area, with almost 400 recorded species. The other national parks also have a wealth of bird life, outstanding being the water birds of the Busanga Plain and the carmine bee eater of the Luangwa Valley. The fish eagle, Zambia's national emblem, is common on large areas of water.

Fish are found not only in Lake Tanganyika in the far north but also in the Luapula Region, which includes Lake Mweru and Lake Bangweulu, and in the Zambezi River system, which includes the Kafue River and Lake Kariba. Commercial fisheries catch bream, barbel, and tiger fish in these waters. The Lake Tanganyika sardine, commonly called *kapenta,* is considered a national dish. The best game-fishing areas for tiger fish are the Kafue River, Lake Kariba, the upper Zambezi, and Lake Tanganyika.

Reptiles include crocodiles, tortoises, terrapins (freshwater turtles), a variety of lizards (including geckos, agamas, and skinks), and many poisonous and nonpoisonous snakes. Insects of most orders are prevalent.

THE PEOPLE

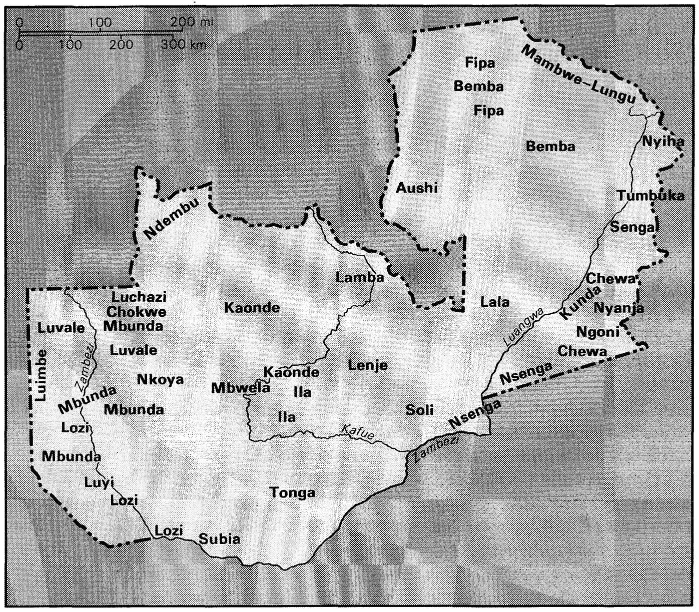
Zambia's population is small in relation to its area. Within the population, the small white (European) minority exercises a disproportionate influence on the social, economic, and—until recently—political development of the country. Two-thirds of the African population is still engaged in traditional subsistence agriculture, although the introduction of a money economy has encouraged many young men to move to the towns.

Tribal peoples

The African peoples of Zambia—with the exception of a few bands of San (Bushman) peoples living on the fringes of the Kalahari and the Twa found in the Bangweulu Swamp, the middle Kafue Valley, and the Lukanga Swamp—are all of Bantu origin and for the most part descendants of immigrants from the Congo region. Within this grouping, however, there is wide cultural and linguistic variety. Tribal affiliations have not been recorded since 1962, but the census of 1969 included a question on mother tongues, from which linguistic groupings can be tentatively derived. The census indicated that about 34 percent of Zambia's population belonged to the Bemba or near-Bemba group, 17 percent to the Nyanja group, 15 percent to the Tonga group, 11 percent to the North-Western Province group, 9 percent to the Lozi group, 5 percent to the Mambwe group, and 5 percent to the Tumbuka group. There are also some Zambians belonging to the Swahili-speaking and other minorities.

The larger aggregations contain numerous small, separately identified groups. In 1962 more than 90 tribal names with membership ranging from a few hundred to 250,000 were listed, but many of these small groups would meet only a few of the accepted criteria for classification as a separate tribe. Similarly, mutually intelligible languages or dialects cover large areas and populations. Radio broadcasting employs seven languages—Bemba, Tonga, Nyanja, Lozi, Kaonde, Lunda, and Luvale—of which the first four are understood far beyond the mother tongue boundaries. The extended ties of kinship involved in the traditional system of society have continued to exert a powerful influence even in the urban areas.

The traditional regions within the country approximately coincide with the administrative division into provinces. The Western (formerly Barotse) Province is dominated by the Lozi, who live chiefly on the floodplain of the Zambezi River. They have an unusually mixed economy, based on garden culture, cattle ownership, fishing, and hunting. They also have a strong tradition of government and law and a distinct aristocracy.



General ethnic composition of Zambia.

The North-Western Province, adjoining the Angolan and Zaire borders, is occupied by tribes descended from the great Luba-Lunda Kingdom of Zaire. These include the southern Lunda and the Luvale, Chokwe, Luchazi, Mbunda, Ndembu, and Kaonde. The area is thinly populated except along the Zambezi, and the economy is based on the cultivation of cassava and millet and on hunting.

The Ila-Tonga group and the Bemba

The Southern Province contains the Ila-Tonga group of about 12 tribes, speaking closely related dialects. The third most numerous group in the country, it was probably among the earliest established. The Ila-Tonga have no chiefs. They are traditionally cattle owning but also cultivate grain crops.

The Northern Province is dominated by the Bemba, who trace their origins to the Luba-Lunda Kingdom and have a strongly centralized chieftainship, led by a paramount chief. Bemba is the lingua franca of the Copperbelt, and Bemba language and culture have spread throughout the province, as well as into nearby areas of Zaire. The Northern Province is generally poor in soil, and there is no tradition of cattle owning. Agriculture is of the *chitemene* system (*i.e.,* clearing land for temporary cultivation by cutting and burning vegetation), which is thought to enhance fertility; the usual crop is millet. The different tribes dwelling in the northeastern area of the Northern Province are, with perhaps the exception of the Senga, for the most part connected with the peoples of Tanzania and Malaŵi.

The Eastern Province is inhabited by four tribes, of which three—the Nsenga, Chewa, and Kunda—originated in Zaire. These three were conquered by the fourth, the warlike Ngoni, who are related to the cattle-owning Zulus of South Africa. Many Ngoni customs have, however, disappeared, and the Ngoni language has been almost entirely replaced by Nyanja, a tongue of neighbouring Malaŵi.

The ethnic boundary between the Ila-Tonga and the Lala-Lamba groups runs approximately through the Central Province, with the Lenje-Soli peoples occupying a buffer area between the two. The Lenje are related to the Ila-Tonga and the Soli to the Lala-Lamba, who, in turn, are connected with the Kaonde of the North-Western Province.

The Copperbelt (formerly Western) Province is the location of the mining industry of the Copperbelt and its surrounding districts. There the population, both densely concentrated and diverse, is composed primarily of Africans from all parts of Zambia, with about a tenth of the total from neighbouring countries. This pattern is repeated among the populations living along the railway that stretches from the Copperbelt to Livingstone. Zambian policy nevertheless discourages the employment of alien Africans and restricts their entry.

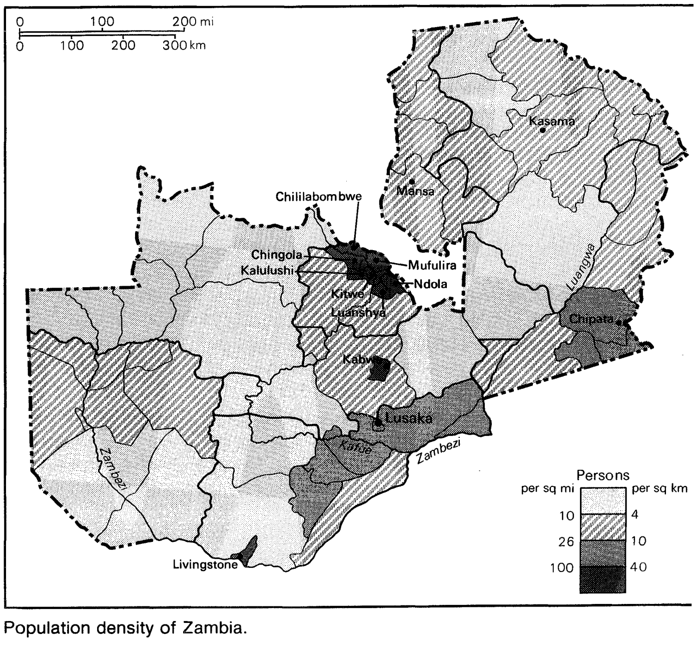
The decline in the populatior

Most of the white population lives in Kitwe, Ndola, and Lusaka or other towns of the railway belt. The European population is multinational in origin but includes notable South African and British elements. Since independence was gained in 1964, restrictions on permanent residence by aliens and the introduction of a contract system of employment for new residents have engendered instability among the white population. The government's policy of Zambianization, aided by the rapid development of education and training, has brought about a gradual decline in the number of whites. Nearly all whites are nominally Christian, with Jews probably the next largest group.

There are several thousand Indians, nearly all of whom are Gujarātī speakers from western India. About two-thirds are Hindu and the rest Muslim. Most of them arrived in Zambia between 1945 and 1954, after which Indian immigration was severely restricted. Most Indians live in Lusaka, Ndola, Livingstone, Kabwe, or the town and district of Chipata, and the majority are shop owners or employees.

There are also a few thousand persons of mixed race, mostly European-African, who are chiefly settled in Lusaka, Ndola, and Chipata.

In religion, the majority of the African population is animist. About a quarter of the remainder are nominally Christian; of these, more than half are Catholic, and the remainder divided among other denominations, which include Jehovah's Witnesses and African separatist churches, and nativistic movements.



Population density of Zambia.

THE ECONOMY

Resources. Zambia has been one of the few African countries that, since independence, has had sufficient income to finance most of its economic and social development. As the fourth largest copper-producing country in the world, Zambia's copper output is exceeded only by that of the United States, the Soviet Union, and Chile. Most economic growth takes place in the Copperbelt or along the railway to the south, despite government efforts to divert development resources to the countryside.

he
sources
' the
opperbelt

The Copperbelt, an area about 70 miles long by 30 miles wide, flanks the border of the Zaire Pedicle and virtually adjoins the industrialized mining area of Zaire's Shaba (formerly Katanga) Province, which belongs to the same geological field. There are 10 producing mines—Luanshya, Mufulira, Chibuluma, Chambishi, Rokana (near Kitwe), Nchanga (near Chingola), Bwana Mkubwa, Konkola, Lufubu, and Baluba—with ore reserves of over 882,000,000 tons, which constitute about one-eighth of the world's known and exploitable copper reserves.

Expansion plans for the Copperbelt area include development of the Baluba ore body and expansion of several other mines. Full production began in 1970 at Kalengwa, a small, high-grade copper-ore deposit about 200 miles west of the Copperbelt; and the old workings at Kansanshi, 100 miles northwest of Chingola, resumed production in 1973. About 100 miles north of Kalengwa, at Lumwana, large tonnages of low-grade copper mineralization are being evaluated. Mkushi Mines Limited is redeveloping the copper deposit at Mkushi, which lies southeast of the Copperbelt.

The Broken Hill mine at Kabwe produces zinc and lead. Coal was first produced in 1966 from deposits in the Zambezi Valley. Extensive iron-ore deposits west of Lusaka and another ore body on the Zaire border near Chililabombwe may provide the basis for an iron and steel industry.

Limestone, underlying large areas in the Lusaka and Copperbelt districts, is quarried for stone, lime, and cement; amethyst is produced from mines near the Zambezi Valley; and emeralds have been produced from a small deposit near Luanshya.

Power comes from the hydroelectric stations on the Kariba Dam, at Victoria Falls, and at the Kafue River project. The Copperbelt mines account for 70 percent of consumption.

Agriculture, forestry, and fishing. While mining and quarrying account for more than 90 percent of the value of domestic exports, and about 20 percent of gross domestic product, its contribution to paid employment is only about 15 percent. Agriculture provides the livelihood of about 60 percent of the population, with most of the production being absorbed by domestic consumption; exports of tobacco, peanuts (groundnuts), and corn (maize) account for less than 2 percent of export earnings. About half the total output is produced by the subsistence sector and half by commercial farmers, mostly European. The decline of commercial farming, which produces about three-quarters of agricultural exports, has caused concern. The difficulty of transforming subsistence agriculture into commercial farming is another major problem. The staple food crops grown by villagers are millet, maize, and sorghum, together with cassava. Sorghum and millet may be grown on relatively poor soils and under fairly low rainfall. Maize matures relatively quickly and can be eaten green in the so-called hunger months (approximately January and February). The cultivation of cassava continues to spread, despite its poor nutritional value. Secondary food crops include sweet potato, taro, yams, peanuts, peas, beans, pumpkins, sugarcane, bananas, rice, and small quantities of other common fruits and vegetables.

