Spain

Lying at the southwestern end of the European continent, Spain (España), or the Spanish State (Estado Español), occupies about 85 percent of the Iberian Peninsula. With Portugal, which forms its western boundary, it is shaped like the hide of a bull, the neck pointing toward Africa in the south and a large base formed by the Pyrenees Mountains and the Bay of Biscay in the north. It is separated from France by the small principality of Andorra and by the Pyrenees; and in the far south lies the small peninsula of Gibraltar, which has been under British sovereignty since 1713. Off Spain's eastern coast lie the Balearic Islands; the Canary Islands, in the Atlantic Ocean off the coast of Africa, are also a part of Spain. The cities of Ceuta and Melilla, in northern Morocco, have belonged to Spain for several centuries and are considered by Spain to be an integral part of that country, despite Moroccan claims to their suzerainty. The total area of the national territory of Spain is 194,900 square miles (504,782 square kilometres).

One of the most ancient countries in Europe, Spain was also long one of the most powerful and, from the 16th to the 19th century, ruled a large empire. Evidence of that empire is the continuing use of the Spanish language in 18 Latin-American states, Puerto Rico, and the Republic of Equatorial Guinea. Lying at the crossroads of Africa and Europe, and holding the key to the Mediterranean from the Atlantic, Spain retains traces of European, African, Mediterranean, and Atlantic cultures that make of it a distinctive country within western Europe.

Under the constitution adopted in 1978, Spain is a constitutional monarchy in which the king assumes a ceremonial position. Its economy is fully integrated in the Western world, with large-scale foreign investments, tourism, and trade relations with other countries of the Atlantic area. Spain is a member of the North Atlantic Treaty Organization (NATO) and maintains a close relationship with that organization through bilateral agreements with the United States. Spain is a member of the United Nations and its specialized agencies and belongs to the Council of Europe and most technical organizations of western Europe. It is tied to the European Economic Community (EEC) with a commercial agreement. Close diplomatic, cultural, and economic links are maintained with most Latin-American countries and international organizations, such as the Andean Pact, the Inter-American Development Bank, and the Organization of American States.

Physical and human geography

THE LAND

Relief. With the exception of the southern triangle closing toward the Strait of Gibraltar, the Iberian Peninsula forms an irregular quadrangle, bordered on the east and southeast by the Mediterranean and on the west, southwest, and most of the north by the Atlantic Ocean. Most of the peninsula is occupied by the Meseta, a large plateau with approximately the same boundaries as the historical Kingdom of Castile (Castilla). The average height of the plateau is 2,000 feet (610 metres), although its northern part is slightly higher than the southern section. The Meseta is almost completely surrounded by mountain ranges: the Cordillera Cantábrica (Cantabrian Mountains) in the north; the Sistema Ibérico (Iberian System) from the Cantábrica to the southeast; the Sierra Morena in the south; and the lower mountains on the border with Portugal in the northwest. The southern plateau descends gently in the direction of Portugal, whereas the transition from the northern plateau to Portugal is marked by rugged terrain and mountain ranges. The Meseta is divided by the Cordillera Carpetovetónica (also called the Sistema Central), which extends across the plateau to the north of Madrid and runs all the way from the Sistema Ibérico to Portugal.

The Meseta

Around the central plateau, five natural regions can be identified. First, in northeastern Spain, there is the valley of the Río Ebro, enclosed by the Sistema Ibérico in the west and southwest, the Pyrenees and the Cordillera Cantábrica in the north, and the mountains of Catalonia (Cataluña) and other coastal ranges in the east. Second, there is the valley of the Guadalquivir River in the south, which is separated from the plateau by the Sierra Morena and from the Mediterranean by the Sistema Penibético (Baetic Cordillera), including the Sierra Nevada in the southeast, but which has unimpeded passage to the Atlantic in the southwest. Third, there is the region of the coastal area of Valencia, in the east, descending from the southern Iberian ranges toward the Mediterranean. Catalonia, a mountainous region between the valley of the Ebro, the eastern Pyrenees, and the Mediterranean, forms the fourth natural region. Finally, there is northern Spain from the Pyrenees to the west, a rugged, mountainous country comprising several small regions separated from each other by high mountains.

Geologically, the peninsula forms a great massif (not to be confused with the Meseta, which it partly overlaps), bordered on the north, east, and south by mountain folds. This massif is a fragment of the former Hercynian continent, which formed across Europe at the close of the Carboniferous Period (about 345,000,000 to 280,000,000 years ago). During the Mesozoic Era (between 225,000,000 and 65,000,000 years ago), the Hercynian system was shattered, and large portions sank below the sea. During the Tertiary Period (between 65,000,000 and 2,500,000 years ago), deposits of the Jurassic and Cretaceous seas, together with the earlier Tertiary beds, were crushed against the old massif to form the ranges bordering the Meseta. Later movements contorted and fractured the peninsula to give it its present general shape.

The Hercynian massif

The Balearic Islands in the Mediterranean are composed of mountain ranges of moderate altitude, not exceeding 5,000 feet. The Canary Islands in the Atlantic, however, are of volcanic origin and contain the highest peak among the Spanish territories, the Teide (12,198 feet [3,718 metres]), located on the island of Tenerife.

Drainage and soils. The most important drainage systems are found in the plateau and the two large valleys of the Ebro and the Guadalquivir. The plateau has three main drainage systems, all flowing into the Atlantic: the Río Duero (Douro) in the northern plateau and the Tagus (Tajo) and Guadiana in the southern plateau. While the Duero and the Tagus follow an almost parallel course from the Iberian range to the west coast of Portugal, the Guadiana turns south at the border with Portugal and empties into the Gulf of Cadiz (Golfo de Cádiz) on the southern Atlantic coast. The Ebro, which has the greatest outflow of the peninsula's rivers, follows an almost straight course from the northern mountains to the Mediterranean, collecting waters from the Pyrenees and the Sistema Ibérico. The Guadalquivir flows from the east to the southwest, gathering waters from the Sierra Morena and the Sierra Nevada. In the southeastern region, the two most important rivers are the Júcar and the Segura.

Three main mineralogical regions can be distinguished in Spain. Crystalline rocks predominate in the central and peripheral basins, whereas the east and north have an abundance of limestones. The soils may be described as generally acid-humid in the northwest, calcareous in eastern and southern Spain, and siliceous in the Cantábrica, northern Iberian, Carpetovetónica, and Sierra Morena ranges as well as in the Duero Valley and the mountains of Zamora and Salamanca. As in most of the western Mediterranean, erosion has played a very important role in the degradation of the soils, especially in the high areas of the plateau and the eastern and southern zones. In addition to natural erosion, humans have contributed considerably through the destruction of forests. Since the 1920s, however, the government has carried out important projects to forestall further erosion.

Soil erosion

Climate. Spain is located in the temperate zone of the Northern Hemisphere, between the latitudes of 27° (for the Canary Islands) and 44° N. In general, Spain belongs climatically to the western Mediterranean. The peninsula is exposed both to the westerly North Atlantic winds, which dominate during most of the year, and to the warm, dry airstream that blows less frequently from the Sahara. The Pyrenees and the Cordillera Cantábrica, however, play an important role in the Spanish climate, for they constitute the northern boundary of the subtropical airstream during the summer months, thereby maintaining dry weather conditions over most of the country.

Three basic types of climate predominate within the peninsula: the coastal climate of the Atlantic and Mediterranean seaboards; the continental climate of the plateau and the valleys of the Ebro and the Guadalquivir; and the mountain climate of areas above 3,000 feet. Northern Spain, from Galicia to northern Catalonia, is characterized by moderate, even temperatures and high rainfall. Thus, La Coruña, in the northwest, ranges from 48° F (9° C) in winter to 64° F (18° C) in summer, while the annual rainfall is about 38 inches (965 millimetres). The plateau has a continental climate, with lower rainfall and greater temperature variations. Thus Albacete, in the southeast of the plateau, varies between 40° F (4° C) in the winter and 75° F (24° C) in the summer, while the annual rainfall is less than 15 inches (380 millimetres). The valleys

of the Ebro and the Guadalquivir also have a continental climate, drier and colder in the Ebro and warmer and more humid in the Guadalquivir. Catalonia, Valencia, and the Balearic Islands enjoy more temperate weather, with higher rainfall in Catalonia, while the Canary Islands have a subtropical, Atlantic climate.

Plant and animal life. *Vegetation.* There are four main vegetation areas: north, centre, south, and southeast. Northern Spain, enjoying humid weather, is covered with deciduous forests and meadows. It is basically a green country, good for forestry and pastures, as well as the cultivation of corn (maize), apples, and other products that thrive in humid areas. The northern plateau and the Ebro Valley, with low levels of humidity and extreme temperatures, mainly produce grains. The upper Ebro Valley, the southern plateau, Andalusia, and the eastern regions produce olives and grapes. Valencia and the irrigated areas of Murcia are noted for their citrus fruits, particularly oranges, but rice is also grown in Valencia, and the production of fruits and vegetables in Murcia has been diversified. Semi-desert areas occur in the valley of the Ebro, around the city of Zaragoza, and in southeastern Spain in the province of Almería, where irrigation projects support the cultivation of flowers, early fruits, and vegetables.

Fruit-growing regions

Livestock. Cattle are raised in the north and in the mountainous areas of central and southern Spain. Sheep are the most common stock animals in the plateau region. Pigs are raised in most of Spain, particularly in the west and northwest. Goats are mostly raised in the south of the peninsula and in the islands. Mules and donkeys, once a part of the Spanish landscape, were vanishing in the late 20th century as a consequence of the mechanization of harvesting and transportation. Spanish-Arabian horses are raised on large estates in Andalusia (Andalucía), and fighting bulls are raised for profit in Andalusia and Castile. Camels are used for tourist purposes in some of the Canary Islands.

Wildlife. Its close links with Africa give Spain more African species than exist in the other Mediterranean peninsulas, while the Pyrenean barrier and extent of the country explains the number of indigenous species. The larger species of wildlife are almost extinct in Spain, although bears and wolves can still be found in the Pyrenees and some of the northern mountain areas. The Spanish ibex (*Capra pyrenaica*) is threatened with extinction, and most are found within preserves. Other types of wildlife, such as deer or wild pigs, can be found in preserves all over Spain. Minor game, such as partridge, grouse, duck, and rabbit or hare, abound throughout Spain. At Gibraltar is confined the Barbary ape, thought either to be indigenous or to have been imported by the Romans or Arabs; it is also present across the strait.

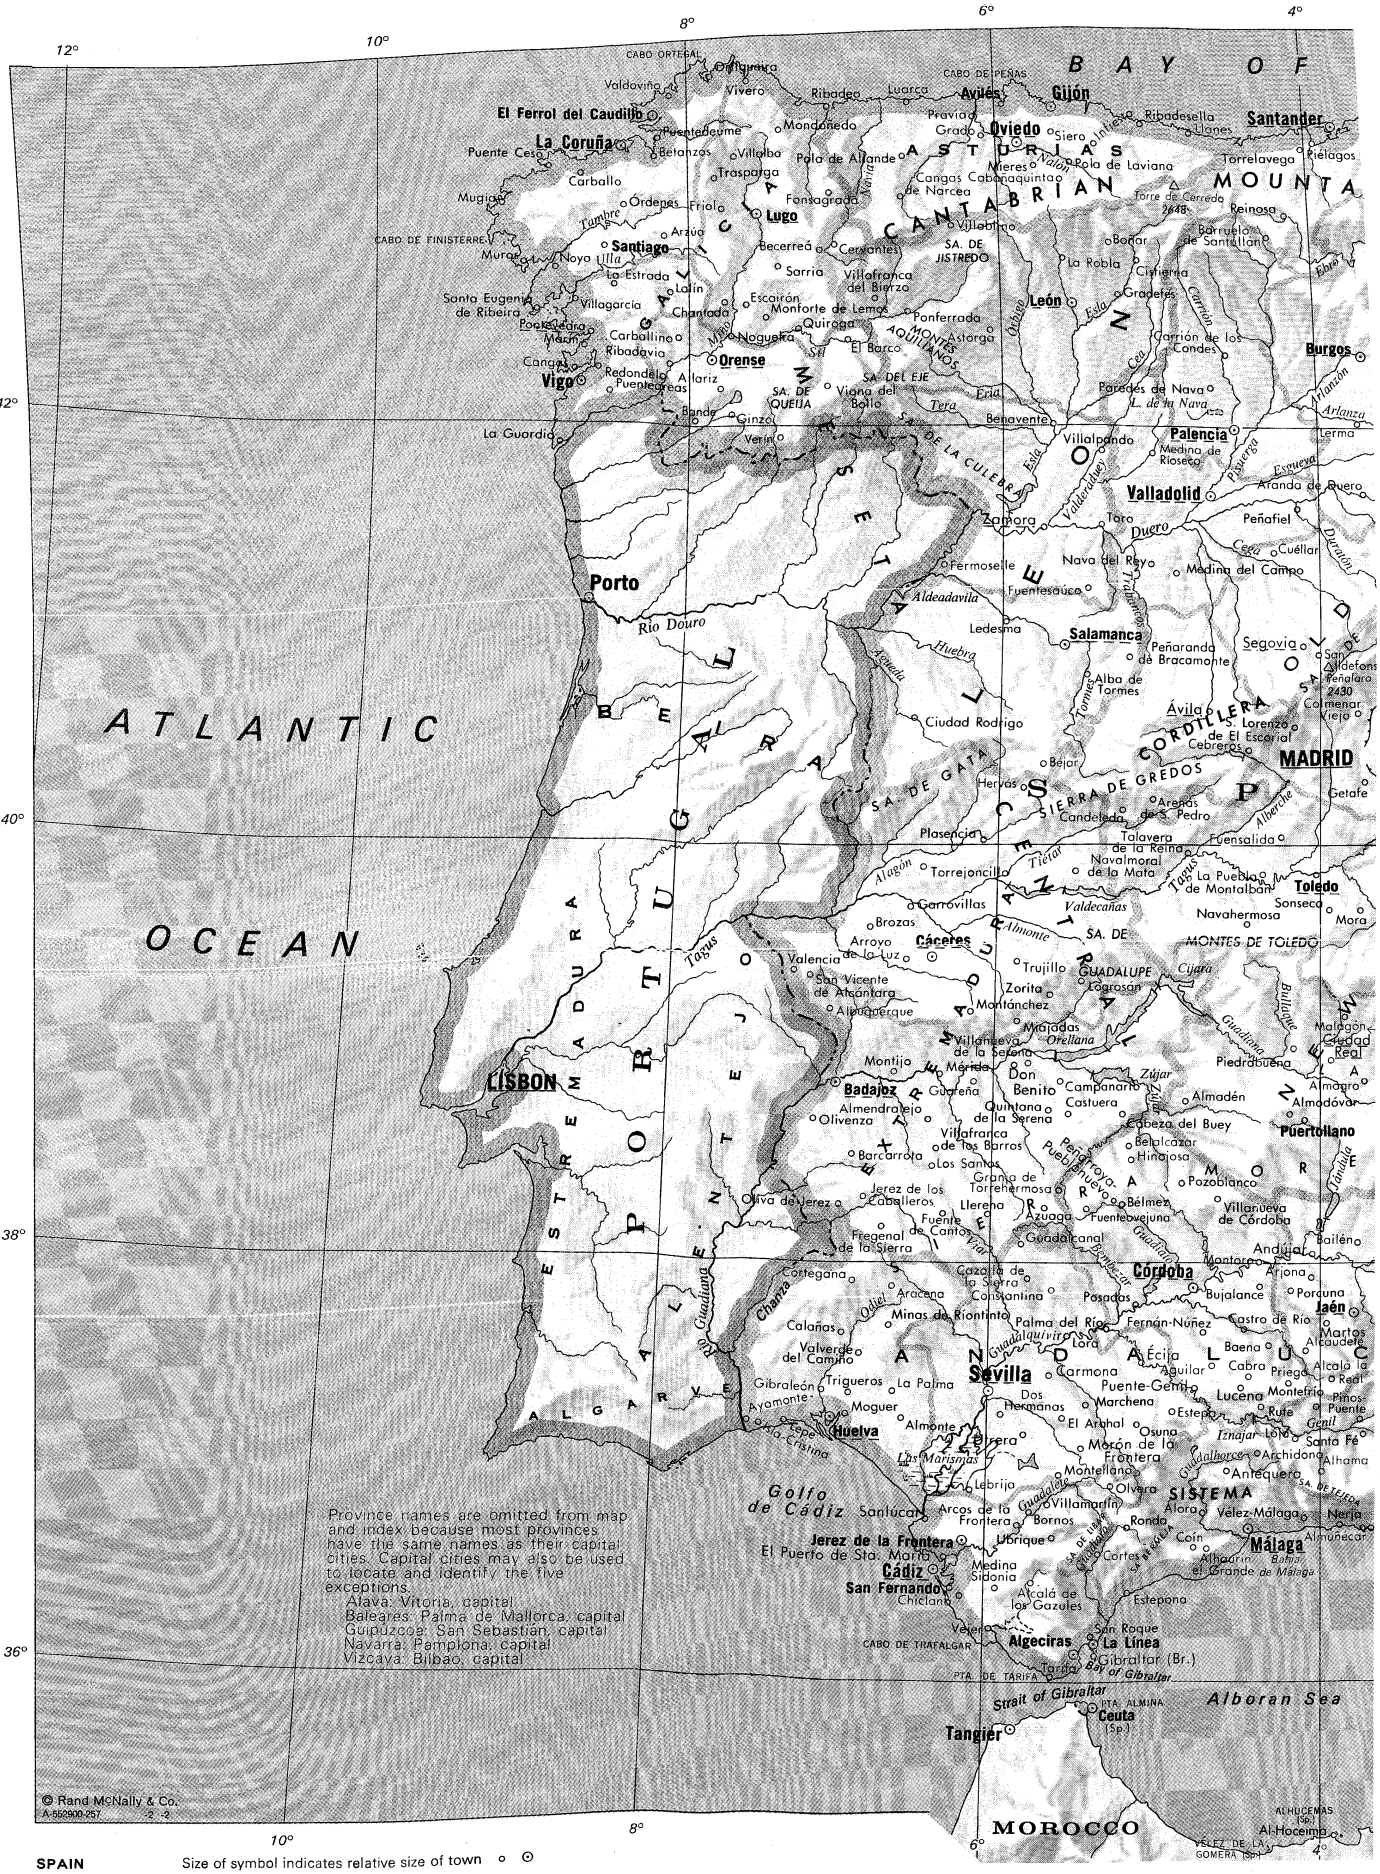
Fish. The Spanish coasts were once rich in fish and shellfish, particularly in the Atlantic and the Bay of Biscay. Overexploitation led, however, to the exhaustion of coastal fisheries within the Spanish territorial waters. This induced the government to adopt a 200-mile offshore fishing zone in 1978, within which Spain claimed the right to manage and exploit fisheries. Trout, luce, carp, and other inland fishes are still found in the rivers and water reservoirs protected by the state.

Settlement patterns. *Traditional regions.* Because of the geographical diversity and the great variety of climates and vegetation, as well as for historical reasons, regional differences are very important in Spain. Their political relevance increased with the approval in 1978 of a new constitution that foresaw a reorganization of the state on the basis of autonomous communities. The country is divided into 14 traditional regions, two of which are the Balearic Islands and the Canary Islands. The old Kingdom of Castile, which covered most of the plateau, included three regions that are still considered to be Castilian: León and Old Castile, in the northern plateau, and New Castile, in the southern plateau. (The province of Santander, located between the Cordillera Cantábrica and the Bay of Biscay, was historically part of Old Castile, although it differs widely from inland Castile in location, climate, and economic structure.) The former kingdom also included six other regions that are no longer considered to be Castilian: the Basque Provinces, Asturias, and Galicia, in the north; Extremadura, in the southern plateau, bordering Portugal; and Murcia and Andalusia in the south. The old Kingdom of Aragón, located on the eastern half of the peninsula, encompassed the four regions of Navarre, bordering France and the Basque country; Aragón, covering the lower course of the Ebro River and extending from the Pyrenees to the Sistema Ibérico; Catalonia, in the northeastern corner of Spain; and Valencia, in the coastal plains between the Sistema Ibérico and the Mediterranean Sea.

The coastal regions differ markedly from each other and from inland Spain. Differences in geography, history, social and economic structures, and especially language have all contributed to a variety of regional identities. Regional nationalism—even regional separatism—has developed wherever a native language other than Spanish is spoken, as in Catalonia, Galicia, and, above all, the Basque country (Vascongadas). And in regions in which only Spanish is spoken, such as Andalusia, the Canary Islands, and Aragón, an acute sense of social and cultural identity has been acquired. Consequently, a movement developed all over Spain to transform the traditionally centralized political system into a decentralized one with an almost federal structure. Thus, traditional regions became the basis for the political reorganization of the country.

Regional consciousness

One of the most sensitive issues in Spanish politics in the late 20th century was the apportionment of powers between the central government and the new autonomous communities recognized by the constitution of 1978. The regionalist trend that had prevailed during the 1970s had become counterbalanced by centralist forces that opposed any further transfer of powers to the regional governments. Thus, a tug-of-war between national and regional identities developed, threatening the stability of democratic institutions and putting in question the nature of the state itself. The strain was particularly noticeable in the Basque country, but was also apparent in Catalonia and other regional communities.



Human settlement. Spain is now a predominantly industrial country, with less than 20 percent of the economically active population involved in agriculture, forestry, or fishing. There has been a sharp movement from the country to the cities in the last 50 years. In 1930, only one-quarter of the population lived in cities, whereas more than half of the Spanish population was settled in an urban environment by the late 20th century. The economic and structural changes that took place in that period are of paramount importance to an understanding of modern Spain.

Traditional rural settlements vary widely from one region to the next. Northern and Mediterranean Spain and the islands follow a pattern of small settlements surrounded by agricultural land. On the other hand, the plateau and the valleys of the Ebro and the Guadalquivir are characterized by highly concentrated rural populations inhabiting large towns. These differences are connected with the history and the landscape of the different regions.

Most of the population lives in towns of 10,000 or more inhabitants. The size of towns does not, however, always reflect their economic activity. In southern Castile, Extremadura, Murcia, and Andalusia, large towns of 20,000 or 30,000 people may concentrate mainly on agricultural tasks, while smaller towns in the Basque country or Catalonia may be predominantly industrial. The two main urban centres are Madrid, the capital, in New Castile, and Barcelona, on the Catalonian coast. The population of the province of Barcelona exceeds that of the province of Madrid, while the metropolitan districts of Madrid and Barcelona are roughly equivalent. Other large urban concentrations include Greater Bilbao, which is in the Basque country; Greater Valencia, in the east; Zaragoza, in the Ebro Valley; and Seville (Sevilla), in the lower Guadalquivir Valley.

THE PEOPLE

Because of its position between two continents and its relative accessibility from the Mediterranean, Spain has been invaded and inhabited by many different peoples. In prehistoric times, peoples from North Africa and western Europe settled in the peninsula, including the Celts,

in the north. The Mediterranean coast appears to have been settled by North Africans, whereas the Basques probably occupied a considerably larger area than the present Basque country. Ancient Greek and Phoenician settlements were established on the eastern and southern coasts, and Carthaginians founded large colonies in the southeast (around what is now Cartagena); but only the Romans were able to conquer the entire area, subjecting it to intensive Romanization. After the fall of the Roman Empire, Suebi, Vandals, and Alani razed the country. The Suebi consolidated a small kingdom in the northwest corner of the peninsula, but the whole peninsula eventually fell to the Visigoths. The Arabs invaded the peninsula in 711 and were not driven out of Spain until as late as 1492. These eight centuries of Arab influence, together with the prolonged Roman colonization, left a permanent imprint on the Spanish population. European influences dominate over non-European influences, however, and Spain is above all a Mediterranean European country that has many similarities to neighbouring countries such as France, Italy, and Portugal.

After almost five centuries of consolidation of the Spanish state, the population has become unified racially; and, with the possible exception of the wandering Gypsies, there are no recognizable racial minorities. Somehow, the Spanish population has incorporated into its genetic pool something from each of the succeeding invaders.

Linguistic groups. *Castilian.* Modern standard Spanish, or Castilian, is spoken throughout Spain. It is basically a Romance language, with some traces of other languages spoken in Spain before and after the Roman conquest, such as Celtic and Arabic. There are, however, important linguistic minorities within Spain—in the Mediterranean regions, in Galicia, and in the Basque country. Within the Castilian-speaking areas, there are some dialects spoken in remote places, such as the Bable of Asturias. There are also minor dialectal differences in Castilian vocabulary and pronunciation in the different regions. The best Castilian is reputed to be spoken in Old Castile, especially in the provinces of Burgos and Valladolid. The language spoken in southern Spain and the Canary Islands bears similarities to the Castilian of Latin America. Regional intonation and dialectal expressions can also be identified in the Castilian spoken in Catalonia, Galicia, and the Basque country. Castilian-speaking immigrants and their descendants living in Catalonia constitute a large and relatively underprivileged minority, particularly in the metropolitan area of Barcelona.

Catalan. Catalan is a Romance language closely related to the Provençal, or Occitan, language of southern France. It is spoken by a majority of the population in Catalonia, the Balearic Islands, and Valencia. The Valencian dialect of Catalan, however, has a strong Castilian influence. Catalan is a highly developed language, with a wealth of literary tradition in the areas of poetry, the novel, and drama. A strong revival of the language in recent years resulted in the naming of Catalan and Spanish as the official languages of Catalonia in the constitution of 1978.

Galician. Modern Portuguese originated in Galician (or Gallego), a Romance language that is still spoken in the Spanish region of Galicia. During the 13th century, Galician was used by the Castilian king Alfonso X the Wise as the literary language of his court, but it later lost its importance and was widely influenced by Castilian. Galician is now rarely spoken in the cities of Galicia, although it survives in the countryside and also among the Galician fishermen. Nonetheless, a revival of literary Galician began in the late 1800s, and the constitution of 1978 recognized Galician as an official language to be taught in local schools.

Basque. The most distinctive of the non-Castilian languages is found in the Basque country. Basque is neither of Romance nor of Indo-European derivation. Its origins are uncertain, but it was spoken in the peninsula before the Romans conquered Spain. Over the centuries, the Basque-speaking area shrank, and it is now spoken mostly in the countryside, in fishing villages, and in the small towns of the Basque country and Navarre and is rarely heard in the cities. The language was a vehicle for the assertion of Basque identity in the 1960s and '70s, however, and there was a revival of the language at the popular level and among intellectual circles. Basque became a local official language in 1978.

Ethnic groups. The Spanish population is basically homogeneous in race and culture, and the only true racial minority within Spain is that of the Gypsies. While a large number of Gypsies have been integrated with the general populace, there still remain a substantial number who lead a nomadic life and who can be seen on Spain's roads and streets, driving carts, begging, or peddling. Although there are no reliable statistics, they are estimated to number a few hundred thousand. The larger Gypsy communities are to be found in the cities of Granada, Madrid, Barcelona, and Murcia. Many of them have regular jobs and send their children to public or private schools, but, in general, they are considered to be a deprived minority, who are discriminated against and unable to achieve full integration in Spanish society.

The Gypsies

Unique ethnic features have been claimed for the populations of some of the Spanish regions, such as the Basque country and Andalusia. While some differences in the style of life and cultural traditions remain, the process of assimilation of the Spanish population has gone so far for so long a time that identification of ethnic groups can now be based only on language. Some of the most extreme Basque nationalists claim that there is a definite ethnic identity for the Basques, but exchanges between the Basque country and other parts of Spain have been so intense during the last two centuries that any original ethnic purity of the Basque population should now be considered to be much diluted.

Religious groups. *Roman Catholicism.* The majority of the Spanish population is Roman Catholic. Most Spaniards are baptized, married, and buried within the church. The process of industrialization and urbanization, however, has influenced the religious habits of the Spanish population, with a marked decrease in the church's influence upon everyday life. Under the constitution of 1978, the Catholic Church is no longer recognized as the established church of the state, although it still enjoys the government's financial support.

After the death in 1975 of Gen. Francisco Franco, who had been Spain's head of state from 1936, the Catholic Church supported the new democratic regime and thereby contributed greatly to an attitude of tolerance within Spanish society in general. The problem of relations between church and state, however, remained sensitive. Traditional anti-clerical attitudes became channelled during the late 20th century into the issues of divorce, abortion, and state financial support to private schools. The church's

opposition to a proposed divorce law, and the general conservatism of Spanish bishops after the election of Pope John Paul II in 1978, led to a revival of old frictions between the church and liberal politicians, which reached its climax shortly before an unsuccessful coup d'état was attempted in February 1981. The dangerous constitutional situation provoked by the attempted coup in turn led the church and the political parties to search for new formulas of compromise between religious liberalization and the maintenance of traditional church privileges. By June 1981, divorce was legalized, and state support of private schools was barely challenged.

Religious minorities. Most of the non-Catholic minority population is Protestant. Among traditional Protestant churches, the most important are the Church of the Brethren and the Evangelical Baptist Church, with a few thousand members each. Since the middle decades of the 20th century, however, other groups have grown rapidly, and the Jehovah's Witnesses have become the most important Protestant sect. The Seventh-day Adventists claim a few thousand baptized members and several thousand additional adherents, and the Mormons claim about 1,000 members.

Eastern Orthodox and non-Christian groups are small. Among the non-Christians, the Jewish community is the most important.

Birth and mortality. The birth rate is about equal to the European average but is less than the figure for most developing countries. The long-range trend of the birth rate has been one of decline, especially since the mid-20th century, with a marked preference for small families. The natural rate of growth varies throughout the country, however, with the higher rates in the Canary Islands, Andalusia, Murcia, and the Basque country. The lowest birth rates are found in the plateau, especially in Old and New Castile.

Immigration and emigration. The traditional Spanish pattern of emigration to Latin America ended after the Spanish Civil War and World War II. During the 1950s and '60s, hundreds of thousands of Spaniards moved to western Europe, taking advantage of the economic boom. In the late 1970s, however, most of these emigrants returned to Spain, while western Europeans and Latin Americans settled in Spain, some temporarily, others permanently. Spain has granted asylum to many Latin-American political refugees. There are a few hundred thousand official foreign residents in Spain, and many others live in Spain without an official residence permit. Spaniards working in western Europe are estimated at between 250,000 and 500,000.

Internal migration

Internal migration became particularly important after the Civil War, showing the familiar industrial pattern of movement from the countryside to the cities. This has caused most Spanish cities to triple their population since the mid-1930s, whereas the population as a whole has grown by only 50 percent. Many small villages, especially those in the central plateau, became almost uninhabited and in a few cases were completely deserted. The main centres of attraction for internal migration were the cities of Madrid and Barcelona. Madrid attracted immigrants who had lived mostly in the centre and the northwest, while Barcelona drew its migrants from the east and the south. Other large cities, such as Bilbao, Valencia, Zaragoza, and Seville, also attracted large numbers of immigrants, as did most provincial capitals. The development of tourism drew migrants to the resort areas of the Costa Brava (Catalonia), Costa del Sol (Andalusia), the southeast (Alicante), and the Balearic and Canary islands. The economic slump of the late 20th century, however, brought internal migration to a halt, and in some cases the trend was reversed, with migrants returning to their places of origin in the countryside. The escalation of violence in the separatist movement pushed many non-Basques out of the Basque country.

Uneven population distribution

Distribution of the population. About two-thirds of the population of Spain is found in the coastal regions, while only about one-third inhabits the plateau and the valley of the Ebro, which are regions that account for more than half of the national territory. Thus, the distribution of the population is not evenly spread throughout the country. The coastal regions of the Basque country, Galicia, Catalonia, Valencia, and the Balearic and Canary islands have population densities that approach those of industrial western Europe, while the northern plateau, Navarre, and Aragón are almost deserted compared to western European standards. One-third of the inland population is concentrated in Madrid, accentuating the semi-deserted character of the central areas. The population within the coastal regions is more evenly distributed, although a substantial proportion is concentrated in the metropolitan area of Barcelona. Among the coastal regions only some areas of eastern Andalusia and Murcia approach the low densities of the plateau.

Most of Spain's population now inhabits cities with populations of 10,000 or more. Within the larger metropolitan areas, most people live in high-rise apartments in the cores of the cities, but suburbs developed during the 1960s and '70s, especially within the metropolitan districts of Madrid, Barcelona, and Bilbao.

General considerations. Because of its open spaces and moderately decreasing birth rate, Spain is not facing a population explosion. Industrialization and urbanization, however, have caused overpopulation and economic imbalance in Madrid, Barcelona, Bilbao, and other industrial areas, where pollution has become acute. The contamination of Spain's rivers and coastal waters threatens the nation's freshwater supplies and fish resources. A peculiar problem is posed by the massive influx of more than 30,000,000 tourists a year, especially during the summer months when the space available to Spaniards for recreation is reduced and public utilities are used to capacity. A decrease in tourism in the late 1970s and early '80s, and the consequent reduction in foreign currency revenues, led the government to develop new programs to improve the quality of life and to preserve natural resources in urban and industrial developments.

The Spanish economy was hard hit by the worldwide economic crisis of the 1970s. The crisis affected all aspects of Spanish life, including population growth, industrialization, and urbanization. The most immediate effect was a reduction in the exponential growth of production, which entailed a slowdown in industrial growth and an increase of the urban population.

The economic crisis appeared to have affected the growth of the population as well. The cumulative effects of inflation and unemployment, which were coupled with more permissive rules regarding contraception and a number of changes in social attitudes, led to a decrease in the birth rate. The increase of life expectancy, combined with the reduction of the birth rate, is expected to change Spain's demographic pyramid, bringing it more in line with those of other European countries; *i.e.,* a pyramid marked by a larger number of older people than younger people.

THE ECONOMY

In the 1960s and early 1970s Spain had one of the fastest growing economies in Europe and was in the process of transformation from an underdeveloped to a developed country. By the end of the 1970s, the country's gross national product per capita was almost as high as that of Italy. Since about the mid-1950s, when Spain emerged from a period of economic and political isolation, its development, especially in trade with other countries, has been notable. In 1958 it joined the International Monetary Fund, in 1959 the Organization for European Economic Cooperation (now the Organisation for Economic Cooperation and Development, or OECD), and in 1963 the General Agreement on Tariffs and Trade. Spain became an associate member of the European Economic Community (EEC) in 1970 and applied for full membership in the EEC in 1977. Despite this rapid growth, Spain still needs increasing industrial investment and modernization of equipment.

Coal mining

Resources. Spain has one of western Europe's largest coal-mining industries. Pits are situated chiefly in Asturias, but there are also some in the lower hills of the Sierra

Morena. Coal imports are mainly of coking coal, although the import of steam-raising coal is increasing. In the mid-1960s a radical reorganization of the industry was begun; uneconomic pits were closed, while investment was diverted to those having the greatest potential.

Discoveries of petroleum have so far proved disappointing, and the potential for commercial production from two natural gas fields—one in the Gulf of Cádiz and one at Jaca—is uncertain. The originally rich veins of hematite (rubious iron ore) of Bilbao are now nearly worked out, but Spain is relatively rich in other minerals, most of which are exported. Mercury is obtained from the ancient mines of Almadén in Ciudad Real, and there is also a good supply of tungsten, lead, zinc, potash, pyrites, and some uranium oxides.

Although Spain is a mountainous country in which, it might be thought, considerable hydroelectric power could be produced, the relatively low rainfall restricts capacity, and all profitable hydroelectric potential had been developed by the late 20th century. Spain is heavily dependent on imported petroleum.

Agriculture, forestry, and fishing. Although Spain is one of western Europe's largest agricultural producers, the barrenness of much of the countryside has always made agriculture and cattle rearing difficult. With the recent rapid increase of the manufacturing industry, it is not surprising that the proportion of national income provided by agriculture has steadily declined. Yet, despite the relative decline, agriculture has maintained a small real growth rate, the more notable in that the proportion of agricultural labourers is constantly diminishing.

The two main problems confronting Spanish agriculture are social and environmental; these involve, respectively, the *latifundia,* large estates owned by absentee landlords, and the still more intractable difficulty springing from the uncertain climatic conditions and the general infertility of the land. The *latifundia* are mainly in the south, in Extremadura and Andalusia, and although some attempt at division of them was begun in 1939, progress has not been great. More success has been achieved, however, in the amalgamation of small holdings into viable farm units.

Uncertain rainfall has a serious effect on crops, and land is mostly poor, with widespread soil erosion as a result of years of overtilling and overgrazing. Frost is frequently a formidable threat to the Valencian orange crop. With periodic widespread drought, irrigation has been an obvious necessity, and the earliest large canals and dams for this purpose, such as the Canal Imperial de Aragón on the Ebro, were built in the 18th century. Major irrigation projects have been carried out in the 20th century.

Barley and wheat are the two most important cereal crops in terms of land use and production. Despite government incentives for greater domestic production of corn (maize) and oil seeds, these are still imported in substantial quantities. Barley is grown in the southeast, while the wheat-producing areas are mainly in Old Castile, Aragón, New Castile, and Extremadura. The cereal lands, those which are less well irrigated, are farmed according to traditional practice, with a two-year rotation of crops. Pulses are a staple crop of the Meseta, while rice is grown in Valencia and the Ebro Delta. Potatoes, beans, and onions are also produced.

Spain's most successful adaptation to its difficult Mediterranean climate has been in citrus fruit production. Citrus fruit is grown mainly in Valencia and Castellón. Other areas specialize in other fruits; apples and pears are grown in the north and northwest, figs and almonds in Castellón and Alicante, and peaches and apricots in Murcia. The main crop of the *latifundia* is olives, almost the whole yield of which is made into oil. Grapes are grown especially in La Mancha, La Rioja, and the hills of Catalonia, Valencia, and Málaga. As the third largest wine-producing country in Europe, Spain has suffered from an overproduction of inferior wines. Brandy and sherry from Cádiz and Jerez de la Frontera and dessert wines from Valencia and Málaga remain in demand. Hemp, cotton, and tobacco are also grown, in comparatively small quantities.

Sheep and cattle rearing is very important, and Spain has one of Europe's largest sheep and goat populations. More than half the cattle are concentrated in the humid north, especially dairy cows in the Cordillera Cantábrica. Sheep, concentrated on the Meseta, are of three main breeds: the long-wooled churro, the short-wooled merino, and the manchegan. Goats are best suited to the arid conditions of the southeast, and pigs are reared in the Holm-oak woodlands of Extremadura.

Sheep, goats, and cattle

Some afforestation is practiced to counter soil erosion. Fishing is concentrated mainly on the northern and western Atlantic coasts and is particularly important in Galicia, where Vigo is the main fishing port. The catch comprises mainly sardines, anchovies, hake, cod, tunny, bream, mollusks, and crustaceans.

Industry. Although historical inertia and traditionalism long hampered the development of Spanish industry, the country's industrial growth rate since the mid-1950s has been one of the fastest in the world, and, in the late 20th century industry and construction contributed more than one-third of the total national output. Some manufacturing industries are long established and are supported by protectionist policies. The historical regional location of light industries still pertains: Manises, in Valencia province, is a centre for ceramic works; paper has been manufactured since Moorish times at Játiva, in the same province; Béjar, Segovia, Soria, and Burgos have long been woollen centres; and cotton manufactures are concentrated around Barcelona. Other light industries include a variety of textiles, clothing and footwear, food processing, liqueurs and wine, and light engineering. Chemical industries include the production of nitrogen fertilizers. During the late 20th century, massive investment was made in newer, high-technology industries.

Industrial growth

Heavy industries are largely centred in the north, where metallurgical works are found in Santander and the Basque country. Bilbao has been a steel centre since the Middle Ages. Madrid has engineering and metalworks, in addition to a range of light industry. One of the most successful and competitive of Spain's heavy industries in the 1960s and early 1970s was shipbuilding. As in other countries, shipbuilding was adversely affected by the recession of the mid-1970s, but a restructuring of that industry, and of the steel and textile industries, was undertaken.

Financial services. The central bank is the Banco de España, in the profits of which the government has participated since 1922. Many dealings of the commercial and savings banks are government regulated, although there has been some loosening of controls. The majority of corporate borrowers, both public and private, have recourse either to these banks or to the state-owned holding corporation created in 1941, the Instituto Nacional de Industria (INI). Largely because the public prefers to keep its savings on deposit rather than invest in securities, the banks control a large part of the issued capital of Spanish limited-liability companies. A considerable amount of private investment is also financed from abroad, and the Spanish stock market has thus remained relatively undeveloped. The most important sources are the United States, West Germany, Switzerland, the United Kingdom, and France. The most important sectors of the economy thus affected have been chemicals, the automobile industry, and real estate.

Trade. Importing considerably more than it exports, Spain has traditionally had a visible trade deficit. The deficits have been attributed to Spain's dependence on crude-oil imports for energy requirements. Trade is most frequent with member countries of the EEC, the United States, and Saudi Arabia. There is also some trade with Latin America. Food and agricultural exports, mainly citrus fruit, wines, fish products, and olive oil, account for about one-fifth of the total bulk of exports. Raw materials exported are mainly iron ores and pyrites, while cotton goods, textiles, and clothing also have a steady market. Engineering and heavy industrial exports, such as ships, automobiles, and electrical goods, are increasingly important. Some agricultural products have to be imported, notably cereals, animal products, and vegetable oils. Spain also imports raw cotton as well as textile products; petroleum and its products account for about one-third of the cost of imports. Engineering goods are also brought in.

Spain's rapid growth in the 1960s and early 1970s was made possible because imports were allowed to outstrip exports so greatly. The resultant gap was mainly financed in two striking ways. First, in the mid-1960s Spain became one of the world's most popular centres of tourism. Secondly, until the rise of unemployment in Europe began in 1973, Spain exported labour to other European countries, and workers' remittances sent home contributed substantially to the country's balance of payments.

Administration of the economy. *Private enterprise and the role of government.* Government influence over the economy is very strong in Spain. A large number of concerns are state-owned, including the railways, telephone services, and radio and television. The state also has large holdings of ordinary shares in a wide range of industrial companies, mostly through the medium of the INI. This corporation, run by the Ministry of Industry, owns wholly or in part some companies representing all facets of the industrial economy. In some industries, such as coal, basic steel, petroleum and petrochemicals, and automobile manufacture, INI's participation in individual firms has exerted an influence on the development of the sector as a whole.