ımmer-
al
rming

Four statutory boards are concerned with the marketing of tobacco, maize, peanuts, cotton, cattle, and milk. Maize production has fluctuated, and the government's aims are to achieve self-sufficiency, to establish a reserve, and thereafter to reduce costs and stimulate exports. Tobacco, mostly Virginia flue-cured, is an important export crop, but production has declined. Although there are training schemes for African tobacco farmers, the continued emigration of white growers, the competition of livestock farming, and an apparent shift to maize production have hindered the government in its efforts to promote an increased tobacco output. It is, nevertheless, hoped to raise Virginia production by means of a price support policy.

Commercial herds of beef and dairy cattle have declined with the departure of white farmers, but the state has invested in ranching, and African owners are encouraged to rear and sell cattle through grazier (rancher) schemes. Zambia is self-sufficient in poultry and eggs but not in beef or dairy products.

About half of the peanut (groundnut) crop, most of which comes from the Eastern Province, is exported for confectionery manufacture. Large amounts of peanuts and peanut oil are imported to meet domestic oil demand.

Improved pest control has resulted in an expansion of cotton growing. Zambia's first textile mill was opened at Kafue in 1968. Sugarcane is grown under irrigation near Mazabuka, but efforts to attain self-sufficiency have met difficulty in keeping pace with the growing demand for sugar.

Timber
resources

About 26,000 square miles of Zambia is reserved as forest estate, and products include sawlogs, poles, fuel, and charcoal wood. The principal timber resources are the vast forests of Rhodesian teak in the Western Province, which have been exploited since 1912 and which produce railway sleepers (ties), timber, and unfinished parquet. The government also has established vast plantations of exotic trees; about one-quarter of the acreage has been planted with tropical pines and the remainder with hardwoods, mainly eucalyptus. Much of the production of exotic trees is used by the mining industry, and the most extensive plantations are consequently located in the Copperbelt Province.

The major fisheries are in Lakes Mweru, Bangweulu, Tanganyika, and Kariba, in the Lukanga and Mweru swamps, and in the Kafue River. The largest contributor is Lake Bangweulu, followed by Lake Tanganyika and Lake Mweru. Production from Lake Kariba has declined—a phenomenon that is being investigated by the Central Fisheries Research Institute.

Administration of the economy. In 1968, in the Mulungushi Declaration, the government of Zambia indicated its intention of fostering a mixed economy in which both public and private enterprise would operate and government intervention would occur where private initiative was absent or inadequate or where developments were not in conformity with public policy—for example, in the Africanization of personnel, in price restraint, and in disengaging economically from Rhodesia and South Africa. To this end, the government acquired equity participation—usually of 51 percent or more—in a number of foreign-owned firms, most of which were engaged in wholesale and retail trade or in transport. These acquisitions were followed in 1969 by a proclamation that all rights of ownership or partial ownership of minerals should revert to the state. Subsequently the two copper-mining companies—the Anglo American Corporation and Roan Selection Trust groups—transferred 51 percent of their shares in Zambian mining enterprises to the state under a compensation agreement.

All the government's equity participation is acquired and managed through state-owned companies. These are the Zambia Industrial and Mining Corporation Ltd. (Zimco) and its two wholly owned subsidiaries—Indeco Ltd., which administers the government's interests in industrial and commercial activities, and Mindeco Ltd., which is the holding company for Zambia's equity participation in mining ventures. The mining interests of the Anglo American Corporation group are consolidated in Nchanga Consolidated Copper Mines Ltd. and those of the Roan Selection Trust group in Roan Consolidated Mines Ltd.

Industrial
development
projects

Indeco Ltd. has also been the vehicle for accelerated industrial development since 1965. By 1970, completed projects included a nitrogenous fertilizer factory, a textile mill, a copper-fabricating plant, the organization of hessian and grain-bag production, an explosives factory, the Tanzania–Zambia oil products pipeline, a vehicle-tire plant and two luxury hotels—all of which include the participation of technical partners.

Transportation. Before Rhodesia's Unilateral Declaration of Independence (UDI) in November 1965, most of Zambia's imports and exports were moved on the three-foot six-inch gauge single-line railway system. The line was constructed along a watershed route, entering the country through Livingstone and reaching Ndola in 1909. Southward, the railway connects with the Zimbabwean, Mozambique, and South African railways. Northwest of Ndola, it enters Zaire to connect with the Benguela railway system, which reaches the sea at the Angolan port of Lobito.

After UDI, however, in accordance with the sanctions policy of the British government and the United Nations and in an effort to reduce its dependence on a single exit route, Zambia took measures to develop alternative routes to the sea. Over half of Zambia's exports and imports are now moved westward by the Benguela railway system or eastward along the Great North Road to Dar es Salaam in Tanzania.

Copper-belt–Dar es Salaam railway

The leaders of both Zambia and Tanzania long favoured the construction of a rail link between the Copperbelt and the port of Dar es Salaam. Following failure to obtain Western support for the project, an agreement was signed in Peking in 1970 under which the People's Republic of China loaned Zambia and Tanzania $400,000,000 including labour and equipment to cover the costs of a 1,060-mile rail link with Dar es Salaam.

Since independence in 1964, efforts have been made to improve the national road system. Internal roads have also been improved; official policy is to bituminize all roads from provincial centres to Lusaka as finance becomes available. Most roads are of semipermanent construction—usually gravel or unsurfaced.

An eight-inch petroleum-products pipeline from Dar es Salaam to Ndola was completed in 1968.

Despite the existence of several major rivers, waterways are of little economic importance. Few tributaries have a perennial flow, and there are numerous natural obstacles in the Kafue, Zambezi, and Luangwa rivers. The three lakes in the north of the country are used for some local transport, and Mpulungu, a small port on Lake Tanganyika, which connects with the East African Railway system, handles a small quantity of goods.

Zambia Airways

Zambia Airways Corporation was established in 1967. Internal services connect provincial centres with the capital, and there are landing strips for light aircraft at most administrative posts and at some mission stations. There is an international airport at Lusaka, airports at Ndola and Livingston, and landing grounds at all the Copperbelt towns.

ADMINISTRATIVE AND SOCIAL CONDITIONS

Government. In August 1973 Zambia's second constitution since independence came into effect. In accordance with the dissolution of all opposition political parties in 1972, it laid the foundations for a one-party state, the government structure paralleling that of the United National Independence Party (UNIP).

The president is the head of state and commander in chief of the armed forces. He is elected by universal adult suffrage to a five-year term of office. The president is empowered to appoint the prime minister, the chief justice and members of the high court, and the secretary general of the UNIP. In the case of the president's absence, his duties are assumed by the secretary general of the party. The president also appoints his cabinet from elected members of the National Assembly. The cabinet is subordinate to the UNIP Central Committee; most of the committee's 24 members are elected in separate elections every five years.

The legislature, called the National Assembly, includes 125 elected members and up to 10 members appointed by the president. Assemblymen are elected by universal adult suffrage from three candidates in each constituency who have been nominated by an electoral college of local party chiefs and approved by the UNIP Central Committee. The 27-member House of Chiefs may consider bills but may not block their passage.

Central government is represented throughout Zambia by the provincial government system, according to which the president appoints a resident Cabinet minister to each of eight provinces. (Lusaka is excluded). Each minister is the president's direct representative and is responsible for the coordination of policy and for liaison with local political parties. Provincial administration is carried out by Central Committee members who each have a senior civil servant as permanent secretary.

The nine provinces are divided into 53 districts, each of which has a district governor responsible to the provincial Cabinet minister; the district governor is particularly concerned with political and economic developments. His civil-service counterpart is the district secretary.

Local government is controlled by the Minister of Provincial and Local Government and Culture. Lusaka, Kitwe, and Ndola have city councils, and there are five municipal councils and 24 township councils. All of these bodies have elected majorities, although the minister may appoint up to three additional councillors to each council.

There are also 34 rural councils with a majority of elected members and up to three members (mainly chiefs and government officials in the district) nominated by the minister. Finally, there are eight mine township management boards that advise mine managements on the needs of residents in the mine areas. They have very limited powers and their revenues and services are provided by the mining companies. Government policy is ultimately to combine these townships into the adjoining local government areas. Local government in the urban areas is wealthy and comparatively powerful, but not in the rural areas, where sources of revenue are slender. Most important public services in the rural areas are provided by various ministries of the central government, under the coordination at district level of district governors and other officials.

Justice. The court system consists of the Supreme Court, the High Court, subordinate magistrate courts, and local courts. The law administered by all except the local courts being based on English common law, decisions of the higher British courts are of persuasive value; a few statutes of the United Kingdom Parliament that were declared by ordinance (decree) to apply to Zambia are in force so far as circumstances permit. Most of the laws on the statute book, however, have been locally enacted by ordinance or, since independence, by Zambian acts.

The Supreme Court consists of the chief justice, and four other justices; it is the court of last resort. The High Court, presided over by the chief justice, has 12 puisne judges and is basically an appellate court. There are four classes of magistrates' court, with progressive degrees of criminal and civil jurisdiction. Local courts consist of a president sitting alone or with other members, all appointed by the Judicial Service Commission. Jurisdiction is conferred by the minister of justice and may encompass any written law, but punishment powers are limited. Local courts also deal with civil cases of a customary nature. Customary law is followed when it is not repugnant to justice or equity and when it is not incompatible with other legislation.

The independence of the judiciary is maintained under the constitution. The chief justice is appointed by the president, and the judges are appointed by the president on the advice of the Judicial Service Commission.

Education. Since independence, Zambia claims to have maintained the highest rate of educational expansion in Africa. The country is now beginning to attain its objective of a seven-year primary-education course for all children. All districts have secondary schools. Enrollments for adult-education classes have increased.

Universit of Zambi

The University of Zambia was opened in 1966 in Lusaka. The first students received their degrees in 1969. There are four-year courses in humanities, social sciences, natural sciences, education, law, social work, business and public administration, and agricultural sciences. There is a school of medicine with a seven-year course and a five-year engineering course.

Technical training is being encouraged to meet the demand for skilled workers. The Commission for Technical Education and Vocational Training is supervising the expansion of institutions to accommodate more trainees and to provide a wider choice of courses. Teacher training has also been much expanded, but large numbers of white teachers are still being recruited.

laria, harziasis, d other pical eases

Health and welfare. Malnutrition, caused by poverty, lack of dietary knowledge, and overcrowding, is widespread in Zambia. The most prevalent tropical diseases are malaria, bilharziasis (schistosomiasis), and other parasitic infections, such as hookworm, and leprosy. With the development of out-patient treatment, the number of lepers is declining. Trypanosomiasis (sleeping sickness, transmitted by the tsetse fly) occurs in some sparsely populated areas, but it is more an economic than a medical threat in reducing the land available for cattle raising. Smallpox and typhoid fever have been successfully controlled through immunization programs. The largest single cause of hospital admissions and deaths is the respiratory group, followed by accidents and injuries (Zambia has one of the world's highest rates of motor accidents), and gastroenteric disorders.

The government has devoted large sums to the extension of the hospital system, and training establishments—apart from the university medical school—include a school of hygiene and nurse and medical-assistant training schools. A government-financed "flying doctor service" and a voluntary organization called "Mission Medic-Air" provide medical services to some remote rural areas and to mission hospitals. Psychiatric services are based on a central hospital at Lusaka, to which are linked small psychiatric units at other centres. There is a specialist pediatric hospital at Ndola. Generally, however, Zambia suffers from a shortage of trained medical staff.

In traditional Zambian society, welfare services are still largely part of the obligations of kinship groups. A rapidly growing urban population, in which family ties are weakened, has, however, necessitated the development of government welfare services concerned with juvenile delinquency, adoption, refugee control, and care for the aged, the indigent, and the handicapped. A contributory National Provident Fund provides retirement benefits.

A shortage of good housing is a pressing problem. Dwellings range from rural huts and urban shanties at one extreme to the large brick and tile homes of the wealthier town dwellers at the other. Zambia is, nevertheless, among the most urbanized countries south of the Sahara. The Department of Community Development is responsible for the improvement of both urban and rural housing and for self-help development projects.