Taxation and public spending. The collection of revenue by means of taxation was one of the least efficient features of the Spanish economy in the 1960s. Although incomes rose rapidly during the period, central government tax revenue did not rise proportionately. Legislation was introduced to enlarge the tax base and to improve the efficiency of collection. This led to a wholesale revision of the taxation structure.

Tax revision

Industrial development in the middle and late 20th century was stimulated by central government subsidies to certain designated regional development areas and by tax and other subsidies to favoured sectors of the economy, such as mining and automobile manufacturing. Social, health, and educational services were neglected until the late 1970s, when central government expenditure in these areas was substantially increased.

Trade unions and employers' associations. Spain's trade-union structure, the syndicalist system, was an integral feature of the country's political development since the end of the Civil War. Broadly speaking, most organized economic concerns, comprising mainly the manufacturing and service industries and a substantial section of agriculture, were covered by "syndicates." In theory, these syndicates represented simultaneously the interests of employers, workers, and the state, and their formal structure reflected the Fascist preoccupations of the 1930s and 1940s.

Early in 1971 the Spanish Parliament approved a new, government-sponsored basic law for trade-union activities. Although the vertical and comprehensive structure of the syndicates was retained—under the control of a Cabinet minister, the minister for syndical relations—the new law allowed management, technicians, and workers to set up independent associations. Workers could hold meetings and would be able to appeal in the courts against certain types of government decisions. But even in its new form, Spanish industrial and trade-union organization was still far from even approximating that of the countries of the European Economic Community.

The trade unions

In 1977, independent trade unions were legally recognized, and by 1981 there were three main trade unions—the Confederación Sindical de Comisiones Obreras, which has connections with the Communist Party; the Unión General de Trabajadores de España, which is linked with the major Socialist party; and the Unión Sindical Obrera. After 1977, labour legislation provided the basis for a new framework for labour relations and in 1980 a Workers Statute was enacted that covered a variety of labour issues.

Contemporary economic policies. From the late 1950s a group that came to be known as the technocrats tried to modernize and internationalize the Spanish economy. The convictions underlying their policies were that adjustment would be easier and more successful in the context of rapid, overall growth and that this would be stimulated by encouraging competition. The technocrats, whose power base was originally in the planning departments, were so successful that it became fashionable to believe that they had effective control of the economy, but their appearance of success stemmed partly from the fact that the overall performance of the economy was at that time reasonably satisfactory. Their influence on individual sections of the economy was often apparent rather than real, and their successful manipulation of overall policy did not mean that they had managed to reform particular monetary institutions and practices. They failed adequately to effect the reduction or elimination of subsidies, and particular business decisions remained subjected to far greater government regulation in Spain than in other Western industrialized economies.

Government economic policy statements have increasingly emphasized the need for lessening government intervention in the economy. Some progress in that direction was made. Industrial planning, for example, became subject to fewer regulations, and the number of prices controlled by the government was made much smaller than it had been. Greater liberalization of the financial system was also envisaged; in 1978, legislation was passed allowing foreign banks to operate in Spain, and, in 1981, banks were permitted to set their own interest rates on most credits.

In common with other European countries, Spain has had to contend with recession, inflation, unemployment, and balance of payments. Priority was initially given to curbing the rate of inflation. With unemployment figures very high, however, the government placed far greater emphasis on the need for incentives and investment that would result in the creation of more jobs.

Transportation. The first system of communications established on the Iberian Peninsula dates back to Roman times, and traces of the extensive Roman road network still remain. A new system of highways was not built until the 18th century, during the reign of the first Bourbon kings. Since their capital, Madrid, was situated in the heart of the country, the new system took the form of radial highways extending to the periphery of the peninsula. During the 19th century and into the 20th, efforts were made to consolidate the system of public works. The maintenance and improvement of highways has been one of the chief features of successive plans for economic and social development that have been undertaken.

The Roman heritage

Roads. Of the national highway network, several thousand miles are classified as basic and complementary highways, and the remaining highways are regional. Additional public roads include municipal roads, rural roads, forestry roads, and roads leading to industrial and other projects.

The Red de Itinerarios Asfálticos (Redia; Network of Asphalt-Paved Roads) program was approved in 1967. Under this plan several thousand miles of frequently travelled state highways were given a coating of asphalt over coal brick and were widened for at least two lanes of traffic. In the late 20th century, the plan was expanded to include all basic highways. Construction of a motorway (expressway) network was initiated in 1967 to build several thousand miles of modern roadways.

The Redia program

Spain's highways carry some of the heaviest traffic in the world. Traffic congestion is especially critical along the coasts. The autonomous regions of Spain were granted the authority to manage the roads within their boundaries, the national government reserving control over certain national network roads.

Railroads. Spain was only the ninth European nation to undertake the construction of railroads, beginning with the lines between Barcelona and Mataró (1848) and between Madrid and Aranjuez (1851). During the second half of the 19th century, the national railroad system was gradually expanded, with Madrid as its centre. The legal arrangement under which the Spanish railroads operated was one of indirect government ownership, whereby the state granted concessions to private companies or individuals for the construction and management of the railroads during a 99-year period, after which the railroads with all their installations and rolling stock would become the perpetual property of the state. This arrangement was radically changed in 1941 by the passage of the law that established

the Red Nacional de los Ferrocarriles Españoles (Renfe; National Network of Spanish Railroads). The Civil War of 1936–39 had done considerable damage to the railroads, and it was said that only the takeover of operations by the state could save them from economic disaster. The greater part of the rolling stock belonging to the railroads consisted of outmoded equipment. In 1964 a major long-term modernization plan was initiated. Outstanding among the new equipment introduced were the Talgo and the Talgo Pendular, light trains of Spanish design. The Renfe lines total several thousand miles of track, a substantial proportion of which is electrified. Madrid, Barcelona, and Seville have metropolitan subway networks.

Ports and maritime transportation. Spain's narrow and mountainous isthmus makes the country almost an island in terms of international trade, with the overwhelming majority of the country's imports and exports being carried by sea. Although the domestic transport of goods is done mainly by land, international trade is carried on by sea. Spain's merchant marine (not including the fishing fleet) was 13th in the world in total tonnage in 1980.

Spain's maritime traffic includes that of the fishing fleet, scheduled and unscheduled coastal shipping, the "Sovereignty Lines," and international lines that carry passengers and cargo. Before 1977, the "Sovereignty Lines" were national shipping concerns that provided coastal shipping, under government concessions, between the peninsula and the Balearic and Canary islands and the provinces of Ceuta and Melilla. The Transmediterranean Corporation had been granted an exclusive concession in 1922, but because of its need for heavy government subsidies despite the poor service given, the corporation was placed under government management and in 1977 became public property under the management of the National Institute of Industry. The most important international passenger and cargo lines are those that operate between Spain and Central and South America and the United States.

Spain's ports

Spain has many major ports that carry on a well-developed and coordinated regional maritime trade. The most important ports are those of Bilbao, Tarragona, Barcelona, Santa Cruz de Tenerife, Algeciras, Cartagena, Gijón, Las Palmas, Valencia, Huelva, Málaga, and Coruña. There are numerous smaller ports that carry on a large coastal trade in the peninsula and the islands. They are an important factor in Spain's socioeconomic structure, providing facilities for fishing, passenger transport, and aquatic sports.

The four autonomous ports of Barcelona, Bilbao, Huelva, and Valencia are run independently except for planning and finance. The other major ports are managed by autonomous government councils with more limited powers. The smaller ports are grouped into 20 administrative units. The coordination of the port system in Spain is the responsibility of the Dirección General de Puertos y Costas (General Administration of Ports and Coasts) of the Ministry of Public Works and Urbanism. Port facilities are financed by anchorage charges and government financing.

Air transport. The two national airlines of Spain, Iberia and Aviaco, are stock companies of which the National Institute of Industry holds the majority of shares. Several other airlines, which conduct unscheduled flights between cities, have tended in the late 20th century toward the creation of regional passenger and cargo services. Iberia, the company that best represents the country, employs many thousands of persons; its fleet of airplanes includes propeller planes used for small airports and short flights and jet aircraft.

Spain has many civil airports and military air bases that are open to civil aviation. International services are available at the majority of the civil airports and at the Reus military air base. Among the newest airports are the Foronda airport in Vitoria, serving the provinces of Navarra, Burgos, and Logroño, and the Queen Sofia airport in Tenerife-Sur. The Foronda airport functions as a regional airport, receiving all the air traffic of the region and channelling it to the others. The Madrid airport handles the greatest percentage of the total volume of passenger traffic; Palma de Mallorca is second, and Barcelona is third.

ADMINISTRATIVE AND SOCIAL CONDITIONS

Between 1938 and 1978, Spain had what was characterized as an open constitutional system in which a series of Fundamental Laws regulated all matters traditionally included in national constitutions. The Fundamental Laws were replaced by a new constitution that came into effect on December 29, 1978. The new document describes Spain's political system as a constitutional monarchy based on democracy, a respect for law, and a mercantile economy. The historical tension in Spain between a centralized government and regional autonomy was addressed by the constitution, which recognizes both the "indissoluble unity of the Spanish nation" and "the right to self-government of the nationalities and regions of which it is composed and solidarity among them all."

Government. *The Crown.* The king is the head of state and the highest representative of the government in international affairs. Among his domestic powers, he may ratify and promote new laws, summon or dissolve the legislature, call for general elections or referendums, propose candidates for the office of president of the government (prime minister), appoint or dismiss the president, and appoint or dismiss members of the Cabinet. The king is also the head of the armed forces; he has the power to declare war and to sign peace treaties.

The Cortes. The bicameral legislature of Spain, called the Cortes Generales, represents the Spanish people and guards their sovereignty. It is comprised of two houses—the Congress of Deputies, or Lower Chamber (Cámara Baja), and the Senate, or Upper Chamber (Cámara Alta). The members of the Congress are elected every four years by universal suffrage in provincial elections. The Senate is composed of four members from each of Spain's autonomous communities and insular provinces; they are also elected every four years.

Powers of the legislature

Both houses, the members of which have parliamentary inviolability and immunity, have the power of legislative initiative, which they share with the executive branch, the assemblies of the autonomous communities, and the people (a popular initiative requiring 500,000 signatures). The Congress, however, has the greatest legislative power. The period of time during which a bill initiated in the Congress can be modified by the Senate is limited to two months, or 20 days in case of emergency. Should the Congress not approve changes called for by the Senate, the bill, as written in the Congress, may be approved and promulgated by the king. Bills proposed by the Senate are sent to the Congress for the usual debate.

The Cortes must approve any international treaty, any law regarding personal rights, and any repeal or reform of any internal law. Either chamber may ask the executive branch for information or help and may demand that members of the executive branch attend their meetings and answer their questions.

The executive branch. The executive branch consists of the president, the vice presidents, and the heads of the various ministries. Through the exercise of its executive and regulatory powers, the executive branch directs international and national policies, civil and military administration, and the defense of the nation.

The presidency

A candidate for the presidency, usually put forth by the majority party in the Cortes, is proposed to the Cortes by the king. After receiving the approval of the Congress, he is named to the presidency by the king. The president and the members of his cabinet are responsible to the Congress and to the Supreme Court.

Members of the executive branch, though not necessarily part of the legislature, have access to meetings of the Cortes and its committees. The executive branch may ask Congress for a vote of confidence, which is granted by a simple majority vote. A motion of censure, requiring an absolute majority vote, results in the downfall of the government and the automatic appointment of the presidential candidate mentioned in the motion. The president may dissolve the Cortes and call for elections if a motion to censure his government is not pending.

Individual rights and liberties. The acknowledgement and protection of individual rights and liberties are as important to the definition of a state as a division of power

and the principle that all power comes from the people. The Spanish constitution of 1978 recognizes these rights and freedoms, incorporating them into the law and providing channels for their guarantee and protection. The rights recognized include those to equality before the law, to life, to religious and ideological freedom, to personal freedom, to privacy, to the inviolability of a person's home, to freedom of residence and of movement, and to freedom of expression and education. They also include the freedom to meet and participate in associations, strikes, and petitions and the right to own property and to attain a good quality of life.

During a state of emergency, the government may suspend certain rights and liberties for a period of 30 to 60 days in all or part of the country. During a state of siege, the period of suspension is to be determined by the Congress. This suspension of rights does not decrease the government's political or legal responsibility for acts committed by its agents during normal or abnormal circumstances.

Autonomous communities. In the late 1970s and early 1980s Spain was in the process of developing a new system of local government. Under Title VIII of the constitution of 1978, "bordering provinces with common historic, cultural, and economic characteristics" may group together in autonomous communities. Each of these communities is to be given the power to govern itself, but this power must not violate the interests of Spain as a whole. The constitution allows for variation within the autonomous communities in accordance with a particular region's historical relationship with the central government. The central government, however, regulates the amount of autonomy to be granted to any particular community.

The granting of autonomous status

Autonomous status is granted following negotiations between the central government and the future community. These negotiations are initiated by the administrations of the provinces that will eventually comprise the new community. Two-thirds of the municipalities within the provinces, representing the majority of the population concerned, must agree to seek autonomous status. During the transition period, all levels of administrative and legislative action are maintained by the central government. By 1984, autonomous status had been granted to 17 "autonomous communities."

The provinces. The old provincial unit of local government, first introduced into Spain in 1883, was defined by the constitution of 1978 as a grouping of municipalities for the purpose of carrying out central government programs. Within each province is a Provincial Delegation of 24 to 51 members; the membership of a delegation is elected from among that province's municipal officials.

The municipalities. A municipality is a unit of local government, the autonomy and local jurisdiction of which are guaranteed by the constitution of 1978. Each municipality is governed by a municipal council, the members of which are elected by universal, direct suffrage by the inhabitants of the municipality. The municipal council elects a mayor, who is president of the council and chief administrator of the municipality, as well as the representative of the central government.

Large cities, such as Madrid and Barcelona, have special municipal governments in which the administrative and fiscal systems are strengthened, thereby making possible the administration and execution of such matters as urban planning.

The political process. Democratic plurality and universal suffrage are guaranteed in the constitution of 1978. The mosaic of peoples that makes up Spain is the basis for decentralized political participation, or autonomy.

Political parties are described in the constitution as expressing political pluralism, contributing to the formation and manifestation of the will of the people, and serving as the fundamental instrument of political participation.

Four major political parties

There were four major political parties in Spain in the early 1980s. The Unión de Centro Democrático (Democratic Centre Union; UCD), led by Adolfo Suárez, was a moderate coalition that took the parliamentary majority in the Cortes in 1977 and 1979. The Partido Socialista Obrero Español (Socialist Workers Party of Spain; PSOE), led by Felipe González, was the successor of the Partido Socialista (Socialist Party), founded by Pablo Iglesias 100 years ago; after the elections of 1977, it absorbed the Partido Socialista Popular (Popular Socialist Party), led by Tierno Galván. The PSOE was the opposition party until 1982, upholding the concept of socialist reform within the democratic framework. In the 1982 national elections the PSOE won a solid majority in the Cortes Generales and 46 percent of the popular vote, becoming the party in power. The Partido Comunista de España (Communist Party of Spain; PCE), led by Santiago Carrillo, was founded in 1921. Since 1968, it has moved away from the Soviet Union and attached itself to the concept of Eurocommunism. The Coalición Democrática (Democratic Coalition; CD), led by Manuel Fraga Iribarne, is basically a successor of the Alianza Popular; it was the most important conservative force in the 1977 election, representing the traditional right.

In addition to the countrywide parties, there are local nationalist parties in the autonomous communities of the Basque country, Catalonia, and Andalusia.

Justice. Spanish judicial structures alone possess the faculty of passing judgment and applying laws. Justice comes from the people and is administered in the name of the king through judges and magistrates who together form the independent judiciary.

The Supreme Court, with jurisdiction over the entire country, is the final arbiter in every question of justice except for matters relating to the constitution, which are referred to the Constitutional Tribunal. The president of the Supreme Court is proposed by the Consejo General del Poder Judicial (General Council of Judicial Power) and named by the king. The Supreme Court is comprised of six courts: the civil court, the penal court, three courts for administrative litigation, and one court for social and labour issues.

The National High Court, also with jurisdiction over the entire nation, is supplemental to the Supreme Court and the Territorial High Courts. It consists of tribunals for criminal matters and for administrative litigation.

The Supreme Courts of the autonomous communities, in which the local High Courts are integrated, are the highest courts within their communities. Their jurisdiction is subordinate to that of the national Supreme Court.

The Territorial High Courts are located in the country's 15 juridical districts. Each high court has a criminal and a civil tribunal, as do each of the Provincial High Courts.

There are more than 500 petty courts (*juzgados*) throughout Spain. Although some of them have separate criminal and civil jurisdictions, most have powers in both areas of the law. District courts hear civil and criminal cases in one or more municipalities; they are also responsible for the Civil Registry, which keeps a record of the civil status of local citizens. There are also courts for labour disputes and for juveniles.

Armed forces. The military forces of Spain include the army, the navy, and the air force, with reservists in each branch. The king is the commander in chief of the military forces; the president, in conjunction with the National Defense Board, is the national leader in times of war. The military forces are part of the Ministry of Defense, which formulates and executes national military policy. The supreme command of all the military forces includes the chiefs of staff of the army, navy, and air force; it is responsible for the regular maintenance and care of the armed forces.

Military service is compulsory for all Spanish males, except for those exempt by law. The length of service is between 15 and 18 months.

The national police corps is structurally and organizationally a military body. It is not part of the military forces, however, but is responsible to the Ministry of the Interior. It is charged with the prevention and repression of criminal acts committed in cities and other important urban areas. The civil guard (Guardia Civil), founded in 1844, is one of the oldest and most typical of Spain's police forces. It is part of the military forces, but in times of peace it is also responsible to the Ministry of the Interior. It is responsible for enforcing regulations regarding

arms and explosives; for guarding Spain's ports, airports, coastline, frontiers, and prisons; and for maintaining civil order in times of natural disaster. (I.C.L.)

Education. The Spanish educational system, based on the General Law for Education (1970), is divided into the following units: preschool education; general basic education; *bachillerato* (see below); university education; professional training; and continuing education for adults. All these types of education are given in both public and private institutions.

The General Law for Education

The General Law for Education, which was directed toward a complete reform of the educational system, is being put into effect gradually and is expected to be fully in force by the 1990s. Associated reforms include free and obligatory basic general education for eight years; removal of rural–urban differentials in educational opportunity; equal access to the university; and university autonomy and the creation of new universities. Aid to students is also to be given in a broad variety of scholarships, loans, and other subsidies.

Preschool education. Preschool education comprises games, language activities, observation of nature, and similar activities. It is not compulsory and is divided into two stages—nursery schools for children between two and three years of age and for those between four and five.

General basic education. Designed for children between six and 13 years of age, general basic education is divided into two stages: in the first (for children between six and 10), the studies are of a general nature; in the second (for children from 11 to 13), subjects are divided into areas of knowledge and taught by specialized teachers. In both public and nonpublic institutions, general basic education is obligatory and without charge. Upon the successful completion of this program of studies, the pupils receive a diploma that allows them to go on to the *bachillerato* program. Those who do not qualify for that program receive a certificate for entrance into the first level of professional training.

The bachillerato. The *bachillerato* program of studies, which follows the general basic education program, covers a three-year period for pupils between 14 and 16. The curriculum includes required subjects and numerous electives. The title of *bachiller* enables the student to enter second-level professional schools or the pre-university course required before admission to the university proper.

The *bachiller* and entry to higher education

University and professional education. University education is preceded by an orientation course that lasts for one year and that is open to those who hold the *bachillerato* or who have completed their second-level professional studies. The course is planned and directed by the university but is taught in schools that offer the *bachillerato* or professional training.

University education proper may be undertaken in the universities or in advanced technical education schools. In the latter case, there are three cycles or programs of study: a first devoted to basic disciplines over a three-year period; a second, of specialization, which lasts for two years; and a third, of specialization and preparation for research and teaching.

Students who have completed their studies in a university or in the first cycle of an advanced technical school obtain the diploma that enables them to work in their field of competency. Those who complete studies through the second cycle receive the degree of licentiate (*licenciado*), engineer, or architect, allowing them to practice professionally or to continue their studies in the third cycle. The completion of studies in the third cycle, together with the writing and approval of a thesis, leads to the degree of doctor in the field of specialization.

In the late 20th century, Spain had many public universities, of which three were autonomous, and four private universities.

Other institutions. A variety of other educational institutions also exist in Spain. These include schools of fine arts, applied arts, and artistic crafts; the music conservatories; the schools of language; and the Institute for Teachers of Physical Education. "Labour universities" offer general, *bachillerato,* and technical education to the children of low-income workers. (E.L.O.M./I.C.L.)

Health and welfare. *Housing.* The administration of housing policy is carried out through the ministry for public works and town planning. Until 1976, government housing policy was aimed at the indiscriminate construction of large numbers of residential units to meet the needs of population growth. This policy led to much abuse and failed to take into account the economic capacity of the population.

Since 1976, government housing policy has been defined in programs that consider local housing needs and purchasing power. Legal measures have been taken to avoid abuses and to ensure that low-income housing is provided where needed. The government asserts pressure on private builders to ensure that public housing guidelines are followed.

Health and social security. Public health services are administered by the ministry of health and social security, the provincial delegations, and local administrative units. The government provides direct health services through health centres, general hospitals, surgical units, maternity centres, children's hospitals, and psychiatric units. In addition to the government health centres, there were several hundred private hospitals, church-run hospitals, Red Cross hospitals, and other health units.

Social security

The social security system protects everyone who works in any form of organized profession or trade, including commercial or industrial workers and those in special sectors such as agriculture, fishing, railroads, or mining. It does not include self-employed professionals.

Health assistance includes maternity and sickness benefits, hospital and medical cost assistance, and medicines that are free or provided at reduced cost. Financial assistance is provided for temporary disability, retirement, death, or unemployment and for economic protection of the family. Financial benefits and social services are provided by the National Institute of Social Security, the National Institute of Health, and the National Institute of Social Services. Social security is financed by workers' contributions, employer participation, and government contributions, the employers and the government providing the majority of the total cost.

Social conditions. The standard of living in Spain greatly increased in the middle and late 20th century, when the economy was centralized and wages were regulated by the Law of Collective Agreements of 1958. In that period, collective bargaining was based on compulsory unionization, with all managers and workers belonging to unions within the Trade Union Organization (Organización Sindical).

Since 1977, Spanish economic structures have greatly changed. The system of "vertical unionism" has been replaced by independent unions that now bear the brunt of salary negotiations, and the decentralization of the economy has begun. These structural economic changes, together with the world energy crisis and high rates of inflation and unemployment since the mid-1970s, have accentuated a sense of insecurity associated with the political changes. It was believed, however, that as democratization is consolidated the Spanish population will gain confidence and the economic situation will improve.

Weakening of social differences

Spain's social class structure has also undergone profound change since the mid-20th century. The great advances in industrialization and the increase in personal income and government-supplied social services produced a vertical growth in the country's social strata and an expansion of the so-called middle class. Differences between the rural and urban populations were reduced, further weakening the old class structure. Spanish society has invested a great deal in the creation and accumulation of human capital that, it is believed, will result in greater social equality. (I.C.L.)

CULTURAL LIFE

The cultural milieu. The Romanization of the greater part of the inhabitants of the Iberian Peninsula brought with it a diffusion of classical culture that was to influence permanently the cultural development of Spain as a nation. Specifically, the deep assimilation of the cultural ideals of Rome enabled them to survive the barbarian invasions that followed Rome's collapse.

During the ensuing centuries of Muslim domination and the entire period of the Reconquest (the expulsion of the Africans from Iberia), Spain continued to develop its unique culture by incorporating elements of both Islāmic–Oriental and Jewish civilizations. This amalgamation of cultures is, perhaps, the explanation for the development of the characteristic Spanish culture, which, while not removed from what is peculiarly European, does not correspond to it fully.

Serving as a meeting place for two distinct cultural worlds, the Islāmic–Oriental and the western European, Spain has performed an important task in the dissemination and extension of culture. The classic works of Greek antiquity were translated into Latin and later into Castilian; and a knowledge of both Muslim and Jewish culture was passed on to other European nations. The Castilian tongue, which was to become the national and official language, acquired vigour and maturity and soon became outstanding among all the languages of Europe. So strong did Spanish culture become that the term Golden Age—which, in Spain, comprises both the 16th and 17th centuries—can be applied not only to the political, literary, and artistic creations of the period but also to its outstanding achievements in theology, philosophy, law, and science.

Traditional Spanish culture, however, being deeply religious in character and specifically Roman Catholic in outlook, found itself farther and farther removed from the cultural life of the rest of Europe, as the latter (from the 18th century onward) assumed an increasingly secular quality. The critical nature of this stage in Spain's development is apparent in the conflict that arose during the 19th century between the nationalistic and the more European-oriented sectors of Spanish society. Spanish culture has also had an enormous effect on the New World.

In the prevailing Spanish viewpoint, Christian inspiration, a humanistic outlook that fosters appreciation of the worth of the individual, a certain eclecticism, and a striving toward universality of spirit are seen as characteristics of Spanish culture in every age. Contemporary Spain, it is felt, finds itself open to the most recent intellectual currents of the rest of Europe, and indeed further afield, but does not as a result intend to relinquish its own characteristic modes of thought and behaviour. It would seem that the mission of Spain continues to be that of creating peculiarly national forms of Western culture. (E.L.O.M.)

Architecture. Madrid and Barcelona are the principal centres of modern architecture in Spain. Major public buildings in Madrid have been designed by such architects as Francisco Javier Saez de Oiza, Alejandro de la Sota, José Antonio Corrales, Ramón Vázquez Molezún, and José Rafael Moneo. In Barcelona, the Catalonian Antonio Gaudí developed an expressive, sculptural style in numerous hotels, apartment houses, and churches in the late 19th and early 20th centuries. His unfinished church of the Sàgrada Familia, an idiosyncratic extrapolation of cathedral Gothic, remains a haunting feature of the city's skyline.

The major contemporary architects

Sculpture. Three great sculptors—Pablo Gargallo, Julio González, and Alberto Sánchez—mark the Spanish school of sculpture in the first half of the 20th century. Each developed a personal style that broke from tradition and paved the way for creativity. In the mid-20th century, José Planes, Cristino Mallo, Carlos Ferreira, and Jorge de Oteiza worked in traditional styles, while Angel Ferrant experimented with new forms. Pablo Serrano attained an integrated style in his search for a synthesis of abstract and representational forms.

The most universal figure of Spanish sculpture is Eduardo Chillida, who is noted for his metal, cement, wood, or alabaster figures. He has been followed by a new generation of abstract sculptors, including Miguel Berrocal, Martín Chirino, Francisco Barón, and José Luis Sánchez y Gabino, while minute representations of everyday life are sculptured by Julio and Francisco López and by Caulonga.

Painting. Spain also produced three major painters in the first half of the 20th century—Pablo Picasso, Joan Miró, and Salvador Dalí. Other talented painters of the period include Daniel Vázquez Díaz and Benjamín Palencia, as well as Francisco Arias, Augustín Redondela, and Manuel Mampaso of the Madrid school.

Since the opening in 1966 of the Museo Abstracto in Cuenca by Fernando Zobel, Gustavo Torner, and Marisa Rueda, the museum has been a centre for such new artists as José Ruiz de Rivera, Rafael Canogar, Manuel Millares, Luis Feito, and José Francés. Together with Antonio Saura, Manolo Mompó, José Guinovart Bertrán, José Guerrero Malagón, Pablo Palazuelo, Eusebio Sempere, and the Catalan group of Antonio Tapies, Modesto Cuixart, and Juan Ponç, they represent the best of contemporary Spanish art. (I.C.L.)

Music. The internationally significant generation of musicians to which Manuel de Falla, Joaquín Turina, Conrado del Campo, and Oscar Esplá belonged was succeeded by a generation of composers born at the turn of the 20th century. They include Federico Mompou, whose work follows the French impressionistic style; and Ernesto Halffter, often considered to be the truest of the disciples of Falla and who, like his master, has sought to combine both aristocratic and popular elements in his music. Composers whose work reveals a tendency to greater innovation include Xavier Montsalvage and Joaquín Homs. The same tendency is even more clearly expressed in the works of Cristóbal Halffter, Luis de Pablo, and Carmelo Bernaola, three figures of international renown in the world of avant-garde music. Other new composers in this field are Tomás Marco, Antón Garcia Abril, Manuel Castillo, and Ramón Barce.

Innovative composers

Among instrumentalists of major reputation are the guitarists Andrés Segovia, Narciso Yepes, and Regino Sainz de la Maza; the cellist Pedro Corostola; the violinists León Ara, Víctor Martín, and Gonzálo Comellas; the harpist Nicanor Zabaleta; and the pianists Rafael Orozco and Eduardo del Pueyo.

Spain's outstanding conductors include Odón Alonso, Antoni Ros Marbá, Enrique García Asensio, Jesús López Cobos, and Rafel Frübeck de Burgos. Major singers are Victoria de los Angeles, Montserrat Caballé, Teresa Berganza, Pilar Lorengar, Alfredo Kraus, and Plácido Domingo. Major orchestras are the National Orchestra, the Symphonic Orchestra of Spanish Radio and Television, and the Camerata of Madrid.

Literature. The illustrious traditions of Spanish literature continue to influence contemporary writers, and the *Don Quixote* of Cervantes has been characterized as the 17th-century prototype of the modern Spanish novel.

The Civil War (1936–39) represented a watershed in Spanish arts as well as politics, driving many artists in disparate fields into exile while substantially altering the focus for those who remained or emerged subsequently. Among its effects was the shift in predominance from poetry to the novel, though the Generation of 1927 movement in poetry, especially through such preeminent figures as Vicente Aleixandre (awarded the Nobel Prize for Literature in 1977) and Dámaso Alonso, continued to influence a host of postwar poets, including the great popular poet Miguel Hernández (who died in jail in 1940) and Luis Cernuda, Rafael Alberti, Luis Rosales, Salvador Espriu, Gabriel Celaya, Blas de Otero, and José Hierro. The best known of 20th-century Spanish poets outside their own country, however, remained the lyric poet Juan Ramón Jiménez, who was awarded the Nobel Prize for Literature in 1956 and died in exile in 1958, and Federico García Lorca, who is perhaps even more renowned as a dramatist. In both poetry and drama Lorca echoed an earlier Spain. His poetry is alive with the labyrinthine and sensuous imagery of a Moorish Spain of several centuries past. The few plays he wrote before he was murdered during the Civil War are both richly poetic and emotionally elemental in their actions, harkening back to the works of Lope de Vega and Pedro Calderón de la Barca, which helped the Spanish stage of the 17th-century Golden Age rival that of Elizabethan England in vigour and popular appeal.

Major poets

Major 20th-century novelists include Ramón Pérez de Ayala, who touched his philosophical themes with an Asturian humour; Gabriel Miró, who was occupied with more poetic themes; and Ramón José Sender, who returned to greater realism and social commentary; as well as Max Aub and Francisco Ayala. During the early 1940s the postwar novel began to emerge in the work of such

writers as Rafael Sánchez Ferlosio and Carmen Martín Gaite, Miguel Delibes, Carmen Conde, Rosa Chancel, and Camilo José Cela and Carmen Laforet. They influenced a younger group including Jesús Fernández Santos, Juan Goytisolo, Luis Goytisolo-Gay, and Juan Marsé. Criticism, previously led by José Ortega y Gasset, champion of a pure, depersonalized art, passed to such younger observers as José Luis Cano and José María Castellet.

(E.L.O.M./I.C.L.)

Theatre. In the post-World War II era, Spanish theatre suffered from a scarcity of materials, an almost total lack of quality works and of thematic imagination, and a disregard for reaching large numbers of people. In response to this situation, the Ministry of Culture created the National Drama Centre in 1978 to bring major national and foreign works to the Spanish stage.

The Independent Theatre

Most interesting in Spanish theatre is the Independent Theatre (Teatro Independiente), which includes amateur and professional groups. Some, such as Tábano and the Teatre Lliure, are well known throughout the country, while others, such as the Cuadra de Sevilla and Els Joglars, have acquired an international reputation. Also of interest are the theatre festivals held in Almagro, Mérida, and Santander. There is a *zarzuela* (comic opera) season in Madrid, which is also the home of the National Ballet and the Classical Ballet.

Motion pictures. Motion pictures are very popular in Spain. In the late 20th century, the Spanish motion-picture industry produced many full-length films—of which a large proportion were joint ventures with Italian, Mexican, French, German, Venezuelan, or Argentinian companies—and short films. Only a small proportion of the films shown are Spanish productions, however. Spain's major motion-picture directors have included Luis Buñuel, who was in exile during the Franco regime, and Luis García Berlanga, Juan Antonio Bardem, and Carlos Saura.

Film festivals are held throughout Spain. Those held in San Sebastián, Barcelona, and Valladolid are of a general nature, while that of Gijón features children's films, those of Huesca and Bilbao feature documentaries and shorts, and that of Huelva features Iberoamerican films. (I.C.L.)

Folklore. *The fiesta.* The form of popular tradition that remains most intensely alive in the Spain of today is that of the fiesta, or popular festival, which never fails to have a certain amount of religious significance even though it may be essentially nonreligious in character. After having been preserved for centuries in a popular, spontaneous form, the festivals suffered from the crisis of traditional values of the 1960s and '70s. A revival of the festivals seemed to have occurred by the late 20th century, however. Each locality, no matter how small, has its own festival, celebrated in honour of a saint for whom the town feels a particular devotion. The list of local festivals is, as a result, almost interminable, but three outstanding ones are the Fallas of Valencia, the April fair of Seville, and the festivities honouring San Fermín in Pamplona. Although the festivals are found all over Spain, it is interesting to note that the coastal regions, despite the fact that they are more exposed to foreign influences, are precisely those that have best preserved their typical festivals.

Major local festivals

The bullfight. The bullfight, too, may be considered something of a hybrid celebration, since it possesses certain characteristics of a sport as well as those of a popular festival. It is customarily regarded, however, as the most typical of Spanish festivals and as the Spanish national fiesta par excellence, even though bullfighting is found in other countries, particularly those of Hispanic America. The tradition of bullfighting can be traced back to ancient times, but the present style of fighting the bull on foot dates back only to the 18th century.

Other aspects of traditional life. There are seemingly innumerable other forms of traditional activity, and many objects still used in daily living also have their roots deep in the past. Some change is taking place, but other activities continue to exist as they have in the past, notably in the remote rural areas. Spanish houses, for example, reflecting as they do both the varying regional climates and the exigencies of a preindustrial society, still continue to be constructed more or less as they were many years ago. On the other hand, the traditional or typical regional garb has undergone a slow evolution as to style, although certain costumes are still considered characteristic of the regions in which they originated.

Traditional arts and crafts, grouped together under their official name of *artesanía* (handicrafts), have become the object of government protection, designed to insure their continued existence in the face of the increasing mechanization of industry.

The academies and related bodies. Spanish cultural institutions have deep and rich roots in the nation's past. The oldest of the Spanish academies is the Royal Academy of Language, usually called the Royal Spanish Academy, which was established by King Philip V in 1713. Its primary purpose is "to cultivate and to set standards for the purity and elegance of the Castilian tongue." An essential aspect of this task involves the publication by the Academy of a Dictionary of the Language and other works, as well as the granting of prizes. Spain also possesses the internationally known Royal Academy of History; the Royal Academy of Fine Arts of San Fernando; the Royal Academy of Exact, Physical and National Sciences; the Royal Academy of Moral and Political Sciences; and the Royal National Academy of Medicine. All the academies form part of the Institute of Spain, founded in 1938 as a coordinating organization.

The Royal Spanish Academy

The Council for Scientific Research, created in 1939, directs research activities of a few hundred scientific centres located throughout the entire nation. The Institute of Iberoamerican Cooperation maintains cultural, economic, and linguistic ties with Latin-American countries. The institute maintains cultural exchange departments, possesses a commissariat in charge of expositions and also the important Hispanic Library, the collection of which numbers about 500,000 volumes. There are many institutes of Hispanic culture located in many countries of North and South America. These collaborate with the parent institute in Spain, which has several affiliated Hispanic-American cultural associations within the country itself.

The famous athenaeums (which carry on varied cultural activities) are located in 20 different Spanish cities. Founded in the 19th century as private political clubs, they have since been gradually transformed into groups influencing the artistic and literary life of their home city. The Casas de Cultura, through lectures, expositions, concerts, and libraries, perform analogous functions in smaller towns.

Museums. The great national art gallery is the world-famous Prado in Madrid. Installed in a magnificent building, it holds a unique place among the great museums of the world. Its collections and galleries have been enlarged in recent years by the acquisition of many Spanish paintings of the 19th century.

Other important museums include the Museo de la Real Academia de Bellas Artes de San Fernando and the Museo Arqueológico Nacional in Madrid, the Museo de Arte de Cataluña in Barcelona, and those of fine arts in Bilbao and Seville. Collections devoted to specific aspects of the art of Spain are found in other museums: thus, religious sculpture is housed in the Museo Nacional de Escultura Policromada in Valladolid; and the art of El Greco is to be found in his museum and house in Toledo.

The Army and Naval Museums in Madrid are interesting from the historical viewpoint, as is the Maritime Museum in the royal arsenals of Barcelona. In addition to numerous provincial and municipal museums, there are others belonging to the cathedrals, dioceses, and parishes. The various museums of the National Patrimony, housing collections that form part of the former royal patrimony, are also very significant. Finally, the country is rich in private museums, including the Cerralbo in Madrid and the Marés in Barcelona. New museums include the Sefardic Museum in Toledo; the Museum of Costume and the Picasso Museum in Barcelona; and the Museum of Abstract Art in Cuenca.

It is notable, however, that in a country that possesses great artistic and historic treasures and in which art, particularly religious art, is alive and active *in situ,* the activity of museums of necessity plays only a secondary role.

Libraries and archives. The most important of Spain's famous historical libraries is that of El Escorial, which served as a model for other European libraries until the 19th century. The Royal Library, established in the 18th century, was in the following century transformed into the National Library of Madrid. It has valuable collections that originally belonged to private libraries or to monasteries that were confiscated by the government. The Private Royal Library, or Palace Library, the libraries belonging to the royal academies, that of the Higher Council of Scientific Investigation, and the public libraries of the provinces form a broad library network throughout the entire country.

The Royal Library

In addition to a great number of smaller archives—regional, local, special, ecclesiastical, and private—Spain has four great general archives in which are assembled the historic documents of the nation. They are: the National Historical Archives, in Madrid; the General Archives of Simancas; the General Archives of the Indies, in Seville (which contains documents relating to the government of the Spanish overseas empire); and that of the Crown of Aragon (of supreme importance for the study of medieval history), in Barcelona.

Other cultural institutions. The National Orchestra, which was founded in the period immediately following the Civil War of 1936–39, has devoted itself chiefly to the promotion of interest in symphonic music. The Symphony Orchestra of Spanish Radio and Television, which gave its first concert in 1965, has, in its shorter existence, been able to reach a wide audience through the use of the communications media. Both of these orchestras are located in Madrid, as are two others with a long and brilliant history: the Symphony and the Philharmonic. Outside the capital, the principal Spanish orchestra is the municipally supported City Orchestra of Barcelona.

Spain has only one theatre for opera that has a regular season for its performances, the Lyceum Theatre in Barcelona, a private enterprise. The Festival of the Opera, however, which, in some respects, corresponds to a short opera season, is held every year in Madrid. Similar festivals, also of brief duration, are held in several of the provincial capitals.

The influence of private foundations

The March Foundation (founded 1955) is outstanding among foundations under private auspices. Its cultural activities include the giving of prizes, grants for research, scholarships for study in Spain or abroad, and annual contributions to the study of literature and the fine arts, as well as subsidies to institutions and enterprises interested in culture. It also publishes books. Other private foundations are the Barrié de la Maza, Rosillo, Urquijo, and Foessa foundations.

The number of literary prizes established has increased notably in recent years; the national prizes for literature remain, however, as the oldest and most distinguished. Other important prizes include the "Nadal" and the "Planeta" for the novel; the "Adonais" for poetry; and the "Cervantes" for foreign authors who write in Spanish.

(E.L.O.M./I.C.L.)

The press. The Spanish press was of fundamental importance to the transition from Franco's regime to democracy in the late 1970s. The repressive aspects of the Press Law of 1966 have since been abolished, and the constitution of 1978 guarantees freedom of the press within the ordinary limits of honour, privacy, self-respect, and the protection of children. Laws further defining press freedom were in the process of promulgation in the early 1980s.

The Spanish press is economically successful. Circulation has increased, and new types of newspapers and periodicals have appeared. Major newspapers in the late 20th century included *La Vanguardia Española* of Barcelona and *El País* and *A.B.C.* in Madrid.

Radio and television broadcasting. The first radio broadcasts made in Spain were carried out by an experimental station in Madrid in 1923. In the following year, the first two commercial radio stations were installed in Barcelona and Madrid. They were the country's only radio stations until the start of the Civil War in 1936. In 1937, a station called Radio Nacional de España (National Radio of Spain) began broadcasting from Salamanca, and after the Civil War had ended in 1939, a national radio broadcasting service was established, centred on the group of transmitters located in Arganda, in the province of Madrid. In 1951, when the Ministry of Information and Tourism was created, the government-operated radio and television stations were placed under its direction.

In 1960 the first station of Radio Peninsular devoted entirely to the broadcasting of music was set up, and stations of a similar type were later established in several of the provincial capitals. The first FM transmitter was installed in Madrid in 1957 by Radio Nacional de España, to be followed by several others of the same type.

The broadcasting of radio and television was restructured in the late 1970s and early '80s. A government plan was approved in 1978 to distribute new radio frequencies according to the provisions of the Geneva Conference of 1975. Another government plan included, among other matters, the broadcasting by both public and commercial stations of educational programs not supported by advertising. A law promulgated in 1980 redefined government radio and television broadcasting as a vehicle to disseminate information and educational and national and regional cultural programming, to promote public participation in the political process, to form public opinion, and to aid in the development of true and effective liberty and equality.

Radio and television broadcasting are regulated by Radiotelevisión Española (R.T.V.E.), a government body subject to civil law. R.T.V.E. is composed of an administrative council, made up of 12 members of the Cortes, and three advisory councils. The director general of R.T.V.E. is named by the government on the advice of the administrative council; he is charged with carrying out the directives of R.T.V.E. and with naming a territorial delegate in each of the autonomous communities.

Spanish television is transmitted on two channels, one of which reaches the majority of the country's population. Most of the programming is broadcast in colour. Television programming is financed by government grants, commercial advertising, and revenue from program sales.

Radio Nacional de España broadcasts three basic programs. The first offers information and entertainment. The second program is devoted to classical music, and the third to culture and education. There are also shortwave broadcasts to other countries in Spanish and foreign languages. Radio Nacional is totally supported by government grants and accepts no advertising.

Radio Cadena Española (Spanish Radio Network; RCE) is composed of the privately owned stations that were in operation before 1978. There are several other private radio networks, including that of the Roman Catholic Church. For statistical data, see the "Britannica World Data" section in the current *Britannica Book of the Year.*

History

PRE-ROMAN SPAIN

Prehistory. The earliest human fossils found in the Iberian Peninsula are those of Neanderthaloid men, dating from about 200,000 BC, whose remains have been discovered at Gibraltar, Játiva (Valencia), and Bañolas (Gerona). But utensils found in Algeciras, Madrid, the Provincia de Soria, Lisbon, and elsewhere point to the existence of even earlier habitation. This indirect evidence suggests that the peninsula was inhabited as early as 500,000 BC. The most important sites are the camps of elephant hunters found at Madrid, Torralba, and Ambrona (Soria), where many animal bones have been discovered. The Neanderthaloids and other pre-*sapiens* disappeared with the last glaciation, when Old Stone Age (Paleolithic) cultures advanced in the peninsula.

The Paleolithic Period

One of the most remarkable achievements of the Late Paleolithic was in the realm of art. The famous Paleolithic cave paintings found at such sites as Pindal, Peña de Candamo, Castillo, El Pendo, Pasiega, Ribadesella, Altamira, and elsewhere in the peninsula represent a broad historical period extending roughly from 25,000 to 10,000 BC. The animals depicted in the paintings are cold-weather vari-

eties—bison, bulls, horses, goats, wild boars, bears, lions, mammoths, reindeer, rabbits, and seals.

The transition to the Neolithic Period coincides with a climatic change the full effects of which came about gradually (beginning around 10,000 BC) and drove the food animals northward. The archaeological deposit at Muge, near Lisbon, undoubtedly belongs to the beginnings of this age, which, in its early stages, is sometimes called Mesolithic. Deposits of great quantities of ocean and river shells, Crustacea, and the remains of birds, fish, oxen, and swine attest to the diet of these early Neolithic men. In Santimamiñe (Vizcaya), a similar economic pattern is found. There are also two important cave sites near Valencia: at Las Cuevas del Oro and at Dos Aguas. At the height of the Neolithic Period, approximately between 4000 and 3000 BC, rock painting flourished in the region of the Levantina, appearing in the open air, sheltered by rock overhangs. Many isolated animal figures are depicted, but human beings are also seen, comprising narrative scenes of hunting, herding, dancing, fighting, and even honey gathering from a hive located on top of a rock. The figures are small and exhibit considerable movement and vitality. The men are shown using bows, and the women usually appear wearing only a long, bell-shaped skirt. The Neolithic Period in western Europe, however, lagged far behind that of the eastern Mediterranean. In the West, cave dwelling persisted, and although agriculture and husbandry were known, their practice was minimal. Settlements were quite rudimentary, being no more than simple groupings of shelters. This was an exclusively coastal culture and did not extend inland.

The age of metals

The Neolithic came to an abrupt end around 2500 BC with the beginning of the use of metals in the south. It was at this time that the first large population centres were formed, along with monumental burial sites; it was at this time also that agriculture, cattle raising, mining, and metallurgy (beginning with copper, then bronze) underwent a period of extraordinary development. It appears that these arts may have been brought from the Aegean, not, however, as the result of an invasion but apparently as the result of a sporadic penetration of "technicians." Concurrently, maritime trade flourished, thereby explaining the presence of artifacts from all over the Mediterranean, among them ivory, turquoise, obsidian, and amber (perhaps from the Baltic). The new economy brought forth a new social organization, founded in a type of monarchy, the support of which came from an aristocracy based on wealth, who lorded it over a more or less enslaved population. This culture, the Almería, ranged over the south of the peninsula, from Algarve to Cabo de la Nao and from the Strait of Gibraltar to the Tagus River, later extending up the coast and into the Meseta Central. The high point in the development of this culture was reached between 3000 and 2000 BC. The best known centres were those in the southeast (Almizaraque and Los Millares) and in the southwest (Vilanova de San Pedro and Zambujal). Settlements with round or oval houses were built on fortified hilltops, indicating a life of constant danger. In Los Millares, the people of the Almería culture raised wheat, barley, millet, rye, lentils, chick-peas, grapes, and olives; as domestic animals they had sheep, swine, oxen, horses, and dogs. Among their usable plants were linen and cotton for fabrics and esparto for baskets, shoe soles, ropes, and nets. At the same time, copper was being used. Contemporary with Los Millares was the mining centre at Almizaraque, where copper and silver were processed, as evidenced by crucibles and slag heaps found next to the mines. This was the culture that built large megalithic burial vaults with corbel-arched ceilings. These tombs are entered from the outside by a tunnel and are covered by a cone-shaped mound. Tombs of this type are found at El Romeral (Antequera), Matarrubilla (Seville), and Soto (Huelva), and there are partial remains at Alcalar (Algarve). In contrast, the dolmen at Viera (Antequera) consists of a rectangular chamber, and the famous "cave" at Menga (Antequera) is slightly oval. The latter is the most remarkable monument of its kind. In its construction, 31 enormous stone slabs were used, weighing a total of 1,600 tons. The flat roof was supported by three thick pillars. The dolmen culture spread through the rest of the peninsula and through Europe, giving rise to distinct dolmenic "provinces" in the central and Atlantic zones. These cultures also reached Italy, Corsica, Sardinia, and North Africa. Accompanying this expansion was an excellent ceramics industry characterized by campaniform, or bell-shaped, utensils, incised with geometric designs.

El Argar culture

Toward the beginning of the 2nd millennium, in the same region (Almería), El Argar culture appeared, in which the metallurgy of bronze, silver, and gold notably flourished. This industry was no longer in the hands of foreigners but constituted instead a native enterprise that produced for domestic consumption (weapons, jewelry, utensils) as well as for trade abroad. The result was a lively trade with other centres in the eastern Mediterranean. But there were substantial differences from previous cultures: dwellings had a rectangular floor plan, and the dead were buried individually in baskets or large urns beneath the floors of the houses, not in collective vaults, as in the previous epoch. Villages continued to be built on hilltops and were well fortified. Governed by kinglets or princes who were supported by an aristocracy, this culture, which at first was limited to the southeast, spread throughout the southern, the central, and the Levantina regions and reached the Balearic Islands. Its apogee came roughly between 1700 and 1000 BC. It was around this time that the kingdom of Tartessus appeared, along with the first Phoenician and Greek colonies.

Tartessus. Near the beginning of the 1st millennium, Spain entered written history. Passages in the Bible and in Greek and Latin texts refer to Tartessus (biblical Tarshish), an important centre of trade, especially in tin. The Tartessians were by this time sailing the Atlantic, southward along the African coast as well as northward in search of tin in the northeastern part of the peninsula and in the Cassiterides Islands (Scilly Islands). With this supply of tin and with the copper found around Huelva, a strong bronze industry developed that was mentioned by the Greeks. The Tartessians had a writing system, and while inscriptions have survived, they have not yet been translated. They also had a literature, but nothing of it remains. Their government was a hereditary monarchy, and while the names of several of the Tartessian kings are known, only one, Arganthonius, has historical status.

Arganthonius

Arganthonius, who reputedly lived 120 years, died in the middle of the 6th century BC, shortly before the Battle of Aleria (Alalia *c.* 540), whereby the Carthaginians gained control of the Mediterranean. His friendship with the Greeks and with the Phocians, to whom he loaned money to fortify their city against the Persians, brought reprisals against Tartessus by the Carthaginians. The exact location of Tartessus has yet to be established, and even the ancient writers themselves were in doubt about it. All that can be said at present is that it was undoubtedly situated along the coast between Huelva and the Strait of Gibraltar, perhaps in the direction of the mouth of the Guadalquivir or the Guadalete rivers.

Phoenician colonization. Textual sources reveal that Phoenicians from Tyre (Sūr, Lebanon) arrived on the peninsula shortly before 1100 BC, the traditional date of the founding of Gadir (Cádiz). This date, established by the Greek philosopher Poseidonius in Cádiz itself, is historically acceptable, though some historians place the Phoenician landing in the 8th century. The Phoenicians were attracted by the thriving trade in metals at Tartessus, the flourishing agriculture of Andalusia, and the rich fishing business of the coast that stimulated such allied industries as preserving, salt evaporation, and the extraction of purple dye from shellfish.

The Phoenician colonies founded after Gadir were Baria (Villaricos), Abdera (Adra), Sexi (Almuñécar), and Malaca (Málaga), all of which minted their own coins, although not until relatively late. Many processing and preserving plants for fish were established along the entire southern coast, and scattered agricultural centres were established inland. Ibiza was founded as a fishing colony by the Carthaginians in 654, though the dates of the founding of the rest of the colonies are not known. There is no definite information about Cádiz from before the 6th or 5th centuries. Hoards of jewelry and a human-shaped

sarcophagus in the Phoenician style have been found in graves there, but nothing remains of the great Temple of Melqart (Hercules), and many other monuments have been lost to the destructive action of the sea along the Cádiz coast. At Baria many artifacts have been found, along with great numbers of painted ostrich eggs. Ibiza's many underground chambers at Puig des Molins have yielded terra-cotta objects, necklaces of glass paste beads, and Greek vases. Important statues of Tanit have been found in the temple at Cuyram, and terra-cottas of a very primitive type have been uncovered at Isla Plana. But the most spectacular finds have been made at the necropolis at Sexi, where Egyptian alabaster amphorae, dating from the 10th century, have been found in tombs from around 700 BC. Inland, engraved combs have been found in tombs at Carmona and Osuna; also important are the treasury found at La Aliseda (Cáceres) and at Sines and the many series of bronze pitchers found all over the western part of the peninsula, from the Strait of Gibraltar to the interior of Castilla (Castile). All the artifacts date from the 7th century BC.

After the fall of Tyre to the Assyrians, the Phoenician colonies were taken over or protected by the powerful Phoenician daughter city of Carthage in North Africa. The Carthaginians quickly turned the resources of the peninsula to the task of creating a staging area for attacks against Rome. Hamilcar landed in Spain in 237, taking possession of the entire south and southeast of the peninsula, where he founded Akra Leuke (Alicante). Shortly thereafter, Hasdrubal founded Carthago Nova (Cartagena), and Hannibal readied his attack against Rome after assuring the subjugation of the native peoples of both mesetas. In 219 Hannibal's successful siege of Saguntum (Sagunto), an ally of the Romans, precipitated the Second Punic War. The Carthaginian conquest of Spain provided the Carthaginians not only with the silver necessary to finance the wars but also with a nearly inexhaustible supply of mercenary soldiers. Hannibal crossed the Alps in 218, attacking the Romans on their home ground. But even as Hannibal ravaged the Italian peninsula, the Romans attacked the Carthaginians in Spain. In 218 the Roman general Publius Scipio landed at Emporia and achieved a temporary success. In 210, Scipio Africanus, the son and namesake of Publius Scipio, took command and won a series of brilliant victories. Scipio first took Tarraco, then Carthago Nova (209), and after a victory at Ilipa (Alcalá del Río, near Seville), he overran Cádiz (206), marking the end of Carthaginian domination in Spain.

The Punic Wars

Greek colonization. Thanks to the greater number of written accounts, much more is known about the Greek colonization. In the 9th and 8th centuries, Greeks were sailing the coasts of the peninsula, and their explorations paved the way for the subsequent arrival of the Phocians. According to the Greek historian Herodotus, the first Greek to reach Tartessus was Colaeus of Samos in the mid-7th century. As early as the 7th century, the Phocians founded Hemeroscopium (near Denia) and Mainake (near Málaga). These colonies maintained close contact with the Tartessians, whose king, Arganthonius, protected and aided them. It was probably also at this time, or shortly thereafter, that Meidakritos, Euthymenes, and Euphemus of Caria sailed along the Spanish coast. Toward 600 BC, the Phocians founded the city of Massilia (Marseille), opening the way for new settlements in the northeast. Emporiae (Ampurias) appeared at this time, and the Rhodian colony of Rhodae (Rosas) was populated by Phocians. Both cities minted their own coins, beginning in the 5th century. The Battle of Alalia (*c.* 540) brought not only the fall of the kingdom of Tartessus but also the collapse of the Greeks' two southernmost colonies, Mainake and Hemeroscopium. Later, with the arrival of Greeks from Sicily and Magna Graecia (southern Italy), contacts with the northeastern coast of Spain were re-established, and there followed the founding of Alonae (Benidorm?) and other trading centres. Of these colonies, only one, Emporiae, has been identified and excavated. Artifacts found there date from the end of the 7th century, and among them are abundant ceramics, representing all Greek styles, along with terra-cottas, figured bronzes, and coins. The most outstanding piece of sculpture is a large marble statue of Asclepius, dating from the 4th century. Few Greek inscriptions, however, have been found. Only the above-mentioned places are referred to as colonies, but textual evidence reveals a considerable number of Greek place names, all of them along the coast, which must refer to trading posts or even smaller population centres. Active trading flooded the Spanish coasts with Greek products. From the Pyrenees to the mouth of the Tagus, great numbers of Greek ceramics have been and continue to be discovered, ranging in date from the 7th century to the Hellenistic era. Many bronze statues, some of them quite large and dating as far back as the 6th century, have also been found, as well as two ancient Greek helmets, also made of bronze. Finally, coins from throughout the Greek world, from Massilia to the Crimea, have also been discovered. These coins span the entire period from the earliest mintings up until the Alexandrine era, with those from Greece, Sicily, and southern Italy in particular abundance.

The Iberians. The broad designation of Iberian culture is generally applied to the civilization that grew up in the south and east of the peninsula during the five or six centuries prior to the birth of Christ. The designation Iberian is derived from the usage of contemporary classical writers. From Neolithic times forward, there were no cultural changes that necessarily imply any change in the ethnic composition of the peninsula. The only important outside influences that brought about any change are those from the East, beginning with the Punic and, later, the Greek settlers. It may be assumed, therefore, that the Tartessians and other peoples who inhabited the Mediterranean coast of Spain were descended from the Neolithic and Chalcolithic peoples of the peninsula, whose direct ancestors may have been closely linked to prehistoric peoples who inhabited "white Africa" from the Red Sea to the Atlantic and the Canary Islands. During the 1st millennium, the ancient Iberians, the creators of the great cultural centre of Tartessus, were subject to the pressure of the Greek and Phoenician–Carthaginian colonization. These maritime influences gave rise in later years to a singular and progressive culture that may quite correctly be called Iberian.

Origins of the Iberians

Iron was in widespread use among the Iberians, who developed a complex economy based on agriculture, stock breeding, fishing, industry (mining, metallurgy, weapons, jewelry, preservatives, textiles, ceramics, thrown pottery), and including general commerce, both domestic and foreign. Cities grew apace, and almost all of the Iberian cities mentioned by ancient writers were highly developed before the Roman conquest. Houses were rectangular in shape. Cremation was universally practiced, and cemeteries often contain rich furnishings, such as Greek vessels, Punic artifacts, damascene weapons, and native pottery. Political organization was monarchical, with a king, princes, and dukes assisted by a council of elders. But there were also popular assemblies in times of stress. In general, these kings were politically independent, although sometimes a single king controlled many cities in military alliance. The Iberians possessed written laws, apparently in verse form, and were highly accomplished in several of the arts, including music and the dance.

Cities were built on well-defended hillocks; individual houses, with straw roofs, were made from rubblework and molded adobe bricks. To judge from the large stone cellars that have been found in Andalusia—in Tutugi (Galera, Granada), Tugia (Toya, Granada), Basti (Baza, Jaén), Almedinilla, Iponuba (Baena, Córdoba)—there must have been public buildings of monumental dimensions, although nothing remains of them. Stone sculpture shows a strong early Greek influence, attested to by the sphinxes found at Agost and El Salobral, the androcephalic bull from Balazote (Albacete), and griffins like the one found at Redován. Temples, particularly those at Albacete, have yielded hundreds of large human figurines, both male and female, in both standing and sitting positions. In general, these are votive statues, used to ward off evil. Among them, the most important are several heads, parts of full-length figures, and the "Gran Dama Oferente" from the Cerro de los Santos. Above all, there is the famous bust of

The "Lady of Elche"

the "Lady of Elche," apparently of late date, perhaps from the 1st century BC, adorned in gold.

It is known that large-scale mural painting was practiced, depicting scenes of hunting, fishing, warfare, and civil ceremonies, but only scant indications of its existence have survived. Some idea of what it was like may be seen in the painted ceramics from Azaila, Numantia, and Liria. This thrown pottery, of excellent workmanship and exhibiting a surprising variety of forms, first appeared with decorations consisting of simple straight-line and circle designs and geometric motifs. But in its final period, corresponding with the wars of resistance against the Roman conquest in the 2nd and 1st centuries BC, this ceramic art was characterized by the depiction of narrative scenes embracing a great variety of decorative motifs, ranging from war and large game hunting to domestic or popular scenes, such as processions, dances, and the earliest known bullfights. These scenes were rendered in a somewhat childlike linear style but with considerable narrative strength. Iberian ceramics were exported to southern France, Liguria, central Italy, Sicily, and North Africa in the 1st century.

Iberian silverwork and goldwork was exceptionally rich; silverwork predominated in the fashioning of vases, paterae (earthenware drinking saucers), and jewelry. Decorative patterns were inlaid on weapons, dishes, and the like, and at times Iberian inscriptions were added. The most important known Iberian treasures are those of Tivissa (Tarragona), which include a beautiful set of dishes, its various pieces nielloed, or engraved, with religious themes. Other Iberian treasures have been found at Abengibre, Salvacañete, Mogón, and Santisteban. Outstanding pieces of goldwork were found in the treasure of Santiago de la Espada (Jaén) and are similar to the jewelry worn by the "Lady of Elche."

The Iberian language

The Iberians developed early a system of writing. The Iberian alphabet has an older (6th–5th century) Western phase called Tartessian and a derived Eastern phase called Iberian. There are both Greek- and Phoenician-derived letter forms in the 28-character alphabet, most of which is of unknown origin. Many inscriptions exist, but few words—except place-names on the coinage, struck by many cities in the 3rd century—can be read. No bilingual inscriptions have been found. The Iberians retained their writing system until the Roman conquest, when the Latin alphabet came into use.

The Celts. While the Iberian culture of the south and the east flourished under the influence of colonizers from the eastern Mediterranean, in the central and western parts of the peninsula, the cultural level was still quite primitive and rooted in the Copper and Bronze ages. But the 9th through the 8th centuries witnessed the gradual and peaceful penetration of the peninsula by peoples from across the Pyrenees from central Europe. These peoples, named Celts by Greek and Roman writers, were primarily herdsmen and agriculturalists—and they were able to smelt iron. In spite of constant reinforcement from new migrations, these people were often absorbed into the native population. This gave rise in a mixed people known as the Celtiberians. In other cases, the native cultural identity was erased almost in its entirety and was supplanted not only by Celtic customs and beliefs but also by the Celtic language, as is attested by the vast number of place-names and family names in certain areas. This new culture never reached the level of the coastal Iberian culture. The Celts did not have their own system of writing; they did not strike coins; nor did they practice sculpture or painting. The Celts did, however, excel in pottery techniques and in ornamental design, characterized by elaborate geometrical patterns. Their weapons and jewelry were exceptionally well made, always from gold (bracelets, torques), and they had mastered such difficult techniques as damascene. The round-shaped dwelling was replaced by the rectangular floor plan. But in the northwest (Galicia, Asturias, and the north of Portugal), the Celtic culture remained virtually unaffected by the native culture it encountered. The houses continued to be built with a circular floor plan, and the dead were buried beneath the floor of the dwellings themselves, reminiscent of the prehistoric cultures found at Los Millares and El Argar. They remained in this area, at least with respect to the round floor plan, until the Middle Ages and have even been found surviving in modern times, although only in remote areas. This "Round House Culture" has also been referred to as the "Castro" culture, after the arrangement of towns on fortified hilltops.

ROMAN SPAIN

The conquest. Scipio's landing in Emporia (218) during the Second Punic War began the Roman conquest of Spain. The Carthaginians were expelled by 206, and over the next two centuries the Romans, against a grudging and stubborn resistance, extended their hegemony over the peninsula. It is significant that in the same year that Cádiz fell, Italica, the first Roman settlement, was established there.

Native uprisings

The harshness of the Roman conquest provoked a large-scale uprising among the Lusitanians (Lusitani) and the Celtiberians that threatened Rome's hegemony in the peninsula. Rome's vast resources and its superior command prevailed, however, first, with the assassination of the rebel leader Viriathus (Viriato) in 139, and, later, with the siege of Numantia, which fell only after a lengthy resistance that required Rome to use 60,000 men against a city of only 4,000 (133). The presence of Scipio Amilianus, the adopted grandson of the Scipio who defeated Hannibal, was even required before the city fell at last. In 138 the Romans arrived in Galicia (Gallaecia), in 121 they landed in the Baleares (Balearic Islands), and in 105 they drove out the Cimbrians and the Teutons, who had made their way into the peninsula.

Early in the 1st century BC, political wars between Marius and Sulla in Rome brought about the revolt of Sertorius, who was on the verge of creating in Spain an independent state. He had organized the native populations along Roman lines and had fought successfully against Metellus and Pompey, but the war became lengthy, and rivalries began to erode the original enthusiasm for the cause. The assassination of Sertorius allowed Pompey the final victory in this civil war in 72. The wars between Caesar and Pompey also had their repercussions in Spain. The Battle of Ilerda (Lérida), in 49, gave Caesar his decisive victory and put all of Spain into his hands. But Pompey's cause had many followers in Baetica (Pompey had died in 48), and Pompey's sons Sextus and Gnaeus took refuge there after the defeat at Thapsus (46). With the remaining members of the defeated armies in Spain and many partisans, they were able to build a powerful army. The sudden arrival of Caesar, however, put a quick end to this dangerous faction in the Battle of Munda (45), where Caesar won a decisive victory. Gnaeus died while fleeing, and Sextus succeeded in escaping from Spain. The armies that fought in these civil wars were made up for the most part of Spaniards, either as legionnaires or as auxiliaries. This fact, along with the great zeal among the adherents to either side of the issues, was evidence of the intense Romanization that had taken place in much of the country.

The Cantabrian War

The final stage of the Roman conquest was the Cantabrian War (29–19 BC) launched by the emperor Augustus. The assault on the Cantabrian mountains was carried out from three bases of operations: Segisama, for the eastern sector (Santander); Asturica, for the central (Asturias); and Bracara Augusta, for the western (Galicia). Seven legions participated, which, along with auxiliaries, amounted to some 70,000 men. The Emperor himself accompanied these forces, aided by the generals Agrippa, Carisius, and Antistius, while a naval squadron kept watch on the coast. After the Cantabrian War, the whole of Spain was under Roman domination, and peace was interrupted only by events occurring outside the country.

One such occurrence was the revolt of Galba against Nero in AD 68. The uprising was begun by Vindex in Gaul, but the central figure was Galba, at that time governor of Tarraconensis. After this uprising, the Roman legions took more responsibility than the Senate for naming the emperor, and they no longer took into account the place of the emperor's birth or his social class. The 2nd-century Roman emperors Trajan and Hadrian, both born in Spain, were the first two emperors of provincial origin to be elected by the Senate. An event of great importance

during this time was the Moorish invasion of 172–175. Armies of Moors crossed the Strait of Gibraltar, invaded Baetica and Lusitania, and laid siege to Singlia Barba and Italica. At the end of the 2nd century, struggles took place for succession to the throne after the death of Commodus. Supporters of Albinus rallied part of the auxiliary forces of the Seventh Gemina Legion (Legio VII Gemina), then quartered in what is now León, against Septimus Severus. Around the middle of the 3rd century the Franks entered Spain, took Tarraco, and, after crossing the Strait of Gibraltar, drove into Mauretania, where they were eventually dispersed.

Administration. The Romans first divided provincial Hispania into two sections, Ulterior and Citerior, but Augustus soon altered this arrangement, creating three provinces: Hispania Tarraconensis, Hispania Baetica, and Hispania Lusitania. Their respective capitals were in Tarraco (Tarragona), Corduba (Córdoba), and Emertia Augusta (Mérida). In the late 3rd century, Diocletian made Spain into a single diocese and subdivided Tarraconensis into three new provinces: Tarraconensis, Carthaginiensis (along with the Baleares), and Gallaecia. In addition, he joined the new Provincia Mauretania Tingitana to the Diocesis Hispania, which took in all of northern Morocco. Of the three Augustan provinces, Baetica, which was considered pacific, had senatorial status and was administered by the Roman Senate through a proconsul. There were no occupational troops in such a province; the others were "imperial" provinces and were thus governed through delegates appointed by the emperor and were controlled by occupational troops.

The provinces

From F. Lot, *The End of the Ancient World*; Routledge & Kegan Paul Ltd., London (published in the U.S. by Barnes & Noble, Inc.)

Spain at the end of the 4th century AD.

Justice was administered through *conventus juridici.* Baetica had four such administrative districts: Astigitanus, Cordubensis, Gaditanus, and Hispalensis. Tarraconensis had seven districts: Tarraconensis, Caesaraugustanus, Carthaginiensis, Cluniensis, Asturicensis, Lucensis, and Bracaraugustanus. Lusitania had three: Emeritensis, Scalabitanus, and Pacensis. There were thus a total of 14.

Roman forces in Spain

Complete information has not survived concerning the exact numbers and the composition of the forces that Rome sent into Spain during the conquest. Some 30,000 men, excluding native auxiliaries, took part in the battles of Viriathus and Numantia. In Augustus' reign, the record became more precise. In the Cantabrian War about 40,000 legionnaires were used; when joined by auxiliaries their number reached a total of about 70,000. With the wars over, the legions were slowly withdrawn, so that around the middle of the 1st century AD only one legion remained. It was later replaced by another one whose permanent base (garrison) was León.

The peninsula supplied the Roman Army with great numbers of auxiliaries in the first century of the empire. Somewhat more than 100 units, alae and cohorts, were composed of men recruited from the least Romanized regions of Spain—Lusitania, the far north, and the northern *meseta.* The majority of them saw action on the Rhine and Danube fronts, although they also fought in Britain, North Africa, and the East.

The decisive factor in the Romanization of Spain was the extension of Roman citizenship. At first colonists of Roman or Italian origin living in Roman colonies in Spain were considered citizens. These colonies were established chronologically as follows: seven were created before Caesar, six during his reign, and three between Caesar and Augustus. Fourteen colonies were then founded by Augustus himself, and four between Augustus and the Flavians. Geographically, the colonies were distributed in the following manner: 12 in Baetica, 16 in Tarraconensis, and five in Lusitania; that is, a total of some 33 colonial seats of government, including some that did not receive the official designation of "colony." It must be noted that the colonization did not follow a studied plan but was determined instead to a great extent by the availability of suitable expropriated territory. In the area where the most conflicts developed (the civil war between Pompey and Caesar, in particular), more punitive action was taken against certain cities, and, consequently, there was in these places more *ager publicus* ("public land") to be distributed among the Roman legionnaires. The total number of Roman colonists may have reached 60,000. But since transient natives of the peninsula could in various ways also obtain Roman citizenship, the total increased by a considerable number. At the beginning of the empire, there were already 24 municipalities of Roman citizens and 48 cities under the *jus Latii* (Latin right). When these figures are added to those for the 33 colonies, there is a total of 142 cities under Roman law, with a population that may have reached 250,000 to 300,000.

Cities

Beyond this there still remain, however, nearly 300 cities and great numbers of non-Romanized people who are not accounted for. The complete Romanization of the Hispanic territory was not achieved until the Edict of Vespasian (74), which extended rights of the empire to all those Spaniards who did not previously have them. The rest of the empire had to wait until the Edict of Caracalla (212), which made Roman citizens of all persons in the empire.

These political advances were accompanied by great steps forward in the process of urbanization. In Tarraconensis, the western borders of which were very little urbanized at the time of Augustus, there were 293 settlements, 179 of which had a capital and 114 of which were rural. A century and a half later, the number of cities had risen to 248, an increase of 69; and the number of rural localities had fallen to 27, a decrease of 87.

Society and culture. Native languages (Iberian and Celtic), and the Greek and Phoenician that were still spoken in what had been their colonies, had virtually disappeared by the end of the 1st century BC, at least in Baetica and in the important cities and Romanized provinces. Languages spoken in the more remote centres of population were much longer in disappearing, and Basque survives even into the 1970s as an example of one of the pre-Roman tongues of the peninsula. It can be said, however, that by the time of Caesar, Latin was the universal language for the cultivated citizens of the peninsula, and there soon developed a native Hispano-Roman literature.

Religion in the Roman period

With regard to religion, in addition to the gods and minor deities of the Roman pantheon, who were quickly identified with the gods of the native Hispanic peoples, there were also adherents of many exotic religions originating in Persia, Asia Minor, Egypt, and North Africa. The most widely practiced religion appears to have been the worship of Isis, followed by the worship of the Magna Mater. Several of these beliefs were brought into Spain before the Roman conquest (Melqart, Tanit-Caelestis, Magna Mater). The majority of the remaining ones were introduced during the empire.

There is no evidence as to how Christianity was first

introduced into Spain. It is quite possible that St. Paul visited Spain at some time between 63 and 67, but it is difficult to distinguish historical fact from legend concerning the "seven apostles." It is certain, however, that in the 2nd and 3rd centuries there were Christian communities throughout the peninsula. The most reliable documents on martyrs speak of persecutions of Christians in various locations under Prudentius. Shortly before (evidently), the Edict of Milan (313) called together the Council of Iliberri (Granada), which was attended by 19 bishops and 24 presbyters. The Nicene Council (325) was directed by Osio, the bishop of Corduba. The emperor Theodosius I (379–395), a Spaniard, made Christianity the only tolerated religion in the empire. The ascetic Priscillian spread the Manichean heresy throughout the western part of the peninsula during the second half of the 4th century, and the heresy persisted into the 6th century. Besides Priscillian, other Christian writers of note were Osio, Juvencus, Prudentius, and Orosius.

Roman remains

Archaeology has brought to light numerous monuments from this era—basilicas, amphitheatres, aqueducts, baths.

Monuments to Roman construction remain in many parts of the peninsula. Roman walls are to be found in Barcelona, Tarragona, Zaragoza, Idanha, Evora, and elsewhere. Bridges stand at Alcántara, Mérida, Piedras Albas, Alconétar, Chaves, Villa Formosa, Bibey, Salamanca, and Villa del Río, and aqueducts in Segovia, Mérida, and Tarragon. The entire peninsula is crossed by Roman roads, the principal ones going from Cádiz (the Via Augusta) along the Río Guadalquivir and continuing along the Levantina coast, from Cartagena north through Valencia and Tarragona to Narbonensis. Another road folows the Ebro from Tarragona to Galicia. Roman lighthouses are found at La Coruña and Caepionis Turris (Chipiona). Sites of military encampments are at León, Numantia, and elsewhere. Castles were built at Lousa and Benavente. Carmona has a necropolis, and there are mausoleums remaining at Tarragon, Fabara, Sádaba (two), Zalamea la Real, and Jumilla. Roman palaces and villas, many with mosaics, are found at Clunia, Milreu, Italica, and many other sites.

Roman art is also abundant throughout the peninsula. Principal centres for sculpture were Barcelona, Tarragona, Mérida, Italica, and Córdoba, while the centres for portrait work were at Italica, Córdoba, Cádiz, Tarragona, and Barcelona. There remain about 40 pagan sculptured sarcophagi, originating primarily in the south, the coast of the Levantina, and the central region. Mosaic work is common in all of the peninsula, with the exception of the northwest and the north.

Spaniards of great importance in the culture of Rome were writers such as the Senecas, Lucan, Mela, Martial, Quintilian, Columella, Canius Ruffus, Decianus, and Moderatus. Trajan, Hadrian, and Theodosius were Spanish emperors, and the Balbos and Lucius Licinius Sura were statesmen of note.

VISIGOTHIC SPAIN TO C. 500

There were many precedents to the great invasions by Germanic tribes of the beginning of the 5th century. Incursions by the Cimbrians and Teutons, the Franks, the Alemanni (Alamanni), and the Ostrogoths were signs of the growing threat to the empire. On the other hand, the peaceful infiltration and coexistence of the barbarians with the Romans along the interior border zones brought about the "barbarization" of the empire on every level, even in its high command. In 401 the Visigoths, under Alaric, crossed the Alps, descended on Italy, and in 410 sacked Rome. Other tribes, made up of Suebi, Alani, and Vandals, had crossed the Pyrenees the previous year (409). After two years of turmoil and anarchy, they at last ceased their movement, signing a treaty of alliance (*foedus*) with Rome that conceded them military settlements within the empire. The Suebi and the Asdingi Vandals settled in Galicia (Gallaecia), the Silingi Vandals in Baetica (Vandalusia = Andalusia), and the Alani in Lusitania and Carthaginiensis. Tarraconensis was occupied only after Ataulphus had been made king of the Visigoths and had invaded the Provincia, where he died the same year. The occupation of the peninsula by Germanic tribes was then complete. Wallia (415–419), through an agreement with Honorius, founded the kingdom of Tolosa in federation with Rome. With this agreement made, Wallia immediately attacked the Vandals and Alani of Andalusia and crushed them. The Vandals who survived joined with their Galician brothers and conquered Cartagena and Seville and, after sailing from Tarifa, crossed the Strait of Gibraltar under the command of Gaiseric (Genseric) and landed in North Africa (429). The Suebi, now in exclusive control of Galicia, established themselves there as an independent kingdom. They later divided the entire western region of the peninsula among their elite troops and extended their effective rule as far as the Tagus River. The kingdom of Galicia, as such, disappeared in 585.

Wallia

With Euric (466–484) the kingdom of Tolosa (Toulouse) became unified and independent from Rome. This kingdom's powers extended through the Galliae (except for the northern zone) and through the Hispaniae (except for Galicia, which continued, along with its Lusitanian possessions, to be a kingdom dependent on the Suebi). Euric was at that time the most powerful ruler in the West. He issued the first laws, which, because of the continuing predominance of Latin culture, were written in Latin, drawn up by Roman jurists, and were influenced heavily by Roman law (475). With the Alani and the Silingi Vandals having been defeated by Wallia and with the Asdingi Vandals in Africa, the only powers in the peninsula were the Suebi in the northwest and the Visigoths. Demographically and ethnically, they stood for very little, numbering only about 250,000, as compared with the 7,000,000 Hispano-Romans of the peninsula. But power was almost exclusively in their hands. They lived in relative harmony with the Hispanic people, a situation made possible largely by two great leaders, Orosius and Idatius, who strongly favoured the idea of a unified Spain under Visigothic protection.

When the Suebi and the Visigoths had arrived in Spain, they were to a great extent already Romanized; thus, there was no drastic cultural difference between the invaders and the invaded. Furthermore, for many years the Visigoths were considered allies and collaborators with the empire and, to a certain extent, its protectors. With the pact of 418, the Visigoths agreed to recognize the supreme authority of the Emperor and to submit to Roman political and administrative organization. The Visigoths arrived in Spain already bearing a certain political and social organization, although it is true that many aspects of it underwent important changes. They brought with them an elective monarchy that was assisted by a popular assembly made up of all free men who were eligible to go to war. The population of Visigothic Spain, however, was composed of two completely distinct societies. On one hand, there was the Hispano-Roman populace with its own laws, its Latin culture, and Catholic Christianity; and on the other hand, there were the Arian Visigothic invaders, who, even though they were a minority, held military power. They were ruled by a sovereign who, in theory, had authority only over his own people and not over the Hispano-Romans, since there was a code of Roman laws for these native people and a tradition of Visigothic common law for the invading people. Two-thirds of the land was redistributed into Visigothic hands, although vast territory remained unoccupied because of the scant numbers of the new colonists. A ban against marriage between Visigoths and Hispano-Romans lasted until its abolition by Leovigild (568–586). The Visigothic capital, which was originally in Tolosa, was transferred later to Toledo (Toletum) with the reign of Leovigild. (A.G. y B.)

THE VISIGOTHIC KINGDOM

Given their distinctive laws and customs and their profession of Arian Christianity, the Visigothic absorption by the Hispano-Roman population of perhaps 6,000,000 was not easy. Visigothic control of the peninsula remained incomplete so long as the Suebi (Suevi) maintained an independent kingdom in Galicia (Gallaecia) and the Basques refused submission to any external authority. Moreover, the Hispano-Romans in the southeast welcomed there the

restoration of Byzantine rule early in the 6th century. Leovigild (568–586), the most capable of the Visigothic kings, who borrowed the Roman symbols and trappings of monarchy and ruled from a central position at Toledo (Toletum), made significant strides toward peninsular unification by conquering the Suebi and subjugating the Basques. Leovigild's attempt to convert the Hispano-Romans to Arianism, however, provoked a revolt in the southern province of Baetica under the leadership of his son, Hermenegild, who had accepted the Catholic religion. Rebel expectations of Byzantine help were unfulfilled, and so the uprising was finally crushed.

Conversion of Recared to orthodoxy

The evident futility of Leovigild's religious policy prompted his son, Recared (586–601), to convert to the Catholic faith professed by the majority of the people. His conversion, together with that of the Gothic nobles and bishops, removed one of the chief barriers to the assimilation of the two peoples. Thereafter, the Hispano-Romans, with less reason to be beguiled by Byzantium, developed a new and strong loyalty to the Visigothic monarchy. This facilitated the conquest of the last Byzantine strongholds in the peninsula during the reign of Swinthila (621–631). From then on, the Visigoths ruled over all of Spain.

The conversion also symbolized the triumph of Hispano-Roman civilization over the barbarians, and it helped to forge an alliance between the crown and the church. Realizing that the bishops were the leaders and spokesmen for the majority, the kings assumed the right to appoint them and to summon them to the Councils of Toledo. Those assemblies, though primarily ecclesiastical, had an extraordinary influence on the political life of the kingdom. After listening to the royal message describing problems of greatest concern, the prelates enacted appropriate canonical legislation as well as decrees relating to secular business, such as the election of the king or cases of treason. The bishops, in their councils, became a principal support of the monarchy, but in their quest for an ordered political regime, they lost some of their independence.

The monarchy was elective, partly because of aristocratic opposition to hereditary succession and partly because of a lack of natural heirs. Knowing the chronic Gothic tendency to assassinate the king, the bishops introduced the ceremony of anointing to give him a sacred character and to make known to all that he was under God's protection. In order to curtail the disorders attendant upon a royal election, they also elaborated an electoral procedure. The king ruled with the aid of a household (*officium palatinum*) based upon Roman models, and when important business required it, he took counsel with assemblies of magnates and other prominent persons (*aula regia*). Territorial administration was entrusted to dukes, counts, or judges. They were also responsible for the towns where self-government had long since decayed. Provinces and other administrative districts were essentially survivals from the Roman era. The economy was mainly agricultural, and there is scarcely any evidence of commercial or industrial activity.

The *Liber Judiciorum*

The influence of Roman civilization can also be noted in the steady subordination of Germanic law to the law of the Hispano-Roman majority. The *Liber Judiciorum,* a code of law promulgated around 654 by Recceswinth (649–672), in both its structure and its substance gives testimony to Roman influence. Intended to have territorial rather than personal application (as was the case with barbarian customary law), it reflected a persistent acceptance of Roman legal principles. Yet there are Germanic elements in the code, such as the ordeal of cold water. The *Liber Judiciorum* was one of the chief legacies of the Visigothic era and a tribute to the Hispano-Romans who were responsible for creating it.

The persistence of Roman tradition is also evident in the remarkable outburst of cultural activity in the 7th century. St. Isidore, bishop of Seville (Hispalis) from *c.* 600 to 636, friend and counsellor of kings, was a voluminous author who left his mark upon the entire medieval era. His works include a history of the Visigoths, a monastic rule, theological treatises, and, above all, the *Etymologies,* an encyclopaedic work that attempted to summarize the wisdom of the ancient world.

At the close of the 7th century, the Visigothic monarchy entered upon a critical time. The deposition, through trickery, of King Wamba (672–680), a competent ruler who tried to reform the military organization, indicated the trend of events. Numerous plots threatened his successors, who sought to blame the unrest upon the Jews, whom they tried to convert to Christianity or to reduce to slavery. Factionalism reached a climax when Witiza (700–710) died, hoping to leave the throne to his son; but Roderick, duke of Baetica (710–711), was acclaimed instead. Witiza's family apparently appealed to the Muslims in North Africa to help them overthrow Roderick. In response, Ṭāriq ibn Ziyād, the Muslim governor of Tangier, landed at Gibraltar (Calpe) in 711 and defeated King Roderick and the Visigoths near Río Guadalete on July 19. The conquest of the rest of Spain, left leaderless by the death of the king, followed quickly. The Visigothic kingdom perished, but its memory survived to inspire the kings of Asturias-Leon to attempt the reconquest of Spain.