CULTURAL LIFE

Traditional Zambian art consists chiefly of wood carving, pottery, basket weaving, and, in some areas, house-wall paintings. Among musical instruments, drums are the most widely used, but there are also stringed bows, flutes, horns and pipes, xylophones, bells, rattles, and the sansa, or "African piano," made of strips of steel attached to a small board at one end and vibrated by the fingers at the other.

Music, dancing, and song are used in tribal rituals and celebrations, as well as for entertainment, varying in form from tribe to tribe. In urban settings, traditional music has often been modified by the use of Western instruments, such as the guitar. The introduction of Western popular music and dance has had a strong influence in the urban areas.

The Zambia Department of Cultural Services was formed in 1966, with a mandate to coordinate the activities of cultural institutions; to arrange participation in national and international cultural festivals, conferences, and exhibitions; and to disseminate information on cultural life and activities.

The department also records and analyzes Zambian oral traditions and folklore, and the Kenneth Kaunda Foundation was established in 1967 to encourage the publication of Zambian literature, as well as the preparation of Zambian-oriented school textbooks. There is a national museum at Livingstone, a small museum on the Copperbelt, and a Commission for the Preservation of Natural and Historical Monuments and Relics.

For statistical data on the land and people of Zambia, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL. (Ri.H.)

History

The discovery in Zambia of split and crudely trimmed pebbles similar to the tools made by *Homo habilis* and found associated with his remains at the Olduvai Gorge in Tanzania lends support to the possibility that earliest man may also have roamed over Zambia between 2,000,000 and 1,000,000 years ago. Early Stone Age sites have been located in a number of places, notably in the vicinity of the Victoria Falls and the Kalambo Falls. During the Middle Stone Age there appears to have been a considerable increase in the population of Zambia and the presence of artifacts similar to those used by *Homo rhodesiensis* indicates that Broken Hill man lived in Zambia about 25,000 years ago. Evidence of the activities of the San (Bushman) hunters of the Late Stone Age is to be seen in the paintings and engravings found in caves and rock shelters such as the Chifubwa Stream cave near Solwezi and the Nsalu cave in the Serenje district, while 20 San skeletons were unearthed during the Cwisho excavations. The earliest Iron Age people entered Zambia from the north about 2,000 years ago, bringing with them an economy based upon agriculture and the rearing of domestic animals. These invaders either married the earlier hunter inhabitants of Zambia or drove them into the less suitable areas of the country. Another group of farmers, quite distinct from the first Iron Age men, inhabited the high plateau country of the southern region between the 8th and 12th centuries; while about AD 800, traders from the east brought beads and cloth to the Kariba Valley and traded them for ivory.

The ancestors of the modern Tonga tribe reached Zambia early in the 2nd millennium AD, but the other modern peoples of Zambia only reached the country from the Congo and Angola in the 17th and 18th centuries. In 1798 a Portuguese trading mission from Tete reached the capital of Chief Kazembe near Lake Mweru, and then in 1835 the Ngoni, a Bantu people in flight from Zululand, crossed the Zambezi in a northeasterly direction. One section of this tribe finally settled on the Lake Nyasa–Luangwa watershed near the future site of Fort Jameson (Chipata). In the west, the Kololo (Makololo), a Sotho people, under their chief Sebituane crossed the Upper Zambezi and made themselves masters of Barotseland.

European exploration

David Livingstone also reached the Upper Zambezi in 1851 and encountered the Victoria Falls in 1855. He subsequently explored the whole Zambezi Basin and the plateau to the south of Lake Tanganyika, dying at Chitambo's village near Lake Bangweulu on May 1, 1873. During the same period Arab slave traders from Kilwa began to penetrate into Zambia in the region of Lake Nyasa and with the support of some of the tribes from east of the lake continued to terrorize the region until very close to the end of the century.

THE BRITISH SOUTH AFRICA COMPANY

The Christian missionary François Coillard established himself in Barotseland in 1884, but the only other Europeans to visit the country were a handful of hunters and prospectors until the emissaries of Cecil Rhodes arrived in Barotseland in 1890 to make a treaty with the paramount chief, Lewanika. The latter had sought Queen Victoria's protection in 1887, and, as the charter of the British South Africa Company included, though vaguely, responsibility for the lands north as well as south of the Zambezi, it was with the company that treaties were concluded by most of the chiefs in Zambia during the 1890s. The company administered the country until it became a protectorate in 1924. Only the warlike Bemba refused to negotiate, and it took several years to drive the Arabs out of the Bemba country and to pacify the Bemba. By orders in council of 1899 and 1900 the western and eastern halves of the region were administered by the company as separate protectorates called Northwestern and Northeastern Rhodesia respectively. In 1911 they were amalgamated as Northern Rhodesia, and Livingstone, near the Victoria Falls, became the first capital. Meanwhile, missionaries, miners, settlers, and traders had begun to move in, and by 1911 there were about 1,500 Europeans in the country.

The lead–zinc–vanadium mine at Broken Hill (now Kabwe) had been discovered in 1902, and copper was found at Bwana Mkubwa soon after the railway from Bulawayo (in Southern Rhodesia) reached the border of the Belgian Congo in 1909. During World War I Northern Rhodesian troops fought in the long campaign against German colonial forces, and many thousands of porters were recruited to keep them supplied.

By 1924, when the development of the Copperbelt was about to begin, there were 4,000 Europeans in the country. Under its agreement with the crown the British South Africa Company was able to retain its mineral rights, and between 1924 and 1960 it reaped a rich reward for its early and completely unprofitable endeavours. During this period, entirely as a result of its output of copper, Northern Rhodesia became a relatively progressive and prosperous country. In 1935 the capital was moved from Livingstone to Lusaka. By 1952 the annual revenue of the country had reached Z£25,000,000 and its European population (living mostly in the Copperbelt) was 43,000.

Political development had followed the pattern usual in British African dependencies with European settlers. By exerting continuous pressure over the years the Europeans had achieved considerable power in the central government, but the Africans were barely represented and did not yet have the vote. After 1930, under the system of indirect rule, Africans had been given increasing powers in local government. However, though territorial self-government was the aim, Africans were not yet thought ready to play a responsible part in national affairs.

FEDERATION

In 1953 the Federation of Rhodesia and Nyasaland was established. This move was welcomed by the European settlers in Northern Rhodesia, who had long advocated closer union with Southern Rhodesia; but it was generally opposed by Africans, who feared domination by the Europeans in Southern Rhodesia.

Constitutional progress in Northern Rhodesia continued, and gradually more power was conceded to the Africans. The nationalist movement was divided between the United National Independence Party (UNIP) and the African National Congress (ANC), and during the 1950s there was a good deal of friction between the parties. By 1962 the Africans had an elected majority in the Legislative Council. Various constitutional devices were tried in order to protect the position of the European minority, but the Africans continued to insist on the principle of "one man, one vote." The federation was dissolved on December 31, 1963.

INDEPENDENCE

In January 1964 full internal self-government was granted. UNIP, led by Kenneth Kaunda, was returned to power with a large majority; and in October 1964 Northern Rhodesia became the independent Republic of Zambia within the Commonwealth of Nations, with Kaunda as president.

In January 1965 proposals for a transitional development plan were announced, emphasizing education, defense, and agriculture. In November 1965 the Ian Smith government in Rhodesia (as Southern Rhodesia was renamed) illegally declared Rhodesia independent, and sanctions were in consequence imposed on that country by Britain. Zambia was placed in a very difficult position, since all of its communications were through Rhodesia and most of its consumer goods were supplied from there. In the following months Britain, the United States, and other friendly countries gave considerable economic aid to Zambia, including an airlift of essential oil supplies. Active steps were also taken to begin the reorientation of Zambia's communications northward to the coasts of East and West Africa. Meanwhile, Zambia had to continue to buy essential consumer goods from Rhodesia in spite of sanctions.

Zambia led the rising demands made on Britain by African countries throughout 1966 to take more effective steps, including force if necessary, to end the Rhodesian rebellion. In December the UN Security Council adopted a resolution proposed by Britain to impose mandatory sanctions on Rhodesia. Diplomatic and trade relations were not reopened until Rhodesia gained independence as Zimbabwe in 1980.

Interparty violence preceded and followed the general elections of December 1968 in which Kaunda and his party were returned to power. He won popular support in June 1969 for his proposal to amend entrenched constitutional clauses on a two-thirds majority vote and announced far-reaching political and economic measures in August. These were, perhaps, the most significant for he proposed that the state should take over all mineral rights, grant to existing companies a 25-year exploitation lease while inviting them to sell 51 percent of their shares to the state, and offer similar terms to other companies in the future. Pending a new constitution Kaunda appointed himself secretary-general of an interim executive committee and assumed emergency powers. (K.Br./K.In.)

Independent Zambia

When, in 1964, Zambia achieved its independence, it was, despite the Copperbelt, a poverty-stricken and backward country with severe class, regional, ethnic, and rural–urban divisions. During the period of the transference of power, Lozi separatism was a serious problem, and in 1964 open warfare broke out between the millenarian Lumpa (Lenshina) Church and the state.

It was not until 1964 that the British South Africa Company ceded its concession rights to copper royalties, which had, over the years, gone to enrich the company and the British treasury. The result was that very little capital had been made available for investment in the increasingly impoverished rural areas or for welfare and educational services. Despite attempts, since independence, at reform, the countryside continues to be drained of manpower as thousands of hopeful young people make their way to the towns. In the towns, however, neither housing nor welfare is adequate, and unemployment grows. Fluctuations in the world price of copper, the oil crisis, food shortages, and the war that ravaged southern Africa in the 1970s greatly aggravated Zambia's weakness. In 1972 Zambia became a one-party state under the UNIP, and in 1973 a new constitution was introduced that bolstered the power of the party. A huge para-statal corporation, the party's response to the need for industrial diversification, appeared by 1980 to have simply increased the possibilities for inefficiency and corruption. The popularity of the President declined, and dissidents were suppressed with an increasingly heavy hand. Kaunda's government sought the advice of the International Monetary Fund in the 1980s to salvage its shattered economy.

For later developments in the history of Zambia, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL. (Sh.M./Ed.)

ZIMBABWE

Zimbabwe is a republic in southern Africa. It achieved majority rule and internationally recognized independence in April 1980.

Zimbabwe shares a 125-mile (200-kilometre) border on the south with the republic of South Africa, and is bounded on the southwest and west by Botswana, on the north by Zambia, and on the northeast and east by Mozambique. Its total area is 150,873 square miles (390,759 square kilometres). The capital of the nation is Harare (formerly called Salisbury).

Physical and human geography

THE LAND

Relief. Zimbabwe lies almost entirely over 1,000 feet (300 metres) above sea level. Its principal physical feature is the broad ridge running 400 miles from southwest to northeast across the whole country, from Plumtree through Gweru (formerly Gwelo) and Marondera (formerly Marandellas) to Inyanga. About 50 miles wide, this ridge ranges in altitude from 4,000 to 5,000 feet, until it eventually rises to 8,503 feet (2,592 metres) at Mt. Inyangani, the highest point in Zimbabwe, in the eastern highlands. This ridge is known as the Highveld and comprises about 25 percent of the country's total area of 150,873 square miles. On each side of this central spine, sloping down northward to the Zambezi River and southward to the Limpopo River, lies the wider plateau of the Middle Veld, which, at an altitude between 3,000 and 4,000 feet, makes up about 40 percent of the area of Zimbabwe. Beyond this again, and mostly in the south, where the Sabi, Lundi, and Nuanetsi rivers drain from the plateau into the Limpopo, lies the Lowveld, which comprises about 23 percent of the total area. The lowest point in Zimbabwe lies at an altitude of 660 feet near Dumela, where the Limpopo flows down toward Mozambique. There are no parts of Zimbabwe that can properly be called desert, although a sector northwest of Plumtree and a lengthy belt across the Lowveld in the south are severely arid.

eology

A characteristic of the landscape is its Precambrian rock, which is between 570,000,000 and 4,600,000,000 years old. The most ancient part of this rock formation, known as the Basement complex, covers the greater part of the country. About four-fifths of the Basement complex consists of granite; the Matopo Hills south of the city of Bulawayo are formed of a hard outcrop of granite and gneiss. These outcrops, known as balancing rocks, have been severely weathered by wind and water, leaving some blocks precariously balanced upon others. Elsewhere are found innumerable rounded hillocks known as kopjes and composed of ball granite. Belts of schist in the Basement complex contain the veins and lodes of most of the country's gold, silver, and other minerals.