CHRISTIAN SPAIN FROM THE MUSLIM INVASION TO C. 1260

The question of peninsular unity is central to the history of Christian Spain from the Muslim invasion in the 8th century to the advent of Ferdinand and Isabella in the late 15th. The Muslims destroyed what unity the Visigoths had been able to impose and introduced religious, cultural, legal, linguistic, and racial differences that impeded their assimilation by the natives. In the ensuing centuries, several Christian states emerged in the northern mountains; partly as a matter of self-preservation, partly for religious hostility, and partly to vindicate the Visigoths, they embarked upon the Reconquista (Reconquest). Their progress depended upon the strength of Muslim Spain at any given moment. In times of Muslim weakness or disintegration, the Christians usually made important gains. The kings of Asturias-Leon-Castile, eventually the largest state, aspired to dominance over the whole peninsula, but their ambitions were challenged and often thwarted by the rulers of Portugal, Navarre, and Aragon-Catalonia, which began to assume definitive form in the 11th and 12th centuries. The Reconquista was largely completed by the middle of the 13th century, with only the small Muslim kingdom of Granada (Gharnāṭah) surviving as tributary to Castile until 1492.

In the later Middle Ages, the problems of peninsular unity took on a new aspect as the kings of Castile tried to gain control of the other Christian states by marriage, diplomacy, and war. The Trastámara dynasty, which came to power in Castile in the late 14th century, consistently pursued this aim. It was achieved in part by Ferdinand and Isabella, whose marriage united Aragon and Castile. They also conquered Granada, thereby terminating the Reconquista, but their attempts to bring Portugal into a family union by marriage failed. In any case, the diversity of languages, laws, and traditions that had developed in the medieval centuries was not erased simply by the political union of kingdoms.

The Christian states, 711–1035. Christian resistance to the Muslim conquest began in the mountains of Asturias, where Visigothic nobles took refuge and joined the native mountaineers in opposing the invaders. Their leader was Pelayo (718–737), a Visigothic lord whose victory over the Muslims at Covadonga, around 722, later was hailed as the beginning of the Reconquista and the "salvation of Spain." Under King Alfonso I (739–757), the Asturians occupied Galicia, abandoned by rebelling Berber troops who had been garrisoned there. Farther south, he laid waste the Duero River Valley, which remained for many years a no-man's-land separating Christian and Muslim Spain. In the western Pyrenees, the Basques seem to have regained their independence; and the Franks, after expelling the Muslims from Septimania, began to penetrate into northeastern Spain. Charlemagne's attempt to take Saragossa (Saraqusṭah) in 778 failed, but his forces eventually moved into Catalonia, seizing Barcelona in 801. The Franks organized this region into several counties, later known collectively as the Spanish March. For several centuries, the March was linked by political and cultural ties to the Carolingian Empire and then to the Kingdom of France.

"Salvation of Spain"

While the Catalans tended to be oriented to the north, the Asturians looked southward and under Alfonso II (791–842) cautiously moved their capital to Oviedo, where they attempted to restore the institutions of the Visigothic monarchy.

Alfonso III

A breakdown of effective government in Muslim Spain in the late 9th century enabled Alfonso III (866–911) to cross enemy frontiers at will in search of plunder and to capture important places, notably Porto. Alfonso also began the process of colonizing the lands stretching southward to the Duero that had been depopulated for so long. On his eastern border, he erected many castles as protection against Muslim attacks, thus giving the area its name, Castile, and its distinctive character. The first extant Christian chronicles of the Reconquista were compiled during this period and sought to establish an essential continuity between the Visigothic and Asturian kingdoms. The Asturians saw themselves as the legitimate heirs of Visigothic power and tradition and consciously assumed responsibility for the reconquest of Muslim Spain. Future challenges to Asturian leadership were beginning to take shape, however, in the northeast, where a strong Basque kingdom, centred at Pamplona in Navarre, appeared under King Sancho I (905–926). In Catalonia, Count Wifred of Barcelona (873–898) took advantage of the disintegration of the Carolingian Empire to assert his independence and to secure control of several other counties. The dynasty he founded ruled in Catalonia until the 15th century.

Encouraged by the expansion of the Asturian kingdom and evident Muslim weakness, García I (911–914) moved his capital southward from Oviedo to the city of León. The optimism revealed by this action was shattered during the course of the 10th century as order and unity were restored in Muslim Spain under the rule of the caliphs of Córdoba (Qurṭabah). Muslim incursions into the Christian north were resumed and caused great destruction, though from time to time the Christians achieved some successes. Ramiro II (931–951) defeated the caliph ʿAbd ar-Raḥmān III at Simancas in 939, a truly remarkable feat. Yet within his own kingdom, Ramiro was faced with the growing defiance of the Castilians, who, as frontiersmen exposed to the hazards of daily conflict with the enemy, seem to have had little use for Leonese tradition and law. Their count, Fernán González (*c.* 930–970), successfully resisted the kings of Leon and laid the basis for Castilian independence.

As the century progressed, the Christian position steadily deteriorated. Muslim ascendancy was demonstrated clearly by the procession of envoys representing Ramiro III of Leon (966–984), Sancho II of Navarre (970–994), Count Borrell of Barcelona (*c.* 940–992), and Count Garci-Fernández of Castile (970–995), who came to Córdoba to offer homage and tribute to the caliph. Even in these depressed circumstances, the Leonese seem to have maintained the traditional Asturian claim to the Visigothic inheritance. As a more explicit assertion of peninsular hegemony, they elaborated a concept of a Hispanic empire centred at León. The theory no doubt served to bolster morale at the close of the century when all the Christian states suffered from the scourge of al-Manṣūr, who assumed dictatorial power in the caliphate. In order to distract the Muslims from his usurpation, he led armies on annual invasions of the north. In 985 he defeated Count Borrell and burned Barcelona; three years later he plundered León and many other towns.

The scourge of al-Manṣūr

The breakup of the caliphate following al-Manṣūr's death freed the Christian states from the threat of destruction. Count Ramón Borrell of Barcelona (992–1018) even gained a measure of retribution by intervening in the Muslim civil wars and sacking Córdoba in 1010. Alfonso V of Leon (999–1028) used the respite from war to repair his kingdom and in 1017, at a council held at León, promulgated the first general laws for the government of the realm. The cessation of Muslim attacks also encouraged a renewal of rivalry among the Christian states. For a few years, Sancho III the Great, king of Navarre (1000–35), succeeded in lording it over the rest of Christian Spain. During his reign, contacts with northern Christendom became more frequent. The pilgrimage route to Compostela, a principal avenue of French influence, was developed; the Cluniac reform of the monastic life was introduced, and feudal ideas began to affect the structure of aristocratic society. In pursuit of his own aggrandizement, Sancho III, who already held the counties of Aragon, Sobrarbe, and Ribagorza and numbered Count Berenguer Ramón I of Barcelona (1018–35) among his vassals, seized the county of Castile and threatened Bermudo III of Leon (1028–37). In 1034, Sancho occupied the city of León and assumed the title of emperor, but his triumph was cut short by his death in the following year.

The medieval empire, 1035–1157. Although Sancho III brought under his sway all the Christian states except Catalonia, he rejected the Leonese tradition of a unified, indivisible kingdom and regarded his dominions as a family patrimony to be shared among his sons. Thus, he gave the kingdom of Navarre to García III (1035–54); Ferdinand I (1035–65) received Castile; and Ramiro I (1035–63) obtained Aragon, to which he added Sobrarbe and Ribagorza in 1045 after the murder of a fourth brother, Gonzalo. As each of the sons bore the royal title, Castile and Aragon were elevated to the status of kingdoms. Although Bermudo III had regained possession of Leon, he was defeated and killed in 1037 by Ferdinand I, who annexed his kingdom and took the imperial title. For the next 30 years, he aspired to domination throughout Spain, overcoming his brothers on the battlefield, conquering Coimbra, and compelling the petty Muslim rulers (*reyes de taifas*) of Toledo (Ṭulayṭulah), Seville (Ishbīliyah), and Badajoz (Baṭalyaws) to pay him tribute.

Ferdinand's contemporary Count Ramón Berenguer I of Barcelona (1035–76) was actively developing Catalan interests and relationships among the lords of Languedoc, in southern France. He also promulgated the earliest legal texts included in the compilation of Catalan law known as the *Usatges de Barcelona* ("Usages of Barcelona").

At his death, Ferdinand I followed his father's custom and divided his kingdoms between his sons, giving Castile to Sancho II (1065–72) and Leon to Alfonso VI (1065–1109). Discord promptly arose and ended only with Sancho's murder in 1072. Alfonso VI thereupon reunited the two kingdoms, but he had to swear to the Castilian nobility that he had had no hand in his brother's death. Chief among the Castilians, who now became his vassals, was Rodrigo Díaz de Vivar, known to history as El Cid Campeador. Court jealousies eventually forced him into exile, and for a time he served the Muslim king of Saragossa before becoming the protector of the king of Valencia.

Alfonso VI

The division of Muslim Spain into several small kingdoms enabled Alfonso VI to levy tribute upon them, but he decided to conquer them and in 1085 received the surrender of Toledo, the fall of which had great symbolic importance because it had been the ancient seat of the Visigothic monarchy, and its possession strengthened the king's claims to hegemony in Spain. For this reason, he called himself "Emperor of Toledo," but he also used the title Emperor of the Two Religions to emphasize his ascendancy over both Christians and Muslims. The conquest brought his frontiers to the Tagus and resulted in the incorporation into his kingdom of large numbers of Muslims and Jews, who in times past usually had withdrawn to the south in the face of advancing Christian armies. Large numbers of Mozarabs, or Arabic-speaking Christians, also lived in Toledo and its environs. The interaction among these differing religious and cultural traditions became especially intense in the ensuing years.

The fall of Toledo alarmed the other petty kings in Muslim Spain, who invited the Almoravids, a fanatical Muslim sect in North Africa, to come to their aid. The Almoravids crushed the Christian army at Zalacca (az-Zallāqah) in 1086, but they also swallowed up the petty kingdoms. The reunification of Muslim Spain kept Alfonso VI on the defensive for the rest of his reign and made further progress in the Reconquista temporarily impossible. The Cid successfully defended Valencia against the Almoravids, but after his death in 1099 his followers had to abandon the city. The Almoravids were then able to occupy the whole of eastern Spain as far north as Saragossa.

The deeper Christian involvement in the world of Islām brought about by these events was counterbalanced by the steady growth of northern European influences, especially that of the papacy. Pope Gregory VII (1073–85), who spearheaded the general reform of the church, imposed uniformity of liturgical practice by insisting upon the abandonment of the ancient Mozarabic liturgy native to Spain and its replacement by the Roman. His assertion of papal sovereignty over Spain was not admitted by the Spanish rulers, and he did not press it. In addition, French monks and clerics discovered ecclesiastical fortunes in Spain, and French knights came to participate in greater numbers in the wars of the Reconquista. Two of them, the cousins Raymond and Henry of Burgundy, married the daughters of Alfonso VI, Urraca and Teresa, and so became the progenitors of dynasties that ruled in Leon and Portugal until the late 14th century.

After Alfonso VI's death, Urraca (1109–26), now widowed, succeeded him. She married Alfonso I of Aragon, "the Battler" (1104–34), but disharmony between them kept the kingdom in constant turmoil. Alfonso I eventually retired in disgust to his own kingdom. Urraca's son by Raymond of Burgundy, Alfonso VII (1126–57), restored the prestige of the Leonese monarchy and affirmed Leonese aspirations to predominance in Spain by being solemnly crowned as emperor in the cathedral of León in 1135. This was apparently the first and last imperial coronation in Spain. Within a few years, however, two formidable challenges to Leonese ascendancy appeared in the newly formed federation of Aragon and Catalonia and in the newly independent kingdom of Portugal.

Alfonso I of Aragon, after ending his marriage to Urraca, conquered Saragossa in 1118, thus advancing his frontiers to the Ebro. Shortly after, he made an extraordinary incursion into the heart of Muslim Spain to liberate the Mozarabs of Granada (Gharnāṭah), whom he settled in Aragon. Thereafter, the Mozarabic population in Muslim Spain seems to have been negligible. When he died, he bequeathed his realms to the military Orders of the Hospital, the Temple, and the Holy Sepulchre, but his people refused to accept this. The Navarrese, who had been subject to Aragonese rule since 1076, elected their own king, García IV (1134–50), and the Aragonese summoned the dead king's brother, Ramiro II (1134–37), from a monastery to become their king. He assumed the responsibility only long enough to marry and to father a child, Petronila, who could inherit the kingdom. She was betrothed in 1137 to Count Ramón Berenguer IV of Barcelona (1131–62), who was entrusted with the administration of the kingdom. The child by this marriage, Alfonso II (1162–96), united in his person the kingdom of Aragon and the country of Barcelona, a union of peoples with different traditions, interests, and languages, which survived innumerable vicissitudes throughout the medieval era. Catalonia developed as a maritime power, interested in expansion in the Mediterranean, while Aragon, a landlocked region, remained largely agricultural, dominated by a landed aristocracy. Each region retained its distinctive laws and institutions, and there was strong opposition on both sides to any attempt at assimilation. The term crown of Aragon appropriately describes the federation of the two territories.

The crown of Aragon

In the west, the county of Portugal, a part of the Kingdom of Leon, which Alfonso VI had given to Teresa and Henry of Burgundy, began to emerge as an independent state. Their son, Afonso I Henriques (1128–85), rejected Leonese overlordship and assumed the title of king, around 1139. In order to protect himself, he became a vassal of the papacy, pledging to pay an annual tribute; but the Pope did not explicitly recognize him as a king until 1179.

The Almoravid Empire, meanwhile, began to break up as a result of internal discord and the rise of the Almohads, another North African Muslim sect. Taking advantage of the Muslim civil wars, the Christian rulers penetrated deeply into Muslim Spain and made some significant conquests. In 1147, Afonso I, with the help of a crusading fleet from northern Europe, conquered Lisbon, while Alfonso VII and Ramón Berenguer IV, aided by Pisan ships, captured the great seaport of Almería on the southeastern coast. In the following year, the count of Barcelona seized Tortosa (Ṭurṭūshah) and Lérida (Lāridah), thereby completing the expansion of Catalonia and extending its frontiers to the mouth of the Ebro. The Almohads, however, after destroying Almoravid power, invaded Spain and reduced all the Muslim areas to their rule. In 1157 they reconquered Almería (al-Marīyah) and thereafter effectively checked any further Christian progress.

The rise of Castile and Aragon. Alfonso VII died in the same year. By dividing his realms between his sons, Sancho III (1157–58), to whom he gave Castile, and Ferdinand II (1157–88), who received Leon, he shattered the unity he had tried to impose upon the peninsula and ruined the concept of a Leonese empire. Although the Almohads kept the Christians on the defensive, Alfonso VIII of Castile (1158–1214) and Alfonso II of Aragon were confident enough of ultimate success to conclude a treaty in 1179 partitioning Muslim Spain. The territory of Valencia (Balansiyah) was reserved for Aragonese reconquest, while the rest of Andalusia fell to Castile. Rivalries among the Christian princes quickly arose, however, when Alfonso VIII tried to dominate his colleagues. Common action against the Almohads was impeded, and in 1195 they inflicted a humiliating defeat upon the king of Castile at Alarcos (al-Arak), south of Toledo. Realizing the seriousness of the Muslim threat, the other Christian kings made peace with Castile. In 1212, Alfonso VIII, supported by Sancho VII of Navarre (1194–1234) and Peter II of Aragon (1196–1213) and by contingents from Portugal and Leon, achieved a remarkable victory over the Almohads at Las Navas de Tolosa (al-ʿIqāb). His triumph opened the road to Christian penetration into Andalusia, and it sounded the death knell for the Almohad Empire.

Active participation in the Reconquista was only one aspect of Aragonese policy. The king of Aragon, as ruler of Catalonia, also had significant interests in southern France, where several lords were his vassals. The Albigensian heresy was spreading through the region, however, and Peter II, while no friend of heretics, concluded that his rights there were jeopardized by the crusade launched by Pope Innocent III against them. When Peter tried to rescue his brother-in-law, the count of Toulouse, he was defeated and killed by the crusaders at Muret in 1213. His death marked the beginning of the end of Catalan ambition and power in southern France.

Advance against the Almohads

The steady collapse of the Almohad Empire in the second quarter of the century enabled the Christian rulers to carry the Reconquista almost to completion. James I of Aragon (1213–76), after a turbulent minority, conquered Majorca (Mayūrqah) in 1229. This was the first important step in the overseas expansion of Catalonia and the first great manifestation of Catalan naval power. He then began the more arduous task of conquering the kingdom of Valencia, but he was distracted briefly by the possibility of annexing Navarre. When Sancho VII died without children, the Navarrese proclaimed his nephew, Count Theobald of Champagne (1234–53), as their king, and thereafter Navarre was drawn closer to French politics. Putting aside his ambitions in Navarre, James I received the surrender of the city of Valencia in 1238 and promulgated a code of law for his new realm, which formed the third constituent element in the crown of Aragon. For the first time, thousands of Muslims were incorporated into his dominions.

In the meantime, Alfonso IX of Leon (1188–1230) was advancing southward to the Guadiana (Wādī Ānā), taking Mérida (Māridah) and Badajoz in 1230 and opening the road to Seville. Upon his death, his son Ferdinand III, already king of Castile (1217–52), by virtue of inheritance from his mother, Berenguela, daughter of Alfonso VIII, was received as king of Leon, thus reuniting the two realms for good. With their combined resources, he conquered Córdoba in 1236, Murcia (Mursiyah) in 1243, Jaén (Jayyān) in 1246, and Seville in 1248. Only the Kingdom of Granada remained in Muslim hands, but it was subject to the payment of annual tribute to Castile. For this reason and because it did not constitute any evident threat, serious attempts to conquer it were seldom undertaken in the next two centuries.

Society, economy, and culture. In the first 300 years following the Muslim invasion, Christian society and institutions developed slowly, but substantial change came rapidly in the 12th and 13th centuries. Among the reasons for this were a general rise in population, increasing contacts with northern Europe, participation in the common European growth of trade and town life, and progress in the reconquest.

By the middle of the 13th century, the kingdoms of Leon-Castile, Aragon-Catalonia, Navarre, and Portugal had attained the frontiers they were to have, with only slight modification, until the close of the medieval era. The crown of Aragon was unique among them because it was a confederation of several distinct entities: the kingdoms of Aragon, Valencia, and Majorca, and the principality of Catalonia.

The principle of hereditary succession was established early, but the idea of election survived in the acclamation of the king when he was anointed and crowned in accordance with Visigothic tradition. Peter II of Aragon was crowned in Rome by the Pope, whose vassal he became, thereby subordinating his kingdom to papal suzerainty. The king ruled with the collaboration of his household, whose chief officers were the chancellor, ordinarily a prelate or cleric responsible for the dispatch of royal letters and the keeping of records, and the *mayordomo* and *alférez* (*majordom* and *senyaler* in Catalonia), magnates whose tasks were, respectively, the management of the household and royal estates and the command and organization of the army. Magnates also served as administrators of provinces and in Castile were known as *merinos* or, later, as *adelantados.* In Catalonia, the several counts originally governed their counties in the name of the Carolingian emperors, but they became in fact independent, and by the 11th century, the counts of Barcelona established an effective sovereignty over the principality. Vicars (*vegueros*), responsible for justice, and bailiffs (*batlles*), for taxes, administered Catalan territorial subdivisions. Bishops, magnates, monasteries, and military orders often enjoyed the privilege of immunity, whereby royal officials were forbidden to enter their estates to administer justice or to collect taxes, except in case of negligence. Among the most important immunities were those of the archbishop of Compostela in Galicia and those of the military orders in the region south of Toledo.

As the old Roman concept of the state had been obscured, private and personal relationships of a feudal character had considerable influence upon the governmental and military structure. The development of feudalism was greatest in Catalonia due to its contacts with France, but in the western states it was retarded and incomplete. The Catalan nobles were vassals of the count of Barcelona, to whom they owed military and court service in return for fiefs, and they often had vassals of their own. In the west, royal vassals had the same obligations, but ordinarily they did not receive fiefs nor did they give fiefs to their vassals. The magnates, known as *ricoshombres* (*i.e.,* rich or powerful men) in the west and as *barones* in Catalonia, usually were vassals of the king or count and served as his principal counsellors and as the backbone of the military organization. Nobles of secondary rank, called variously *infanzones, fijosdalgo, caballeros* or *cavallers,* usually were vassals of the magnates.

Inasmuch as the economy of the Christian states was mainly agricultural, the king and nobles of both ranks were landlords who derived the greater part of their income from the exploitation of landed estates. Peasants living on the estates cultivated the soil and paid a variety of rents and services to their lords. The burden fell heaviest upon the serfs (*solariegos* in Castile, *payeses de remensa* in Catalonia), who were effectively bound to the soil and denied freedom of movement. Catalan serfs, especially, were subject to abuse by their lords by means of the so-called evil usages. Leonese peasants occupying lands known as *behetrías* enjoyed the right of freely choosing their lord and of changing their allegiance as they wished, but this right was being limited in the 13th century. Peasants who were willing to accept the risks and the adventure of living on the frontier were the freest of all, and like pioneers in all ages, they developed a strong sense of personal worth and independence.

The serfs

As the Reconquista progressed, the crown encouraged the colonization of the Duero Valley by erecting fortified urban centres (*concejos*) with extensive rural areas dependent upon them. The people who settled there received charters (*fueros*) defining their liberties and giving them rights of self-government under their own elected magistrates (alcaldes). The economy of these towns was based not so much on industry and commerce as upon the raising of sheep and cattle and the booty taken by the urban militia in the wars of the Reconquista. Aragonese and Catalan towns enjoyed a lesser degree of autonomy, but the latter began to achieve a real importance as mercantile centres. The incorporation of such cities as Toledo, Saragossa, Lisbon, Córdoba, Valencia, and Seville greatly increased the urban population and contributed substantially to the development of trade and industry. Artisans appeared in greater numbers and began to organize guilds; a merchant class engaged in buying and selling on a large scale and commonly using money as a medium of exchange also emerged. The development of shipbuilding at such places as Santander and Barcelona made possible a native overseas-carrying trade.

The advance of the Reconquista also added large numbers of Muslims and Jews to the Christian kingdoms. The former, known as Mudéjares, were settled chiefly in rural areas, though there were always important Muslim quarters in the towns. The Jews lived mainly in the cities, where they were involved in trade and moneylending and were often employed as royal tax collectors. Both Muslims and Jews were permitted to practice their religions and to govern themselves according to Islāmic or Judaic law, but they were subject to the payment of regular tribute, and from time to time the Jews were assaulted by their Christian neighbours.

In view of the growing administrative, military, and economic importance of the towns, the crown summoned their representatives to meet in the royal council with prelates and nobles. In 1188 at León, Alfonso IX held the first such assembly (*curia plena*), but similar gatherings began to be held regularly in the other states in the early 13th century. Meetings of the Cortes, as these assemblies were called, served a number of purposes, one of which was to enable the king to obtain consent for the levy of extraordinary taxation to meet ever increasing financial needs caused by the expansion of royal activities and responsibilities. Parliamentary growth in the peninsular kingdoms was a manifestation of a common European phenomenon, but it is noteworthy that it occurred earlier in Spain than elsewhere.

Government of the towns

The Reconquista was also accompanied by the restoration of bishoprics or the expansion of older ones. Spain was divided ecclesiastically into five metropolitan sees: Toledo, which claimed the primacy, Tarragona, Braga, Compostela, and Seville. Papal intervention in their affairs became much more frequent in the 12th century. Monastic reforms emanating from Cluny and Citeaux in France profoundly affected religious life in the 11th and 12th centuries. Early in the 13th century, the mendicant orders, the Franciscans and Dominicans (whose founder was the Spaniard Domingo de Guzmán), spread through the peninsula. The military orders of the Temple and the Hospital, originating in the Holy Land, appeared in Spain in the 12th century, but in the second half of the century, several indigenous orders were founded—Calatrava, Alcántara, Santiago, and Avis. These knights tried to observe the monastic life, but they also provided much of the armed might responsible for the successes of the Reconquista.

The clergy were the guardians of the cultural tradition and the authors of the scant literary remains of the first centuries of the Reconquista. In the 8th century, the adoptionist controversy over the nature of the Trinity engendered many polemical works; the writings of the Mozarabs of Córdoba, Eulogio (died 859) and Alvaro (died 861), illustrate the difficulties faced by Christians living under Muslim rule. Under the influence of northern Europe, theology, philosophy, and Roman and canon law became

formal subjects of study in the universities of Palencia and Salamanca, founded early in the 13th century by Alfonso VIII of Castile and Alfonso IX of Leon, respectively. The existence of the universities was problematical for some time, but eventually Salamanca attained international renown. In the meantime, a vernacular literature was developing, and around 1140 there appeared the first great epic in the Castilian tongue, *The Poem of the Cid.* The output of Spanish writers was still slim, however, though the historical works of Rodrigo Jiménez de Rada, archbishop of Toledo (died 1247), set the pattern for future generations of Spanish historians.

CHRISTIAN SPAIN, C. 1260–1479

Castile and Leon, 1252–1479. In the late medieval centuries, a power struggle developed between the kings of Castile, who sought to concentrate all authority in their hands, and the nobility, who tried to use the monarchy for their own aggrandizement. The struggle began during the reign of Alfonso X the Wise (1252–84), who is perhaps best known for the literary and scientific labours accomplished by the scholars who enjoyed his patronage. From a political standpoint, his reign ended in failure. Although he showed some interest in continuing the Reconquista and had to suppress a revolt by the Mudéjares of Andalusia and Murcia, he preferred to play a larger role upon the European scene. In 1257 he was elected Holy Roman emperor and spent most of his energy and resources in the next 17 years trying to overcome a rival candidate and to win papal recognition. His extraordinary need of money for this purpose eventually brought to a head a domestic crisis that had been developing since his first years in power.

Legal reform

Like his father, Ferdinand III, Alfonso perceived the need for a uniform royal law that would supersede all local and regional laws, such as the *fueros* of the towns and the Liber Judiciorum used in Leon (and translated into Castilian as the Fuero Juzgo on the orders of Ferdinand III). A code of law, known as the Fuero de las Leyes, intended to be common to the whole realm, was prepared; it was the earliest redaction of the Siete Partidas, the great code that received definitive form early in the 14th century. The new code drew heavily upon Roman law, but the King's attempt to impose it provoked outcries from the nobles and from the towns. In 1272 they forced him to confirm their traditional laws and customs and to abandon the attempt to create a single body of law for the kingdom. This disappointment was followed in 1274 by the Pope's final rejection of Alfonso X's claims to the empire. In 1275 Alfonso's eldest son and heir, Fernando de la Cerda, died, and the King recognized Fernando's son, Alfonso de la Cerda, as his successor. The King's second son, Sancho, refused to accept this decision, and, posing as the defender of the nobles against the crown, took up arms against his father. An assembly of nobles, prelates, and townsmen deprived Alfonso X of his right to rule and entrusted the government to Sancho, but civil war raged until the King's death.

Sancho IV (1284–95) had to contend with domestic and foreign opposition in support of his nephew, and he was also threatened by invasion from Morocco. The latter danger initiated a long struggle to control the Strait of Gibraltar and thus to close that invasion route. The minority of Ferdinand IV (1295–1312) saw a renewal of efforts on behalf of Alfonso de la Cerda, but he was finally persuaded to renounce his claims to any share in the royal inheritance. In 1309 the King captured Gibraltar (Jabal Ṭāriq), but the Muslims recovered it a quarter century later. Disorders recurred in the minority of Alfonso XI (1312–50), but when he came of age he crushed his opponents among the nobility with great brutality. For 25 years he waged war against Granada. In 1340, with help from the other Christian states, he won a great victory over the combined forces of Granada and Morocco at Río Salado, thereby putting an end to any further Moroccan attempts to gain a foothold in Spain. Four years later he seized Algeciras (al-Jazīraha al-Khaḍrā'), but his effort to take the adjacent fortress of Gibraltar ended with his death as a victim, like so many other thousands, of the Black Death.

Conflict between the crown and the nobility flared again in the reign of Peter I the Cruel (1350–69), whose half brother, Henry of Trastámara, an illegitimate son of Alfonso XI, challenged his right to rule. To further his aims, Henry secured French support, and in 1366, with a mercenary army commanded by Bertrand du Guesclin, he was able to expel Peter from the kingdom. The King, however, persuaded Edward, the Black Prince, to assist him in regaining his throne. The combined Anglo-Castilian forces routed Henry of Trastámara at Nájera in 1367. But once the Black Prince withdrew, Henry and du Guesclin returned; they defeated and killed Peter at Montiel in 1369.

Henry II (1369–79), the first of the Trastámara dynasty, had to defend his title against his neighbours in the peninsula and to overcome domestic opposition. But he succeeded in consolidating his position and was even able to supply ships to support his French allies against the English. One consequence of the French alliance was Castilian recognition of the Avignonese pope during the Great Western Schism. The ambitions of the Trastámara family to unify the peninsula were revealed when Henry's son John I (1379–90) claimed Portugal by right of marriage. His intervention evoked the spirit of nationalism among the Portuguese, who defeated him at Aljubarrota in 1385. In the next year, John of Gaunt, duke of Lancaster, who had married Peter I's daughter, claimed the Castilian throne and with Portuguese help invaded Galicia. The campaign failed, however, and he made peace in 1388, agreeing to the marriage of his daughter Catharine to Henry III, oldest son of John I. Thus the enmity between the two branches of the Castilian royal house was laid to rest.

Avignon papacy

During the minority of Henry III (1390–1406), the nobility again tried to further their own fortunes at the expense of the crown, but when the king came of age he effectively repressed them. The long reign of his son, John II (1406–54), proved to be disastrous to the prestige and authority of the crown. Stability was maintained during his minority by his uncle, Fernando de Antequera, who acted as regent until his election as king of Aragon in 1412. Fernando's sons, Henry and John of Navarre, continued to participate actively in Castilian affairs and tried to dominate the King, but the royal favourite Alvaro de Luna had already gained ascendancy over the King and successfully resisted these intrigues. For most of the reign, he was the effective instrument of royal power, and only in 1453 was the King persuaded to be rid of him and to order his execution.

Rivalry among the nobles for influence and power was intensified during the reign of Henry IV (1454–74). Juan Pacheco, marquess of Villena, long dominated the King, but others succeeded in winning royal favour. Henry's alleged impotence caused the magnates to cast doubt upon the legitimacy of the infanta Joan, who, it was charged, was the child of the queen and of Beltrán de la Cueva, one of the King's most recent favourites. In derision, the little girl was called La Beltraneja. Henry IV disowned her at Los Toros de Guisando in 1468 and recognized his sister Isabella as heir to the throne. Villena and his followers evidently hoped to be able to control her, but they were mistaken. Although she had promised not to marry without her brother's consent, she did precisely that in 1469. Her husband was Ferdinand, son and heir of the king of Aragon. Angered by this, Henry IV tried to deprive Isabella of her rights, but when he died, she was proclaimed as Queen Isabella I (1474–1504). Afonso V of Portugal, who was betrothed to Joan (La Beltraneja), invaded Castile on her behalf, but in 1479 she renounced her claims. In the same year, Ferdinand ascended the Aragonese throne, thus effecting the personal union of Aragon and Castile.

The infanta Joan

Castilian institutions, society, and culture. The reemergence in the 13th century of the idea of the state as a public institution, partly as a result of the revival of Roman law and the rediscovery of Aristotle's *Politics,* had important consequences for the development of the Castilian monarchy. As the embodiment of the state, the king (whom the Siete Partidas described as God's vicar on earth) tended to concentrate power in his own hands. The jurists who staffed and dominated the royal bureaucracy tried to push

royal claims to authority as far as they would go. The influence of Roman law, though originally opposed, grew steadily, and when Alfonso XI promulgated the Ordenamiento de Alcalá in 1348, the place of Roman law and legal procedure in the courts was assured. The royal tribunal (*audiencia*) was reorganized in the reign of Henry II, but it did not receive definitive form until the end of the Middle Ages. The tendency toward centralization also prompted the crown to intervene more frequently in the government of the towns, where rivalry among factions was becoming endemic. The urban aristocracy, originating as a class of non-noble mounted warriors, had gained control of the government and tended to exclude the lower orders from participation, while seeking the status of nobility—with its attendant exemption from taxation—for themselves. In order to repress urban conflicts, the crown began to send corregidores (governors) to supersede local governmental officials; at first this was a temporary measure, but by the 15th century it had become a permanent arrangement.

The trend toward absolutism encountered opposition both from the nobility and from the Cortes. Under pressure from the Cortes, John I in 1386 organized a royal council (*consejo real*) composed of representatives from the three estates, who would have a permanent influence on royal policy. The experiment failed, chiefly because the nobility succeeded in gaining control of the council and in the 15th century used it for their own advantage. The magnates wielded great power in the territorial administration of the realm, for they held the posts of *adelantado mayor* (governor) in Castile, Murcia, and Andalusia. Moreover, the Trastámara kings gave the magnates extensive territorial lordships as well as lordships over some of the principal towns and cities. In so doing, the crown divested itself of control of some of the major bulwarks of royal power in the past. In general, a pro-aristocratic mentality pervaded Castilian society in the 15th century, encouraging the usurpation of royal authority by the magnates.

The Cortes

The Cortes played a prominent role in the political life of the kingdom, especially from about 1250 to 1350, and again during the reigns of the first two Trastámara kings, who needed its support to consolidate the dynasty. The Cortes met frequently to give consent to taxation (*servicio*) for fixed periods and for specific purposes. Ferdinand IV was compelled to declare formally that he could not levy an extraordinary tax without consent, and John I had to allow the Cortes to audit his accounts. Petitions presented by the Cortes and accepted by the king became the law of the land. The role of the Cortes was circumscribed in the reigns of John II and Henry IV, who abused the rights that the assembly had gained in the 14th century. The crown often appointed the procurators to represent the towns, and the number of towns summoned declined steadily. Many towns were not summoned because they were held in lordship by magnates who claimed to speak for them.

The Castilian economy, for the most part, remained agricultural and pastoral. Sheep and cattle grazing became extremely important as immense pasturelands were opened up in Extremadura and Andalusia. The Mesta, a national sheep-raising organization chartered by Alfonso X, wielded great influence. The manufacture of woollen cloth became an important industry in the towns, but on the whole the urban middle class was weak, and a powerful guild organization never really developed. The urban aristocracy, which had come to power in the wars of the Reconquista, was not inclined to engage in trade and crafts. A substantial maritime trade with England, Flanders, France, and Portugal was carried on by the ports of the Bay of Biscay. The Genoese maintained a large colony at Seville, the chief southern port, and had a great share in the carrying trade originating there.

The Black Death

The outbreak of the Black Death in the middle of the 14th century contributed to a radical decline in population and a steady succession of social and economic upheavals. In order to compel workers to accept the same wages as before the plague, Peter I enacted the Ordenamiento de Menestrales in 1351. Forty years later, social unrest vented itself in a great pogrom against the Jews, which quickly spread to many parts of the peninsula. Accepting Christianity rather than death, many Jewish converts (*conversos*) attained prominence in various aspects of public life, but they were always held in suspicion and accused of practicing Judaism in private. Deliberate attempts were made to exclude them from important positions by requiring them to prove *limpieza de sangre; i.e.,* that their ancestry was untainted by Jewish or Muslim blood.

Culturally, Castile was now fully integrated into western European life. Alfonso X gave great impetus to learning and to the development of Castilian as a literary language. Under his aegis, translations from the Arabic were undertaken, a "General Chronicle" of Spain was written, the Siete Partidas was compiled, and he personally gained renown as the author of the *Cantigas de Santa María,* a collection of more than 400 poems. His nephew Juan Manuel (died 1348) won lasting fame as the author of *El Libro de los enxiemplos del conde Lucanor et de Patronio* (a collection of Oriental fables), the *Libro de los estados* (a treatise on social classes), and numerous other works. His contemporary Juan Ruiz, the archpriest of Hita (died *c.* 1350), who wrote the *Libro de buen amor,* ranks as one of the greatest medieval poets. Interspersed with beautiful hymns in praise of the Virgin Mary are ribald and comic poems of love. A series of royal chronicles relates the history of this period. Perhaps the best among them are the chronicles of the reigns of Peter I, Henry II, John I, and Henry III by Pedro López de Ayala (died 1407), a brilliant writer who searched for motives and who realized the importance of social and institutional developments. In the 15th century, the influence of the Italian Renaissance was being felt at the court of John II, a patron of many poets and scholars. Among them were the marquess of Santillana (died 1458), whose lyric poems have great beauty; Jorge Manrique (died 1479), whose *Coplas,* written on the death of his father, are a reflection on the vanities of the world; and Fernán Pérez de Guzmán (died *c.* 1460), whose *Generaciones y semblanzas* is a series of sketches of the characters and personalities in the court of Henry III.

Aragon, Catalonia, and Valencia, 1276–1479. The aristocratic challenge to royal power that characterized Castilian history of the later Middle Ages was also evident in the kingdom of Aragon. The growing influence of Roman law and lawyers evoked protest in both Aragon and Catalonia. In 1265, at the Cortes of Egea, James I had to confirm traditional Aragonese laws and agree that the nobles should be tried by the *justicia,* a judge appointed by the king from the knightly class rather than from the ranks of professional jurists. The controversy reached an acute stage during the reign of Peter III the Great (1276–85), who received Aragon, Catalonia, and Valencia as his share in the inheritance while his younger brother James received the kingdom of Majorca.

Annexation of Sicily

Peter III conquered Sicily in 1282 in the wake of the rebellion against French rule known as the Sicilian Vespers. Peter's wife represented Hohenstaufen claims to both Naples and Sicily, in opposition to Charles of Anjou, to whom the papacy had awarded the kingdom. The annexation of Sicily was the second major step in the expansion of Catalonia into the Mediterranean, but it was also the cause of a long international conflict with serious domestic complications. The Pope excommunicated and deposed Peter III, offering his realm to a French prince. In the midst of these troubles, the Aragonese nobles formed a union to defend their liberties and in 1283 forced the King to grant the General Privilege. Confirming the right of the nobles to be judged by the *justicia,* the King also promised to convene the Cortes annually and to take its counsel in matters affecting the realm. He made similar promises in Catalonia and Valencia, but there he could count more fully on the support of his subjects. The crusade launched against him by the Pope and led by King Philip III of France ended in failure, but the problem of Sicily remained the primary concern of Peter's three sons.

Alfonso III (1285–91) inherited the peninsular dominions and also annexed Majorca because of his uncle's treachery during the crusade. His younger brother, James, inherited Sicily. Together, they struggled valiantly to overcome the formidable opposition of the papacy, the French, and the Angevins. The Aragonese nobles again threatened the

King and compelled him to issue two privileges in 1287, confirming the rights already ceded by his father and allowing them to appoint and to remove certain members of the royal council. James II (1291–1327) succeeded his brother as king of Aragon, but in order to obtain an undisputed title, he yielded his rights to Sicily in 1295 and also restored Majorca to his uncle James. In compensation, Pope Boniface VIII gave him title to Sardinia. The third brother, Frederick, was proclaimed king of Sicily, and in 1302 the Pope finally agreed to accept him. A force of *almogavares* (medieval Spanish mercenaries), who had fought in the Sicilian wars, found employment thereafter in the Byzantine Empire as the Grand Catalan Company and eventually established lordship over the duchy of Athens in 1311. Sicily and Athens, though not directly under the rule of the king of Aragon, remained outposts of Catalan influence and power.

James II, who achieved a favourable modification of his frontier with Murcia, occupied Sardinia only in 1325. Genoa contested Aragonese rights, and a series of wars on this account took place during the reigns of Alfonso IV (1327–36) and Peter IV the Ceremonious (1336–87). In 1343, Peter IV dispossessed his cousin, the king of Majorca, for disloyalty and reunited that kingdom to the crown of Aragon. A constitutional crisis arose in 1347 when the King proclaimed his daughter as heir to the throne, contrary to the ambitions of his brother, the Count of Urgel, who argued that only males could wear the crown. The Aragonese union, which had been relatively quiet in the preceding reign, renewed its challenge to royal authority and forced Peter to confirm the privileges granted by his predecessors. The Valencian nobility also formed a union and extorted similar concessions, but the ravages of the Black Death and the triumph of the royalists over the Aragonese at Epila in 1348 enabled the King to dissolve the union and to tear up its privileges. The union never appeared again.

The constitutional crisis of 1347

After midcentury, Peter IV had to defend his realm against a vigorous invasion by Peter I of Castile. He supported Henry of Trastámara's bid to gain the Castilian throne, but his subsequent efforts to secure territorial concessions from Henry II were unsuccessful. In 1377, however, he was able to reincorporate Sicily into the dominions of the crown of Aragon. Although Peter IV was inclined to neutrality in the Great Western Schism, his son John I (1387–96) recognized the Avignonese pope. Continued unrest in Sardinia and Sicily occupied much of his attention and that of his younger brother and successor, Martin I (1396–1410). The death of the latter without immediate heirs created the most critical situation ever to confront the crown of Aragon. Numerous claimants came forward, but none had wide support. In order to resolve the issue, the estates of Aragon, Valencia, and Catalonia appointed nine commissioners who met at Caspe. Their decision, the compromise of Caspe, published in 1412, declared that the throne belonged by right of inheritance to Fernando de Antequera, brother of King Henry III of Castile. Despite opposition from the Count of Urgel, Ferdinand I (1412–16) became the first of the Trastámara family to rule in Aragon and thereby prepared the way for the eventual union of Aragon and Castile. His principal accomplishment was the withdrawal of obedience from the Avignonese pope Benedict XIII, thus helping to bring the schism to an end.

His son, Alfonso V the Magnanimous (1416–58), generally neglected his peninsular realms to pursue ambitions in Italy. There he seized the Kingdom of Naples in 1442, aspiring to dominate the rest of Italy and even to extend his power into the eastern Mediterranean. His long absence from Aragon fostered a spirit of discontent that reached a crisis during the reign of his brother, John II (1458–79), who inherited the mainland kingdoms as well as Sicily. (Naples was given to Alfonso V's illegitimate son, Ferrante.) By his marriage in 1420, John had become king of Navarre, thus adding a third kingdom to the Trastámara holdings. Conflicts with his son, Prince Charles of Viana, alienated his subjects and aroused overt Catalan hostility. When Charles died suddenly in 1461, many supposed he had been poisoned. The Catalans, who had grown restive because of economic and social hardships, revolted and tried to find another king to rule over them. Meanwhile, Louis XI of France took advantage of the situation to occupy Roussillon and Cerdagne, thus laying the groundwork for future hostilities between France and Spain. By 1472, however, John II had succeeded in overcoming the Catalan revolt and was able to assist his daughter-in-law Isabella in securing the Castilian throne. When he died in 1479, his son Ferdinand succeeded as king of Aragon and Sardinia, and his daughter Eleanor inherited Navarre.

Aragonese institutions, society, and culture. During the late Middle Ages, the Aragonese confederation, amplified and at times dismembered or nearly so, consisted of the essential nucleus of Aragon, Catalonia, and Valencia. In 1319 James II declared the indissoluble union of these three states. From time to time, Majorca, Sicily, Sardinia, and Naples were added to, occasionally separated from, and finally reunited to the crown of Aragon. An attempt to sever parts of Valencia for the benefit of Peter IV's younger brother was opposed not only by the King but also by the people of Valencia. Only at the close of the Middle Ages was the Aragonese federation menaced by dissolution, when the Catalans rebelled against John II and tried to secede, without success. The crown of Aragon had been held as a fief of the papacy ever since Peter II in 1204; this allowed the papacy to intervene directly in Aragonese affairs and even to try to dispose of the throne.

As in Castile, the bureaucracy was much more complicated; it came to be dominated by jurists who encouraged royal absolutism. Peter IV, known as the Ceremonious, took special care to organize the administration around the four principal officials—the chancellor, the chamberlain, the majordomo, and the *mestre racional,* or chief financial officer. There was intense opposition in each of the several states to the employment of non-natives in administrative positions. Even after the suppression of the union of Aragonese nobles by Peter IV, the *justicia* continued to be the ordinary judge in litigation involving them, but he always served at the king's pleasure.

The king's oldest son usually was named as procurator general for all the realms and served as his father's lieutenant. In Valencia and Majorca, which the king visited only occasionally, a procurator or governor general became a permanent representative of the crown. The towns gained a much greater degree of self-government, though the crown was represented in them by a vicar or *justicia.* In Barcelona, a council of five acted as the executive authority, responsible to a larger *consell de cent,* or council of 100.

The Usages of Barcelona remained the basic law for Catalonia and Majorca, and in 1251 James I had to pledge that Roman law would not replace them. After the conquest of Valencia, he promulgated the Fori regni Valentiae (1240), a code of law—largely Roman—for use in that kingdom. The customary law of Aragon was compiled in the Code of Huesca, promulgated in 1247. As additions were made to it, a new compilation called the Fueros de Aragón was issued in the 15th century.

Revisions of the law

The states of the crown of Aragon developed a vigorous parliamentary structure. Each of the mainland states had a parliament, and from time to time the king convened a general assembly for all three. In 1283, at Barcelona, Peter III made two significant pledges of fundamental importance for Catalan constitutional development. He promised to convene an annual Corts "to treat of the good estate and reformation of the land," and he also promised not to make any general statute for Catalonia without the consent of the Corts. Although the assembly did not meet annually, it did gain great power in legislation, as the body of constitutions and *capitols de Corts* enacted in these gatherings makes clear. The parliaments in the three states also voted taxes. The Catalans, distrustful of the crown in this respect, created a commission of the Corts to control collection and expenditure of taxes authorized by the assembly. This commission became permanent in the latter part of the 14th century and was known as the Diputació del General de Catalunya, or simply the Generalitat. It represented the Catalan community when the Corts was not in session, and it assumed the responsibility for

defending Catalan liberties against royal encroachments. Similar bodies were created in Aragon and Valencia early in the 15th century.

In Aragon proper, agriculture and pasturage were the chief economic activities. In lower Aragon and Valencia, farming was largely in the hands of the numerous class of Mudéjares, Muslims living under Christian rule and retaining many of their own institutions. The manufacture of woollen goods was the main industry in the towns of Catalonia, where a strong guild organization was developed. Barcelona and Valencia ranked among the major ports of the Mediterranean, trading with Tunis, Alexandria, Sicily, Sardinia, the Holy Land, and the Black Sea area. Settlements of Catalan merchants and consuls to represent their interests were found in many of the principal African ports. A compilation of Catalan maritime law, known as the *Llibre del consolat de mar* (*Book of the Consulate of the Sea*), was prepared about 1370 and quickly gained general acceptance in Europe.

After the Black Death worked its destruction, frequent social and economic crises disturbed the peace and resulted in such horrors as the massacre of the Jews in Valencia and other cities in 1391. The decline of trade, financial difficulties, and the failure of many private banks in the late 14th century added to the general misery. In Barcelona a popular party (the Busca) began to agitate against the ascendancy of the wealthy urban aristocracy (the Biga) and helped to bring on the Catalan revolt against John II. The *payeses de remensa* joined in the struggle in hopes of gaining their liberty.

Massacre of the Jews

The crown of Aragon enjoyed a flourishing cultural life in the late Middle Ages. James II, in 1300, founded the University of Lérida, the first in Aragonese territory, and others were later established at Huesca, Barcelona, and Saragossa. Outstanding representatives of the university tradition were the Dominicans St. Raymond of Peñafort (died 1275)—a great canonist—and St. Vincent Ferrer (died 1419), a preacher of exceptional eloquence. A series of historical works, generally regarded as gems of Catalan literature, helped to mold the vernacular as a literary language: *The Chronicle of James I,* purportedly written by the King himself; Bernat Desclot's *Chronicle of the Reign of King Pedro III;* Ramón Muntaner's *Chronicle,* recounting the adventures of the Catalan Company; and the *Chronicle of Peter IV,* of which the King claimed to be the author. The most prolific writer of the era, equally facile in Latin, Catalan, and Arabic, was Ramón Llull (died 1315). A philosopher, theologian, and mystic, he was also an active propagandist concerned about the recovery of the Holy Land and the conversion of the Muslims. His writings include *The Book of the Lover and the Beloved; Blanquerna,* a romance; and *The Book of the Order of Chivalry.* Francesc Eiximenis (died 1409) was best known for his *Lo Crestià,* an encyclopaedic work dealing with moral and political theory; and the poet Ausiàs March (died 1459) explored the psychological dimensions of love. MUSLIM SPAIN

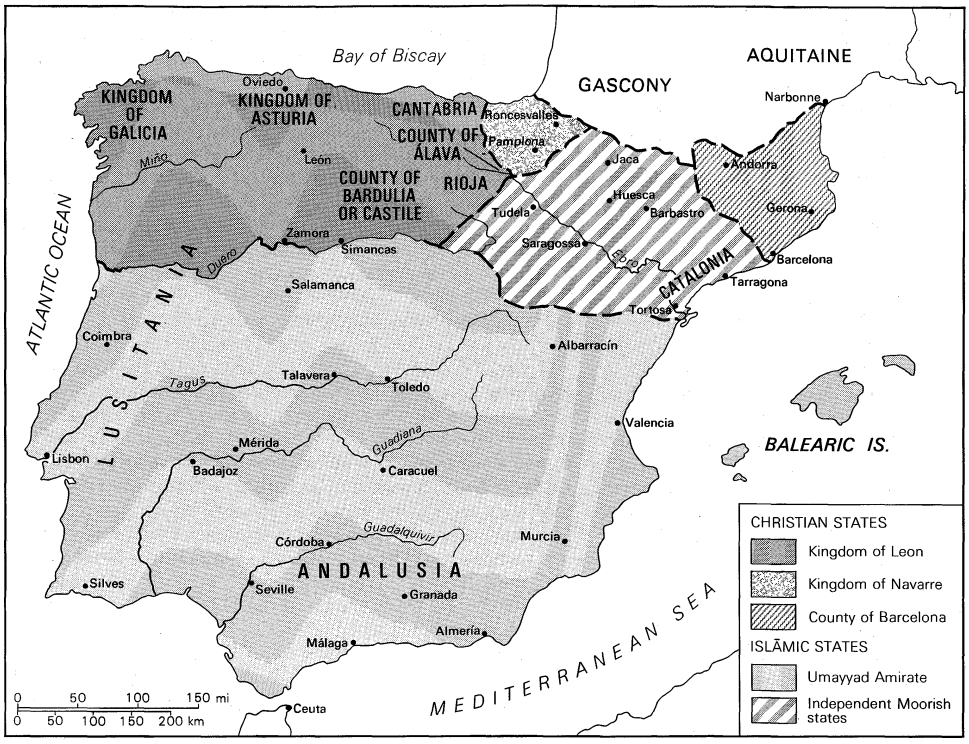
The conquest. During the 7th century, Byzantine strongholds in North Africa gave way before the Arab advance. Carthage fell near the end of the century, and in the early 8th century the caliph al-Walīd I appointed a new governor in the west, Mūsā ibn Nuṣayr, who annexed all North Africa as far as Tangier (Ṭanjah), leaving his general Ṭāriq ibn Ziyād to administer and Islāmize the native Berbers. Only Ceuta (Sabtah), which was supplied from Spain by the Goth Witiza, remained in Christian hands (see also NORTH AFRICA; ISLĀMIC WORLD).

But the Muslim invasion of Spain was the result of Visigoth invitation rather than Muslim initiative. The death of Witiza in 709 precipitated civil war in the Visigothic kingdom, in which the dispossessed family of Witiza and their partisans appealed to Mūsā for support against the usurper Roderick (see above *The Visigothic kingdom*). Ṭāriq crossed the Strait of Gibraltar with a Berber army and in 711 decisively defeated Roderick at a battle the precise location of which is disputed.

Ṭāriq

Ṭāriq, having accomplished his purpose, should have returned to Africa; but, believing that the legendary treasure of Solomon was located at Toledo (Ṭulayṭulah), he marched north and took the city. Much to his surprise, many Spaniards submitted to him voluntarily. In the following year, Mūsā himself brought an Arab army to the peninsula. Mūsā reduced Mérida (Māridah), the last stronghold of Roderick's followers, entered Toledo (Ṭulayṭulah) and Saragossa (Saraguṣṭah) (modern Zaragoza), and may have crossed the northern Meseta Central, forcing the Visigoths to submit or flee. Both Mūsā and Ṭāriq were recalled to the East by the Caliph; by the time of their departure most of the Iberian Peninsula was under their control.



The swift surrender of the peninsula to an army numbering at most 20,000 men appears to be accounted for by the fact that the Hispano-Visigoth society had not yet succeeded in achieving a compact and homogeneous integration. The Goths and Hispano-Romans preserved a clear consciousness of their differences, while lords and vassals found themselves in opposite camps because of profound economic and social factors. The Jews, harassed by the legal ordinances of Toledo, were particularly hostile toward the Christian government. Moreover, the Muslim conquest brought advantages to many elements of society: the burden of taxes was on the whole less onerous than it had been in the last years of the Visigoth epoch; serfs who converted to Islām advanced into the category of freedmen (*mawlās*) and enrolled among the dependents of some conquering noble; Jews were no longer persecuted and were placed on an equal footing with the Hispano-Romans and Goths who still remained within the Christian fold (the Mozarabs). Thus, in the first half of the 8th century, there was born a new and quite different society in Muslim Spain. The nobility of blood was now comprised of the Arab invaders ranked on the basis of the date of their arrival in the peninsula. The *baladiyyūn* were those Arabs who entered Spain in 712 under Mūsā ibn Nuṣayr; the Syrians were those who arrived in 740 under Balj. After the Arab aristocracy were the Berbers, who constituted the majority of the invading troops and whose numbers and influence constantly increased over the course of the centuries because of their continual influx from Africa. The Muslims, or *mawlās*, and their descendants, the *muwallads*, comprised by far the majority of the population, since, as indicated above, economic motives induced a considerable number of landowners to abandon Christianity. Then came the Mozarabs, whose numbers diminished in the course of the centuries; the Jews; and, on a lesser scale, Turkish and eastern European slaves who entered the peninsula later.

Muslim society

This new society was still in a period of gestation when decisive clashes took place between the Muslim troops, led by ʿAbd-ar-Raḥmān al-Ghāfiqī, and the army of the Franks, under Charles Martel at Poitiers (732). Between 711 and 756 Spain was ruled as part of the amirate dependency of Damascus. The period is so called because the governors of the peninsula were appointed, in the final analysis, by the Umayyad caliph at Damascus. This was a turbulent era, marked by continuous civil wars and by armed clashes between Arabs and Berbers. A major Berber uprising against the Arabs in Africa produced powerful repercussions in the peninsula. The Arab army that the caliph dispatched from Syria to subdue the Berber dissidents was defeated. The Syrian army under Balj was forced to seek refuge in Ceuta, whence it moved on to Spain, where its leaders seized power in Córdoba (Qurṭubah). This situation was altered with the establishment of an independent amirate (756) by ʿAbd ar-Raḥmān I ad-Dākkil, an Umayyad prince who, having succeeded in escaping from the slaughter of his family by the ʿAbbāsids, arrived at Córdoba and became politically independent of them (not religiously; he did not adopt the title of caliph).

The independent amirate. The dynasty of the Andalusian Umayyads (756–1031) marked the zenith of the Arabic civilization in Spain. Its history may be divided into two major periods—that of the independent amirate (756–929) and that of the caliphate (929–1031)—and may be interpreted as revolving around three persons of like name—ʿAbd ar-Raḥmān I (756–788), II (822–852), III (912–961)—and one dictator, al-Manṣūr (976–1002).

state. Cruel, energetic, and devoid of scruples, he vigorously checked all dissident elements in the peninsula. He endeavoured to base his power on the Eastern aristocracy affiliated with his house and heaped upon it property and riches, though he nonetheless treated it ruthlessly when it showed signs of rebellion; he protected the religious authorities who represented orthodoxy, and, through a series of punitive campaigns, he held in check the Christians of Asturias, who sought to reoccupy the desert to the north of the Duero. In the eastern part of the country he was troubled by intrigues of the ʿAbbāsids, and in the north he had to cope with the ambitions of Charlemagne, who menaced the valley of the Ebro (Ibruh). Charlemagne failed ignominiously in being forced to raise the siege of Saragossa and in the course of his retreat he suffered a defeat at Roncesvalles (778), which is celebrated in the great medieval epic *La Chanson de Roland.* The Franks had to be content with occupying the upper valleys of the Pyrenees. The Frankish advance ended with the Muslim seizure of Barcelona (Barshilūnah) in 801 and Old Catalonia.

The reign of ʿAbd ar-Raḥmān II

ʿAbd ar-Raḥmān I's successors, Hishām I (788–796) and al-Ḥakam I (796–822), were confronted with severe internal dissidence among the Arab nobility. A rebellion in Toledo was put down savagely, and the internal warfare caused the amir to increase the numbers of Slav and Berber mercenaries and to impose new taxes to pay for them.

ʿAbd ar-Raḥmān II inaugurated an era of great political and cultural splendour for Muslim Spain. The arrival in Spain of the Persian musician Ziryāb, for example, marked the beginning of a sharp "Orientalization," or, more precisely, of an "Iraquization" of customs that lent sophistication and refinement to the court. Certain technical advances were introduced, such as the technique of cutting rock crystal by ʿAbbās ibn Firnās and the importation of exotic seeds by the poet al-Ghazāl. ʿAbd ar-Raḥmān's greatest problems sprang from his restless vassals in the Ebro Valley, namely, the convert Banū Qasī family and, above all, before his death, from the Mozarabs, who, incited by extremist chiefs Alvaro and Eulogio (the latter, after his death, being canonized), sought to strengthen their ideas through the aura of martyrdom and began to revile publicly the Prophet Muḥammad—an action punishable by death (850). ʿAbd ar-Raḥmān II sought to persuade the "criminals" to retract, by alleging some pretext or by affirming that the insult had been proffered involuntarily. Failing in this effort, he was obliged to impose the death penalty. The "vogue" of seeking martyrdom voluntarily continued even after the death of the Amir. Both the latter and his successors, however, comported themselves with extraordinary tact and sought to soften the rough edges of friction, and this persecution, provoked by the Christians themselves, took a toll of 53 victims, the last of whom found themselves disavowed by their own ecclesiastical authorities.

In foreign policy ʿAbd ar-Raḥmān II conducted intensive diplomatic activity: he exchanged ambassadors with the Byzantine Empire and with the Frankish king Charles the Bald and maintained friendly relations with sovereigns of Tāhart, which supplied Spain with needed grain. He was able to confront the constantly growing incursions of the Northmen, whom he defeated in the vicinity of Seville. Furthermore, he established permanent defenses against the Viking invaders by the creation of two naval bases, one facing the Atlantic at Seville and another on the Mediterranean shore at Pechina near Almería.

His successors, Muḥammad I (852–886), al-Mundhir (886–888), and ʿAbd Allāh (888–912), were confronted with a new problem, which threatened to do away with the power of the Umayyads—and perhaps with Islām itself—in the peninsula: namely, the *muwallads,* who, having become more and more conscious of their power, rose in revolt in the north of the peninsula, led by the powerful Banū Qasī clan, and in the south (879), by ʿUmar ibn Ḥafṣūn. The struggle against both these enemies was long and tragic—especially against the latter, who was well protected by the walls of the fortress of Bobastro near Córdoba. Ibn Ḥafṣūn was on the verge of delivering the final blow to the Umayyad dynasty, but he lacked the power to win the decisive Battle of Poley (891), which, if it did not put an end to his excursions, at least confined them to eastern Andalusia. ʿAbd Allāh was able to reduce the rebels one after the other, starting with the weakest, and, when he died, he left in the hands of his grandson, ʿAbd ar-Raḥmān III, more than sufficient means to challenge Ibn Ḥafṣūn successfully. The latter, moreover, committed the political stupidity of reverting to the Christianity of his Spanish ancestors, and, consequently, he was deserted by numerous *muwallads,* who regarded themselves as good Muslims. When Ibn Ḥafṣūn died in 917 his sons were forced to capitulate, and in 928 ʿAbd ar-Raḥmān III was able to capture the hitherto impregnable fortress of Bobastro.

The Caliphate of Córdoba. One of the first political problems of an international nature that was posed for ʿAbd ar-Raḥmān III was that of his juridical status vis-à-vis the ʿAbbāsid caliphate at Baghdad. As long as religious unity existed in the Islām dominions, the Umayyads in Spain were content to acknowledge the religious leadership of Baghdad. When after 910 there grew up in Tunis the heterodox caliphate of the Fāṭimids, ʿAbd ar-Raḥmān III did not hesitate to proclaim himself caliph or to adopt the caliphal title of an-Nāṣir (929). The new Muslim state, known as the Caliphate of Qurṭubah, was to rule in Spain for little over a century. His internal situation was already almost assured; the last bulwarks of resistance were not long in capitulating (Toledo, 933), and from that time on he was able to devote all his efforts to foreign affairs. As to Christian Spain, his successes were meagre, and, what was more serious, he suffered a severe defeat in 939 at Simancas (Shānt Mānkus). From then on, however, the internal debilitation of the Kingdom of Leon enabled him to restore his predominance in its peninsula by political means. He consolidated his position by a series of embassies to the Roman emperor Otto I, to the Christian sovereigns of the peninsula, to the Pope, and to Constantinople. He furthermore extended his protection to the Muslim pirates who established a base in southern France. In Africa the Fāṭimids fought the establishment of an empire that would reach as far as the Atlantic and encompass Andalusia (al-Andalus). And, in order to forestall a Fāṭimid attack on Spain, an-Nāṣir occupied Melilla (Malīlah) and Ceuta (931). Intense naval warfare between the two western caliphates coincided with clashes on land in Morocco and attempts at subversive wars in the enemy states. In the latter area, an-Nāṣir came near to overthrowing the Fāṭimid caliphate by his support of the rebel Abū Yazīd; the conflict between the Umayyads and the Fāṭimids dragged on and ended when the latter conquered Egypt (969) and lost interest in Morocco, thus leaving a power vacuum that was rapidly filled by the Umayyads.

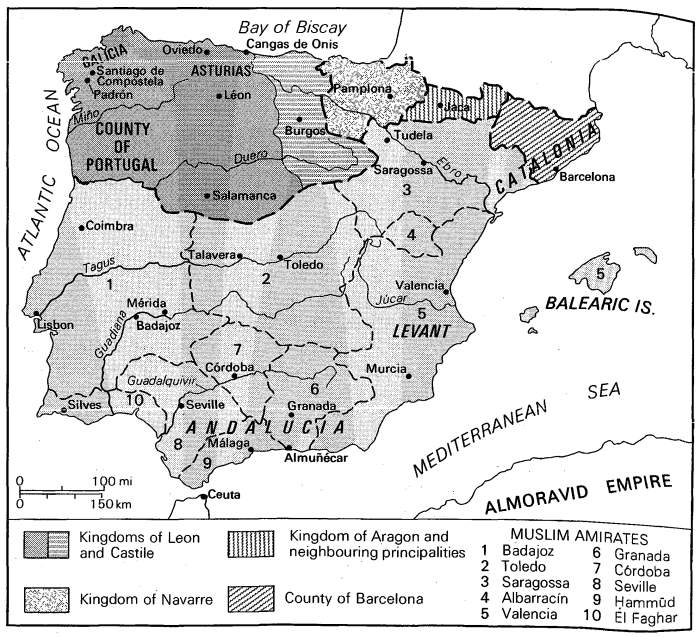
An-Nāṣir was succeeded by his son al-Ḥakam II (961–976), who adopted the caliphal title of al-Mustanṣir. His reign was peaceful, and he succeeded in resolving the problem of Morocco, thanks to the strategic ability of General Ghālib and the policy of the general of the African army, Abu ʿĀmir al-Maʿāfirī, later known as al-Manṣūr, the Victorious One (Almanzor).

Al-Manṣūr

On the death of al-Mustanṣir, his throne was occupied by his son, a minor, Hishām II al-Muʿayyad, who grew up under the tutelage of his mother, Aurora, and of the prime minister al-Muṣḥafī, who before long was liquidated by al-Manṣūr (governed 976–1002). The latter succeeded in eliminating all temporal power of the caliphs, whom he dominated, and acquired dictatorial power for himself.

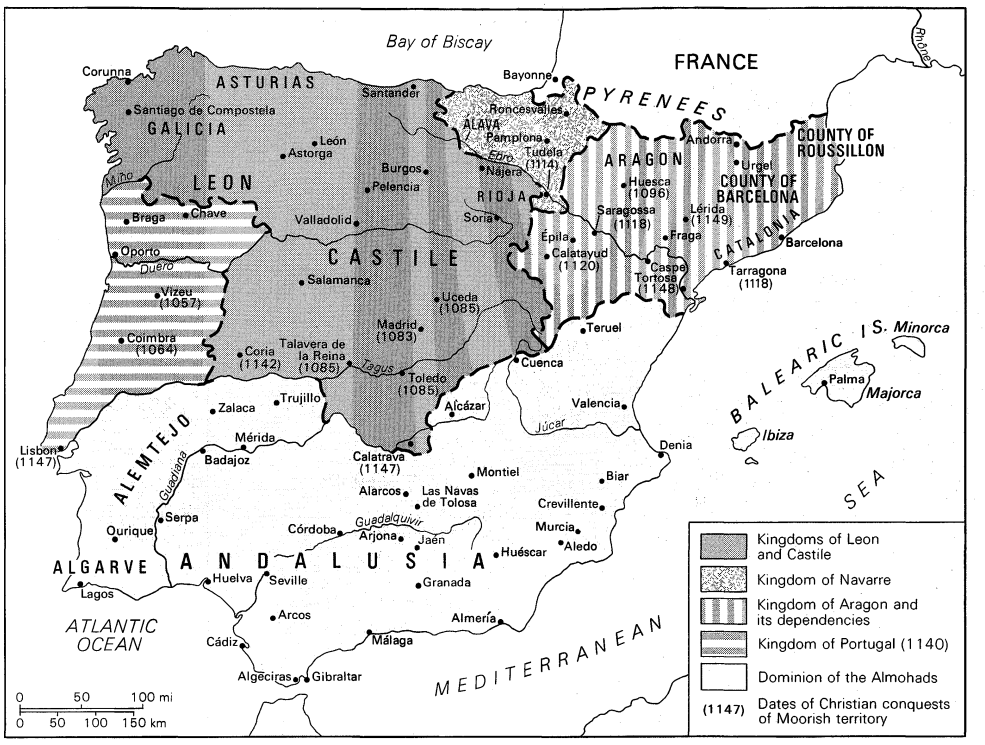
He won complete control over Morocco, which he transformed into the viceroyalty of Córdoba, and he arrested the expansion of the Christian kings from the north through a series of raids—usually every six months—in which he sacked nearly every Christian capital. With the support of a professional army consisting predominantly of Berbers, many of them recent arrivals from Africa who obeyed him blindly, he managed to dispense with the Arab aristocracy, which for the most part was pro-Umayyad, and to hold in check the influence of the slaves, whose numbers had been increasing since an-Nāṣir had placed them in posts of high responsibility. But this balancing of forces—Arabic aristocracy, Berbers, and slaves—could only be sustained by the strong hand of a ruler such as himself.

Al-Manṣūr played the role of a grand lord. A protector of poets and scholars, he concealed his rationalism under a cloak of piety and was the darling of the *faqīh*s (scholars versed in the traditions of Islām); he contrived to attract to himself the outstanding poets of that era. At the time of his death, after a victorious campaign in Aragon, he succeeded in leaving a robust and well-organized state for his son al-Muẓaffar.



Al-Muẓaffar (1002–08) continued the policies of his father. He hemmed in Hishām II and fought against the Christians, but he died prematurely; his brother ʿAbd ar-Raḥmān Sanchuelo lacked the fortitude to maintain the structure built by his father. An uprising that sought to vindicate the political rights of Hishām II, whom Sanchuelo kept in seclusion, resulted in his death and brought about the beginning of the end of the Umayyad dynasty in Spain.

The ṭāʾifas. Upon the death of ʿAbd ar-Raḥmān Sanchuelo, 21 years of unrest followed (1009–31), during which al-Muʾayyad was lost trace of and during which constant clashes occurred among Arabs, Berbers, and the slaves. The consequence of those years of anarchy was the formation of numerous independent kingdoms, or *ṭāʾifas*, which may be classified into the following: (1) Arab factions in the valleys of the Guadalquivir (al-Wādī al-Kabīr) and Ebro rivers; (2) Berber factions in the Meseta Central, in the steppelike part of Aragon, in Granada (Gharnāṭah), and in nuclei dispersed throughout western Andalusia (Gharb al-Andalus); and (3) groups of slaves in the east.



The political history of the period constitutes an uninterrupted series of internecine wars. Pre-eminent is the confrontation between the Arab factions, under the leadership of Seville (Ishbīliyah), governed by the dynasty of the Banū ʿAbbād, and the Berbers, presided over by Granada. Little by little, Seville succeeded in uniting southern Spain under its aegis. This state was ruled over, first of all by al Muʿtaḍid, a sovereign devoid of scruples, who pretended at first to have found the vanished Hishām II al-Muʾayyad (at the most, the pretender was a mat maker from Calatrava who bore some resemblance to the old caliph), and then by a poet-prince, his son al-Muʿtamid. In the east, except for a brief period when the petty state of Denia (Dāniyah) built a powerful fleet that enabled it to stage incursions throughout the western Mediterranean as far as Sardinia, the various *ṭāʾifas* preserved a certain static equilibrium; farther to the north, the various *ṭāʾifas* also wasted their time in interminable internal quarrels.

This fragmentation facilitated the expansion of the Christian states of the north, which, lacking the demographic potential to repopulate the lands they had succeeded in occupying, wisely annexed only those that they were capable of repopulating and garrisoning. The Christian states also imposed a heavy economic burden of tribute on the *ṭāʾifas*. Christian armies forced the Andalusian petty kings to buy peace by paying annual tribute, the famous *parias*. This tribute, while it revitalized the economy of the Christian states, created sharp friction between the Muslim authorities and their subjects. The *ṭāʾifas* had constantly to increase the yield from their imposts, and they constantly laid new and heavier tax burdens on their subjects; when cash was lacking, they devaluated the currency, minting low-standard coins that were not accepted by the Christians. This, in turn, gave rise to new tax increases and to popular discontent, which was considerably aggravated by the clerical party of

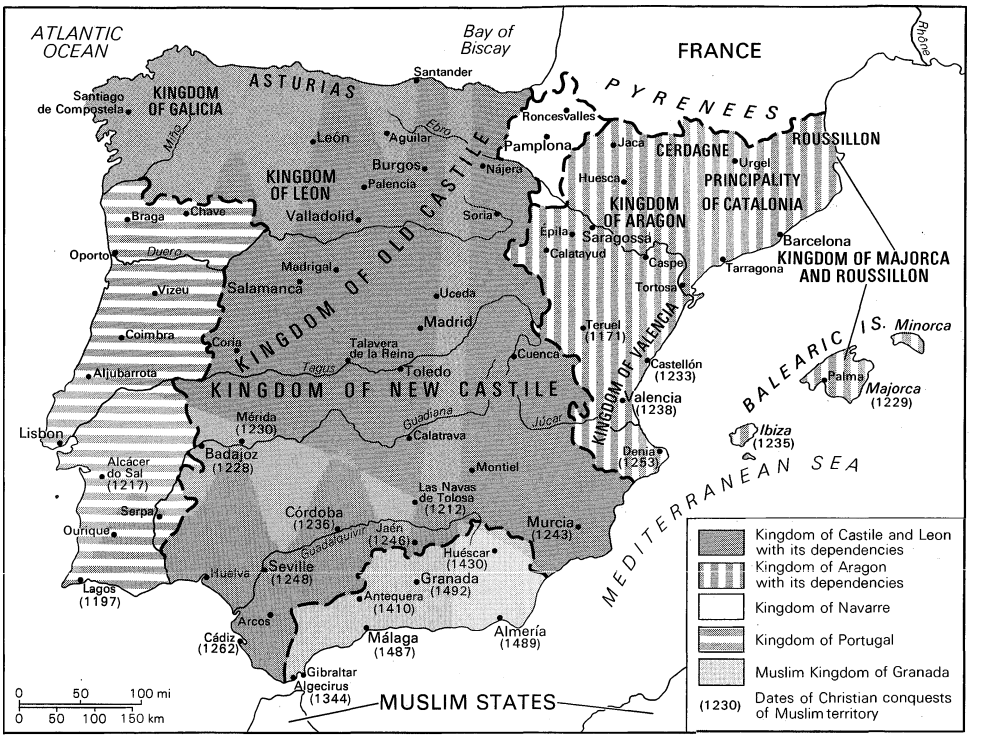
the *faqīh*s. Furthermore, the petty local courts were characterized by extravagant luxury and lavish public outlays. This situation rendered Andalusia ripe for the foreign intervention that came when the Castilians occupied Toledo (1085), the key to the Meseta Central and to the peninsula. The factional chiefs, alarmed by the Christian advance, called in the help of the Almoravids.



The Almoravids. The Almoravid ruler Yūsuf ibn Tāshufīn entered the peninsula and by a slow advance reached the fields of az-Zallāqah, north of Badajoz (Baṭalyaws), where in 1086 he defeated a Castilian army under Alfonso VI; then he became an independent prince either unwilling or unable to exploit their victory. For four years Almoravid policy in Spain remained indecisive, but it appears that the siege of Aledo (1088) convinced Yūsuf ibn Tāshufīn of the urgent necessity of putting an end to the *ṭā'ifa*s if he were going to rescue Spanish Islām. In 1090–91, he deposed their rulers—except for Banū Hūd of Saragossa—and inflicted a series of defeats on the Christians. Only one of the chiefs of state, Rodrigo Díaz de Vivar (the Cid), exiled from his native Castile by King Alfonso VI, was able to resist the Africans, and he furthermore set himself up in an independent kingdom—a new *ṭā'ifa,* that of Valencia. The figure of the Cid—the Lord, a title that the Arabs conferred upon him—is quite curious: first he served as a mercenary under Alfonso VI; then he became an independent prince in the east, ruling over states that were entirely inhabited by Muslims. He led a retinue of men who were hardened in combat and who understood nothing of the ways of peace. He had the good fortune, however, of finding efficient administrators from among the Mozarabs residing in his states; further, his superb grasp of Almoravid tactics enabled him to overcome his numerical inferiority. Upon his death, Valencia remained under the control of his men until 1102, when they were forced to evacuate it and seek refuge in Castile. Following the fall of Valencia, the Almoravids were unopposed; and in 1110, under the leadership of ʿAlī ibn Yūsuf (1106–43), they were able to occupy Saragossa.

The Cid

The conquest of Saragossa, however, marked the beginning of the Almoravid decline. The Aragonese king Alfonso el Batallador (the Battler) and his stepson, Alfonso VII of Castile, launched renewed Christian assaults against the entire frontier of Islām in Spain. The Almoravids, who after 1121 experienced serious difficulties in Africa as a result of the preachings of a Berber reformer, Ibn Tūmart, could not successfully parry the blow; indeed, they had to hire Christian mercenaries to help them. In 1118 Saragossa fell into the hands of the Battler, who reconquered a large part of the valleys of the Jalón and of the Jiloca. A resounding Almoravid victory over the Aragonese at Fraga (Ifrāgah) in 1134 bore no fruit because the Almoravids lacked the resources to exploit their victory.

The Almohads. In Africa, the Almohads finally triumphed, and ʿAbd al-Muʾmin (1130–63), successor to Ibn Tūmart, was able to turn his attention to Spain and to undertake the integration of all the Muslim states—the second *ṭā'ifa*s—formed under the shield of the latest internecine wars caused by the Almoravid decline. Of these states, there stood out especially that under Ibn Mardanīsh (1147–72), who, with a largely Christian army, was successful in becoming the master of southeastern Spain.

The Almohads assumed the title of caliph, introduced a series of severe religious measures, and sought to strengthen their states through religious unification, in practice, by compelling the Jews and Christians to emigrate. Two great sovereigns, Abū Yaʿqūb Yūsuf (1163–84) and Abū Yūsuf Yaʿqūb al-Manṣūr (1184–99), raised western Islām to the zenith of its power. Taking advantage of the quarrels that divided the Christian kingdoms of Castile and Leon, al-Manṣūr defeated the sovereign of the former, Alfonso VIII, in 1195 at the Battle of Alarcos (al-Arak); but, despite this victory, he proved unable to exploit his triumph—repeating the fate that befell the Almoravids after al-Zallāqah. Years later, during the reign of his successor an-Naṣīr (1199–1214), the Christians avenged this defeat in the Battle of Las Navas de Tolosa (al-ʿIqāb). This battle created a power vacuum into which stepped some of the *ṭā'ifa*s, or petty kingdom states, prominent among which were those of Banū Hūd of Murcia (Mursiyah) and of the Naṣrids of Arjona (Arjūnah). The policies of the two states were quite divergent: Muḥammad ibn Hūd (1228–38) emphasized resistance on the part of the Muslims against the Christians who, led by Ferdinand III the Saint, were occupying the Guadalquivir Valley; Muḥammad I ibn al-Aḥmar (ruled in Granada 1238–73), on the other hand, acknowledged himself to be a vassal of the King of Castile and even helped him against his own co-religionists. This realistic policy enabled him to preserve in his possession the territory of what are the modern provinces of Málaga, Granada, and Almería, together with portions of neighbouring provinces.

Spain in 1300.

Thus, after the middle of the 12th century and the reconquest of Jaén (Jayyān), Córdoba, Seville, and Murcia by the Castilians, and of Valencia and the Balearic Islands by the Aragonese under James I the Conqueror, no independent dominions of Islām remained in Spain with the exception of Granada and the tiny area of Crevillente (Qarbalyān), which soon disappeared.

Granada. The Naṣrid dynasty founded by Muḥammad ibn al-Aḥmar in Granada, however, was destined to endure for two and a half centuries. The Muslims of Granada lacked sufficient forces to constitute a genuine danger to the Christians, who limited themselves to collecting tribute and launching, from time to time, an attack against them, snatching from them some city or other. The people of Granada, for their part, always bore in mind what had happened in the cases of the Almoravids and the Almohads, who, having arrived from Africa as auxiliary troops, became masters in Spain. Vis-à-vis the new Moroccan empires, particularly the empire of the Banū Marīns, they maintained a policy of balance of power. They did permit the influx of volunteers from Africa to enroll in their army to fight against the Christians, but never permitted the crossing of the Strait of Gibraltar by massive organized contingents. The years between 1302 and 1340 are of an extraordinary complexity from a diplomatic as well as a military point of view. Both Morocco and Castile vied for the possession of the Granadine ports of Tarifa (Ṭarif) and Algeciras (al-Jazīrah al-Khaḍraʾ), ports that dominated the Strait. Granada, therefore, allied alternately with the Africans and Christians, hoping thus to maintain the balance of power. A fourth state, Catalonia, torn by discord under James II, aspired to obtain a larger slice of the Reconquista and intervened with its fleet and laid siege to Almería (al-Marīyah), under the pretext of a crusade (1309).

When Ismāʿīl I (1314–25) ascended the throne, another branch of the Naṣrid family gained the power. Ismāʿīl was able to check the reconquest ambitions of Alfonso XI—who later, in 1340, with the aid of the Portuguese, won a decisive victory over the Berber army of Abuʾl-Ḥasan at the Battle of the Salado.

The defeat of the Berbers and the lack of interest in reconquest on the part of the successors of Alfonso XI created a favourable climate for Granada, which found itself free from political pressures of both Moroccans and Castilians. During the reign of Muḥammad V (1354–59; 1362–91) Granada reached its greatest splendour; its ministers included some of the most learned men of the epoch, such as the historian Ibn al-Khaṭīb, the physician Ibn Khātima, and the poet Ibn Zamraq. It protected Ibn Khaldūn, the great philosopher of history.

The reign of Muḥammad V

During this era there grew up also the institution of the "judge of the frontier," *juez de la frontera y de los fieles del rastro,* a Moorish official who heard Christian complaints against the Granadinos; this did much to reduce frontier incidents between Moors and Christians.

Little is known about the decline of the Naṣrid dynasty, since with Ibn al-Khaṭīb died the last great Muslim historian of Andalusia. The extant records and reports from the 15th century are as a rule from Christian sources or from the tales of travellers. The narrative poems that are of the utmost interest as historic sources for other periods in Muslim history are completely lacking in this era. The conventional verses of the king-poet Yūsuf III (1408–17) or the anonymous Arab poet of the romance *Abenamar, Abenamar, moro de la morería* do little to illuminate the history of this period. More illustrative, however, are the neglected verses of ʿAbd al-Karīm al-Qaysī (*c.* 1485), an esteemed member of Granada's middle class, who eschewed classic themes and wrote of such mundane phenomena as the increase in the cost of living or the decline in the power of the sovereign.

Foreign relations enjoyed a long period of tranquillity as a result of the ghastly losses of life from the Black Plague (1348–51) and, afterward, from the internal wars that weakened Christian Castile. Furthermore, border incidents were quickly disposed of by the "judge of the frontier and the faithful of the trail." Only an occasional confrontation served to remind the Muslims and Christians that the Reconquista had not yet come to an end. In the 15th century, however, the Reconquista proceeded apace. Prince Ferdinand seized Antequera (Antaqīrah) in 1410; Jimena and Huéscar fell in 1435, Huelma in 1438, and Gibraltar in 1462. One result of these events was that the people of Granada became increasingly less tolerant of Christians, and the Granadine *faqīh*s professed the most extreme xenophobia. This policy, common to both point to the existence of a Granadine school of law, which before long exerted an influence on the other side of the Strait; for the Moroccans, subjected to the constant pressure of the Portuguese—who had gained possession of their coastal areas (Ceuta, first, in

1415)—realized like the Granadinos that the only way to escape Christian hegemony was through the profession of the most rigorous Islāmic ideals and in the practice of the most extreme xenophobia. This policy, common to both sides of the Strait of Gibraltar, did not achieve equal results. It saved Morocco from the hands of its enemies, but in Granada it became the *casus belli* for the campaign that was to inaugurate the end of the Reconquista.

The end of Andalusian Islām

The sultan Muley Hacén (Abū al-Ḥasan ʿAlī) refused to pay the annual tribute he owed to the Catholic kings and seized the fortified town of Zahara (1481), thus launching hostilities that were destined to liquidate the last bastion of Andalusian Islām. The campaign proved to be difficult for the Christian army despite the discord that split the royal Granada family, and that was exploited in Machiavellian fashion by Ferdinand the Catholic: Boabdil (Arabic: Muḥammad Abū ʿAbd Allāh), son of Muley Hacén, rebelled in Guadix against his father and was recognized in Granada with the aid of the Abencerrajes, a powerful Granada family. Muley Hacén, however, who had taken refuge in Málaga, succeeded in recapturing the capital with the assistance of the Zegries, or border people. But he was successfully deposed by his brother, el Zagal (Abū ʿAbd Allāh Muḥammad az-Zaghall—the Valiant One), who was supported by the Venegas family.

Boabdil was captured by the Catholic kings during his attack at Lucena and, in order to regain his freedom, signed the Pact of Córdoba, in which he pledged himself to deliver the portion of the kingdom that was in the hands of el Zagal, in exchange for help from the Castilians to recover Granada, part of which (Alhambra) was still in the hands of Muley Hacén. The latter and el Zagal allied themselves against Boabdil, who had to flee and seek asylum in the court of the Catholic king. The death of Muley Hacén in 1485 enabled Boabdil, with the help of the inhabitants of Albaicin, to occupy the Alhambra. El Zagal, who had been routed by the Christians before Vélez Málaga, in 1487 retreated to Guadix and, being incapable of further resistance, delivered his states to the Catholic kings and emigrated to Tlemcén (1491). Taking advantage of this civil war, the Christians had seized Ronda, Marbella, Loja, Málaga, and Razo and were in a position to lay siege to Granada. When the siege began, the population divided into factions: one consisted of pacifists and the other of belligerent persons who, despite their quarrels, fiercely defended the city.