The Great Dyke, which is up to eight miles wide and about 320 miles long, is another notable feature. The Alkali Ring complexes are igneous intrusions of volcanoes; they occur in the Sabi Valley and near Beitbridge. The Karroo System—a thick layer of sedimentary rocks consisting of shale, sandstone, and grit—covers the Zambezi Valley and the valleys of its tributaries from Hwange (formerly Wankie) southward to Bulawayo and spreads across parts of the southern Lowveld from Tuli, near the southern border, to the Sabi River.

Drainage and soils. Major faulting from southwest to northeast formed the middle Zambezi trough, which is now partially flooded by Lake Kariba. Other faulting affected the depressions of the Sabi and Limpopo rivers. As a result of subsidiary rifting a few sizable rivers drain north and south from the Plumtree–Inyanga watershed.

ɔw
rtility of
ils

The light, sandy soils developed on granite rocks are highly weathered and leached, even in the areas of lower rainfall, and do not easily retain water. Since the bulk of the rain occurs in heavy showers during a few months of the year, problems of drainage and of retaining nutrient reserves also occur. The meagre mineral reserves in the soils imply an inherently low fertility; under cultivation, productivity drops rapidly. The difficulty of cultivating these lighter soils is greatest in the black farming areas, where population pressure no longer allows land to be temporarily abandoned after cultivation; black farmers, because of a lack of capital, are also less able than white farmers to maintain the mineral fertility with manure and chemical fertilizers.

Climate. Zimbabwe lies north of the Tropic of Capricorn but enjoys subtropical conditions because of its altitude. Toward the end of the hot, dry months, which last from August to October, monsoon winds that have crossed the Indian Ocean and Mozambique cause rainfall when they meet the rampart formed by the eastern highlands. The eastern districts consequently receive the heaviest rainfall and have a more prolonged rainy season (lasting from October into April) than the rest of Zimbabwe. The altitude of the broad plateau of western Zimbabwe helps to guarantee fine weather for most of the country during the cool, dry winter months of May to August. June is generally the coolest month and October the warmest; temperature variations correspond closely to altitude. Inyanga, at about 5,500 feet in the eastern highlands, varies in temperature from a mean of 52° F (11° C) in July to one of 65° F (18° C) in October. Harare, at about 4,800 feet, has temperatures varying from 57° F (14° C) to 70° F (21° C), and Bulawayo, at 4,400 feet, has temperatures varying from 57° F (14° C) to 70° F (21° C). On a 20-year average, Harare and Bulawayo have had a year-round daily mean of eight hours of sunshine, and this average does not drop below six hours during the rainy season. (For rainfall patterns, see below *Settlement patterns.*)

Savanna
country

Plant and animal life. Zimbabwe is predominantly savanna (tropical grassland) country, with a generous tree growth encouraged by the wet summers. The only true forests, however, are the evergreen forests of the eastern border and the savanna woodland, which includes teak, northwest of Bulawayo. Various species of *Brachystegia* (a hardwood tree up to 90 feet high with pale reddish-brown wood) are dominant in the Middle Veld and Highveld. Other common varieties include the mohobohobo (a medium-sized tree with large spadelike leaves) and the thorn tree. In the valleys of the Zambezi and Limpopo rivers the mopani, which resembles the mohobohobo, is common, together with baobab and the knobby thorn tree. Australasian eucalyptus trees have been widely introduced, predominantly on white-owned farms, where they are used as windbreaks and for fuel; Australian wattle has been planted in the eastern districts as a source of tannin. Pure grassland is uncommon but occurs particularly along the eastern border around Mandidzudzure (formerly Melsetter). Swamps are widespread on the Botswana border.

Hwange
National
Park

Cultivation of the land has resulted in the disappearance of many forms of animal life from large areas. Hwange (formerly Wankie) National Park has an area of more than 5,000 square miles and stretches from the Bulawayo–Victoria Falls railway line westward to the Botswana border. Among the flesh-eating animals found there, and occasionally elsewhere, are the lion, leopard, cheetah, serval, civet, aardvark, spotted and brown hyena, black-backed and side-striped jackal, zorilla, ratel, bat-eared fox, ant bear, and scaly anteater. Elephants are found in the northern region and giraffes in the western bushland; hippopotamuses and crocodiles live in the larger rivers. Among a great variety of hoofed and horned ruminant animals are the eland (which is immune to the deadly tsetse fly), greater kudu, blue duiker, impala, klipspringer, steenbok and grysbok, and sable and roan antelope. Snakes include mambas, boomslangs, and the black-necked cobra. Baboons, which are the bane of farmers whose crops they damage, include the Rhodesian and yellow species, as well as the chacma, the largest known baboon species. Notable among the birdlife are the martial eagle, the bateleur eagle, and the little hammerhead, which builds enormous nests and is revered as a bird of omen.

Settlement patterns. Zimbabwe may be divided into six different regions, with the amount of rainfall constituting the determining factor in land use. Of the nation's 96,500,000 acres, (39,000,000 hectares), some 1,500,000 acres in the eastern highlands, with more than 25 inches of rainfall annually, are suitable for diversified farming with cattle and plantation and orchard crops. A further 18,000,000 acres sweeping west along the central spine past Harare and to the midlands receive 20 to 25 inches of rain and are used for intensive farming of corn (maize) and tobacco and the raising of livestock. An almost equal area to the southwest, enclosing Bulawayo, receives 16 to 20 inches of rain a year; it is suitable for mixed farming and for raising livestock on a semi-intensive scale. One-third of the country, lying farther outward from the spine of Zimbabwe, mostly to the south, and receiving 14 to 18 inches of rain a year, is used for semi-extensive farming, while 25,000,000 acres in the Lowveld toward the Limpopo and Zambezi rivers, receiving less than 16 inches a year, are fit only for ranching. Finally, some 3,000,000 acres, mostly toward the Zambezi River, are unsuitable for either agriculture or forestry.

The Rhodesian Front came to power in 1962 with the promise to maintain land segregation, despite the evidence gathered in 1960 by a Rhodesian parliamentary committee that the black reserves could not support all the families with land rights under the Native Land Husbandry Act of 1951. The Front put aside the implementation of this act and attempted to establish racial division "for all time" with the Land Tenure Act of 1969. In consequence, the nationalist struggle focussed sharply upon the issue of land ownership, and a major concern for the Zimbabwe government after independence was to carry through land reform and launch large-scale settlement of black families on former white farms.

The Land Apportionment Act made no provision for blacks who chose an urban life, for towns were designated as white areas. As a result, though urban blacks now outnumber whites by four to one, blacks mostly live in rented homes in townships located some miles from city centres. The cities of Harare and Bulawayo therefore constitute studies in contrast, with impressive office buildings and quiet white suburbs partially ringed by crowded black townships. The Land Tenure Act was amended, while the civil war was still being fought, to allow blacks to purchase white farms and urban property, and after the end of hostilities residential segregation began to be significantly breached.

THE PEOPLE

he
ıona and
debele

The majority of the population of Zimbabwe speaks Shona; these are nearly four times the number of those who speak Ndebele as their first language. Both Shona and Ndebele are Bantu languages; from the time of their great southward migration, Bantu-speaking tribes have populated what is now Zimbabwe for more than 10 centuries. Those who speak Ndebele are concentrated in a circle radiating from Bulawayo, with Shona-speaking peoples beyond them on all sides—the Kalanga to the southwest, the Karanga to the east around Nyanda (formerly Fort Victoria), the Zezuru to the northeast, and the Rozwi and Tonga to the north. Generations of intermarriage have to a degree blurred the linguistic division between the Shona and Ndebele peoples.

Among the whites in Zimbabwe at independence were the descendants of the country's first European immigrants. Only about one-quarter of the adult white population, however, was born in Zimbabwe. Since World War II the white population has been trebled by heavy immigration, and more than two-thirds of the present white population have their origins in Europe, the great majority from Britain. The rest have come from South Africa.

There are several thousand Asians, forming a community that is predominantly concerned with trade. There are also Zimbabweans of mixed race, in Zimbabwe called Coloureds, who are mainly skilled and semiskilled workers. Of the whites living in rural areas, about one-quarter are Afrikaners. English is the language of government; teaching in schools is also conducted in English, except for the instruction of the youngest children in black schools.

Traditional religion

The great majority of the black population adheres to traditional religion based on reverence for ancestors. The Shona have preserved their ancient reputation for prophecy, divination, and rainmaking; they believe in Mwari, a supreme being. The stone ruins of Great Zimbabwe are regarded as a shrine of deep religious significance, as also are parts of the Matopo Hills. In the last 50 years mission schools have exercised much influence, and most of the members of the first Cabinet of independent Zimbabwe were graduates of these schools. The strongest Christian influence has been that of the Roman Catholic Church. The Anglican, Methodist, Presbyterian, Baptist, and Dutch Reformed churches are also represented. Because the Catholic Church supported nationalist aspirations, it held a position of influence in the post-independence period.

White migration patterns

Immigration and emigration. Migration has been the most important factor influencing the size and composition of the white population. Net migration figures have fluctuated in reaction to political events. In the years immediately preceding the breakup of the Federation of Rhodesia and Nyasaland, there was a net emigration of 13,000 whites; this was followed during the first 10 years of UDI by a net immigration of 40,000 (with 111,270 immigrants and 71,330 emigrants). As warfare spread after 1976, the pendulum swung again from a peak white population of 260,000 to fewer than 200,000 after independence. These net figures obscure, however, the gross turnover during 1965–79 of 132,560 immigrants and 133,864 emigrants. Even when allowance is made for the subsequent return of some emigrants, it is probable that at least half of the country's adult whites were newcomers after 1965.

Distribution of population. About one-fifth of the total population lives in Zimbabwe's 19 urban centres, nearly two-thirds of them in either Harare or Bulawayo. Among urban blacks, there is a disproportionately high number of males of working age, leaving an excess of older people, women, and children in rural areas. At least half of the black households are partly or wholly dependent on incomes earned in the wage economy.

THE ECONOMY

Agriculture, forestry, and fisheries. Agriculture contributed nearly one-fifth of Zimbabwe's national income until about 1973, when the war caused its contribution to decline. Even in years of drought, agriculture provided one-third of the country's total foreign exchange and about 35 percent of total employment in the wage economy.

Tobacco production

Economic sanctions over the 14 years of Ian Smith's Unilateral Declaration of Independence (UDI) had a broad effect on patterns of commercial agriculture. Tobacco, primarily the Virginia variety that is flue-cured and grown on white-owned farms, accounted for more than half of the gross value of output in 1965 but fell below 20 percent during UDI. There were 1,750 white farmers still growing tobacco at the time of independence, however, and the flue-cured production in 1979 was the highest since 1965.

Livestock—mainly beef and milk production—became more valuable than tobacco, but the cattle industry was hurt in the later stages of the war. Disease spread because of breakdown in dipping services, and the national beef breeding herd was reduced by more than 30 percent. Recovery was hampered somewhat by cattle rustling.

Soy bean and cotton production have increased rapidly, and cotton has become an important crop for smallholders in the Middle Veld.

Corn (maize) production was high enough in the mid-1970s to permit export but slumped so low in the late 1970s that the country imported maize from South Africa. Although the collapse of tribal agriculture during the war, one reason for the slump, was remedied in the early 1980s, commercial farmers found maize to be an unprofitable crop and cut their acreage. Wheat was a minor crop in 1965, but by the late 1970s the country was able to export to neighbouring territories. Sugar output in the Lowveld toward the Limpopo increased with the lifting of sanctions and the rise in world prices. Other crops that thrived during the diversification prompted by the sanctions were coffee and various vegetables.

The country remained dependent upon a small group of white farmers. During UDI, their numbers decreased by 900, and at independence only 5,400 whites were actively farming. In comparison, there were some 700,000 black farming families.

Mining. Although mining accounted for about 5 percent of the gross domestic product (GDP) and provided work for only an equally small percentage of the employed labour force in 1979, its significance in the economy was considerable as a major earner of foreign exchange. Direct mineral exports account for about one-third of total value.