By the end of 1491, the situation became desperate, and Boabdil capitulated, but, before making the news public, he brought a detachment of Castilian troops into the Alhambra on the night of January 1–2, for the purpose of avoiding a disturbance on the part of his vassals that might render it impossible for him to comply with the terms of the pact. The official surrender, and with it the end of Muslim occupation of the peninsula, took place the following day, January 2, 1492.

Society. In discussing the influx of the Muslims into Spain, the various categories of the population that settled there were earlier pointed out: Arabs (*baladiyyūn* and Syrians), Berbers, *muwallads*, Mozarabs, Jews, and slaves. The Muslim masses continued to increase during the early centuries of the occupation, because of the wave of conversions that markedly reduced the number of Christians. Precise figures cannot be given, but it is estimated that at the time of the conquest some 4,000,000 Spaniards inhabited the peninsula, while the total number of immigrant Arabs did not exceed 50,000. The population was primarily rural, and large cities were few in number. At the end of the 10th century one can estimate the following urban populations: Córdoba, 250,000; Toledo, 37,000; Almería, 27,000; Granada, 26,000; Saragossa, 17,000; Valencia, 15,000; and Málaga, 15,000.

At the peak of the administrative pyramid was the amir, caliph, sultan, or king, depending on the era, and all the functionaries exercised their power by delegation from the sovereign, who embodied within himself all executive, legislative, and judicial authority, even though at times he delegated power to a *ḥājib* (chamberlain) or, after the 11th century, to a prime minister (*dhū al-wizāratayn*). In the discharge of his functions he was assisted by various viziers. At times, there was, at the head of the various departments, a *kātib*, or official secretary. The provinces were governed by *wālīs* who enjoyed wide autonomy. There existed no uniform municipal organization, and the duties fulfilled by some officials cannot be considered as representative; such are, for example, the chief of police (*ṣāḥib al-shurta*) and the market inspector, known until the 10th century as *ṣāḥib al-sūq* (zabazoque) and later as *muḥtasib*. The Muslim cities of Spain, with their baths, parks, markets, mosques, and high cultural level, were quite different from and, some believe, superior to those of Christian Europe.

The military

The army was based on the voluntary recruitment of soldiers or on contracts with them from abroad. The units (*jund*), grouped according to the places of origin of their men, were strategically deployed along the borders and possessed extraordinary mobility at the time of the caliphate. Holding castles close to the enemy lands as their bases of operation, they were glad to welcome into their midst the Muslims, who were eager to die in combat, in order thus to open for themselves the gates of paradise. These volunteers, who became more and more numerous with the passage of time and about whom numerous details are known, were frequently second class soldiers, since they enrolled during years when they constituted a hindrance rather than a source of help. The *marina*, or navy, organized by ʿAbd ar-Raḥmān II, remained an effective force until the middle of the 14th century.

The entire state structure was supported, theoretically, on a foundation of the most rigid Islāmic orthodoxy and interpreted by the Mālikī school, which in Spain manifested special characteristics of hyperconservative nature. It is not known whether the school acquired these traits upon settling in the peninsula because intolerance was indigenous to the inhabitants there or whether it indoctrinated the Spanish Muslims in this manner, who transmitted it, in turn, to the Christian reconquerors.

The economy. The Moorish conquerors divided the lands seized from the Christians by force of arms and operated them, as a general rule, by means of "tenant farmer" leases. Possibly about the 10th century the woodlands achieved their widest expansion, and the cultivation of irrigated lands was encouraged by means of drastic regulations, which, however, were favourably received. Plants used in the manufacture of textile (flax, cotton, esparto grass, and silk) as well as those with medicinal properties were protected by the state.

In addition to agriculture, the raising of livestock (Christian sheep and Arabian horses) occupied a central position in the peninsular economy. As in the Roman period, lead, iron, gold, and mercury were mined. Domestic industry, which never went beyond the handicraft state, culminated in the production of luxury cloths such as silk (a state monopoly), in the tanning of hides (Cordoban leather), and in the export of ivory objects. Commerce was selective and carried on in products "of low weight and high value" that frequently reached the most remote regions of the known world. There are reports of Andalusian travellers as far as Sudan, central Europe, and even China.

The evolution of economic life was conditioned by political events; in proportion as the productive centres passed into Christian hands, the commercial vigour of the Muslims kept diminishing. No phenomenon is more illustrative of this than the confidence attached to the currency. In the 11th century, Barcelona was counterfeiting Muslim coins; in the 14th century, Granada was doing the same with Barcelona coins.

Culture of Muslim Spain. Arab civilization in the peninsula reached its zenith when the political power of the Arabs began to decline. In the 8th century, in the years immediately following the conquest, there are no traces of a cultural level higher than that attained by the Mozarabs who lived among the Arab conquerors. All available evidence points to the fact that in this period popular works of medicine, agriculture, astrology, and geography were translated from Latin into Arabic. Many of these texts must have been derived from the *Etymologies* of Isidore of Seville and from other Christian writers. In the 9th century, the situation was changed abruptly: the Andalusians, who travelled east in order to comply with the injunction to conduct a pilgrimage to Mecca at least once in their lifetimes, took advantage

of their stay in those regions to enhance their knowledge, which they then introduced into their native country.

Poetry

Literature. In the 9th century there flourished such court poets as ʿAbbās ibn Nāṣih, ʿAbbās ibn Firnās, Yaḥyā al-Ghazāl, and the knight Saʿīd ibn Jūdī. Towering above all these, however, is Ibn Hāniʾ, nicknamed the "Mutanabbī of the West," who by virtue of his religious ideas was obliged to forsake his native land and enter in the service of the Fāṭimid caliph al-Muʿizz. In the 10th century, another bardic tradition grew up around al-Manṣūr. Bards performed the functions of modern journalists; they accompanied their protector on war expeditions and celebrated his exploits in verse the singsong rhyme of which became engraved in the folk memory of the people of Andalusia. This occasional poetry did not always attain literary heights, but at times that was indeed the case. And al-Manṣūr himself chose as "poet-journalists" the foremost talents of his time—men such as Ibn Darrāj al-Qasṭallī, ar-Ramādī, Saʿīd of Baghdad, at-Ṭalīq, and numerous others. And it was in the 10th century that Ibn Faraj of Jaén deemed himself to possess sufficient background to compose the *Kitāb al-Hadāʾiq* ("Book of Orchards")—the first anthology of Andalusian poets. This was soon followed by another, that of the physician Ibn al-Kittānī.

The highest peak in Islāmic literature in Spain was attained during the era of the *ṭāʾifa*s, when the poet-king al-Muʿtamid established an embryo of an academy of belles lettres, which included the foremost Spanish intellects, as well as Sicilians who emigrated from their native land before its conquest by the Normans. Other petty kings in the peninsula endeavoured to compete with al-Muʿtamid but did not succeed in assembling a constellation of writers of comparable stature.

In the 12th century, in the Andalusian Levant, outstanding poets included Ibn Khafajā of Alcira and his nephew Ibn az-Zaqqāq. In the era of greatest decadence in the 13th century were Abū al-Baqāʾ of Ronda (*c.* 1285), Ibn al-Khaṭīb, Ibn Saʿīd al-Maghribī, and Ibn Zamraq, whose verses are preserved in the stuccos of the Alhambra.

Prose

In Arab literature, including that of contemporary times, poetry possesses greater vitality than prose. But, even so, it is necessary to mention Ibn Shuhayd (*c.* 1035), author of a work that lent inspiration to al-Maʿarrī for his *Risālat al-ghufrān* ("Epistle of Pardon"). The prolific Ibn Ḥazm of Córdoba (died 1064) wrote the delightful *Tawq al-ḥamāmah* ("The Ring of the Dove"), dealing with love and lovers, which is still popular today. The enormous output of Ibn Ḥazm is not possible to enumerate here. Nevertheless, it suffices to cite his *Kitāb al-fiṣal,* a history of religions that was not surpassed by Western scholars until well into the 19th century. Another polymath was the vizier-historian Ibn al-Khaṭīb (died 1375). Two 12th-century histories of literature, by Ibn Bassām and Ibn Khāqān, are excellent sources of information concerning the apogee of Andalusian letters. Often the best grammars and dictionaries of a language are written by authors living in the peripheral zones who endeavour to prevent gross errors being committed by their countrymen in the region. This perhaps explains why Andalusia, located at the western fringe of the Muslim world, produced works that to this day are used as texts in certain traditional Islāmic universities. Among these grammarians should be mentioned al-Zubaydi, tutor of Hishām II and Ibn Maḍā of Córdoba, who proposed a drastic reform of grammatical methods. Ibn Mālik of Jaén's didactic poem *Alfiyya* ("The Thousand Verses") constitutes an excellent handbook of grammar; and Abū Ḥayyan of Granada (died 1344), who emigrated to the east, wrote an outstanding commentary on the Qurʾan as well as the first Turkish grammar. In the field of lexicology the blind Ibn Sīda of Denia (died 1066) is pre-eminent; he was also the author of a sort of "dictionary of ideas."

In the field of Qurʾānic science there stand out Abū ʿAmr of Denia and Ibn Fierro of Játiva, whose handbooks made possible the correct cantilation, or intonation of the chanting, of the Qurʾān. Also produced there were various collections of *ḥadith*s (traditions referring to the Prophet), but none of these was of particular importance. In this domain, the Andalusians were imitators of the East, and personalities such as Ibn ʿAbd al-Barr, a certain Ibn Rushd (the grandfather of Averroës), and an Ibn ʿĀṣim are of merely marginal interest.

The first extant chronicles in Muslim Spain, such as the *Taʾrīkh iftitāḥ al-Andalus* ("History of the Conquest of Spain"), by Ibn al-Qūṭiya, date back to the 10th century. In the *ṭāʾifa* era the pre-eminent Spanish historian is Ibn Ḥayyān of Córdoba (died 1076), whose *Muqtabis,* preserved for the most part, is an anthology of historic texts based to a great extent on the work of his predecessors. From the point of view of human interest are the *Memoirs* of the king Ziri ʿAbd Allāh, who was deposed by the Almoravids and who sought to justify in those memoirs his deeds as a statesman. In the Naṣrid era is found the frequently aforementioned Ibn al-Khaṭīb. The works of the North African historians Ibn Khaldūn and al-Maqqari (died 1631) supply much information concerning the Arab domination of Spain.

Science. In the mid-11th century, the *qāḍī* of Toledo, Ibn Ṣāʿid, composed a noteworthy handbook of history of science that contained much information on technical subjects. Mathematical sciences received little attention, but mention should be made of Maslama of Madrid (died 1008), who probably took part in the translation of Ptolemy's *Planispherium* and made some contributions to pure mathematics. Also during the heyday of Granada, there was al-Qalaṣādī, commentator on Ibn al-Bannāʾ, who did important work on fractions. Despite their lack of interest in the physical sciences, the Andalusians excelled in astronomy, both theoretical and practical. An array of these scholars sought to simplify the astrolabe, and finally al-Zarqālī (died 1087) achieved success by inventing the apparatus called the *azafea,* which was widely used until the 16th century. Al-Zarqālī also anticipated Kepler by suggesting that the orbits of the planets are not circular but ovoid. Jābir ibn Aflaḥ (12th century) criticized the Ptolemaic system.

Astrology was popular in Muslim Spain, and the Umayyad rulers, after 788, maintained an official astrologer in their courts. The most widely used astrological treatises were those of the Tunisian ʿAlī ibn Abī Rijāl and another anonymous scientist, who made a translation from Vulgar Latin into Arabic in the 8th century. This book was translated from Arabic into Spanish during the era of Alfonso under the title of *Libro de las Cruces* ("Book of the Crosses").

Natural science

The treatises on esoteric or occult subjects attribute to Maslama two works on natural science that are not properly his but may be ascribed to one of his pupils. They are *Ghāyat al-ḥakīm* ("The Goals of the Scholar"; also known as *Picatrix*) and *Rutbat al-ḥakim* ("The Step of the Scholar"). Greater interest is merited by the *Materia Medica,* a revision of the Eastern Arabic text of the 1st-century Greek physician Pedanius Dioscorides, ordered by an-Naṣir, on which Jews, Arabs, and Christians collaborated. Gradually, the Andalusian Arabs kept adding new medicinal "simples" (which described the properties of various medicinal plants) to those described by Dioscorides, and the last eminent essayist on the subject, Ibn al-Bayṭār (died 1248), describes more than 1,400 of these. The Arabs of Andalusia were familiar with the texts of the great Latin classics relating to natural science, and Ibn Wāfid, Ibn Baṣṣāl, and Ibn al-ʿAwwām (11th and 12th centuries) quote Varro, Virgil, and others. The most notable geographers in Muslim Spain were al-Bakrī (died 1094), who wrote the *Kitāb al-masālik wa-l-mamālik* ("Book of Highways and of Kingdoms"), and al-Idrīsī (died 1166), who was in the service of Roger II of Sicily and is the author of the leading universal geography composed by the Arabs. Somewhat later (1323) there appeared the first Arabic nautical map, possibly of Granadine origin. In technology, Muslim Spain was noted for its windmills and for its manufacture of paper. (J.V.G.)

UNITED SPAIN UNDER THE CATHOLIC KINGS

The union of Aragon and Castile. When Ferdinand II (1479–1516, also Ferdinand V of Castile from 1474) succeeded to the crown of Aragon in 1479, the union of Aragon (roughly east Spain) and Castile (roughly west Spain) was finally achieved, and the Trastámara became, after the Valois of France, the second most powerful monarchs in Europe. The different royal houses of the Iberian Peninsula had long thought in terms of a union of their crowns and had practiced intermarriage for gen-

erations. Nevertheless, the union of the crowns of Castile and Aragon was far from inevitable in the last quarter of the 15th century. A union between Castile and Portugal was equally feasible, and it has been argued that it would have made more sense, for it would have allowed the two western Hispanic kingdoms to concentrate on overseas exploration and expansion, and it would not have involved Castile in Aragon's traditional rivalry with France. The reasons that led John II of Aragon to arrange the marriage of his son and heir, Ferdinand, with Isabella of Castile, in 1469, were essentially tactical: he needed Castilian support against French aggression in the Pyrenees. In Castile an influential party of magnates, led by Archbishop Carillo of Toledo (who later reversed himself) and opposed to King Henry IV, supported the succession claims of the princess Isabella, the King's half sister, against those of his daughter, Joan. They were anxious for the help and leadership of the Aragonese prince and content with the alliance of a country in which the magnates had such far-reaching privileges as the Aragonese nobility. It needed a forged papal dispensation for the marriage, the blackmailing of Henry IV into (wrongly) denying the paternity of his daughter (Joan), and, finally, several years of bitter civil war before Ferdinand and Isabella defeated Joan's Castilian supporters and her husband, Afonso V of Portugal.

Reasons for union

Ferdinand and Isabella ruled jointly in both kingdoms and were known as the Reyes Católicos (Catholic Kings). It was, however, a union of crowns and not of kingdoms. In size, institutions, traditions, and, partly, even in language, the two kingdoms differed greatly. Within the Kingdom of Aragon, Aragon and Valencia (easternmost Spain, halfway up the coast) each had about 270,000 inhabitants, of whom some 20 percent and more than 30 percent, respectively, were Moors and Moriscos (Moors officially converted to Christianity). Catalonia (northeast Spain) had about 300,000 inhabitants. In each of these kingdoms the powers of the crown were severely limited. The barons ruled their estates like kings, dispensing arbitrary justice over their peasants. In Catalonia they had the right to wage private war. In Aragon anyone arrested by order of the king could put himself under the jurisdiction of a *justicia* who held his office for life and was therefore independent of the king's pleasure. It was this highest judge who crowned the kneeling king and made him swear to observe the *fueros,* the laws and privileges, of the kingdom. It is now known that the formula "We who are as good as you swear to you who are no better than we, to accept you as our king and sovereign lord, provided you accept all our liberties and laws; but if not, not" is a forgery, most probably of the mid-16th century. It does, however, summarize very well the relations between the kings of Aragon and the Aragonese nobility.

Ferdinand made no attempt to change this position; nor did he do so in Catalonia, where the crown had just emerged successfully from a long and confused civil war. The nobility and the urban aristocracy of Barcelona (Spain's northeast coast) had been faced by violent social movements of the peasants and the lower classes of the cities and were themselves riven by family and factional strife. The crown intervened, mainly on the side of the lower classes but, inevitably, in alliance with some of the noble factions and against the French who had taken the opportunity to occupy Cerdagne and Roussillon. In 1486 Ferdinand settled the Catalan problem by a compromise, the Sentencia de Guadalupe, which effectively abolished serfdom and the more oppressive feudal obligations of the peasants, in return for monetary payments to the lords. Otherwise, the political and legal privileges of the rural nobility and the urban aristocracy were left intact. Effectively, therefore, Ferdinand made no attempt to strengthen the powers of the crown and to give the principality a more efficient system of government. One hundred and fifty years later his successors were to pay a high price for this failure. In the meantime, Ferdinand had given Catalonia peace, a considerable degree of social stability, and the opportunity to make good the ravages of the civil wars and the losses of commercial markets to Italian competitors. This opportunity was only partially taken by the Catalans. They failed completely to prevent the Genoese from establishing a dominant position in the economy of Castile and, more especially, in the vital and rapidly expanding Atlantic trade of Seville (south Spain, 90 miles [140 kilometres] north of Gibraltar). The union of the crowns of Aragon and Castile therefore led to neither a political and institutional union nor to an economic integration of the Iberian Peninsula.

Catalonia's situation

Castile. Castile, too, was a poor country. Much of its soil was arid, and its agriculture was backward. The armed shepherds of the powerful sheep-owner's guild, the Mesta, drove their flocks over hundreds of miles, from summer to winter pastures and back again, spoiling much cultivated land. Despite the violent hostility of the landowners, the government upheld the Mesta privileges, since the Mesta paid generously for them and was supported by the merchants who exported the raw wool to the cloth industry of Flanders (modern Belgium). The power of the Mesta and the harm it did increased in the 16th century, for the Catholic Kings supported its privileges, anxious, as always, to increase their revenues by following the line of least resistance. Thus, the impoverished Spanish peasant was unable to buy the manufactures of his urban industries, and hence the Castilian towns remained comparatively small and their industries underdeveloped, compared with those of Italy and the Netherlands. Only the cities of Andalusia (south Spain) were relatively large, but, except for Seville, they were not primarily trading or manufacturing centres but were dominated by an urban nobility living on revenues from the surrounding countryside.

Underdeveloped Castilian industries

In the northern provinces of Castile there lived a large class of minor nobles, the hidalgos. The inhabitants of Guipúzcoa (by the westernmost French border) even claimed that they were all of noble birth. But the south, New Castile (southeast of Madrid), Extremadura (southwest of Madrid), and especially Andalusia—that is to say, those provinces most recently reconquered from the Moors—were the domain of the great nobility. There the families of the Enríquez, the Mendoza, the Guzmán, and others owned vast estates, sometimes covering almost half a province. They had grown rich during the 15th-century boom in wool exports to Flanders, at a time when there were more than 2,500,000 sheep in Castile, and it was they, with their hordes of vassals and retainers, who had attempted to dominate a constitutionally almost absolute, but politically weak, monarchy.

It was in this kingdom that the Catholic Kings determined to restore the power of the crown. Once this was achieved, or so it seemed, the liberties of the smaller kingdoms would become relatively minor problems. Like their contemporary, Henry VII of England, they had the advantage of their subjects' yearning for strong and effective government after many years of civil war. Thus, they could count on the support of the cities in restoring law and order, without having to make any important concessions to the Castilian Cortes. The Cortes of Toledo of 1480 accepted the appointment of corregidores, or royal officials, to supervise the administration of the principal towns. At the same time, both municipal efficiency and civic pride were enhanced by the obligation imposed on all towns to build a town hall (*ayuntamiento*).

With the great nobles it was necessary to move more cautiously. The Catholic Kings revoked usurpations of land and revenues by the nobility if these had occurred since 1464, but most of the great noble estates had been built up before that date and were effectively left intact. From a contemporary chronicler, Hernán Pérez del Pulgar, historians know how they proceeded piecemeal but systematically against the magnates, here using a nobleman's defiance of the law, there a breach of the peace or of a pledge, to take over or destroy his castles and thus his independent military power. Even more effective in dealing with the nobility was the enormous increase in royal patronage. Isabella was stage manager to Ferdinand's election as grand master of one after another of the three great orders of knighthood: Santiago, Calatrava, and Alcántara. This position allowed the King to distribute several hundred commanderships with their attached income from the huge estates of the orders. Equally important was royal control over all important ecclesiastical

appointments, which the Catholic Kings insisted on with ruthless disregard of all papal claims to the contrary. In the Spanish dependencies in Italy, Ferdinand claimed the right of exequatur, according to which all papal bulls and breves (authorizing letters) could be published only with his permission. There exists a letter of Ferdinand to his viceroy in Naples, written in 1510, in which he upbraids the viceroy for permitting the Pope to publish a brief in Naples, threatens that he will renounce his own and his kingdoms' allegiance to the Holy See, and orders the viceroy to arrest the papal messenger, force him to declare he never published the brief, and then hang him. In Spain the Catholic Kings had no formal right of exequatur, but they and their Habsburg successors behaved very much as if they did. From now on the Spanish clergy had to look to the crown and not to Rome for advancement, and so did the great nobles who traditionally claimed the richest ecclesiastical benefices for their younger sons.

Perhaps most effective of all in reducing the political power of the high nobility was their virtual exclusion from the royal administration. The old royal council, a council of great nobles advising the king, was transformed into a bureaucratic body for the execution of royal policy, staffed by a prelate, three nobles, and eight or nine lawyers. These lawyers, mostly drawn from the poor hidalgo class, were entirely dependent on the royal will and became willing instruments of a more efficient and powerful central government. The Catholic Kings set up a Council of Finance (1480, but not fully developed until much later), the Council of the Hermandad (1476–98), the Council of the Inquisition (1483), and the Council of the Orders of Knighthood (for the administration of the property and patronage of the orders of Santiago, Calatrava, and Alcántara), and they reorganized the Council of Aragon. Charles I and Philip II were later to continue this work and to add further councils, notably those of the Indies (1524) and of Italy (1558).

When Isabella died, in 1504, the nobles appeared to be tamed and politically innocuous. In fact, their social position and its economic basis, their estates, had not been touched. Of the soil of Castile 97 percent was owned by 2 or 3 percent of the population, and some 50 percent of this was owned by a quite small number of families, mostly linked through intermarriage. In 1520 Charles I agreed to their demand for establishing a fixed hierarchy of rank, from the 25 grandees of Spain, through the rest of the titled nobility, down to some 60,000 hidalgos, or caballeros, and a similar number of urban nobility, all of them distinguished from the rest of the population, the *pecheros,* by far-reaching legal privileges and exemption from direct taxation. The Laws of Toro (1505), extending the right to entail family estates on the eldest child, further safeguarded the stability of noble property. The Catholic Kings had therefore shifted the balance of political power within the traditional ruling classes of Castile in favour of the crown, but they had not fundamentally altered the economic and social position of these classes.

Nobility's strong base

The Spanish Inquisition. With its large Moorish and Jewish populations, medieval Spain was the only multiracial and multireligious country in western Europe, and much of the development of Spanish civilization in religion, literature, art, and architecture during the later Middle Ages stemmed from this fact. The Jews had served Spain and its monarchs well, providing an active commercial class and an educated elite for many administrative posts. But, inevitably, their wealth created jealousy and their heterodoxy hatred in a population that traditionally saw itself as the defender of Christianity against the infidel. The Catholic Kings, ever good tacticians, profited from this feeling. In 1478 they first obtained a papal bull from Sixtus IV setting up the Inquisition to deal with the supposedly evil influence of the Jews and *conversos* (converted Jews). Since the Spanish Inquisition was constituted as a royal court, all appointments were made by the crown. Too late, Sixtus IV realized the enormous ecclesiastical powers that he had given away and the moral dangers inherent in an institution the proceedings of which were secret and that did not allow appeals to Rome.

With its army of lay familiars, who were exempt from normal jurisdiction and who acted both as bodyguards and as informers of the inquisitors, and with its combination of civil and ecclesiastical powers, the Spanish Inquisition became a formidable weapon in the armoury of royal absolutism. The Supreme Council of the Inquisition (or Suprema) was the only formal institution set up by the Catholic Kings for all their kingdoms together. Nevertheless, they thought of it primarily in religious and not in political terms. The Inquisition's secret procedures, its eagerness to accept denunciations, its use of torture, the absence of counsel for the accused, the lack of any right to confront hostile witnesses, and the practice of confiscating the property of those who were condemned and sharing it between the Inquisition, the crown, and the accusers—all this inspired great terror, as indeed it was meant to do. The number of those condemned for heresy was never very large and has often been exaggerated by Protestant writers. But during the reign of the Catholic Kings, several thousand *conversos* were condemned and burned for Judaizing practices. The whole family of the philosopher and Humanist Luis Vives was wiped out in this way. Many more thousands of *conversos* escaped similar fates only by fleeing the country. Many Catholics in Spain opposed the introduction of the Inquisition, and the Neapolitans and Milanese (who prided themselves on their Catholicism and who were supported by the popes) later successfully resisted the attempts by their Spanish rulers to impose the Spanish Inquisition on them. Even in Spain itself, it was the sumptuous autos-da-fé, or the ceremonial sentencings and executions of heretics, rather than the institution and its members that seem to have been popular. But most Spaniards never seem to have understood the horror and revulsion that this institution aroused in the rest of Europe.

The fate of the *conversos*

The first inquisitor general, Tomás de Torquemada, himself from a *converso* family, at once started a propaganda campaign against the Jews. In 1492 he persuaded the Catholic Kings to expel all Jews who refused to be baptized. Isabella and most of her contemporaries looked upon this explusion of about 170,000 of her subjects as a pious duty. At the moment when Spain needed all its economic resources to sustain its new European position and its overseas empire (see below), it was deprived of its economically most active citizens and laid open to exploitation by German and Italian financiers.

The conversos. Nevertheless, the explusion of 1492 did not signify the end of Jewish influence on Spanish history, as used to be thought until quite recently. It is not, however, easy to establish a clear-cut direction or pattern of this influence. At the end of the 15th century, there may have been up to 300,000 *conversos* in Spain, and the majority of these remained. They had constituted the educated urban bourgeoisie of Spain, and the richer families had frequently intermarried with the Spanish aristocracy and even transmitted their blood to the royal family itself. After 1492 their position remained precarious. Some reacted by stressing their Christian orthodoxy and denouncing other *conversos* to the Inquisition for Judaizing practices. Others embraced some form of less conventional, more spiritualized Christianity. Thus the followers of Sister Isabel de la Cruz, a Franciscan, organized the centres of the Illuminists (Alumbrados), mystics who believed that through inner purification their souls should submit to God's will and thus enter into direct communication with him. While they counted some of the high aristocracy among their numbers, most of the Illuminists seem to have been *conversos.* Again, it was among the *conversos* that Erasmianism (after Erasmus, a famous Humanist of the time), a more intellectual form of spiritualized Christianity, had its greatest successes in Spain. The Erasmians had powerful supporters at court in the early years of Charles I, when, as emperor, his policy was directed toward the healing of the religious schism by a general reform of the church. But in the 1530s and 1540s, the enemies of the Erasmians, especially the Dominican Order, launched a systematic campaign against them. The Inquisition annihilated them or forced them to flee the country, just as it had done in the case of the Illuminists as early as the 1520s. Nevertheless, the influence

Converso reactions

of Erasmus did not completely disappear from Spanish intellectual life, and it has been traced into the latter part of the 16th century.

But the majority of the *conversos* and their descendants probably became and remained orthodox Catholics, playing a prominent part in every aspect of Spanish religious and intellectual life. It has now become clear that without them the "Golden Century" of Spain would be inconceivable. They ranged from such saints as Teresa of Avila and St. John of God, one a mystical writer and founder of convents, the other an organizer of care for the sick, to Diego Laínez, a friend of St. Ignatius of Loyola and second general of the Jesuit Order. They included Fernando de Rojas, author of *La Celestina,* the first great literary work of the Spanish Renaissance, and, two generations later, Mateo Alemán, who wrote a picaresque novel, the *Guzmán de Alfarache;* and they could boast Luis de León, a Humanist and poet; a Dominican, Francisco de Vitoria, perhaps the greatest jurist of any country in the 16th century; and another famous Dominican, the defender of the American Indians and historian of the Indies, Bartolomé de Las Casas.

These, with Luis Vives, mentioned earlier, are only the most famous among the many distinguished *converso* names who played such a central and varied role in creating the cultural splendours of Spain's "Golden Century." It is an extraordinary phenomenon that had no parallel anywhere else in Europe before the 19th or even 20th century.

Converso contribution

Any attempt at an explanation is bound to be speculative, but the following may be suggested. The Spanish Jews and *conversos* formed a comparatively large section of the relatively small educated elite of Spain who were primarily responsible for the cultural achievements of the period. The *conversos,* moreover, having deliberately broken with the Jewish tradition of Talmudic (from the Talmud, the body of Jewish civil and canonical law) scholarship, found the glittering Renaissance world of Christian Spain ambivalently attractive and repellent but always stimulating. Their response to this stimulus was probably sharpened, their need to excel given a double urgency, by the hostility that they continued to meet from the "old" Christians. For these latter were very much aware of the ubiquity of the *conversos,* however much these were assimilated, and many resented it bitterly. Religious, racial, and even anti-aristocratic class prejudices combined to create the obsession with "purity of blood" (*limpieza de sangre*), which became characteristic of the Spaniards in the 16th and 17th centuries.

It first crystallized with a statute of *limpieza,* imposed in 1547 on the cathedral chapter of Toledo, by which purity of ancestry from the taint both of *converso* blood and from any accusations of heresy by the Inquisition was made a condition of all future ecclesiastical appointments. The author of this statute was Archbishop Siliceo, a man of humble and hence, by definition, untainted origins, who had found himself despised by the aristocratic canons, many of whom, however, had *converso* blood in their veins. In 1556 Philip II gave his royal approval to the statute on the grounds that "all the heresies in Germany, France and Spain have been sown by descendants of Jews." As far as Germany and France were concerned, this remark was sheer fantasy, and it is especially ironic that, just at this time, Pope Paul IV, at war with Spain, described Philip II himself quite correctly as a Marrano, or descendant of Jews.

But statutes of *limpieza* now spread rapidly over Spain. They helped to perpetuate a set of values, the equation of pure ancestry, orthodoxy, and personal honour, which certainly helped to prevent the spread of heresies in Spain but which in the long run had a blighting effect on Spanish society, the more so as they were linked so closely with the basically corrupt institution of the Inquisition. For not only did they encourage the practice of denunciation, with inevitably corrupting and divisive effects, but they also educated generations of Spaniards to see their personal honour as a value depending on a set of circumstances substantially outside their own control or achievement.

Deadening effect of *limpieza* statutes

The conquest of Granada. The impact of the Moors on Spanish life and traditions had been rather different from that of the Jews. It was most evident, perhaps, in the position of women in southern Spain, who for long remained semi-veiled and in much greater seclusion than elsewhere in Christian Europe. It was evident also where Jewish influence was practically nonexistent, in the visual arts and especially in architecture. Not only did houses in southern Spain for a long time continue to be built facing inward, on to a patio, but a whole style of architecture, the Plateresque, derived from an imaginative fusion of the Moorish and the Christian: classical Renaissance structures were decorated with Gothic or Renaissance motifs but executed in the Moorish manner, as if a carpet had been hung over the outside wall of the building. This charming style, which was invented during the reign of the Catholic Kings, spread far and wide over Spain and eventually even to the New World.

To Ferdinand and Isabella, the Moorish problem presented itself in the first place in a political and military form, for the Moors still ruled their independent Kingdom of Granada (Spain's southeast corner). The Catholic Kings had to concentrate all their military resources and call on the enthusiastic support of their Castilian subjects to conquer the kingdom in a long and arduous campaign, which ended with the capture of Granada (some 130 miles east of Seville), the capital, in 1492. In this campaign Gonzalo Fernández de Córdoba, the "Great Captain," developed the tactics, training, and organization that made Spanish infantry almost unbeatable for 150 years. The Moors were granted generous terms and religious freedom. But, against the advice of the saintly Hernando de Talavera, the *converso* archbishop of Granada, who was trying to convert the Moors by precept and education, the Queen's confessor, Francisco (later Cardinal) Jiménez de Cisneros, introduced forced mass conversions. The Moors rebelled (1499–1500) and, after another defeat, were given the choice of conversion or expulsion. Jiménez and Isabella did not regard this new policy as a punishment of the Moors for rebellion, for Christian Baptism could never be that. It was rather that the rebellion released them from their previous undertaking, which they had entered into only with misgivings. Though many Moors chose conversion, the problem now became virtually insoluble. There were never enough Arab-speaking priests or money for education to make outward conversion a religious reality. The Moriscos remained an alien community, suspicious of and suspect to the "old" Christians. There was with the Moriscos very little of the intermarriage with Christians and of the deliberate acceptance of Spanish Christianity that, in spite of all the statutes of *limpieza,* allowed the *conversos* to become such an integral part of Spanish society.

Hopelessness of the Moorish position

Acquisition of Naples. Ferdinand's foreign policy was dominated by the traditional Aragonese rivalry with France along the Pyrenees and in Italy. Aragon still held Sicily and Sardinia from the much more extensive medieval Aragonese empire. French intervention in Italy, from 1494, gave Ferdinand his chance. Charles VIII of France, to secure his southern flank while he led his army into Italy, agreed to return to Ferdinand the counties of Cerdagne and Roussillon (Treaty of Barcelona, 1493), which Louis XI had seized during the Catalan civil wars, in 1463. But it was through Ferdinand's own diplomacy and through the generalship of Gonzalo de Córdoba that he acquired the Kingdom of Naples (1503). For the first time the union of Aragon and Castile had shown its strength, and Spain now rivalled France as the most powerful state in Europe. Ferdinand had carefully arranged the marriage of his children to strengthen his diplomatic position against France by alliances with Portugal, England, and Burgundy (which ruled the Netherlands). The unexpected deaths of the two eldest and their children, however, left the succession of Castile after Isabella's death (1504) to the third, Joan the Mad, and her husband, Philip I (the Handsome) of Castile, ruler of the Burgundian Netherlands. The Netherlands nobility were delighted to see this enormous accretion of power to their ruler and looked forward to the advantages that they might reap from it. They accompanied him to Castile, where a large section of the high nobility, in their turn, were anxious to acclaim

him rather than the redoubtable Ferdinand. Ferdinand was therefore forced to recognize Philip's claims; but this latter died in 1506, and Ferdinand was left as uncontested ruler. His last great success was the annexation of the Spanish part of the Kingdom of Navarre in 1512.

Spain and the New World. While the exploration of the Atlantic coast of Africa had been mainly a Portuguese concern in the 15th century, the Castilians had not been entirely disinterested in such activities and had occupied the Canary Islands (off northwest Africa). In the Treaty of Alcáçovas (1479), when Afonso V of Portugal renounced his claims to the crown of Castile, he also recognized Castilian possession of the Canaries in return for Spanish recognition of Portuguese possession of the Azores (in the Atlantic Ocean west of Portugal), the Cape Verde Islands (off West Africa), and Madeira (north of the Canaries). The conquest of Granada allowed Castile, for the first time, to concentrate major resources and effort on overseas exploration. The support that Columbus received from Isabella was indicative of this new policy. In 1492 Columbus discovered the West Indies, and, in the next half century, the Spaniards conquered huge empires in America and made their first settlements in the Far East. From the beginning there were disputes with the Portuguese, who were conquering their own colonial empire. The Catholic Kings obtained a series of papal bulls (1493) from the Spanish pope Alexander VI and as a result concluded the Treaty of Tordesillas with Portugal (1494) to settle their respective claims. Everything west of an imaginary line 370 leagues (here, the league was just over three nautical miles) to the west of the Cape Verde Islands in the Atlantic was assigned to Spain; everything east went to Portugal. The rest of Europe saw no reason to accept the Pope's decision, and the result was constant and brutal warfare in the overseas colonies, even when the European governments were officially at peace (see also LATIN AMERICA).

Growing Castilian activity

Colonial policy. Unlike the other European colonists of that age, the Spaniards were vitally concerned with the moral problems of conquest, conversion, and government of heathen peoples. If the great majority of conquistadores ruthlessly pursued gold, power, and status, they took with them Dominican and Franciscan friars who set themselves to convert and educate the American Indians and, sometimes, to protect them from their Spanish masters. The Dominican Bartolomé de Las Casas fought long battles to modify at least the greatest evils of colonial exploitation. His debates with a theologian, Juan Ginés de Sepúlveda, and the writings of Francisco de Vitoria provide the first systematic discussions of the moral and legal problems of conquest and colonial rule. Their importance lay in their effects on Spanish colonial legislation. The Leyes Nuevas ("New Laws of the Indies") of 1542 were based largely on the arguments of Las Casas. While in the colonies these laws were honoured more in the breach than in the observance, yet they provided at least some protection for the Indians, and there was nothing like them in any of the other European overseas colonies of the period. Even Las Casas, however, supported the transatlantic slave trade of black Africans, until, late in his career, he came to recognize its evils.

The Atlantic trade. The crown insisted that all trade with the colonies should be carried on through Seville and should be reserved for Castilians on the argument that it was Castilian money and blood that had built the Spanish overseas empire. This trade was closely regulated by the Casa de Contratación (1503), or the House of Trade, in Seville. The city itself rapidly became one of the greatest trading centres in Europe, and its population rose from 25,000 in 1517 to 90,000 in 1594. Yet Castile was unable to supply all the manufactures that the colonists demanded and for which they paid in solid gold and silver. So far from seeing this trade as an opportunity for Castilian industry, the Cortes actually petitioned the crown in 1548 to prohibit exports to the Indies that, they claimed, were raising prices in Castile. The government did not accept this petition, but Castile had to import much of what its colonists needed from Italy and the Netherlands. The Castilian monopoly of trade with Spanish America in practice had only the effect of giving the rest of Europe the chance to compete on equal terms for the American trade with the monarchy's non-Castilian subjects. The organization and financing of the Spanish Atlantic trade were largely in the hands of Genoese and south German merchants. From the 1540s, when a new method of extracting silver from ore with the use of mercury was discovered, silver mining became a major industry in both Mexico and Peru, and silver shipments in rapidly increasing quantities soon surpassed the earlier gold shipments in value. Precious metal was exported from the Indies to Spain, partly as the crown's right of one-fifth (*quinto real*), but, more important, as payment for imports. The average annual quantities, as registered by the Casa de Contratación (not counting the unknown quantities that were smuggled), rose rapidly from about 1,000,000 pesos in the five-year period 1526–30, to 5,000,000 during 1541–54, and then to the peak of more than 35,000,000 during 1591–95. The growth of overall trade between Seville and the New World followed a very similar pattern, rising until 1550, then stagnating until the early 1560s, and rising again to a peak in the last decade of the 16th century. Prices, especially of agricultural produce, had started to rise in Spain, as in the rest of Europe, long before American silver was imported in considerable quantities. But, whatever the ultimate causes of the price revolution of the 16th century, there can be little doubt that American silver greatly aggravated the inflation in Spain in the second half of the 16th century. The theologians of the university of Salamanca (some 100 miles [160 kilometres] west-northwest to Madrid) in the 1550s were the first to see this connection and to formulate the earliest version of a quantity theory of money (in which money is worth more when scarce than when abundant). Very little of this American treasure seems to have been invested in economic production. Most of it was used for display by the court and ruling circles, to pay for Spanish imports, for the Spanish armies abroad, and to satisfy the government's German, Italian, and Netherlandish creditors. Thus Spain, with all the treasure of the New World at its command, remained a poor country.

Castile's demand for monopoly

SPAIN UNDER THE HABSBURGS

Charles I. Ferdinand died on January 23, 1516, and the crowns of the Spanish kingdoms devolved on his grandson, Charles I (1516–56), the ruler of the Netherlands and heir to the Habsburg dominions in Austria and south Germany. This new union had not been planned in Spain, and, at first, it was deeply resented. Cardinal Jiménez, the regent until Charles's arrival in Spain, had to battle against the old antagonisms between nobles and towns that were flaring up again when the magnates took the opportunity of the regency to try to regain their old power. When Jiménez tried to raise a militia, nobles and cities both sabotaged the plan. The old hostilities between the different Spanish kingdoms were as bitter as ever, with the men of Navarre, for instance, claiming that they would rather accept a Turk than an Aragonese as governor of the fortress of Pamplona. Although the court at Brussels had been careful to hold its hand in the distribution of patronage, the Spaniards, nevertheless, accused the Netherlanders of greed and place hunting. It took Charles's Netherlandish ministers a year and a half to settle the Netherlandish government and to make agreements with France and England that would allow the boy-king to take possession of his new kingdom without outside interference. It was a considerable achievement, but for Spain the time was still too long. When Charles arrived in Spain, in September 1517, his supporters were already disillusioned, and the country was apprehensive of the rule of a foreigner. Charles himself, ugly, inexperienced, speaking no Spanish, and surrounded by Burgundian councillors and courtiers, did not initially make a good impression. The different Cortes of Castile, Aragon, and Catalonia granted his financial demands but attached to them much pointed advice and criticism.

The comunero movement. On June 28, 1519, Charles was elected Holy Roman emperor as Charles V and prepared to go to Germany. His chancellor, Mercurino

Gattinara, summoned the Castilian Cortes to Santiago in northwest Spain (April 1520) to demand more money, even though the former grant had not yet expired. The towns immediately made difficulties. The Toledans refused to appear; the others demanded the discussion of grievances before supply. By a mixture of bribery and concessions, the government finally induced a majority of the delegates (who had transferred from Santiago to La Coruña on the northwest coast of Spain) to vote the new grant. Many of the delegates were immediately disowned in their home towns, and one from Segovia was murdered by an enraged mob. As Charles set sail (May 20, 1520) the Castilian revolution had already begun.