It was the prospect of great mineral wealth—comparable to the gold deposits of the Witwatersrand in neighbouring South Africa—that attracted the first permanent European settlers in the 1890s. These great expectations faded for many years after the peak of gold production was reached in 1915. By the 1950s, however, production of the chrome mines along the Great Dyke was significant, as was that of asbestos and copper. During UDI, the value of mining output increased. The rise in gold prices in the 1970s revived gold as the country's leading export and led to the reopening in 1979–80 of more than 100 dormant mines. Nickel mining, which began in the late 1960s, continues; the Great Dyke may indeed contain more nickel than chrome ore. The known coalfields in Zimbabwe contain proved reserves of 500,000,000 tons of salable coal.

Industry. Manufacturing has been the fastest growing sector of the economy. From 1954 to 1963, Southern Rhodesia was able to rely on the resources and larger market of the Federation of Rhodesia and Nyasaland for a 150 percent increase in manufacturing output. Then, after UDI in 1965, hundreds of new manufacturing projects were begun in the effort to defeat economic sanctions by import substitution. By 1979 manufacturing contributed one-quarter of the gross national product.

Energy. Electricity and water production contributes only about 3 percent of the gross domestic product. Its principal users are industries, mines, and farms. Electrification of the railways was begun in 1980, and there has also been considerable electrification of low-cost housing in urban townships. Less than half the black homes in Bulawayo and Salisbury, however, had their own electricity at the time of independence.

During the 14 years of UDI, the consumption of power trebled, and the increase was covered by drawing heavily upon the Central African Power Corporation grid (capacity: 11,500,000 kilowatt-hours per year), with its twin stations on the Zimbabwean–Zambian shores of Kariba Gorge. The manufacturing, transportation, and construction industries consumed nearly 50 percent of the power distributed in the grid, and the mining industry about 20 percent.

Finance and trade. Finance and insurance services contribute about 6 percent of the gross domestic product. In the later stages of the civil war, the demand for commercial bank loans fell and, after 1974, the total assets of financial institutions began to decline. This decline reflected a fall in demand for hire-purchase and lease-hire facilities and a reluctance by the general public and the business sector to commit themselves to long-term credit. The principal cause of growth in the money supply has been government borrowing for increased expenditure.

Economic sanctions, which had been imposed by stages from 1966 to 1968 on both imports and exports, were lifted in December 1979. They had been widely breached, particularly in mineral exports and in the supply of petroleum, but they nevertheless strongly affected certain commodities, such as tobacco exports. Although the country's trade surplus was diminished in 1979 by the rise in oil prices, the value of exports still outpaced that of imports. As a landlocked country, Zimbabwe faces heavy freight and travel costs, as well as outflows on investment account and transfers such as pensions and migrants' remittances; these payments turn the trade surplus into a small deficit.

Private enterprise and socialism

Administration of the economy. *Private and public sectors.* The government of independent Zimbabwe moved cautiously to alter the pattern of management that it inherited from the white minority regime. The first budget of July 1980 was described by the finance minister as "conservative [with] a mild and pragmatic application of socialism." But the whites had passed on government machinery that included many levers of economic power. While the whites by inclination were wedded to a system of private enterprise, they had evolved a system of government intervention to support infant industries and maintain agricultural prices through marketing boards. The need to cushion the blows dealt by economic sanctions during UDI brought acceptance of the imposition of exchange and import controls.

Prime Minister Robert Mugabe was swift to use this apparatus in 1980 to guarantee farmers a pre-planting price for maize more than 40 percent higher than the price of 1979–80, while subsidizing the price to consumers of this staple food. To benefit foreign investors, foreign exchange controls were gently applied in the 1980 budget, 50 percent of after-tax profits were allowed to be remitted to non-resident shareholders, and new foreign investment was to be freely repatriated. The government machinery by which the Smith regime controlled the economic affairs of rural blacks was altered after independence by the establishment of district councils that took on the major task of grass roots economic development.

Taxation. The government raises nearly half of its revenue from personal and corporate income taxes which, since 1966, have been collected on a pay-as-you-earn system. About two-fifths of government revenue comes from customs and excise duties and sales taxes, and much of the rest from government borrowing and, since independence, international aid.

The independent Zimbabwe government removed sales taxes on the staple items of food and fuel for the poorest people and extended sales taxes to travel, hotel accommodations, taxis, telecommunications, and other services. It continued the former rates of personal income tax.

Consolidation of trade unions

Trade unions and employers' associations. The evolution of the trade-union movement was some two years behind the pattern of political change by 1980. The Mugabe government dealt with immediate labour problems, such as strikes for a higher minimum wage, rather than institute a thorough revision of the basic Industrial Conciliation Act of 1959. The government seemed to favour the strengthening, by mergers or amalgamation, of small unions in the same industry; the strengthening of the whole movement by the formation of a single trade-union congress from the five or six existing confederations of unions; and an arm's-length relationship of government with such a congress. Despite the large number of unions in existence, the largest sections of the labour force—the agricultural workers and domestic servants—remained outside the system.

Employers' groups, such as the Associated Chambers of Commerce of Zimbabwe and the Association of Rhodesian Industries, remained influential.

Transportation. The main road system, which is excellent, generally follows the line of white settlement along the spine of the country, with two branches north to Victoria Falls and Kariba and a network fanning out from Nyanda (formerly Fort Victoria), close to the Great Zimbabwe ruins. Wartime operations brought an improvement in certain areas, including the construction of strategic roads in the eastern highlands and near the Zambian border. The roads in white farming areas and the gravel and earth roads in the Tribal Trust Lands received barely adequate maintenance, however.

Railways

The railway closely follows the main road network; its single track has a gauge of three feet six inches. Economic sanctions, followed by the closure of the Zambian border in 1973, drastically cut rail traffic and transit revenues from Zambia's copper exports. The southern routes, however, became the Smith regime's lifeline after the British

Navy imposed an oil blockade on the Mozambique port of Beira and effectively cut the Beira–Mutare (formerly Umtali) pipeline supply in 1966. Rail links with South Africa remained intact after independence and the link with Zambia Railways was reopened. Two lines connect with lines through Mozambique to give landlocked Zimbabwe access to the ports of Maputo and Beira.

Air Zimbabwe replaced Air Rhodesia, a government-backed company that had operated only within Rhodesia and to and from South Africa. The international airport at Harare has one of the longest civil runways in the world. Seven other airports—at Bulawayo, Kariba, Gweru, Masvingo, Hwange, Buffalo Range, and Victoria Falls—can accommodate medium-sized jet aircraft.

ADMINISTRATIVE AND SOCIAL CONDITIONS

he 1979 onstitu-on

The independence constitution of Zimbabwe, which was written in London during September–December 1979, secured majority rule for Zimbabweans. Under the 1979 constitution, white voters, registered on a separate roll, elect 20 of the 100 members of the National Assembly. Although these members no longer can veto constitutional amendments, a unanimous vote is required during the first 10 years to alter the Declaration of Rights, which stipulates (among other matters) that, if land is acquired for settlement schemes, there must be "prompt payment of adequate compensation . . . remittable within a reasonable time to any country outside Zimbabwe." The British insisted that there be a constitutional head of state, a president elected by the National Assembly, and an executive prime minister, and that citizenship of Zimbabwe be automatically available to anyone who was (or had the qualifications to be) a citizen of Rhodesia immediately before independence.

There is a Senate of 40 members, half of whom are either nominees of the white Assembly members or of the Council of Chiefs. The Senate has the power to delay ordinary legislation for 90 days and constitutional amendments for 180 days.

Local governments. At the time of independence, whites controlled the municipal councils, but legislation was soon introduced to amalgamate each municipal council with the council of its surrounding township and, for the first time, black mayors were elected in 1981. Local government elections in rural areas replaced the old apparatus of district commissioners with a party-based council structure.

The political process. In the elections held in February 1980 under the 1979 constitution, Ian Smith's Rhodesian Front took all 20 seats on the white voters' roll. Of the nine parties that contested the 80 common roll seats, Bishop Abel Muzorewa's United African National Council (UANC) secured only three seats; Joshua Nkomo's Zimbabwe African People's Union (ZAPU) won 20 seats, representing nearly all in Matabeleland, and Mugabe's Zimbabwe African National Union (ZANU) won 57 seats, nearly all in Mashonaland. A total of 2,649,529 valid votes were cast, and the Commonwealth Observer Group drawn from 11 nations declared their satisfaction that the elections had been "free and fair."

Justice. The Ministry of Law and Order of Smith's period was renamed the Ministry of Justice by the independent government. The government voted to extend the state of emergency, first declared at UDI, because of unsettled conditions, mainly in rural areas.

Under the constitution of 1979, a four-member Judicial Service Commission advises the president on the appointment of judges to the High Court. High Court judges may not be removed from office except for misconduct or incapacity. The first black lawyer was appointed a High Court judge in 1980. In addition to magistrates who preside over criminal and civil litigation, other courts adjudicate on matters of African law and custom.

Education. The dismantling of Rhodesia's segregated system of schooling began less than two years before independence. The minority government had concentrated upon providing compulsory (and virtually free) education to white children between the ages of five and 15, and had left the schooling of black children in the hands of missionaries. In 1950 there were only 12 government schools for blacks, compared with 2,230 mission and independent schools. The disparities continued through the 1970s. Facilities were sharply reduced after the lower primary stage, and the civil war cut opportunities for blacks even further; from 1978, at least one-quarter of all black primary schools were closed. Enrollment fell at the University of Zimbabwe, where blacks had become a majority of the student body by 1979. Priority has been given to reopening and reequipping schools and to providing new schools in the drive toward free primary education. Because of the many opportunities in higher education offered Rhodesians by Commonwealth and other countries during UDI, the leadership of Zimbabwe was particularly well-educated.

Health and welfare. Health services were biased toward curative medicine in central hospitals. Before 1980, missionaries had the major responsibility for running rural clinics and small hospitals. After independence health allocations were increased.

A severe housing shortage in the main urban centres was aggravated by the influx of rural refugees and by the trebling of the cost of building materials during UDI. The government appealed to private contractors and individual employers to aid in the development of housing for lower paid workers.

Infant mortality

As in other Third World countries, the burden of disease is heaviest on Zimbabwe's youngest children. The infant mortality rate for the black population in malarial parts of the Zambezi Valley has been as high as 300 per 1,000, and the rate is thought to lie between 120 and 220 per 1,000 for the black population as a whole. Measles and pneumonia are major causes of death; a tuberculosis control scheme of the mid-1970s was relatively effective. Improved nutrition is increasingly seen as the most important health need.

CULTURAL LIFE

The year-round temperate climate of the Highveld has combined with the natural inclinations of the white population to produce an outdoor society. Tennis—whether on farms or at urban clubs—and bowling have many more followers than any ballet group. Happily for the cause of reconciliation, the first sport heroes after independence were the members of the all-white team that was awarded the first gold medal for women's field hockey in Olympic history at Moscow in 1980. The most famous of Rhodesian-bred writers, Doris Lessing, settled in England in 1949. In some contrast, the nationalist struggle prompted a renaissance of Shona culture. A forerunner of this renaissance (and a victim of the liberation struggle) was Herbert Chitepo, both as abstract painter and epic poet. Stanlake Samkange's novels reconstruct the Shona and Ndebele world of the 1890s, while those of the much younger Charles Mungoshi explore the clash of Shona and Western cultures in both the Shona and English languages. Folk traditions have survived in dance and pottery. The revival of sculpture has drawn on tribal religion and totems to produce some remarkable works, particularly those of Takawira and the Tengenenge school of craftsmen who sculpt in hard serpentine.

Cultural renaissance

For statistical data on the land and people of Zimbabwe, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL. (C.W.S.)

History

The remains of Stone Age cultures dating back 500,000 years have been found in Zimbabwe, and it is thought that the San, who still survive mostly in the Kalahari Desert of Botswana, are the last descendants of these original inhabitants of southern and central Africa. They were driven into the desert by the Bantu-speaking tribes during the long migrations from the north in the course of which the Bantu-speaking peoples populated much of Africa from Lake Chad to Zululand. The first Bantu are thought to have reached Zimbabwe between the 5th and 10th centuries AD. The stone ruins of Zimbabwe date mainly from about the 9th century, although the most elaborate belong to a period after the 15th century and are of Bantu origin.

PORTUGUESE EXPLORATION

The Portuguese, who arrived on the east coast of Africa at the end of the 15th century, dreamed of opening up the interior and establishing an intercoastal route to connect their eastern settlements with Angola in the west. The first European to enter Zimbabwe was probably António Fernandes, who tried to cross the continent and reached the neighbourhood of Que Que (now Kwekwe). Nearly 50 years afterward the "emperor" Mwene Matapa was baptized by a Jesuit father, and in 1569 an abortive military expedition entered the interior in search of gold.

A second great movement of the Bantu peoples began in 1830, this time from the south. To escape from the power of the great Zulu chief Shaka (Chaka) three important tribes fled northward, one of them the Ndebele, who carved out a kingdom for themselves in what is now Zimbabwe. The Ndebele were warriors and pastoralists, in the Zulu tradition, and under their formidable chief Mzilikazi they mastered and dispossessed the weaker tribes, known collectively as Shona (Mashona), who were sedentary, peaceful tillers of the land. For more than half a century, until the coming of European rule, the Ndebele continued to enslave and plunder the Shona. During this period, however, British and Afrikaner hunters, traders, and prospectors had begun to move up from the south, and with them came the missionaries. Robert Moffat visited Mzilikazi in 1857, and this meeting led to the establishment in 1861 of the first mission to the Ndebele by the London Missionary Society.

THE BRITISH SOUTH AFRICA COMPANY

In South Africa, Cecil Rhodes formed the British South Africa Company, which received its charter in October 1889. Its objects were: (1) to extend the railway from Kimberley northward to the Zambezi; (2) to encourage emigration and colonization; (3) to promote trade and commerce; and (4) to secure all mineral rights, in return for guarantees of protection and security of rights to the tribal chiefs.

European settlement

In 1890 a pioneer column set out from Bechuanaland and reached the site of the future capital of Rhodesia without incident on September 12. There, the new arrivals settled and began to lay claim to prospecting rights. The Ndebele resented this European invasion, and in 1893 they took up arms, being defeated only after months of strenuous fighting. Lobengula fled, and the company assumed administrative control of Matabeleland. In 1895 many of the pioneers were persuaded to take part in the Jameson Raid into the Transvaal and were captured and sent to England for trial. In the same year the company-administered territories, which had previously been loosely known as Zambesia, were formally named Rhodesia, by proclamation. In 1896 the Ndebele rose again. Returning from London, Rhodes met with the Ndebele chiefs and persuaded them to make peace. The Shona had at first accepted the Europeans, but they too became rebellious and the whole country was not pacified until 1897.

Economic and political development. By 1892 about 1,500 settlers from the south had arrived in Rhodesia. The railway reached Bulawayo in 1896 and the Victoria Falls in 1904. By the following year there were 12,500 settlers in the country, and in 1909 gold exports were worth more than £2,500,000. Agricultural development, however, was slower, and it was not until 1907 that steps were taken to facilitate the acquisition of land. By 1911 tobacco to the annual value of nearly £35,000 was being exported and the European population had risen to 23,600.

From the earliest years the settlers had demanded representation on the Legislative Council, which in 1903 comprised seven company officials and seven elected representatives of the settlers. In 1907 the settlers were given a majority of seats. In 1914, when the 25-year term of the company's charter was due to expire, the settlers, faced with the alternative of joining the Union of South Africa, asked for the continuation of the charter pending the grant of self-government. The British government therefore extended the charter for 10 years, with the proviso that self-government could be granted earlier if the settlers showed themselves capable of administering the country unaided.

Self-government. Immediately after World War I the pressure for self-government was resumed and a royal commission was appointed to consider the future of the territory. As a result of the commission's report a referendum of the electors among the 34,000 Europeans in the country was held in 1922, on the choice between entry into the Union of South Africa as its fifth province and full internal self-government. In spite of the offer of generous terms by the Union prime minister, Gen. J.C. Smuts, a majority voted for self-government. On September 12, 1923, Southern Rhodesia was annexed to the crown and became a self-governing colony. The British government retained control of external affairs and a final veto in respect of legislation directly affecting Africans.

The interwar period was one of material progress, with the development of a reasonably prosperous economy based on copper, gold, and other minerals, corn (maize), tobacco, and cattle. By 1953 Southern Rhodesia had a European population of 157,000 and an annual revenue of more than £28,000,000.

Lord Malvern's governing principles

The policy of Sir Godfrey Huggins (later Lord Malvern), who served as prime minister of Southern Rhodesia for 20 years, was to build a society in accord with Rhodes's dictum of "equal rights for all civilized men," one in which merit and not colour should be the test of political and economic advancement. He believed that political power should not be given to the Africans until they were sufficiently experienced to know how to exercise it in cooperation with the Europeans and thus to maintain the economic development built up over the years.

A second principle in which Lord Malvern and most other Europeans in Southern Rhodesia and Northern Rhodesia (later Zambia) profoundly believed was that the two countries should be joined together, both for their mutual economic benefit and to ensure the establishment of a powerful state based on British culture and traditions. Malvern failed to secure their amalgamation, but he supported the federation of Southern Rhodesia, Northern Rhodesia, and Nyasaland (later Malaŵi) when that solution was eventually accepted by the British in 1953.

FEDERATION

In 1957 a new electoral law was passed providing for a common roll of voters with a special roll for those with lower qualifications. At the same time there was growing political consciousness among the African population, together with increasing hostility to the idea of federation. In 1960 disturbances broke out after the arrest of some African nationalist leaders belonging to the National Democratic Party (NDP). In the following year proposals for a new constitution were strongly criticized by the NDP, which considered them insufficient to meet African demands. The NDP was subsequently banned for acts of intimidation. After that, the African nationalist movement split into two rival organizations, the Zimbabwe African People's Union (ZAPU)—led by Joshua Nkomo—and the Zimbabwe African National Union (ZANU)—led initially by Ndabaningi Sithole and later by Robert Mugabe—both of which were later banned and their leaders placed under restriction. In June 1962 the UN General Assembly called for a more liberal constitution for the territory.

The election of December 1962, when the 1961 constitution came into force, was boycotted by the African nationalists. It resulted in the defeat of the ruling United Federal Party by the more conservative Rhodesian Front, and Winston Field became prime minister. At the end of 1963 the federation was dissolved, and Southern Rhodesia reverted to its former status as colony. (K.Br./K.In.)

FROM RHODESIA TO ZIMBABWE

In Southern Rhodesia majority rule was not won easily. The white response to the collapse of federation and to African independence in the north was a massive swing to the right. In 1961 the Rhodesian Front party had been formed and voted into power on a platform of immediate white independence. This Britain was unwilling to concede, and in 1965 the Rhodesian Front, under the leadership of Ian Smith, unilaterally declared Rhodesian independence.

Despite international pressure, Britain refused to use force against the illegal regime. Economic sanctions initially boosted the Rhodesian economy because of the activities of South Africa, Portugal, and the multinational oil companies. The sanctions did, however, put considerable strain on Zambia, especially after Smith closed the Zambia–Rhodesia border in 1973 and the Benguela railway in Angola was sabotaged in 1975. In an attempt to find alternatives, new roads were constructed and in 1974 the Tanzania–Zambia railway was completed.

The banning of successive nationalist organizations and the detention and exile of their leadership led to fierce criticism of Nkomo, and by 1964 the splinter group ZANU had formed from ZAPU. Internal divisions were matched by mass disillusion, as the exiled leaders continued to appeal to Britain and the United Nations while their followers attacked each other inside the country. With the Frelimo liberation of northeastern Mozambique in 1972, a new guerrilla strategy began to make headway. At the same time, Smith agreed on a settlement with the British government that required African agreement in a referendum to be held under the supervision of the British Pearce Commission. This allowed for fresh political organization, and at the end of 1971 Bishop Abel Muzorewa formed the United African National Council (UANC) to campaign against the constitutional proposals, which were overwhelmingly rejected in May 1972.

he
nternal
ttlement"

Over the next few years, as the war began to affect the Rhodesian economy, Smith came under heavy pressure from South Africa and the West to negotiate with imprisoned black leaders. They, in turn, were under pressure from their hard-pressed neighbours to come to terms. Between 1974 and 1978 several attempts at talks broke down, and in 1976 the war was resumed with vigour by a ZANU and ZAPU alliance, the Patriotic Front. The Smith regime pursued the war with increasing ferocity, recruiting large numbers of unemployed Africans to fight in the rural areas, while concentrating white troops on defending white farming and industrial areas. The havoc of an unwinnable war and fear of Communist intervention led the Western powers and South Africa to seek to get rid of minority rule in the extreme form represented by the Rhodesian Front, and in 1979 Smith agreed to an "internal settlement": multiracial elections were held and won by the UANC. The foundations of white power were unaltered by Muzorewa's victory, however, and the war escalated.

In 1979 fresh negotiations in London ultimately led to peace, and new elections were supervised by the British in 1980. A landslide victory was won by Robert Mugabe and the ZANU wing of the Patriotic Front, and Zimbabwe was declared independent. (Sh.M./Ed.)

Mugabe's new government moved deliberately to redress inequalities of race and class, redistribute land, and promote economic development, with a one-party socialist state as its long-term goal. Nkomo and ZAPU broke with Mugabe's government, chiefly over the issue of one-party rule.

Hostility to South Africa increased markedly in independent Zimbabwe, especially in response to South African attacks against alleged African National Congress operatives on the Zimbabwe border. Zimbabwe joined the Southern African Development Coordination Conference and established diplomatic ties with several nations of the West and with China and the Soviet Union.

For later developments in the history of Zimbabwe, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL. (Ed.)

BIBLIOGRAPHY

Traditional cultures. The classic reference work is I. SCHAPERA, *The Khoisan Peoples of South Africa* (1951), a review and synthesis of the literature up to 1928 with a full bibliography. J.A. ENGELBRECHT, *The Korana* (1936), is an account of a now virtually extinct Hottentot people. ELIZABETH MARSHALL THOMAS, *The Harmless People* (1959), is a popular account that conveys better than any other book in English the quality of !Kung Bushman life. A series of papers based upon sustained anthropological fieldwork among Bushmen by LORNA MARSHALL were published in various numbers of *Africa:* vol. 29, no. 4 (1959); vol. 30, no. 4 (1960); vol. 31, no. 3 (1961); and vol. 32, no. 3 (1962). Also useful are GEORGE B. SILBERBAUER, *Report to the Government of Bechuanaland on the Bushman Survey* (1965), which describes a six-year survey of the Bushmen of Botswana; RICHARD B. LEE, "What Hunters Do for a Living, or How to Make Out on Scarce Resources," in R.B. LEE and I. DEVORE (eds.), *Man the Hunter* (1968); and "!Kung Bushman Subsistence: An Input-Output Analysis," in D. DAMAS (ed.), *Contributions to Anthropology: Ecological Essays* (1969).

ARRIGHI, *The Political Economy of Rhodesia* (1967); R. PALMER, *Land and Racial Domination in Rhodesia* (1977); C. VAN ONSELEN, *Chibaro: African Mine Labour in Southern Rhodesia 1900–1933* (1976), a major pioneering study in social history; T.O. RANGER, *The African Voice in Southern Rhodesia, 1898–1930* (1970); R.I. ROTBERG, *The Rise of Nationalism in Central Africa: The Making of Malawi and Zambia, 1873–1964;* G. SHEPPERSON and T. PRICE, *Independent African: John Chilembwe and the Origins, Setting and Significance of the Nyasaland Native Rising of 1915* (1958); B. PACHAI, *Land and Politics in Malawi, c. 1875–1975* (1979); R. MACDONALD (ed.), *From Nyasaland to Malawi* (1975); E. BERGER, *Labour, Race and Colonial Rule: The Copperbelt from 1924 to Independence* (1974); C. PERRINGS, *Black Mineworkers in Central Africa* (1979); P. KEATLEY, *The Politics of Partnership* (1963); W.H. MORRIS-JONES, *From Rhodesia to Zimbabwe: Behind and Beyond Lancaster House* (1980); R.S. HALL, *The High Price of Principles: Kaunda and the White South* (1969; rev. ed., 1973); and W. TORDOFF *et al.* (eds.), *Politics in Zambia* (1974). For events of the 1970s, see the publications of the South African Institute of Race Relations, the Catholic Institute for International Relations, and C. LEGUM (ed.), *Africa Contemporary Record* (annual). (*Angola and Mozambique*): J. MARCUM, *The Angolan Revolution,* vol. 1, *The Anatomy of an Explosion (1950–1962)* (1969), and vol. 2, *Exile Politics and Guerrilla Warfare (1962–76)* (1978); and F.W. HEIMER, *Der Entkolonisierungskonflikt im Angola* (1979; Eng. trans., *The Decolonization Conflict in Angola, 1974–76: An Essay in Political Sociology,* 1979). For Mozambique, VAIL and WHITE, as cited above, replace the previous sparse literature.