Insurrection against Charles V

The towns, led by Toledo, formed a league and set up a revolutionary government. They claimed—more boldly even than the Third Estate during the French Revolution in 1789—that they were the kingdom and that the Cortes had the right to assemble without a royal summons and to discuss all matters relating to the welfare of the realm. There was talk of dethroning Charles in favour of his mother, Joan the Mad. The *comunero* leader, Juan de Padilla, actually captured the castle of Tordesillas (100 miles northwest of Madrid), where Joan was kept as prisoner; but the Queen, whether out of madness or calculation of the interests of the monarchy, would not commit herself to Padilla's proposals. The *comunero* movement spread rapidly through Castile, and the nobles did nothing to check it. They had not forgiven Charles his quest for the imperial title (which they thought inferior to that of king of Castile) nor his foreign councillors and courtiers. They resented above all his bestowal of the archbishopric of Toledo on a young Burgundian, Guillaume de Croy, and the appointment of his former tutor, Adrian of Utrecht (later Pope Adrian VI), as regent of Castile. Even the appointment of the admiral Fadrique Enríquez and the constable of Castile, Iñigo de Velasco, as Adrian's coregents did little to mollify the offended grandees. Only when the more radical and popular elements in the cities were gaining control of the *comunero* movement and beginning to spread it to the nobles' estates did the nobles combine to raise an army and defeat the *comunero* forces at Villalar (April 23, 1521).

The power of monarchy was thus restored in Castile, never to be seriously shaken again under the Habsburg kings. The towns kept much of their autonomy, but royal control in the town councils was safeguarded by the appointment of royal officials, the corregidores. The Cortes continued to function; but the deputies of the 18 "royal towns," which alone were summoned, were mostly members of the urban nobility, exempt from direct taxation and therefore not unduly concerned about voting the taxes the government asked for. As to their petitions, the King granted or ignored them as he saw fit. The nobles had won the civil war, but they could no longer break their alliance with the monarchy. The monarchy, now that it could manage the Cortes and afford a standing army, was the stronger partner. But when, in 1538, Charles I proposed a tax from which the nobles should not be exempt, there were immediate rumblings of revolt. Charles had to give way, but he never summoned the nobility again to the meetings of the Cortes. The monarchy had thus won its political victory in Castile only at the cost of letting the nobility contract out of the financial obligations of the state and the empire. The rising burden of taxes fell, therefore, on those least able to bear them and on the only classes whose activities and investments could have developed the Castilian economy.

The crown's expensive political triumph

The nobility. The traditions of the grandees and hidalgos, formed in the centuries of struggle against the Moors, made them even more averse to economic activities than the rest of the European nobility. They invested their money in land, without, however, improving agriculture, and preferred careers in the army, the church, and the civil service to the ignoble occupations of commerce. In the long run, the economic weakness of Spain, aggravated by its social traditions and its system of taxation, proved a serious handicap in Spain's struggle with its western European rivals. After Villalar, however, the Spanish nobility had come to accept Charles I. His championship of Catholic Christianity against the Muslim Turks and German heretics appealed to their own traditions of Christian warfare against the Moors. While Charles kept the grandees out of the central government of Spain itself, he had many prizes to offer in military commands, provincial governorships, and even viceroyalties in Italy and Spanish America. The hidalgos, trained as lawyers at Salamanca or as theologians at Alcalá de Henares (just east of Madrid), could look forward to dazzling careers in the King's councils and in the Spanish church. Even though Charles spent only 16 of the 40 years of his reign in Spain, the Spanish upper classes were beginning to accept and enjoy their monarch's position as the greatest ruler in Europe.

Charles I's foreign policy. Spain as a result, however, became involved in interminable wars. The necessity of defending southern Italy from the Turks brought Charles's empire into collision with the Ottoman Empire, with the central Mediterranean as the chief battle ground. Ferdinand's failure to complete the conquest of North Africa now brought a bitter revenge. The corsair leader Khayr ad-Dīn, known as Barbarossa, had made himself master of Algiers (1529) and acknowledged the suzerainty of the Sultan of Constantinople. Thus, the purely local problem of the Moorish raids on the Spanish south coast became merged into the much more formidable struggle with the Ottoman Empire. In 1535 Charles captured Tunis. It was, perhaps, his most satisfying triumph; for in this enterprise he manifestly appeared in his chosen role of "God's standard bearer," as he said himself. He now seriously considered carrying the war into the eastern Mediterranean, even conquering Constantinople itself. But in 1538 Barbarossa with a Turkish fleet defeated Charles's Genoese admiral, Andrea Doria, at Préveza (west Greece), and in 1541 the Emperor himself failed against Algiers. At the end of the reign, the balance of the two great naval powers in the Mediterranean, the Spanish and the Turkish, was still even.

Problems with the Turkish Empire

Rival Aragonese and Angevin (cousins of the ruling French house) claims to Naples also brought conflict with the French kings, against whom Charles fought four wars. His armies conquered Milan (north Italy) and reduced most of the still independent Italian states to Spanish satellites. An increasing part of the burden of these wars fell on Spain, and especially on Castile. The Spanish *tercios* (infantry regiments) were not only the Emperor's best troops, but it was in Castile that he could raise the largest part of his imperial revenues, and this, moreover, without having to account for the way he spent them, as he had to do with the taxes voted by the States General of the Netherlands. It is therefore not surprising that the empire in Europe with Charles V as head became gradually transformed into a Spanish, or, rather, Castilian, empire of Charles I. In the latter part of his reign, Spaniards and Hispanicized Italians monopolized all high positions in the empire south of the Alps and began to appear in Germany and the Netherlands. More and more they came to interpret the international and Catholic ideals of the Emperor in terms of the political predominance of Spain in Europe and overseas.

Philip II. When Charles abdicated his various lands (1555–56), Philip II (1556–98) succeeded to all his father's dominions except Germany. His empire in Europe, now without the imperial title, was still only a loose union of independent states recognizing the same head. Philip, a great traditionalist, was not the man to inspire his different subjects with a new unifying idea, though he improved the central administration of his empire by the creation of the Council of Italy (1558). But his own Castilian upbringing and preferences increased the tendency toward transforming the empire into a Castilian empire. Six of the nine viceroys Philip appointed to govern Sicily were Spaniards, as were all those of Naples, with the single exception of one Cardinal Granvelle, and 10 out of 13 governors of Milan. In the Spanish viceroyalties of Aragon, Catalonia, Valencia, and Navarre and in those of Mexico and Peru, none but Spaniards, and preferably Castilians, were ever thought of at all. These were the key figures in Philip II's empire, and they were backed by the commanders of the Spanish regiments. Fortresses were nearly always governed

Role of the Castilians in the armies

by Castilians. Only in the Low Countries was it necessary to appoint natives to military commands. When the viceroys and governors were appointed, they were given "secret" instructions—in short, ones not meant for purely propagandistic purposes. These instructions reflected the current commonplaces of Christian government that could be found in scores of "Mirrors of Princes" (handbooks of government popular at the time) published in the 16th century and that Philip had made his own. The governors were to represent the King—not the state or the Spanish Empire—as if he were present in person; it was stressed that they were not appointed for their own benefit but for that of the community they were sent to govern; they were to watch so that the King's subjects might sleep in peace and quiet and to dispense equal justice to rich and poor. Many of the Castilian grandees who were appointed to these high offices undoubtedly strove to live up to these precepts. In practice, however, their success depended largely on the strength of the local opposition they met: this was a great deal in Sicily, which had won the reputation of being "fatal to its viceroys," but very much less in Naples, about which at least one viceroy remarked that no one should wish to be viceroy there because of the pain he would have to suffer when he had to leave that post at the end of his term. A great part of the viceroys' difficulties, however, stemmed from the unreliability of the King himself. Philip was always anxious to maintain the dignity of their office, but he encouraged the local ministers and officials to report on their viceroys behind their backs, and he had no compunction about recalling a viceroy, governor, or minister when it suited him in this way to appease local opposition.

The King kept control over his viceroys and governors by weekly, sometimes daily, correspondence, carried by the excellent postal service that the House of Austria had organized in Europe. All important political decisions were thus taken in Madrid, and there the King relied almost entirely on Spaniards for advice. Only one non-Spaniard, Cardinal Granvelle of Franche-Comté, was ever summoned to Madrid to play a leading role in the King's inner councils (1579–86). It was Granvelle who had earlier, as the King's chief minister in the Netherlands, reminded his master of the international character of his empire. He advised a more international dispensation of royal patronage, as, for instance, the appointment of the Prince of Orange (William I the Silent) to the viceroyalty of Sicily so that Netherlanders and Italians would no longer think that the King regarded only the Spaniards as his "legitimate subjects." But Philip had refused to listen, and the bitter Castilian hostility at court to Granvelle ended by making the Cardinal's ministry in Madrid less and less effective in the last two or three years before his death in 1586.

Philip's refusal of non-Castilian appointments

Finance and imperial policy. Philip II on his accession inherited an unfinished war with France and a debt of some 20,000,000 ducats. While his ally England (to whose queen, Mary Tudor, Philip was married) lost Calais, Philip's own armies won considerable victories, and he was able to conclude the Peace of Cateau-Cambrésis (1559) with France, which confirmed Spanish possessions and hegemony in Italy and which left the frontiers of the Netherlands intact. But the financial position had become irretrievable, and Philip's governments, both in Madrid and in Brussels, had to declare a moratorium on their debts. It was the first of three such moratoriums in Philip II's reign—the other two were declared in 1575 and 1596—and it set the tone for the remainder of Habsburg rule in Spain, marked by growing disparity between the monarchy's imperial policies and the financial resources at its disposal to carry out these policies. For the rest of the 16th century this disparity was still largely masked by the fluctuating, but generally increasing, shipments of silver from the New World. These shipments inspired both the King and his German and Genoese creditors with the perennial hope of new treasure to pay off ever growing debts. But the armies and navies continued to swallow up more than the stream of American silver. In the end the financial burden of empire fell more and more on Castile, and it was this fact that came to determine the course of Spanish history for the next 100 years.

When Philip II returned to Spain, in 1559, he still had a naval war with the Turks on his hands, and, in the following year, his galleys suffered a humiliating and costly defeat at the island of Jarbah (off Tunisia's east coast). In 1566 the steadily deepening crisis of the Netherlands came to a head in an outbreak of image breaking. In that year Sultan Süleyman the Magnificent died, and, for a time, the Turkish danger faded into the background. Philip could therefore risk sending his commander, the Duke of Alba, with his best Spanish and Italian troops to the Netherlands (1567) in order to settle the problems of that dominion once and for all. Alba was to root out heresy, punish those responsible for the rebellion, and impose taxes sufficient to relieve Castile of the need to send any more financial help to the government in Brussels. It was the King's most terrible miscalculation, for rebellion now became revolt and involved Spain in an Eighty Years' War, 500 miles (800 kilometres) from its own borders (1568–1648). It was in the pursuit of this war that the Spanish Empire in Europe eventually foundered.

Repression in the Netherlands

The key to Philip II's and his successors' strategic thinking, however, was always France. This was reasonable; for France was potentially the strongest military power in Europe, and its hostility to Spanish greatness was absolute, despite occasional short periods of rapprochement. But, until 1595, France was paralyzed by a long succession of civil wars. Much as Philip II hated and feared a possible Huguenot (French Protestant) victory in France, he was content to see the civil wars continue, anxious, most often, to intervene on the side of the Catholics yet sometimes covertly offering help to the Huguenots. Until the late 1570s, the threat from the Turks rivalled in importance the problems of the Netherlands. Philip switched his limited resources from the Low Countries to the Mediterranean and back again, unable to achieve a decisive victory in either theatre. It was natural, therefore, that for 20 years after the Peace of Cateau-Cambrésis Spanish foreign policy remained on the defensive. There were, moreover, still formidable internal Iberian problems to be solved.

The Moriscos. The most immediate problem was that of the Moriscos of Granada. The attempt to Christianize and assimilate them had proceeded only very slowly. In the 1560s, the ineptitude and the mutual wrangling of the different public authorities in Andalusia brought government to a virtual standstill. The Captain General of Granada, in charge of defense and internal security, was quarrelling with the municipal council of Granada and with the *audiencia,* the supreme court for Andalusia, over precedence, rights of jurisdiction, and the ownership of some pastures. The *audiencia,* in its turn, quarrelled with the Inquisition over disputed rights of jurisdiction, as did the Captain General. He was supported by the Archbishop of Granada, who was, however, involved in a lawsuit with his cathedral chapter. Such disputes were typical of the Spanish system of government, and it was also characteristic that they became immediately involved in faction fights at Philip II's court. These were therefore rarely settled according to their merits but according to the prevailing political alignment at court. In this case the Governor General, who had usually acted as the protector of the Moriscos against the exploitation of the Christians, lost. The government in Madrid first sent a commission to inquire into titles of land, and this commission confiscated mainly Morisco land. In 1567 a decree was published forbidding the Moriscos the use of their Moorish names, dresses, and even of their Arabic language. Internal security was transferred from the governor general to the *audiencia.* This was the last straw, for now there was no one to protect the peaceful Morisco farmers from the murderous Morisco bandits of the sierra ("mountains"). On Christmas Day, 1568, they rose against the hated Christians. It took two years of ferocious campaigning, with dreadful atrocities committed by both sides, before the rebellion was put down. The Moriscos of Granada were then deported in small groups to different parts of Castile and settled in a last attempt to achieve assimilation. In the absence of systematic education and in the face of the hostility of the Christian population, this attempt was also doomed to failure.

Portugal and Aragon. There remained the question of the complete unification of the Iberian Peninsula. In the case of Portugal, Philip's opportunity came when his nephew, King Sebastian of Portugal, lost his life and a great Portuguese army in an ill-prepared crusade in Morocco at the Battle of the Three Kings in north Morocco (1578). During the short reign of Sebastian's old uncle, King Henry (1578–80), Philip carefully prepared his ground in Portugal by intrigue and bribery. Nevertheless, when Henry died the opposition to Castile was still so strong in Portugal and the attitude of France and England so threatening that it was necessary for Philip to send the Duke of Alba with an army to conquer Portugal in 1580. Philip respected the laws and privileges of his new subjects and left them to administer their own colonial empire. But the union increased rather than diminished the old hostility between the Castilians and the Portuguese.

Philip II's last action in the peninsula was against Aragon. It was precipitated by a court intrigue that led to the flight (1590) of the King's secretary, Antonio Pérez, to Aragon. Since Pérez was unlikely to be convicted in the *justicia's* court there, the King demanded his transfer to the court of the Inquisition. The populace of Saragossa (some 160 miles [260 kilometres] west of Barcelona) rioted, freed Pérez, and killed the King's special representative (1591).

Aragonese liberties defended

To the Aragonese it meant the defense of their liberties; to Philip it meant open rebellion. A Castilian army marched into Aragon (1591), and Philip made a number of constitutional changes. The *justicia* was, from now on, removable at royal pleasure; the viceroy could be a Castilian, and majority voting was substituted for the principle of unanimity in the Castilian Cortes. These changes gave the crown the ultimate power of decision in Aragon but preserved the kingdom's autonomy.

Lepanto. In the Mediterranean the Spanish fleet was inferior to that of the Turks, and Philip had to remain on the defensive, even when the Turks were besieging Malta (1565). Their failure to capture the island from the Knights of St. John, who had leased it from Charles V as emperor, marked the end of their great offensive. Six years later, the combined Spanish, Venetian, and papal fleets—in alliance the numerical equals of the Turks—virtually annihilated the Turkish fleet at Lepanto (1571). The strategic effects of this great victory were negligible, but its moral effects were immense. It confirmed the Spaniards in their chosen role of champions of Christendom and explains much of their continued willingness to support their King's religious and imperial policies, even in the face of ruinous costs and mounting disasters. After Lepanto, however, it became clear that the stalemate in the Mediterranean could not be broken. In 1580 Spain signed a truce with the Porte (Turkish government).

The Armada. From about 1580 the Spanish government became convinced that the rebellion (1568–1609) and heresy in the Netherlands could not be crushed as long as the rebels received help from England and France. These countries, moreover, gave active support to the Portuguese pretender, Antonio, prior of Crato (mid-Portugal), and their privateers committed continual acts of piracy against Spanish trade in the Americas. Philip began to give financial aid to the League, the ultra-Catholic party in France. From 1586 he prepared the invasion of England. The Armada, which set sail from Lisbon in May 1588, numbered 130 ships and nearly 30,000 men, bravely and not at all incompetently commanded by the Duke of Medina-Sidonia. But it had been set an impossible task: that of convoying the army under Alessandro Farnese, Duque de Parma, from the Netherlands to England in the face of a better armed English fleet and without control of a single deepwater channel port. The defeat of the Armada was inevitable but not dishonourable.

Spanish intervention in France from 1590 was equally doomed to failure. The Duke of Parma, with his Spanish veterans, won great tactical victories, but Spain failed to prevent the succession of Henry of Navarre as Henry IV of France and the collapse of its ally, the League, when Henry became Catholic (1593).

Philip saw his role and that of Spain essentially as that of defender of the Catholic Church against the aggression of the heretics, an aggression that now seemed to have become mainly military and that therefore had to be met by military force. It was therefore essential that the King should safeguard and extend the power of Spain and the just claims of his house, such as those he claimed for his daughter for the throne of France. Every other consideration was subordinated to this obligation, even to the point at which the Spanish ambassador in Rome, the Count of Olivares, intervened in three successive conclaves in order to assure, by a mixture of promises and threats, the election of popes congenial to his master (conclaves of Urban VII, Gregory XIV, and Innocent IX, 1590–91). He just failed in the fourth, but crucial, election of Clement VIII, who was to receive Henry IV back into the Catholic Church (1595).

But, if Philip II could thus justify his aggressive policies to himself, both Spain's enemies and its allies were convinced that they were witnessing the quest for Spanish dominance over Europe. Many Spaniards themselves believed this; but, as the war dragged on and the costs mounted, even the faithful Castilian Cortes began to question the King's policy. After 1580, silver shipments from the New World to Seville reached new record levels, and this undoubtedly helped to persuade Philip II to embark on his grandiose schemes against England and France. Yet they only represented a quarter of his annual revenues. The rest was derived from taxation and from loans for which future revenues were pledged. The Armada campaign was said to have cost 10,000,000 ducats. The combined cost of the continuing naval war against England, the campaigns in the Netherlands, and the military intervention in France was even greater. In 1590 the Cortes accepted the royal demand for a new excise tax that was to raise 8,000,000 ducats in six years and that was appropriately nicknamed the *millones.* But by 1595, a deputy from Seville said bitterly that "the reason why taxes have been raised without noise is because they have not fallen on the rich who are those who have a voice . . . and the sweetness which they find, that is the blood of the poor." A year later, in 1596, Philip II's government declared its third bankruptcy (moratorium), but the *millones* were increased rather than lowered.

Spain had gambled its own prosperity and its American treasure on a decisive victory over the heretics in western Europe and with it its own hegemony over the Continent, and it had failed. Shortly before his death, Philip II concluded the Treaty of Vervins (1598) with France, which substantially re-established the position of 1559. Yet, if Spain failed in its highest ambitions, at the end of the 16th century it was still the greatest power in Europe. It had brought Christianity to millions overseas—and to most contemporaries, if they thought about it at all, it seemed worth the appalling price paid for it in terms of the lives and freedom of non-European peoples—and Protestantism, though not destroyed, had been contained. Spanish monks and mystics had given Catholicism a new content, and Spanish theologians and jurists had created the basis of international law. Spanish literature and art were only now entering their greatest period. Morally and economically there were dark sides to the picture, but to the Spaniards the 16th and early 17th centuries have always been their "Golden Century."

Philip's admission of defeat

Spain in 1600. It is not surprising that the enormous exertions of the last quarter of the 16th century, with its mixture of triumphs, disappointments, and miseries, should have been followed by a general mood of introspection and even disenchantment. This was particularly evident in economic and social thinking. The *arbitristas* (literally, "projectors") were writers who combined an economic analysis of the social ills of Spain with projects for economic recovery and social and moral regeneration. They saw clearly the central weakness of Spain, the attitude of mind that despised productive work and those who engaged in it. Far too many strove to live the life of a hidalgo. The treasures of Mexico and Peru, so far from stimulating investment and industrial production, had only encouraged men to look for shortcuts to riches and to live the life of *rentiers,* investing their money in the *censos,* the government annuities. These *censos* were

the greatest plague and perdition of Spain, wrote González de Cellorigo, perhaps the most acute of the *arbitristas* of 1600. "It seems," he concluded, "as if we had wanted to turn these kingdoms into a republic of enchanted men, living outside the natural order."

The positive plans (among many fantasies) advocated by the *arbitristas* included the drastic cutting of government expenditure, the reform of the tax system, the encouragement of immigration into Castile, systematic and extensive irrigation, protection of industry, improvement of transport, and, finally, the sharing of the cost of empire among the constituent kingdoms of the monarchy. These were reasonable proposals, not unlike those put forward by mercantilist writers in the rest of Europe who treated economic activity as a means of increasing the power of the state. But it was not clear that the Castilian ruling classes would be capable and willing to act on them. Its attitudes were varied and often ambivalent, and this ambivalence is also reflected in the imaginative literature of the period.

Proposals for reform

Spain's Golden Age in literature. At one extreme there was the picaresque novel with its implicit satire of a society in which one could make one's way by cleverness and roguery rather than by honest work—that is, if one did not happen to be born a nobleman. Thus, the hidalgo in the *Lazarillo de Tormes* (published 1554), the first of the picaresque novels, is down and out but would rather starve than work, and he expects his servant, the boy Lazarillo, to scrounge for them both. In *Don Quixote* (published 1605 and 1615), the author, Cervantes, raised the picaresque novel to a completely new level of social and psychological insight. It is, among other things, a parable of Cellorigo's "republic of enchanted men," living in a world of illusions and tilting at windmills.

At the other extreme, there was the drama from exponents such as Lope de Vega to Tirso de Molina and Calderón. As with the picaresque novel, the comedy of the "Golden Century" was concerned with the contemporary social scene. The psychological problems faced by its characters arose nearly always directly out of social conflicts. But the social purpose of these plays was essentially conservative: the defense of the highly structured Spanish society of the time. This was achieved by insisting for all social ranks, from the king down to the peasants, on the special dignity and honour of their status. Thus Lope, for the first time, introduced the common people as fully rounded characters on the stage, allowing, for instance, to the daughter of a blacksmith the emotions of love formerly reserved on the stage to aristocratic ladies. Heredity and blood are the principles of a social order that in the comedies may be threatened but that are always reaffirmed in the end. Here may, perhaps, be seen a link with the visual arts of the age and with the Baroque style.

The "Golden Century" in architecture and painting. In the second half of the 16th century, in the more severe artistic climate of the Catholic Counter-Reformation, the playful Plateresque style of buildings fell into disfavour. Philip II preferred the unornamented and monumental classical architecture of Juan de Herrera, the greatest Spanish architect of the century. This could be very effective, as in Philip's monastic palace of El Escorial (20 miles [30 kilometres] northwest of Madrid), which embodied the gloomy and ascetic spirit of the King and also blended with the stark and forbidding landscape of the Sierra de Guadarrama (a range of mountains northwest of Madrid). But only too often the style produced an ugly and pompous monumentality, such as not infrequently afflicts the architecture of countries at the height of their imperial careers. But at the turn of the century this style gave way to the Baroque, which Spanish architects found no difficulty in acclimatizing in their country from Italy. This style could achieve monumentality without being pompous. It could display the grandeur of the church, or the monarchy, or anyone rich enough to build himself a palace. Perhaps most important of all, it was a style that, by its love of ornamentation and its essentially theatrical character, became immensely popular with the mass of the population.

Success of the Baroque style

The painting of the period does not lend itself as easily to a social interpretation; but certain patterns may still be observed. The greatest painter of the Spanish Counter-Reformation, the Cretan El Greco, made his home in Toledo, where the local aristocratic and ecclesiastical society (but not Philip II) seems to have fully appreciated his genius. El Greco's superb portraits, but above all his religious paintings, with their elongated figures rising like so many flames to heaven, seem like the embodiment of the most spiritual aspects of Spanish Catholicism.

El Greco left no school. The painters of the following generation, especially Murillo, had a different religious sensibility, more naturalistic than El Greco, more personal, and more romantic; and again, as did Baroque architecture, they appealed successfully to a popular religiosity. But the greatest of them, Velázquez, was hardly a religious painter at all. His subjects were the King with his family and court and, characteristic for the age and parallel with the drama of the period, the common people. All these he represented with a realism and psychological insight unmatched in the 17th century, except perhaps by Rembrandt.

The reign of Philip III. It was the tragedy of Spain that its ruling classes failed to respond to the social and political problems of the age as creatively as its writers and artists. For this failure there are at least some good reasons. In the first place, the system of royal government, as it was understood at the time, depended ultimately on the king's ability to lead and to make decisions. Philip II's very consciousness of his divinely imposed obligations in this respect, compounded by his almost pathological suspiciousness of the intentions and ambitions of other men, had led him to deprecate independent initiative by his ministers. Philip thus failed to educate an effective ruling class with a tradition of statesmanlike thinking and decision making.

Philip III (died 1621) was a devout, phlegmatic nonentity, totally incapable of carrying on his father's methods of personal government. He therefore had to have a minister who would do all his work for him, a *privado.* His choice, the Duke of Lerma, however, turned out to be a singularly unfortunate one. Amiable, incompetent, and, inevitably, under heavy attack from those who envied his position, Lerma strove to maintain himself by the lavish dispensation of royal patronage to the high nobility. He was not the man to translate the schemes of the *arbitristas* into effective reforms. During the reign of Philip III the government of Spain either became the victim of events that it did not attempt to control or allowed its hand to be forced by outsiders.

Lerma's incompetency

Not all events could have been controlled. In 1599–1600 an epidemic plague claimed some 500,000 victims in Castile. This sudden decimation of the labour force caused a sharp rise in wages that acted as another disincentive to capital investment by Spaniards. Yet the advantages that the labourers had reaped from the rise in wages were quickly offset by renewed inflation. This was the result of the government's decision to solve its perennial financial problems by the massive coinage of the *vellón,* a debased copper coinage. This did not prevent the need for another moratorium on government debts, in 1607, and in 1608 the King had to promise the Cortes of Castile not to issue any more *vellones* for 20 years. But by 1617 he had to ask the Cortes to allow another issue, and yet another one in 1621.

The expulsion of the Moriscos. The most serious social crisis of the reign was, however, entirely man-made. The great majority of the Moriscos lived in the Kingdom of Valencia. Like those of Andalusia, they had been forcibly but ineffectively converted to Christianity. Most of them were relatively poor farmers, agricultural labourers, or small tradesmen and hucksters. They were hated and despised by the poor Christian peasants but protected by the landowners for whom they provided industrious tenants and labourers.

For many years a controversy raged between those who wanted to "solve" the Morisco problem by expulsion and those who pleaded for time and money to achieve their genuine assimilation and Christianization. While the practical, economic aspects of these two views were not ne-

glected, it was characteristic of the Spain of the period that the main emphasis of the debate was on the religious and moral problems involved. In 1609 Lerma's government ordered the expulsion of the Moriscos. By 1614 some 275,000 had been forced to leave Spain. The majority of Spaniards undoubtedly approved of the expulsion. About its economic effects there was at the time and there is still today considerable controversy. In Castile the effects were probably slight. In Aragon and Valencia, where the Moriscos had constituted between 20 and 30 percent of the population, they were certainly much greater. Some but by no means all Morisco land was resettled by "old" Christians. There was a shift from labour-intensive sugar and rice production to mulberry (silk) cultivation and viticulture (vines). The greatest difficulties were caused by the indebtedness of the Morisco peasants and the consequent losses suffered by their urban creditors. An ironic footnote to the expulsion was the plight of the Aragonese and Valencian inquisitions. Once hot for expulsion, they were now left without their major source of income, the composite fines for Moorish practices by which they had formerly milked the Morisco villages.

Effects of the expulsion

Spain and Europe. Neither Philip III nor Lerma were emotionally or intellectually capable of the fundamental reappraisal of foreign policy that Philip II's failures called for. Very few even of the *arbitristas* had seen this need sufficiently clearly. The court, the nobility, and, above all, the clergy and the King's confessors remained caught in the now hardening tradition of Spanish imperialism, simplistically interpreted as the cause of God. Once again, this attitude caused a serious misjudgment of the political forces in England: the absurd hope of placing the infanta Isabella on the English throne when Elizabeth I should die. In 1601 a small Spanish force was disembarked at Kinsale, in Ireland, to cooperate with the Irish rebels. The English army had no difficulty in forcing it to surrender.

Fortunately, the new government of James I was anxious for peace. On the Spanish side, the Treaty of London (1604), which ended 16 years of Anglo-Spanish war, was negotiated on the initiative of Philip II's son-in-law, the archduke Albert, to whom, in his last year, Philip II had handed over the nominal sovereignty of the Spanish Netherlands. It was also Albert and his Genoese general, Ambrogio Spinola, who virtually forced Madrid to negotiate with the Dutch rebels. Between 1604 and 1607, Spain sent unprecedentedly large sums to Flanders. Spinola captured Ostend (on modern Belgium's coast) and won victories in Friesland (north Holland). But it would take 300,000 ducats a month to continue the war successfully, he now wrote to Madrid. After the moratorium of 1607, Philip III was in no position to raise such sums; but still he could not bring himself to recognize the independence of his rebellious and heretical subjects. He compromised by concluding a truce for 12 years, to run from 1609.

In 1610 a new war with France threatened, but Henry IV was assassinated, and once more, for almost 20 years, Spain's most formidable opponent in Europe became preoccupied with its internal problems. The years from 1610 to 1630 were the last period in which Spain clearly dominated Europe. For the first of these two decades Europe enjoyed a kind of Pax Hispanica. Spanish armies controlled Italy, Flanders, and parts of the Rhineland. Spanish and Spanish-inclined Jesuits were confessors at the courts of the Austrian Habsburgs, of Poland, Bavaria, and of some of the minor German and Italian princes. Spanish subsidies, pensions, and bribes made clients even of Protestant politicians in England, Holland, and the Swiss cantons (although much less effectively so than Madrid hoped); and Spanish-paid spies fed the governments of Madrid and Brussels with valuable, if not always accurate, information about its potential enemies in the United Provinces (or Holland), England, and France. Yet, to a much greater degree than most contemporaries realized, this Spanish domination of Europe rested on default: the disunity and temporary weakness of Spain's political and religious opponents. The psychological effects on Spain of this position were wholly disastrous, for it confirmed the Castilian ruling classes in their imperialist attitudes.

While for Philip III and Lerma this attitude led, for reasons both of finance and temperament, to a largely defensive stance, it was quite otherwise for the Spanish representatives abroad. In the absence of an effective lead from Madrid, the Spanish grandees who were the King's viceroys and ambassadors in Europe took it upon themselves to advance Spanish interests as they saw them—that is, in terms of Spanish power. They fortified the route from Milan to the Tirol (now west Austria) through the Valtellina, the vital link with the Austrian Habsburgs; they annexed several small Italian lordships; they inveigled Dalmatian pirates (operating from what is now the Yugoslav coast), the Uskoks, to prey on the trade of Venice, and they even seem to have plotted the complete overthrow of that republic.

More fateful still were their activities in Prague and Brussels. At the courts of the emperors Rudolf II and Matthias, the ambassador Baltazar de Zúñiga organized an effective "Spanish" party. His successor, the Count of Oñate, negotiated the secret Treaty of Graz (1617) by which the Jesuit-educated archduke Ferdinand of Styria (later Emperor Ferdinand II) was designated as heir to Matthias. In return for giving up Philip III's claims to the Austrian succession, which Madrid had never seriously pursued in any case, Oñate obtained the promise of full Spanish sovereignty of the Tirol and Alsace (in modern east France), the two German pillars of the "Spanish Road" between Italy and the Netherlands. At the same time, the "Spanish" party in Prague managed the preelection of Ferdinand as king of Bohemia in case of Matthias' death. Zúñiga and Oñate had undoubtedly strengthened Spain's strategic position in central Europe; but they had also, for the first time since the abdication of Charles V, involved Spain again in the local politics of the Holy Roman Empire. For Philip IV, this involvement turned out to be even more disastrous than it had to Charles V. Spanish leadership, as practiced by the self-willed Castilian grandees abroad, had proved to be energetic and clever; but it was ultimately as devoid of true statesmanship as the slackness of the King and his *privado*.

Spain's position in central European politics

In 1617 Lerma's enemies at court finally managed to overthrow him. Zúñiga returned to Madrid and became the leading advocate of aggressive policies. The Marquis of Bedmar, former Spanish ambassador to Venice and the organizer of the anti-Venetian conspiracy, went as ambassador to Brussels and immediately began to press for the reopening of the war against the United Provinces. In 1621 Philip III died, and with him disappeared the last restraints on the neo-imperialists. Philip IV, a boy of 16, left the effective powers of kingship in the hands of his former gentleman of the chamber, the Count (later Count-Duke) of Olivares. Olivares shared his uncle Zúñiga's political views, and he soon dominated the Council of State.

Philip IV's reign. *Spain and the Thirty Years' War.* In 1620, following the defeat of Frederick V (the elector Palatine, or prince, from the Rhineland who had accepted the crown of Bohemia, now western Czechoslovakia, when offered it in 1618) and the Bohemians, Spanish troops from the Netherlands entered the "Winter King's" hereditary dominions of the Rhine Palatinate. Militarily, Spain was now in a favourable position to restart the war with the United Provinces at the expiration of the truce in 1621. The decision to do so was, however, taken on more general grounds. The Dutch had used the truce only to capture the carrying trade of western Europe and the Baltic with Spain, Zúñiga argued. On the oceans they had never observed the truce but continued their piracies against Spanish and Portuguese shipping. If they were allowed to continue, first the Indies would be lost, then the rest of Flanders, Italy, and, finally, Spain itself, for it would have lost the dominions that had made it great. These were very different grounds for resuming the war from those habitually advanced by Philip II. Little was said about religion or even the King's authority, while the protection of the overseas empire had become the central consideration in Spanish relations with the Dutch rebels." Olivares dismissed the counter-arguments of the Council of Finance. The young King, content to be told that he was not responsible for the debts of his predecessors, piously declared his intention not to burden his subjects any

further. Neither he nor his ministers could foresee that a recent slump in silver shipments from America was not a temporary setback but heralded a rapid, long-term decline. The Dutch, it is true, were equally anxious for war, partly, at least, because of the vain hope that the Belgians would rebel against Spain and join the United Provinces.

Having decided on war, Olivares pursued a perfectly consistent strategy: communications between Spain and the Spanish Netherlands must be kept open at all costs, and the Dutch must be hit wherever they were most vulnerable. The first objective led Spain to cultivate the friendship of James I of England and even to contemplate the restoration of Frederick V to the Palatinate and the marriage of Philip IV's devoutly Catholic sister to the heretic Prince of Wales (later Charles I). It led to very close cooperation with the Austrian branch of the Habsburgs and the need to fight for the control of the Valtellina. The second objective, which followed the advance of the imperial armies under Wallenstein (an adventurer who made himself indispensable to the Habsburgs as a military organizer) to the Baltic, led to grandiose schemes of building an imperial Spanish fleet in the Baltic with Hanseatic (the Hanse towns on the Baltic were independent mercantile organizations) and Danish help in order to destroy the Dutch Baltic trade and with it the economic prosperity of the republic.

However rational and limited these aims and plans seemed in Spain, in the rest of Europe they appeared to show only too clearly the limitless ambitions of the House of Austria. The now habitual talk in Spanish court and military circles of restoring Spain's greatness did not help to persuade Europe otherwise. Spinola's and Wallenstein's victories in the mid-1620s convinced the Spanish Council of State that victory against the Dutch was possible and blinded them to the danger of raising up new and more powerful enemies. Thus, they let slip the last chances of a favourable peace. Yet, despite enormous sums sent annually from Castile to Flanders, the Spanish armies could not break Dutch resistance. They could not even supply their own provisions and ammunition without the covert help of Dutch merchants, who, in their turn, argued that this trade with the mortal enemy brought in the money needed to pay for the troops fighting this enemy. From 1630, when Sweden and France actively intervened in the war, Spain rapidly lost the initiative. Spanish armies could still win tactical victories in Italy and Germany, but the number and seriousness of Spanish reverses, especially at sea, were now steadily mounting.

Improved government under Olivares

The government of Olivares. Olivares was undoubtedly the most able politician directing the Spanish government since Cardinal Granvelle. All contemporaries remarked on the contrast between his energetic and bustling administration and the sleepy regime of Philip III and Lerma. The Catholic Kings, the Emperor, and Philip II had kept the high nobility, to a greater or lesser degree, out of the central government. Lerma had reversed this policy, and Olivares could not go back on this position, although he bitterly lamented the incompetence of his fellow aristocrats and sharply reduced the overgenerous flow of royal patronage to them. He could and did develop the system of committees (juntas) of experts within the councils, which took over a great deal of government business and made its administration more efficient.

In 1623 and 1624 Olivares presented to the King and Council of State a number of memorandums that were nothing less than plans for a far-reaching reform of government and society, on the lines advocated by the *arbitristas.* Like them, Olivares saw the need to change mental attitudes: restraints on the aristocratic love of splendour and display, the need to appreciate the dignity of work and productive economic activity, an end to the economically harmful and morally indefensible mania for *limpieza* (Olivares himself, through his grandmother, had *converso* blood flowing in his veins). On the more immediately practical level, Olivares' memorandums were concerned principally with finance; for, with an annual expenditure of 8,000,000 ducats, there was a deficit of 4,000,000. The Count-Duke proposed the abolition of some of the most harmful taxes, the *millones* and the *alcabala,* the sales tax, and their substitution by other, simpler, and more equitable taxes. Finally, Castile should not be expected to continue to bear almost alone the cost of the war. Like Granvelle, Olivares recognized that the King's non-Castilian dominions could only be expected to share in the burdens of empire if they could also enjoy its advantages, the honours, commands, and control over policy that had been all but completely reserved to the Castilians.

None of these plans was put into practice. The Spaniards were unwilling to change their mode of life and their ingrained beliefs at the behest of a royal favourite. Olivares did manage to arrange loans with a consortium of Portuguese Marrano businessmen, but he was bitterly attacked for this action. Philip IV consulted a committee of theologians about a proposed canalization of the Tagus River, flowing east–west across Spain and Portugal. They forbade it as an interference with God's design. The court itself gaily abandoned a short-lived austerity in the celebrations that followed the arrival of the Prince of Wales in his romantic but abortive quest for a Spanish bride (1623). The financial reforms foundered on the opposition of vested interests to taxation by the Cortes and on the opposition of the whole Castilian ruling class to the plan for the decentralization of the empire. Just as had happened to Granvelle's proposals, there was not even any serious discussion of Olivares' plan. In the 1560s the result of this failure had left Philip II with no alternative but Alba's policy of repression—which caused the revolt of the Netherlands; in the 1620s it left Olivares with no alternative but his Union of Arms—which caused the revolts of Catalonia and Portugal. The Union of Arms was a scheme for the creation of a reserve army of 140,000 men that was to be paid for by the dominions of the Spanish Empire in proportion to their estimated resources. But the non-Castilian dominions disliked this proposal because it infringed their liberties. They also distrusted Castilian intentions, and with some justice; for in 1625 Olivares had advised the King in a secret memorandum to "secretly plan and work to reduce these kingdoms of which Spain is composed to the style and laws of Castile."

Hopelessness of reform

The revolt of Catalonia. Apart from Portugal, Catalonia was the state with the greatest degree of autonomy. Its medieval form of government had not been changed since Ferdinand the Catholic had settled it in 1486. Its countryside, especially on the French border, was infested with smugglers and bandits and riven by local feuds. Its taxes were administered by the Diputació, a self-perpetuating and corrupt committee of the Catalan Corts that functioned during the long intervals between the meetings of that body. The viceroys, hemmed in on all sides by local privileges and without control over the finances of the province, were virtually powerless. In 1626 Philip IV summoned the Cortes of the realms of the crown of Aragon. Aragon and Valencia reluctantly voted some money but refused conscription of troops. Catalonia refused everything. Nevertheless, Olivares published the royal decree for the Union of Arms. Relations between Madrid and Catalonia deteriorated rapidly.

Increasing financial troubles

As the costs of warfare continued to soar, the government resumed the inflationary minting of *vellones* and had yet to declare another moratorium, in 1627. In 1628 the *vellón* coins were withdrawn, causing a collapse of prices and a business recession. The 1630s added new taxes in Castile and outright confiscations from private individuals, both of income from government annuities and of American silver imported in commercial transactions. Not surprisingly, Madrid was becoming obsessed with what it considered to be the injustice of Catalonia's immunity from taxation. In 1639 Olivares opened a campaign against southern France from Catalonia. It had no rational strategic objective except to pitchfork Catalonia into the war. If the Catalans had to defend their country, Olivares argued, they would have to support the army.

This logic was lost on the Catalans. The peasants, urged on by their clergy, refused to support the troops. During the winter the soldiers were billeted in the countryside. Soon there were clashes with the population, then riots and open rebellion. Too late, Olivares attempted to draw back and conciliate the Catalans. On June 7 the mob

murdered the Viceroy in Barcelona. The higher nobility and the urban aristocracies were still most anxious for an accommodation; but the countryside was now completely out of control. The Diputació, which was the only remaining legal authority, was led by a strong-minded cleric named Pau Claris, canon of Urgel, located west of Barcelona, who was unwilling to make concessions. In the autumn of 1640 Olivares scraped together the last available troops and sent them against the Catalan rebels. Claris countered by transferring Catalan allegiance to the king of France, "as in the time of Charlemagne" (January 1641). French troops now entered Catalonia. Only when the renewed French civil wars (the Fronde) induced the French to withdraw their army were the Castilians able to reconquer Catalonia (1652). The Catalan upper classes, at least, were relieved, for they had found the French even less congenial masters than the Castilians. For once, Madrid did not repeat its previous mistakes: the liberties and privileges of Catalonia were fully restored.