General works: The Cambridge History of Africa (in progress) has long chapters on southern Africa by leading authorities and places southern Africa in the context of African history; for a more condensed attempt to do the same, see P. CURTIN, S. FEIERMAN, L. THOMPSON, and J. VANSINA, *African History* (1978). D. DENOON and B. NYEKO, *A History of Southern Africa* (1972), deals with the region as a whole; while R. PALMER and N. PARSONS (eds.), *The Roots of Rural Poverty in Central and Southern Africa* (1977), contains key essays on its political economy in the 19th and 20th centuries. For South Africa, C.W. DE KIEWIET, *A History of South Africa, Social and Economic* (1941), is still a useful, though dated, introductory essay; M. WILSON and L.M. THOMPSON (eds.), *The Oxford History of South Africa,* 2 vol. (1969–71), was the first general history of all the peoples of South Africa; E.A. WALKER, *A History of Southern Africa,* 3rd rev. ed. (1962); and T.R.H. DAVENPORT, *South Africa: A Modern History* (1977), provide basic factual material; and SHULA MARKS and ANTHONY ATMORE (eds.), *Economy and Society in Preindustrial South Africa* (1980), contains essays that challenge the existing historiography, especially for the 19th century. For Central Africa, including the Portuguese colonies, see DAVID BIRMINGHAM and PHYLLIS M. MARTIN (eds.), *History of Central Africa* (1983), containing essays by acknowledged experts and replacing most previous accounts. There is, as yet, no equivalent to A.D. ROBERTS, *A History of Zambia* (1976), for either Zimbabwe or Malaŵi. For early Zimbabwe, see D.N. BEACH, *The Shona and Zimbabwe 900–1850: An Outline History* (1980). For Malaŵi, see G.J. PIKE, *Malawi: A Political and Economic History* (1968), a somewhat inadequate introduction. For Mozambique and Angola there are similarly no satisfactory overall general accounts, but see D.L. WHEELER and R. PELISSIER, *Angola* (1971); and G.J. BENDER, *Angola under the Portuguese: The Myth and the Reality* (1978). Similarly, L. VAIL and L. WHITE, *Capitalism and Colonialism in Mozambique* (1980), covers that territory's 19th- and 20th-century history in masterly and original fashion, but there is no general introductory work. General works for the rest of the region are far less satisfactory. For Namibia and Lesotho, Botswana, and Swaziland (the former High Commission Territories): J.H. WELLINGTON, *South West Africa and Its Human Issues* (1967); and R.P. STEVENS, *Lesotho, Botswana and Swaziland: The Former High Commission Territories in Southern Africa* (1967), provide general introductory accounts, though both are dated; R. FIRST, *South West Africa* (1963); and J. HALPERN, *South Africa's Hostages: Basutoland, Bechuanaland, and Swaziland* (1965), are equally dated but were considered classics of investigative journalism in their time. Knowledge of the history of southern Africa was transformed in the 1970s, and general accounts usually did not keep pace with the explosion of research in that period. Some of the new material can be found in specialist journals such as the *Journal of African History,* the *Journal of Southern African Studies,* and *African Affairs.* There is also a growing literature available comparing different aspects of U.S. and South African history: STANLEY B. GREENBERG, *Race and State in Capitalist Development: Comparative Perspectives* (1980); GEORGE M. FREDRICKSON, *White Supremacy: A Comparative Study in American and South African History* (1981); HOWARD LAMAR and LEONARD THOMPSON (eds.), *The Frontier in History: North America and Southern Africa Compared* (1981); and JOHN W. CELL, *The Highest Stage of White Supremacy: The Origins of Segregation in South Africa and the American South* (1982).

Angola. JOHN A. MARCUM, *The Angolan Revolution,* 2 vol. (1969), a history of the Angolan liberation struggle up to 1970, sympathetic to FNLA; BASIL DAVIDSON, *In the Eye of the Storm: Angola's People* (1972), on the building of a national liberation movement by MPLA; WILLIAM MINTER, *Portuguese Africa and the West* (1972), a brief history of Western influences and actions on the liberation struggle; BASIL DAVIDSON, JOE SLOVO, and ANTHONY R. WILKINSON, *Southern Africa: The New Politics of Revolution* (1976), the struggle in the Portuguese colonies, South Africa, and Rhodesia, following the Portuguese coup of 1974; EDUARDO DE SOUSA FERREIRA, *Aspectos do Colonialismo Portugues* (1974), economic and political analysis of Portuguese colonies in Africa and of links with South Africa and Namibia; HENRIQUE GUERRA, *Angola, Estrutura Economica e Classes Sociais* (1975), an account of the colonial economic structures and class formation; CARLOS ROCHA DILOLWA, *Contribuição á Historia Economica de Angola* (1978), the colonial economic history of Angola, with many statistical tables, by an MPLA economist and planner; MPLA, *Historia de Angola* (1975), a first attempt by the liberation movement to write a history of the country, for use as a textbook in schools; JOSE REDINHA, *Distribuição Étnica de Angola* (1975), brief notes on ethnic and linguistic groups, plus map of distribution; C.R. BOXER, *Race Relations in the Portuguese Colonial Empire, 1415–1825* (1963), the reality of race relations in the colonies; GROUPE AFRIQUE CENTRALE DU CEDETIM, *Angola: La Lutte continue* (1977), account and analysis of the period from the start of the liberation struggle to February 1976, by a collective of African studies experts; ALLISON BUTLER HERRICK *et al., Area Handbook for Angola* (1967), though out of date, still useful in many respects.

Botswana. *Physical geography:* HARM J. DE BLIJ, *A Geography of Subsaharan Africa* (1964); ANTHONY SILLERY, *Africa: A Social Geography,* 2nd ed. (1972); ALAN BERTRAM MOUNTJOY and CLIFFORD EMBLETON, *Africa: A New Geographical Survey* (1967); WILLIAM A. HANCE, *The Geography of Modern Africa,* 2nd ed. (1975).

Land, vegetation, and water resources: I.B. POLE-EVANS, *Report No. 2: A Reconnaissance Trip Through the Eastern Portion of the Bechuanaland Protectorate in Search of Pasture Grasses* (1930); A.J.C. MOLYNEUX, "A Contribution to the Geology of the Bechuanaland Protectorate," *Rhodesian Scientific Association,* 6:73–86 (1906), and "Prospecting in Bechuanaland," *S. Afr. Min. Engng. J.,* 51:705–707 (1940); DARRELL RANDALL, *Factors of Economic Development in the Okavango Delta* (1957).

People, institutions, culture, and history: RICHARD P. STEVENS, *Historical Dictionary of the Republic of Botswana* (1975); JACK HALPERN, *South Africa's Hostages: Basutoland, Bechuanaland and Swaziland* (1965); VERNON G. SHEDDICK, *The Southern Sotho* (1953); C.W. DE KIEWIET, *A History of South Africa: Social and Economic* (1941); ERIC WALKER, *A History of Southern Africa,* 3rd ed. (1957); RICHARD STEVENS, *Lesotho, Botswana and Swaziland* (1967); I. SCHAPERA, *A Handbook of Tswana Law and Custom,* 2nd ed. (1955, reprinted 1970), and *The Tswana* (1953); ANTHONY SILLERY, *Sechele: The Story of an African Chief* (1954), and *Botswana: A Short Political History* (1974); CHIEF TSHEKEDI KHAMA, *Bechuanaland and South Africa* (1955), and *Political Change in African Society: A Study of the Development of Representative Government* (1956).

Administration, and social, political, and constitutional affairs: ZDENEK CERVENKA, *Republic of Botswana: A Brief Outline of Its Geographical Setting, History, Economy and Politics* (1970); COLIN LEGUM *et al.* (eds.), *Africa Contemporary Record* (annual); COLONIAL OFFICE, BECHUANALAND, *Annual Report* (HMSO, to 1966), useful official reports reviewing all aspects of policy and development; *Basutoland, the Bechuanaland Protectorate and Swaziland: History of Discussions with the Union of South Africa, 1909–1939,* Cmd. 8707 (HMSO, 1952); MARY BENSON, *Tshekedi Khama* (1960), a biography; RICHARD VENGROFF, *Botswana: Rural Development in the Shadow of Apartheid* (1977).

Economy: PENELOPE HARTLAND-THUNBERG, *Botswana: An African Growth Economy* (1978); *Basutoland, Bechuanaland Protectorate and Swaziland: Report of an Economic Survey Mission* (the Morse report) (HMSO, 1960); *National Development Plan, 1970–75: National Development Plan, 1979–85* (1980).

Lesotho. *Land and water resources:* JEFFARES and GREEN, *A Water Resources Survey of Basutoland* (1951); VERNON G. SHEDDICK, *Land Tenure in Basutoland* (HMSO 1954); G.M. STOCKLEY, *Report on the Geology of Basutoland* (1947).

Demography: R.R. KUCZYNSKI, *Colonial Population* (1937); a primary source of population information about Africa.

People, institutions, culture, and history: HUGH ASHTON, *The Basuto* (1952), the accepted standard work on the Basotho people; PETER SANDERS, *Moshoeshoe, Chief of the Sotho* (1975); D.F. ELLENBERGER (comp.), *History of the Basuto,* Eng. trans. by J.C. MACGREGOR (1912, reprinted 1969); GORDON HALIBURTON, *Historical Dictionary of Lesotho* (1977); H.V. MEYEROWITZ, *A Report on the Possibilities of the Development of Village Crafts in Basutoland* (1936); JACK HALPERN, *South Africa's Hostages: Basutoland, Bechuanaland and Swaziland* (1965); VERNON G. SHEDDICK, *The Southern Sotho* (1953); C.W. DE KIEWIET, *A History of South Africa: Social and Economic* (1941); ERIC WALKER, *A History of Southern Africa,* 3rd ed. (1957); RICHARD STEVENS, *Lesotho, Botswana and Swaziland* (1967); G.P. MURDOCK, *Africa: Its Peoples and Their Cultural History* (1959); C.G. SELIGMAN, *Races of Africa,* 4th ed. (1966).

Administration, and social, political, and constitutional affairs: LORD W.M. HAILEY, *The Republic of South Africa and the High Commission Territories* (1963), *An African Survey* (1938); COLIN LEGUM *et al.* (eds.), *Africa Contemporary Record* (annual); COLONIAL OFFICE, LESOTHO, *Annual Reports* (HMSO, to 1966), useful official reports reviewing all aspects of policy and development; *Basutoland, the Bechuanaland Protectorate and Swaziland: History of Discussions with the Union of South Africa, 1909–39,* Cmd. 8707 (HMSO 1952); BASUTOLAND CONSTITUTIONAL COMMISSION, *Report* (1963); J.E. SPENCE, *Lesotho: The Politics of Dependence* (1967).

Description: AUSTIN COATES, *Basutoland* (1966), a well-written useful introduction to the country; LESOTHO, DEPARTMENT OF INFORMATION, *Lesotho: Land of Rolling Mountains and Running Streams* (1960–70).

Economy: GABRIELE WINAI STRÖM, *Development and Dependence in Lesotho, the Enclave of South Africa* (1978), covering the period between 1960 and 1975; PERCY SELWYN, *Industries in the Southern African Periphery* (1975); G.M.E. LEISTNER, *Lesotho: Economic Structure and Growth* (1966); BASUTOLAND, *Development Plan, 1963/66* (1963); GREAT BRITAIN. HIGH COMMISSIONER FOR BASUTOLAND, THE BECHUANALAND PROTECTORATE AND SWAZILAND, *Basutoland, Bechuanaland Protectorate and Swaziland: Report of an Economic Survey Mission* (1960); INTERNATIONAL BANK FOR RECONSTRUCTION AND DEVELOPMENT, *Lesotho: A Development Challenge* (1975); LESOTHO NATIONAL DEVELOPMENT CORPORATION, *Annual Report.*

Bibliography: SHELAGH M. WILLET and DAVID P. AMBROSE, *Lesotho: A Comprehensive Bibliography* (1980), extensive, classified, and well indexed, with English-language annotations.

Malaŵi. The most extensive bibliography on Malaŵi is R. BOEDER, *Annotated Bibliography of Malawi* (1979). The following works are especially recommended: S. AGNEW and M. STUBBS, (ed.), *Malawi in Maps* (1972); EDWARD ALPERS, *Ivory and Slaves in East Central Africa: Changing Patterns of International Trade to the Later 19th Century* (1975); W.J. BARBER, *The Economy of British Central Africa* (1961); B. BINNS, *A First Checklist of the Herbaceous Flora of Malawi* (1968); E. DEAN, *The Supply Responses of African Farmers: Theory and Measurement in Malawi* (1966); H. DEQUIN, *Agricultural Development in Malawi* (1969), a study of agricultural development in Malaŵi between 1890 and 1967; F. and L.O. DOTSON, *The Indian Minority of Zambia, Rhodesia and Malawi* (1968); W.J.C. GERKE and C.J. VILJOEN, *Master Plan for Lilongwe: The Capital City of Malawi* (1968), an example of urban design, land use, and traffic planning in the context of traditional Malaŵi life; I. and J. LINDEN, *Catholics, Peasants and Chewa Resistance in Nyasaland 1889–1939* (1974); MALAWI GOVERNMENT, DEPARTMENT OF CENSUS AND STATISTICS, *Malawi Population Census 1966: Final Report* (1969), includes many detailed tables; MALAWI GOVERNMENT, ECONOMIC PLANNING DIVISION, *Statement of Development Policies, 1971–1980* (1971); MALAWI GOVERNMENT, NATIONAL STATISTICAL OFFICE, *Population Census, 1977: Preliminary Report* (1978); R.J. MACDONALD (ed.), *From Nyasaland to Malawi* (1975); J. MCCRACKEN, *Politics and Christianity in Malawi, 1875–1940: The Impact of the Livingstonia Mission in the Northern Province* (1977); B. PACHAI, *Malawi: The History of the Nation* (1973), and (ed.), *The Early History of Malawi* (1972); J.G. PIKE, *Malawi: A Political and Economic History* (1968), and with G.T. RIMMINGTON, *Malawi: A Geographical Study* (1965); T.O. RANGER (ed.), *Aspects of Central African History* (1968); M. READ, *The Ngoni of Nyasaland,* 2nd ed. (1970); N.R. HINTON and S. CARRENO, *Smiling Malawi: A Tenth Anniversary* (1976), with a 20-page introduction and 100 pages of photographs; and T.C. YOUNG, *Notes on the History of the Tumbuka-Kamanga Peoples of Northern Nyasaland* (1972). Periodicals and journals published in Malaŵi include the *Malawi Journal of Social Science,* and *The Malawian Geographer,* both from the University of Malaŵi; *Malawi Economic Report,* an annual publication

of the Malaŵi government; *Financial and Economic Review,* by the Reserve Bank of Malawi; and the *Society of Malawi Journal.*

Mozambique. D.M. ABSHIRE and M.A. SAMUELS (eds.), *Portuguese Africa: A Handbook* (1969), a good survey of Mozambique's history, government, and colonial economy; A.C.G. BEST and H.J. DE BLIJ, *African Survey* (1977), an examination of the political geography of Mozambique and its neighbours; JAMES DUFFY, *Portugal in Africa* (1962), a historical overview of Portuguese colonialism; MARVIN HARRIS, *Portugal's African "Wards"* (1958), a description of the forced labour and forced cropping system, written by a well-known anthropologist; and ADRIANO MOREIRA, *Portugal's Stand in Africa,* Eng. trans. (1962), a reply by a former Portuguese Cabinet minister to the criticism of Portuguese colonial policy. Three of the best analyses of Portuguese colonialism are A.F. ISAACMAN, *Mozambique: The Africanization of a European Institution—The Zambezi Prazos, 1750–1902* (1972), and *The Tradition of Resistance in Mozambique: The Zambezi Valley, 1850–1921* (1976); and M.D.D. NEWITT, *Portuguese Settlement on the Zambezi* (1973). I. KAPLAN (ed.), *Area Handbook for Mozambique* (1977), an excellent comprehensive survey of colonialism, the independence struggle, and contemporary development issues; EDUARDO MONDLANE, *The Struggle for Mozambique* (1969), a history of resistance in Mozambique and Frelimo's war against Portugal by Frelimo's first president; EDUARDO DE SOUSA FERREIRA, *Portuguese Colonialism in Africa: The End of an Era* (1974), a brief review of Portugal's politics and attitudes toward Mozambique; R.J. HAMMOND, *Portugal and Africa 1815–1910: A Study in Uneconomic Imperialism,* on Portuguese settlement and the colonial infrastructure; and MANFRED KUDER, *Moçambique: Eine geographische, soziale und wirtschaftliche Landeskunde* (1975), and MOZAMBIQUE GOVERNMENT, *Geografia Humana de Moçambique* (1975), two excellent surveys of Mozambique's physical landscapes and the economic and social geographies on the eve of independence.

Namibia. HEINRICH VEDDER, L. FOWIE, and C.H.L. HAHN, *The Native Tribes of South West Africa* (1928, reprinted 1966), with chapters on the Bushmen, Damara, Herero, and Nama; HEINRICH VEDDER, *Das alte Südwest-afrika* (1934; Eng. trans., *South West Africa in Early Times,* 1938, reprinted 1966); A.W. HOERNLE, "The Social Organization of the Nama Hottentots of Southwest Africa," *Am. Anthrop.* 27:1–24 (1925); H.R. MACCALMAN and B.J. GROBBELAAR, "Preliminary Report of Two Stoneworking Ovatjimba Groups in the Northern Kaokoveld of South West Africa," in *Cimbebasia,* no. 13 (1965); GORDON LE SUEUR, *Germany's Vanishing Colonies* (1915), concerned with the effects on colonialism of World War I; MARY E. TOWNSEND, *Origins of Modern German Colonialism, 1871–1885* (1921) and *The Rise and Fall of Germany's Colonial Empire, 1884–1918* (1930); WILLIAM O. HENDERSON, *Studies in German Colonial History* (1962), an important work; W.W. SCHMOKEL, *Dream of Empire: German Colonialism, 1919–45* (1964), an excellent book on the period between World Wars I and II; JON BRIDGMAN and DAVID E. CLARKE, *German Africa: A Select Annotated Bibliography* (1965); ODENDAAL COMMISSION, *Report on South West Africa* (1964), published by the South African government and therefore reflecting its views; J.H. WELLINGTON, *South West Africa and Its Human Issues* (1967), an authoritative work; and INTERNATIONAL COMMISSION OF JURISTS, *Apartheid in South Africa and South West Africa* (1967).

Swaziland. Descriptive works include DUDLEY BARKER, *Swaziland* (HMSO 1965); and DOUGLAS POTT, *Swaziland: A General Survey* (1965). HILDA KUPER, *An African Aristocracy: Rank Among the Swazi* (1947), is the accepted work on the social life and institutions of the Swazi; JACK HALPERN, *South Africa's Hostages: Basutoland, Bechuanaland and Swaziland* (1965), is a useful survey written by a political observer. For administration and political and constitutional affairs, see LORD HAILEY, *The Republic of South Africa and the High Commission Territories* (1963); COLONIAL OFFICE, SWAZILAND, *Annual Reports* (to 1966); RICHARD P. STEVENS, "Swaziland Political Development," *Journal of Modern African Studies,* 1:327–350 (1963); *Lesotho, Botswana and Swaziland* (1967); DENIS V. COWEN, *Swaziland: Report on Constitutional Reform* (1961); and COLIN LEGUM and JOHN DRYSDALE, *Africa Contemporary Record,* 3 vol. (1968–71). J.F. HOLLEMAN (ed.), *Experiment in Swaziland: Report of the Swaziland Sample Survey, 1960* (1964), is a detailed scientific study of the country's physical resources.

Zambia. *General references:* AMERICAN UNIVERSITY, WASHINGTON, *Area Handbook for Zambia* (1969), a handbook covering social, economic, political, and military institutions and practices, prepared by the university's Foreign Area Studies program; and W.V. BRELSFORD (ed.), *Handbook to the Federation of Rhodesia and Nyasaland* (1960), a compendium of information about the former Federation (Northern and Southern Rhodesia and Nyasaland) covering prehistory, history, and natural resources as well as many other subjects.

Land and people: D. HYWEL DAVIES, *Zambia in Maps* (1970); J.A. HELLEN, *Rural Economic Development in Zambia 1890–1964* (1968), an inventory of the land and people and a study of regional development; GEORGE KAY, *A Social Geography of Zambia* (1967), a study of the physical and historical setting of the population and its economic activities; CENTRAL STATISTICAL OFFICE, LUSAKA, *Census of Population and Housing, 1969: First Report;* W.V. BRELSFORD, *The Tribes of Zambia,* 2nd ed. (1965), a comprehensive historical survey.

Mines and minerals: J.A. BANCROFT, *Mining in Northern Rhodesia* (1961), a history of mining exploration and development; F. MENDELSOHN (ed.), *The Geology of the Northern Rhodesian Copperbelt* (1961), a technical description; and *Mining Year Book of Zambia* (annual).

Economy and development: UNITED NATIONS (ECA, FAO), *Economic Survey Mission on the Economic Development of Zambia* (1964), a report that paved the way for the transitional development program introduced after independence; OFFICE OF NATIONAL DEVELOPMENT AND PLANNING, *First National Development Plan 1966–70* (1966); and INTERNATIONAL LABOR OFFICE, *Report to the Government of Zambia on Incomes, Wages, and Prices in Zambia: Policy and Machinery* (1969).

Zimbabwe. PHILIP MASON, *The Birth of a Dilemma: The Conquest and Settlement of Rhodesia* (1958), the best account of the early days (up to 1918) of white settlement and race relations; and T.O. RANGER, *Revolt in Southern Rhodesia, 1896–97* (1967), a full-length study, drawing from African sources, of the risings against white rule in 1896–97, with significance in terms of the modern liberation movement. LAWRENCE VAMBE, *An Ill-Fated People: Zimbabwe Before and After Rhodes* (1972), a family history which portrays the humour and sadness of occupation; COLIN LEYS, *European Politics in Southern Rhodesia* (1959), an analysis of the flow of immigrants and of the continuously rightward trend in party politics before federation; CLYDE SANGER, *Central African Emergency* (1960), describing the first years of federation and the growth of the nationalist movement in territories that have since become Zimbabwe, Malaŵi, and Zambia; NDABANINGI SITHOLE, *African Nationalism* (1959) and *Letters from Salisbury Prison* (1976), a balanced political analysis and an exhortation of a father's concern for six children scattered by the civil war; NATHAN SHAMUYARIRA, *Crisis in Rhodesia* (1965), a broad description of the racial disparities and political collisions that culminated in the unilateral declaration of independence; ROBERT BLAKE, *A History of Rhodesia* (1977), including a commentary sympathetic to the white Rhodesian leaders; MARTIN MEREDITH, *The Past Is Another Country* (1979), a detailed and objective account of the political moves inside Rhodesia from 1965 to 1979; MARTIN BAILEY, *Oilgate: The Sanctions Scandal* (1979); ROGER RIDDELL *et. al., From Rhodesia to Zimbabwe,* 8 vol. (1977–79), a thorough investigation of the major problem areas for change; and D. MARTIN and P. KOHNSON, *The Struggle for Zimbabwe* (1981), an authoritative account of the liberation movement. DIANA MITCHELL and ROBERT CARY, *African Nationalist Leaders in Rhodesia* (1977), and DIANA MITCHELL, *Who's Who 1980,* provides invaluable background on the careers of the new leaders.

Of official reports published in Salisbury, the following retain more than historical interest: *Second Report of the Select Committee on the Resettlement of Natives* (1960), covering the heart of the dispute over landholdings and important recommendations on land apportionment reform; *Final Report of the 1962 Census of Africans in Southern Rhodesia* (1964), a basic source of information on socioeconomic conditions; *Census of Population, 1969* (1971); and *Report of the (Phillips) Advisory Committee on the Development of the Economic Resources of Southern Rhodesia, with Particular Reference to the Role of African Agriculture* (1962), containing details of the country's resources and potentialities. Three reports published in London cover more recent historical landmarks: *Report of the Commission on Rhodesian Opinion* (1972), known as the Pearce Report, a critically important state document; *Report on the Supply of Petroleum and Petroleum Products to Rhodesia* (1978), known as the Bingham Report, a painstaking but incomplete investigation of circumventions of sanctions by oil companies and connivance by British officials; and *Southern Rhodesian Elections* (1980), the report of the Commonwealth Observer Group, an illuminating picture of how the main actors behaved under strain in the final scenes before independence.