The revolt of Portugal. The revolt of Catalonia gave the Portuguese their opportunity. The lower classes and the clergy had always hated the Castilians. The Portuguese aristocracy and the commercial classes, previously content with the patronage and the economic opportunities that the union with Spain had provided, had become dissatisfied during the last 20 years. They resented the introduction of Castilians into their government (1634), the ineffectiveness of Spanish naval support in the defence of Brazil against the Dutch, and the growing reaction of the Spanish colonies against Portuguese economic penetration during this period of contracting economic activity. Rather than allow themselves to be sent to fight the Catalan rebels, the Portuguese nobility decided to seize power in Lisbon and proclaimed the Duke of Bragança as King John IV of Portugal (December 1640). Madrid, with an aristocratic conspiracy in Andalusia on its hands (1641), no longer had the means to react.

Portuguese grievances

The last years of Philip IV. The disasters on Spain's periphery were matched by continued mismanagement of Spanish finances at the centre. Once more the government tampered with the *vellón* coinage and then reversed course into a sudden and catastrophic deflation (1641–42). In January 1643 the Castilian grandees were finally able to force Philip IV to dismiss Olivares. The King now decided to run his own government. He dissolved the juntas, and the councils resumed their authority. Soon, control of the government slipped into the hands of Olivares' nephew, Don Luis Méndez de Haro, a clever but colourless politician with neither his uncle's imperial vision nor his panache.

The defeats continued. The Great Condé (the French King's cousin) broke the Spanish *tercios* and their reputation for invincibility in the Battle of Rocroi, north-east France (1643). In 1647, popular revolutions broke out in Naples and Palermo (Sicily), and soon these two cities were in the hands of revolutionary governments. In Naples, at least, it was again the excessive taxation, imposed for Spain's war effort, that had precipitated the rebellion. The Spanish monarchy, wrote the Venetian ambassador to Madrid at the time, "resembled that great colossus that during an earthquake had collapsed in a few moments while everyone hurried along to enrich himself with the fragments."

In fact, Spain survived and even managed to hold on to much of its empire. The revolts of Naples and Sicily, directed as much against the local nobility as against Spain, were put down in 1648. When the Emperor conceded French claims to Alsace and the Rhine bridgeheads, the "Spanish Road" to the Netherlands was irrevocably cut, and the close alliance between the Spanish and the Austrian branch of the House of Habsburg came to an end. With Portugal in revolt and Brazil no longer an issue between the Dutch and the Spaniards, Philip IV drew the only possible conclusion from this situation and rapidly came to terms with the United Provinces, recognizing their full independence and agreeing to the closing of the Scheldt, a river emptying into the North Sea west of Antwerp (Treaty of Münster, January 1648). But Philip IV had not changed his basic policy. He wanted to have his hands free for a final effort against France, even after Catalonia had surrendered. Once again the temporary weakness of France during the Fronde confirmed the Spanish

court in its disastrous military policy. Haro passed up the chance of concluding a very favourable peace in 1656.

The war dragged on, with England joining France, capturing Jamaica, and contributing to the Spanish defeat in the Battle of the Dunes on the northern coast of France (1658). The Treaty of the Pyrenees (1659) cost Spain Artois (now northernmost France), Roussillon, and part of Cerdagne. More important than these relatively minor territorial losses was the realization throughout Europe that Spain's pretensions to hegemony had definitely and irremediably failed. The Spaniards themselves were slow to admit it. Philip IV had made concessions to France in order, once again, to have his hands free against the last unforgiven enemy, Portugal. There was no longer any rational basis for his hopes of success. All schemes for financial and tax reforms were still being blocked by vested interests, and the government had declared two more bankruptcies, in 1647 and 1653. Once more the Council of Finance issued a debased coinage to pay for the Portuguese campaign. But the Portuguese routed the last Spanish armies at Ameixial (1663) and at Villaviciosa on the north coast of Spain (1665). In 1668 Spain formally recognized the independence of Portugal.

The Treaty of the Pyrenees

Charles II. For 10 years Philip IV's widow, Maria Anna of Austria, acted as regent for the child Charles II (1665–1700). She allowed her government to be dominated by her confessor, the Austrian Jesuit Nithard. He was overthrown by John of Austria, an illegitimate son of Philip IV, who, however, proved quite incapable of providing effective leadership for the country. From then on, the high nobility dominated the government as effectively as it had done in the days of Philip III, playing court intrigues, first with the regent and, later, with the two successive wives of the incapable Charles II. The majority of these aristocrats were self-seeking and incompetent; but some, notably the Count of Oropesa, were men of considerable ability. They finally restored the coinage, in 1680, although not before they had caused another catastrophic deflation. They set up a committee for commerce that pursued orthodox mercantilist policies, encouraging trade and industry. They even took the unprecedented step of investigating the Inquisition and recommending a right of appeal to the secular courts.

Decline of Castile

But these were palliatives. Until the mid-1680s the Castilian economy declined, and this at such a rate that the French ambassador, the Marquis of Villars, claimed to see an appalling deterioration between his two visits, in 1668–69 and in 1671–73. In the 1690s the Venetian ambassador characterized the reign of Charles II as "an uninterrupted series of calamities." The population of Castile declined from about 6,500,000 at the end of the 16th century to a low point of under 5,000,000 about 1680. Figures for the whole of Spain followed a similar pattern, from 8,500,000 to about 6,600,000. The reasons for this decline were not so much emigration to the overseas colonies, which averaged 4,000–5,000 a year in the 17th century, as military casualties from all causes, which averaged the frightening figure of 10,000–12,000 a year. More devastating still were the recurrent plagues and, perhaps, the sheer misery of the rural population, who lived on estates that their noble and ecclesiastical owners could not be bothered to manage with even a minimum of efficiency. The shortage of labour, especially skilled labour, and the high wages attracted many foreign workers, perhaps as many as 70,000 Frenchmen. Nevertheless, Castilian industries continued to decline. The nadir was reached in the decade 1677–86, with crop failures, earthquakes, an epidemic that sharply reversed a slight upward trend in population since about 1650, and, on top of these natural disasters, the government's deflation of the coinage.

The French wars. In these circumstances it is not surprising that Spain now became the victim rather than the initiator of aggression. In three successive wars with France (1667–68, 1672–78, 1689–97), Spain lost Franche-Comté (Treaty of Nijmegen, 1678) and some Belgian frontier towns to France but still managed to hold on to the greater part of the southern Netherlands and its Italian dominions. The reason was less Spain's own military efforts, which were puny compared with those of the first half of the century, than the unwillingness of other European powers, especially the United Provinces, to see the Spanish dominions in Europe swallowed up by France. After the last and, for Spain, most disastrous of these wars, the War of the Grand Alliance (1689–97), Louis XIV himself restored Flanders and Catalonia, which his troops had occupied, for he now had his eye on the inheritance of the whole Spanish Empire.

The last years of the childless and evidently dying Charles II were occupied by the manoeuvres of the European powers for the Spanish succession or, alternatively, for the partition of the Spanish Empire. Amid cabals, intrigues, exorcisms of evil spirits, and blood feuds at court, while riots were going on in the streets of Madrid, the rule of the House of Austria came to an end with the death of Charles II, on November 1, 1700.

The decline of Spain. There can be no doubt about the economic and political decline of Spain in the 17th century and especially in its second half. Moreover, Calderón, Velázquez, and Murillo had no successors of remotely comparable stature. It need not be reasonable, however, to speak of decadence, as many non-Spaniards did at the time and later. The term decadence, except perhaps when applied to the person of Charles II, that last unhappy offspring of constant Habsburg intermarriage, does not explain the timing of the decline nor its duration. In the first place, the economic decline was mainly a Castilian phenomenon and did not affect Catalonia and Valencia to anything near the same degree. For Castile, it is perhaps best to see the problem of decline as the *arbitristas* saw it: in the depreciation by Castilians of economic activity, an attitude that was rooted deeply in Castile's past history but that was particularly baleful in a period of general European economic depression, such as the 17th century. To this must be added the aggressive militarism that was central to the Castilian aristocratic tradition and that led to the political hubris (overweening pride) of Spanish imperial policy, from Philip II to Philip IV. The Castilian ruling classes never produced, or perhaps gave no chance to, a leader who could break out of this tradition. Velázquez seems to have known it or felt it instinctively when he painted his "The Surrender of Breda" as the beginning of a hoped-for reconciliation and when, in his portraits of Philip IV, he showed the pathos of a man half aware of his personal inadequacy for the role he is called upon to play. It was the wars that devoured Castile, though they were fought beyond its borders. They do not directly explain the end of the "Golden Century." But it may be suggested that a society that has invested most of its energies and all its pride in war, even though it be war for an ideal, will not provide a congenial ground for the exercise of creative genius when its ideal has failed and it is left with nothing but a now hollow pride. (H.G.K.)

THE EARLY BOURBONS, 1700–53

The wars of the 17th century, though they had weakened Spain's power in Europe, had left it still the greatest imperial power in the world. Spain's central problem in the 17th century had been to maintain what remained of its European possessions and control of its American empire. In 1700 both tasks appeared to be beyond the military and economic resources of the monarchy. In the 17th century the greatest threat had come from a land power, France, jealous of Habsburg power in Europe; in the 18th it was to come from a sea power, England, while the Austrian Habsburgs became the main continental enemy of Spain.

The War of the Spanish Succession. In 1700 (by the will of the childless Charles II) the Duc d'Anjou, grandson of Louis XIV of France, became Philip V of Spain. Austria refused to recognize Philip, a Bourbon, and concede the defeat of its hopes of placing an Austrian candidate on the throne of Spain. To England, a Bourbon king in Spain would disrupt the balance of power in Europe in favour of French hegemony.

Louis XIV conceived of Spain under a Bourbon king as a political and commercial appendage of France to be ruled by correspondence from Versailles; he wished to regenerate and strengthen his ally by a modern centralized administration. This task was both complicated and

facilitated by the War of the Spanish Succession (1701–14) when the allied armies of Britain and Austria invaded Spain in order to drive out Philip V and establish the "Austrian" candidate, the archduke Charles, on the throne.

Administrative reforms

An efficient administration had to be created in order to extract resources from Spain for the war effort, and thus relieve pressure on the French treasury; at the same time financial shortages imperilled administrative reform while war taxation and war levies drove Catalonia and Aragon to revolt against the demands of the Bourbon dynasty.

The instruments of centralizing reform were French civil servants (Jean-Jacques Amelot, Louiv XIV's ambassador, and Jean-Henri-Louis Orry, a financial expert) and a handful of Spanish lawyer-administrators such as Melchor de Macanaz. They were supported by the queen, María Luisa of Savoy, and her friend the 60-year-old Princess of Ursins. The opponents of reform were those who suffered by it: the grandees who had dominated the cumbersome inefficient councils; the councils themselves; the regions like Catalonia, Aragon, and Valencia, in which the establishment of effective royal rule was seen as a Castilian, centralizing, imposition in conflict with the local privileges, or *fueros;* the church, whose position was threatened by the ferocious and doctrinaire regalism of Macanaz, who wished to subject the independent jurisdictions of the church (especially that of the papal nuncios and the Inquisition) to the absolute monarch.

The disaffection of all these elements easily turned to opposition to Philip V as king. Opposition to the new dynasty accentuated the determination of Bourbon civil servants to end special privileges that covered treasonable sympathy with the Austrian and English invaders.

Castile was ferociously loyal to the new dynasty throughout the war, in spite of severe financial difficulties (consequent on the loss of revenues from the Indies). The support of Castile and of France (until 1711) enabled Philip V to survive severe defeats and two occupations of Madrid. In 1705 the archduke Charles landed in Catalonia and took Barcelona. When Philip V tried to attack Catalonia through Aragon, the Aragonese, in the name of their *fueros,* revolted against the passage of Castilian troops.

It was this revolt, backed by the local nobility, that turned the King's advisers resolutely against local privileges and aristocratic treason. After the victory over the archduke Charles at Almansa (April 1707) the *fueros* of the kingdoms of Valencia and Aragon were abolished and the property of rebels confiscated. When the Archbishop of Valencia resisted attempts to make priests of doubtful loyalty appear before civil courts, the regalism of Macanaz was given full course.

This was the last direct triumph of the reformers. With the death of Queen María Luisa in 1714 and the arrival of Philip's new wife, Isabella (Elizabeth Farnese), court support for radical reform disappeared. Macanaz was condemned by the Inquisition, and a less rigid administration, more inclined to compromise with the church and the higher nobility, controlled the country's policy.

The last stages of the war were a Spanish concern. The allies deserted the archduke Charles; the French gave little help to Philip V. In 1714 Philip recaptured the Archduke's capital at Barcelona. By the Decree of Nueva Planta (1716) the *fueros* were abolished and Catalonia was integrated into Spain. Integration, criticized as it was by later generations of Catalans as the destruction of Catalan "nationality," was nevertheless a precondition for industrial revival; it gave Catalonia a domestic market in Spain and later an overseas market in America.

The integration of Catalonia into Spain

Paradoxically, a disastrous war had for the first time created a unitary Spanish state: except for the Basque Provinces and Navarre, Spain was under direct royal administration.

It was in its possessions outside Spain that Spain paid the price of defeat: the treaties of Maastricht and Utrecht (1713) stripped the country of its European possessions (Belgium, Luxembourg, Milan, Sardinia, and Naples) and gave Britain Gibraltar and the right to send one ship a year to trade with Spanish America.

"American" and "Italian" policies. Two tendencies can be discerned in Spanish policy until 1748: a desire for revenge and recovery in Italy, and an "Atlantic" policy; *i.e.,* the protection of America from British incursions and the revivification of Spanish colonial rule. Both policies demanded a strong army and navy. The "Italian" tendency is connected with Philip V's second wife, Isabella, and her desire to get Italian thrones for her sons. The instruments of her ambitions were two foreigners: the Italian cardinal Julio Alberoni, the exiled son of an Italian gardener, and the Dutch-born adventurer Johan Willem Riperdá. The attempt to recover its possessions in Italy involved Spain in an unsuccessful war with Austria, now the great power in Italy. Spain suffered a serious naval defeat at Capo Passero in 1718. Nevertheless, Isabella's persistence was rewarded when her son, the future Charles III, became the duke of Parma in 1731 and king of Naples in 1733, relinquishing his claims to Parma.

The American–Atlantic tendency was the work of Spanish ministers with a particular interest in the navy and foreign trade—José Patiño, Marqués de la Ensenada, and José de Carvajal y Lancáster. The "Italian" and "Atlantic" tendencies existed side by side in the late years of Philip V's reign. Atlantic rivalries in the form of a dispute over the interpretation of British trading privileges in Spanish America granted at Utrecht brought on the War of Jenkins' Ear (1739–43), during which the British sacked Porto Bello in the Caribbean. The Spanish fleet nevertheless was surprisingly effective and worsted Adm. Edward Vernon at Cartagena. The Italian–Mediterranean policy led directly to Spanish involvement in the War of the Austrian Succession (1740–48). It made possible an alliance of France and Spain against Austria, now the dominant power in Italy, giving Isabella the opportunity to settle her second son, Philip, in an Italian duchy. Spanish troops entered Milan (1745). Ferdinand VI (reigned 1746–59) was concerned with the domestic recovery of Spain rather than the extension of its power in Europe. He hoped to recover Gibraltar at the general peace that ended the War of the Austrian Succession. But the Anglo-French rapprochement made recovery of Gibraltar an impossibility at the Treaty of Aix-la-Chapelle (1748); the treaty merely strengthened Spain's position in Italy when Philip became duke of Parma, Piacenza, and Guastalla.

With Ferdinand VI the Atlantic tendency became dominant. Since Britain was Spain's great enemy in the Americas (as Austria had been in Italy) its "natural" ally was France as Ensenada and Carvajal had seen (hence a series of family pacts with France in 1733 and 1743). It was only in the last years of his reign that Ferdinand's minister, Ricardo Wall, attempted a policy of strict neutrality as the best means of saving Spain from the hostility of Britain, Austria, or France.

This American interest was reflected in increased trade (the old system of convoyed fleets was abandoned for individual sailings), the founding of privileged trading companies (1725), and the founding of new naval arsenals at Ferrod and Cartagena (1726). But the central weakness of Spain as an imperial power remained. The Spanish economy could not supply America with the consumer goods it needed in return for its increased exports. These were supplied either by British merchants through the "legitimate" trade from Cádiz or by smuggling. The Spanish navy, in spite of considerable efforts, could not suppress a contraband trade that, from the colonists' point of view, was a necessity.

The ministers of Ferdinand VI revived the reforming traditions weakened during the latter years of Philip V, whose lethargy deepened into chronic melancholia.

One of the most important imitations from French administrative practice was the use after 1749 of crown officers, or intendants, to rule in the provinces. The intendants strengthened royal control over local government, especially in its financial aspects; together with the captains general (set up by Philip V), they were responsible for a renewal of provincial public works. Carvajal reorganized the postal system; Ensenada, at one time the all-powerful minister of Ferdinand VI, was a great road builder; he opened the Seville tobacco factory, botanical gardens, and observatories; above all, he increased royal receipts by rationalization of the tax structure. The reforms of Ferdi-

nand's successor, Charles III, though more dramatic, were a continuation of those of Ferdinand VI.

THE REIGN OF CHARLES III, 1759–88

Two features distinguished the Caroline reforms from those of the early Bourbons. First, Charles III was a "reformer's king" in that he consistently supported reforming ministers. This was surprising in a monarch who had no great intellectual gifts, was obsessed by hunting, and turned his court into the most boring society in Europe. Second, the civil servants were distinguished from their predecessors by their adherence to a philosophy of government derived from the commonplaces of the European Enlightenment.

Penetration of Enlightenment ideas

Nevertheless, there were sharp differences among the civil servants. The Conde de Aranda and Pablo de Olavide y Jáuregui were influenced by the French Philosophes; Gaspar Melchor de Jovellanos y Ramírez was a disciple of Adam Smith; Pedro Rodríguez Campomanes drew more directly on such Spanish reformers as Macanaz; José Moñino Floridablanca was a professional administrator. All would have taken as their slogan *Felicidad* ("Felicity")—a well-ordered monarchy based directly on the productivity of people who are made happy by the intelligent application of the principles of political economy. There were, however, impediments (*estorbos*), such as traditional privileges (*e.g.*, grazing rights held by a sheep breeders' corporation, the Mesta) or attitudes (*e.g.*, the prejudice of the nobility against the "mechanical trades"); they could not be allowed to stand in the way of greater prosperity and, therefore, of a higher tax income for the state.

Economic revival. The years after 1714 had seen a gradual economic recovery, quite marked in the last half of the 18th century. How much of this revival of the last half of the century was the work of conscious but often confused government policy must remain doubtful. Thus the famous decree (1783) "ennobling" the mechanical trades had little practical result; the attempt to establish government factories and replace religious charity by the productive employment of the poor was a relative failure. Government policy had little to do with the growth of population, which rose during the century from 8,000,000 to 12,000,000. The increased demand for food and the consequent sharp rise in prices encouraged agriculture, benefitting the large landowners of the south and the small farmers near growing towns such as Barcelona. The most remarkable feature of this economic revival was the emergence in Catalonia after 1745 of a modern textile industry, based on cotton. The industry benefitted from a protected market in Spain and the colonies. In the Basque Provinces the archaic iron industry began a slow process of modernization. In Galicia, Catalan immigrants established a flourishing fishing fleet. The brandy trade brought sudden prosperity to the ports of Catalonia and their hinterland.

Nevertheless, the financial reforms of the earlier years and the abolition of internal customs duties removed obstacles to the expansion of the internal market, and the opening of the American trade (see below) acted as a strong stimulant.

One important feature of these developments was that they took place not in the old Castilian core of the monarchy but in the peripheral regions; not in the countryside but in the towns. It was on the periphery that price rises were steepest, outstripping wages in Barcelona and thus creating the beginnings of a social problem. The role of Catalans in the economic revival lies at the origins of the Castilian stereotype of the Catalans as selfish, thrusting businessmen, indifferent to traditional values and exploiting their fellow Spaniards.

Imperial problems. To Charles III the key to prosperity lay in the Indies, for a prosperous Spain demanded an American market. He saw clearly that Spain alone could not preserve an overseas market closed to the outside world against Britain. Ricardo Wall's policy of strict neutrality had allowed Britain to make gains in Canada that must weaken France—the only other anti-British power in America. If Britain would respect Spain's possessions, or if Charles could mediate between France and Britain in such a way as to preserve the balance between them in America, then to commit Spain to the French alliance was a dynastic luxury. Once it was clear to Charles that British terms were non-negotiable, then the Family Compact with France of 1761 was a piece of realpolitik. It was signed by the "anglophile" Ricardo Wall.

The consequence of such an alliance was involvement in the Seven Years' War—too late to save France. In 1762 the British occupied Havana—the greatest single blow sustained by Spain in the war. Spain theoretically allowed no foreigners to share directly in the colonial trade: the effect of this had been to starve the colonies of necessary imports and to encourage smuggling. In 1762, 15 ships entered the port of Havana; during the 11 months of British occupation, 700. This was a dramatic indication to the colonists of the drawbacks of the Spanish monopoly, especially when that monopoly was exercised by what was, in European terms, an underdeveloped nation.

The Seven Years' War

The Treaty of Paris (1763) concluding the Seven Years' War destroyed France as an American power. Spain lost the territory between Florida and the Mississippi, in return gaining Louisiana from France. Spain also had to recognize Portuguese advances in the Río de la Plata (the fort of Sacramento) and the British right to cut mahogany in Central America. The Family Compact was therefore an immediate military failure, and it was only the revolt of the American colonies against Britain that enabled Spain to recover the ground it had lost; the successful alliance with France to aid the colonists resulted in the Treaty of Versailles (1783), which gave back Sacramento, the two Floridas, and Minorca. Not until later did it become apparent that an alliance of revenge with colonial insurgents is a shortsighted policy for an imperial power.

The problems of imperial defense were thus temporarily solved by British weakness after 1765. The positive side of Charles III's imperial policy was an attempt to create an efficiently administered colonial empire that would provide the crown with increased revenues and with a closed market for the exports of an expanding Spanish economy.

Reform of imperial administration

The rationalization of the administration of the Indies had started before Charles III with the creation of a new viceroyalty at Santa Fe de Bogotá (now Bogotá) in 1717. To protect the south against the British and against Portuguese incursions from Brazil, the Viceroyalty of La Plata was created in 1776. The centrepiece of Caroline reform was the introduction of the intendant system in the colonies to tighten up local administration. Most dramatic of all was the abolition of the monopoly of Cádiz, by which all trade to the colonies had to go through that port. Beginning in 1778 non-Castilian ports could trade directly with the colonies.

The new policies brought some immediate and striking results. Energetic viceroys and ministers and ruthless intendants doubled or tripled imperial revenues. The volume of Spanish goods in the American trade increased tenfold in 10 years, so that Britain became seriously concerned at the Spanish revival. But imperial free trade would not satisfy the growing demand from Creole producers for free trade with all nations. Nor did the colonial oligarchs desire efficient government and higher taxation; they preferred bad government that let them control their own affairs. They showed their discontent in a series of revolts in the 1780s; only the fear of the native Indians drove them back to allegiance to the Spanish crown.

Domestic reforms. The domestic reforms of Charles III are more interesting for what they intended than for what they accomplished. They were not directed, as has often been maintained, at fostering a "bourgeois revolution." The middle classes were too weak, in a predominantly agrarian country, for the role of a modernizing elite; nor did Charles III contemplate a frontal attack on the traditional nobility. The purpose of reform was to remove what seemed to civil servants to be "traditional" constrictions on economic growth and administrative anachronisms that prevented the efficient exercise of royal power.

Reorganizations of the machinery of central government made for greater executive efficiency, but complete rationalization was never achieved; the old machinery of the councils persisted, with the Council of Castile as the ultimate decision-making body. An attempt to establish

royal control of municipalities (without which, reforms could not get past the oligarchic councils) was likewise only a partial success. Most of the public works that characterized the late 18th century were the achievement of vigorous captains general. The extensive civil functions of these military officials was the first sign of a hybrid military–civilian government that, in another form, was to be developed in the 19th century.

Nor was the economic structure of agrarian Spain modified. All the chief reformers believed that the great and extensively cultivated estates, especially in Andalusia and Extremadura, constituted the greatest bar to agricultural prosperity. The landless underemployed proletariat who worked the large estates began to alarm reformers. "Why in our villages and towns are these men without land and in the countryside land without men? Bring them together and all will be served." Property should be more widely distributed, it was felt; there should be a free market in land. Yet none of the reformers was radical enough to push through a wholesale assault on private property or on the civil entail (the juridical instrument by which the *latifundios,* or large estates, were preserved intact). Acts such as the limitation of future entail, which preserved great estate intact over generations (1789), the limitation of the privileges of the Mesta (1779), and the right to enclose olive groves and irrigated land (1788) showed that the reformers believed primarily in the right of private individuals to do what they liked with their own; the unrestricted pursuit of private profit, they believed, would bring public prosperity. *Corporate* property was the enemy: hence the proposal that common lands owned by municipalities and the crown should be sold for individual cultivation and hence the proposals to end ecclesiastical entail (mortmain).

The regalist attack on the church

The attack on the privileges of the greatest corporation in Spain, the church, was less radical than has sometimes been maintained. Charles III himself was a devoted Catholic—he dedicated Spain to the Immaculate Conception. Some of his servants were fashionable anticlericals. Most were regalists; that is, they asserted the right of the crown to control over the church in civil matters. In the extreme regalists' view, the state should take care of charity and education; it should subject priests to civil jurisdiction for civil crimes and assert the traditional rights of the crown over church appointments.

The main attack of the regalists fell on the Jesuit order. In 1766 a serious riot in Madrid revealed some of the difficulties confronting the reformers. The abolition of fixed wheat prices during a bad harvest (a step that reflected the reformers' belief in the virtues of a free market) and an attempt to reform outlandish fashions in popular dress brought out the mob in Madrid. The Jesuits were alleged to have fostered the riot and were expelled from both Spain and America in 1767. The importance of this expulsion has been overestimated. Already expelled from France and Portugal, the Jesuits were bitterly criticized by rival orders and by the secular clergy: 42 of the 56 bishops approved of the expulsion. Again the expulsion was a *negative* achievement; more ambitious plans to set up a state university system and a state welfare organization failed.

The question arises of the extent to which the policies of Charles III resulted from the acceptance by his servant of the precepts of the Enlightenment. Certainly Aranda, the "Hammer of the Jesuits," and Olavide, whose flippant anti-clericalism was to be his undoing at the hands of the Inquisition, were what were called *esprits forts* (*i.e.,* French-influenced radicals); their views gave a sharp edge to traditional regalism. Jovellanos was a disciple of Adam Smith. Although his famous *Informe sobre la ley agraria* ("Report on the Agrarian Law") contains not a single original thought, the book is significant in that it attempts to apply dogmatic laissez-faire ideology to Spanish conditions. Here was one of the foundations of Spanish liberalism.

One of the aims of the Enlightenment was to produce a bourgeois society in which no traditional prejudices or traditional institutions should limit the pursuit of private profit—the foundation of national prosperity. But in Spain the social base was too narrow. In spite of economic changes over the century, the bourgeoisie was limited to the coastal towns, Barcelona and Cádiz in particular, with branches in Saragossa and the Basque country. Patriotic societies, organized with government encouragement from 1765 onward, were meant to provide the provincial basis for a progressive society and to familiarize Spaniards with European advances in technology and agriculture. They did not get much beyond the status of local reading rooms and debating societies.

Traditional Catholic society was still strong, if under attack from a minority of intellectuals and civil servants. As the reaction of the countryside after 1808 was to show, the church was still a great social power. The Duke of Wellington observed that "the real power in Spain is in the clergy. They kept the people right against France." To most of the clergy the new ideas of the Enlightenment were "foreign" and dangerous, and there could be no such thing as moderate progress encouraged by the king himself—the notion of a "revolution from above" that was to haunt subsequent Spanish history. Voltaire, Locke, and Rousseau were quite simply dangerous heretics, though the Inquisition proved powerless to prevent the clandestine circulation of their works. It was the clerical attacks on heretics as much as the subversive works themselves that familiarized a narrow stratum of society with new ideas. When the French Revolution exposed the dangers of progressive thought, the traditionalist cause was immensely strengthened and the Inquisition appeared to the crown itself to be a useful instrument to control the spread of dangerous ideas.

CHARLES IV AND THE FRENCH REVOLUTION

The influence of Godoy

In 1788 Charles III, who had been the "nerve" of reform in the sense that he loyally supported able ministers, was succeeded by his son, Charles IV, a weak, amiable man dominated by a lascivious wife, María Luisa. Spain was ruled after 1792 by her favourite, Manuel de Godoy, a handsome, plump officer from the lower nobility. It was not merely that Godoy was incompetent and self-seeking; the French Revolutionary and Napoleonic Wars put unbearable pressures on a weak power. Reform was now dangerous. Neutrality was impossible; alliance with either France or the anti-Revolutionary coalitions engineered by Britain proved equally disastrous.

Floridablanca, the prime minister, disliked both the internal effects of the Revolution (the spread of radical as opposed to government guided reform) and its external consequences (the weakening of the anti-British alliance). His hostility to France was the cause of his dismissal. Aranda, a friend of France, was discredited by the excesses of the Revolution (1792). Godoy became prime minister at age 25 because the old ministers of Charles III had failed to devise a foreign policy. In domestic affairs, Godoy supported a mild version of the enlightened reformism of his predecessors; but, like them, he failed to find a satisfactory place for Spain in the Europe of the French Revolutionary and Napoleonic Wars (1800–15).

Spain had no alternative but to declare war on France after the execution of Louis XVI (1793). The war was popular but disastrous; in 1794 the French armies invaded Spain, taking Bilbao, San Sebastián, and Figueras. Godoy feared the spread of revolutionary propaganda in the wake of the French armies in Catalonia and the north (there was a republican conspiracy in 1795). Above all, he was convinced that Britain was the true enemy of Spain. Thus the Treaty of San Ildefonso (1796) represented a deliberate choice: the French alliance, irrespective of the nature of the French regime, as the only policy for a weak imperial power.

The consequences of this choice were disastrous. War with Britain became inevitable and cut off Spain from America, opening its colonial markets to Britain and the United States; Godoy invaded Portugal with success in the War of Oranges (1801) but the defeat of the Franco-Spanish fleet by the British at Trafalgar in 1805 and the "selfishness" of Napoleon caused him to seek a rapprochement with the allies. Had Napoleon lost the Battle of Jena (1806) against the Prussians, Godoy would have joined the Fourth Coalition against him.

Godoy's position was now extremely weak. He was unpopular at home. The court aristocracy disliked him as an upstart; severe inflation produced great hardship among the poorer classes; a campaign of gossip was mounted against him by those intellectuals whom he did not patronize. He now hoped, with French help, to dismember Portugal and to secure personal salvation in a principality. This curious hope was the basis of the Treaty of Fontainebleau (1807) by which Napoleon and the Spanish government agreed upon the conquest and partition of Portugal. When French troops on the way to Portugal occupied the fortresses of northern and central Spain and when Napoleon demanded territorial gains in Spain itself, Godoy's policy was bankrupt. It was obvious that Napoleon had lost all faith in Godoy and Spain as an ally: the "dirty intrigues" of the heir to the throne, Ferdinand, prince of Asturias, against his father and Godoy led Napoleon to think of drastic intervention in Spanish affairs.

Appointment of Joseph Bonaparte

The opportunity for direct intervention by Napoleon was given by the Revolt of Aranjuez (March 17, 1808), in which the partisans of Ferdinand (an alliance of discontented aristocrats and others opposed to Godoy) impelled the abdication of Charles IV and the dismissal of the favourite. Napoleon summoned both the old king and Ferdinand VII to Bayonne, where both were impelled to abdicate. The Spanish throne was offered to Napoleon's brother Joseph.

THE FRENCH INVASION AND THE WAR OF INDEPENDENCE, 1804–14

Joseph could count on the support of cautious, legalistic administrators and soldiers, of those who believed resistance to French power impossible, and of those who considered that Napoleon might "regenerate" Spain by modern reforms. These groups became convinced *afrancesados,* as members of the pro-French party were called. Relying on their support, Napoleon entirely underestimated the possibility of popular resistance to the occupation of Spain by French armies. Although the rising of May 2 in Madrid was suppressed, local risings against the French were successful wherever French military power was weak.

The War of Independence. After the deposition of King Ferdinand, "patriot" Spain outside the control of the French armies split into a number of autonomous provinces. Resistance centred in provincial committees (juntas) that organized armies. A Central Junta at Aranjuez sought to control this nascent federalism and the local levies, and Spanish regular troops defeated a French army of inferior, ill-supplied troops under Dupont at Bailén in July 1808. The French retired from Madrid. Napoleon himself invaded Spain and by 1809 was in control of most of the peninsula. The Spanish regular army, led by incompetent generals, suffered defeat after defeat.

The War of Independence, or, as the English call it, the Peninsular War, became for Napoleon the "Spanish ulcer," and he attributed his defeat in Europe to its requirements for men and money. He was defeated not by the inefficient Spanish regular army but by British troops under Wellington advancing from Portugal with the aid of Spanish guerrillas. The guerrillas represented popular resistance as against the supposed pro-French proclivities of the "possessing classes." As the main battles—Talavera (July 1809) and Vitoria (June 1813)—were fought by Wellington, the guerrillas pinned down French garrisons, intercepted dispatches, and isolated convoys.

The Constitution of Cádiz. The significance of the war years lies in the re-creation of a patriotic spirit to cover the bare bones of Bourbon administrative centralism and in the explicit formulation of a liberal ideology that was to be a dynamic factor in Spanish history.

The Central Junta and its successor, the Regency, were compelled to summon a Cortes (Parliament) in order to legitimize the situation created by the absence of Ferdinand VII, who was in France. Conservatives conceived of its task as the mere supply of the sinews of war on behalf of an absent king. The Cortes, when it met at Cádiz in 1810, was dominated by liberals who wished to go beyond the mere support of the war effort and establish a constitution that would make impossible the revival of rule by a favourite like Godoy. The Constitution of 1812 was to become the "sacred codex" of Latin liberalism.

The Constitution of Cádiz gave Spain a strictly limited monarchy (the king must work through his responsible ministers), a single-chamber Parliament with no special representation for the church or the nobility, and a modern centralized administrative system based on provinces and municipalities. All this had little basis in the medieval precedents quoted in the debates and was inspired by the constitutions of revolutionary France. Bourgeois individualism inspired legislation against entail, favouring instead the sale of common lands and the individual's right to dispose of his property as he might wish. The abolition of the Inquisition represented a mixture of historic regalism and modern anti-clericalism. This measure produced a conservative reaction, as did all liberal anticlericalism through to the Second Republic in the 1930s. This reaction gave a popular underpinning to Ferdinand VII's destruction of liberalism and all its works in 1814 (see below).

Abolition of the Inquisition

In addition to initiating a liberal tradition, the War of Independence bequeathed two problems: first, generals chafed at control by civilian juntas and on occasion overthrew them, thus initiating the phenomenon of the pronunciamento, or military revolution; second, the *afrancesados,* often men of liberal inclinations but tarred with the accusation of collaborationism with the French, were left as an indigestible element within liberalism itself.

FERDINAND VII, 1814–33

With the help of an army corps and of conservative sentiment that had been outraged by the liberalism of 1812, Ferdinand returned from exile in France to rule Spain as an absolute monarch. In 1820 he was forced by military sedition to return to constitutionalism (1820–23). For the last "ominous" decade of his reign he returned to a relatively enlightened form of ministerial despotism. The years 1814–20 were dominated by the attempt to reestablish Spanish rule in America and by the problem of maintaining an inflated wartime army with a permanent economic deficit.

The failure of liberalism. The solution of the Cádiz liberals to the imperial problem had been to make the colonies constitutionally part of metropolitan Spain by giving them representation in the Cortes. This did not stop the revolt of the colonies, where the Creoles wanted local self-government and free trade rather than liberal centralization. In 1814 it was not clear that the rebels under Simón Bolívar in the north and San Martín in the south would succeed; but all of Ferdinand's efforts to assemble a large army and a fleet to send to America failed. In 1820 the army that was to subdue the colonies revolted against the king in a pronunciamento organized by Major Riego y Núñez and supported by the local liberals organized in Masonic lodges.

The Revolution of 1820

The Revolution of 1820 brought into power the "jail birds"—liberals of the 1812 vintage who had been persecuted by Ferdinand VII. The Constitution of 1812 was reestablished together with other liberal legislation, including the sale of monastic property.

The liberal system failed once more because it was a minority creed sustained by a section of the army—the military radicals such as Riego—against a mounting conservative reaction that had been fed once more by an attack on the church, especially the monasteries. The liberals themselves split. The more conservative wing (led by Martínez de la Rosa, a dramatist) wished for a more moderate constitution, based on the French Charter of 1814, which would give better representation to the upper classes and would not be totally unacceptable to the King, as was the "prison" of the Constitution of 1812. The King gave no support whatsoever to this movement and, in a cowardly fashion, disowned a rising of the guards' regiments that backed it. Thus the extreme radicals (*exaltados*) gained control by means of demonstrations in the streets, organized by clubs run on the lines of the Jacobins of the French Revolution.

The conservative reaction developed in the north around the regency set up at Seo de Urgel. Without French help,

the movement would not have been successful, but when Louis XVIII sent French troops (the "Hundred Thousand Sons of St. Louis"), the liberal armies disintegrated and the liberal system fell.

Once more revolution at home favoured revolution in the colonies. Mexican conservatives, who had no desire to be ruled by Spanish anti-clericals, successfully established an independent Mexico under Agustín de Iturbide (1822). Spanish military power in South America finally foundered on the decisive Battle of Ayacucho (1824). Of Spain's far-flung empire, only the islands of Cuba, Puerto Rico, and the Philippines remained.

The "ominous decade," 1823–33. The "ominous decade," as it was called by the persecuted liberals, began with a severe purge of liberals; but in its later stages the regime became increasingly unacceptable to extreme conservatives, who looked to the King's reactionary brother, Don Carlos. Ferdinand had to rely either on inefficient traditionalists who could raise no money on the European money markets or on the more liberal ministers who were able financiers. Ministers such as Luis López Ballesteros, a friend of the *afrancesados,* set the tone with a serious attempt at a government-fostered economic revival.

The Carlists

This return to 18th-century "ministerial despotism" did not satisfy the liberal exiles, who mounted ineffective invasions in 1824 and 1830. More important, the conservatives of Don Carlos' court faction accepted Ferdinand VII's rule only on condition that Don Carlos would inherit the crown. In 1829, Ferdinand married his niece María Cristina of Naples, who realized that her influence depended on the elimination of that of Don Carlos. In March 1830, her faction at court persuaded the King to exclude Don Carlos from the succession even if María Cristina produced a female heir. This attack on the rights of Don Carlos was the origin of the Carlist party and of the Carlist Wars, which were for over a half century to be a disrupting influence in Spain. After the defeat of an attempt to force María Cristina to recognize Don Carlos' rights during Ferdinand's illness (September 1832), María Cristina's faction was dominant at court. She succeeded in securing all important military commands in the hands of supporters of the claims of her daughter, Isabella. When, on September 29, 1833, Ferdinand died, Isabella was proclaimed queen, with María Cristina as regent. The First Carlist War (1833–39) broke out almost immediately.

ISABELLA II, 1833–68

The Carlist Wars. The dynastic war between Isabelline liberalism and Carlism was a savage civil war between urban liberalism and rural traditionalism, between the poorly paid and equipped regular army of the liberal governments, supporting Isabella, and the semi-guerrilla forces of the Carlists. The Carlist strength lay in the north, especially in the Basque Provinces and Navarre, where there was strong support for the *fueros* against liberal centralism and for the traditional Catholic order represented by the religious bigotry of Don Carlos and his circle. But the Carlists could not break out of their bases in the north to capture an important city. The great Carlist leader Tomás Zumalacárregui y de Imaz was killed in an attempt to capture Bilbao, and Don Carlos' expedition to Madrid failed (1837). In 1839 the Carlist commander staged a mutiny against the clerical court of Don Carlos and came to terms with Baldomero Espartero, the most successful of Isabella's generals.

María Cristina allied with liberalism out of military necessity, not from conviction. She would have preferred to grant administrative reforms rather than consent that her daughter should become a constitutional monarch. But the liberals alone could save her daughter's throne from the Carlists, and the minimum demand of all liberals was a constitution. As regent from 1833 to 1840, she therefore consistently supported conservative liberals against the radicals. The Royal Statute (1834) represented this alliance between respectable upper-middle-class liberals and the crown.

This conservative constitution, with its property franchise and the great powers it gave the crown in the choice of ministers, could not stop the drift toward the left implicit in liberalism itself. The radicals, who were the heirs of the *exaltados* of 1820–23, were installed in power first by a series of provincial town risings in 1835 and later, after a short-lived conservative reaction, by an army mutiny that forced María Cristina to accept the Constitution of 1812. The radical politicians, however, accepted a more moderate compromise constitution—that of 1837. Of more enduring importance was the sale of church lands to finance the war. The great disentailment carried out by Prime Minister Juan Alvarez Mendizábal and his successors altered profoundly the social structure of Spain by putting on the market large quantities of land, most of which was bought by large landowners or prosperous peasants.

Moderates, progressives, and the generals. The Carlist Wars left civilian politicians discredited, and generals became the arbiters of politics not, as in 1814–20, as intruders but as part of the political machinery. They became the "swords" of the two main political groups. The *moderados,* who were upper-middle-class oligarchic liberals fearful of democratic violence and upholders of the prerogatives of the crown, represented the conservative stream in liberalism. Their rivals, the *progresistas,* were the heirs of the *exaltados* and represented a lower stratum of the middle class; the *progresistas* were prepared to use the discontent of the urban masses in order to bring pressure on the crown to give them office. Their instrument was the Urban Militia. Espartero used his military faction and his supporters among the younger *progresista* politicians and their artisan followers in the great cities to oust María Cristina and establish himself as regent (1841–43). Espartero proved a disappointment to the radical *progresistas,* who now allied with his conservative opponents under his military and political rival, Ramón María Narváez. In 1843 Espartero was thrown out by a pronunciamento.

The pronunciamento of Narváez

Narváez jettisoned his *progresista* allies through a court intrigue, and between 1844 and 1854 he and his fellow generals dominated domestic politics as representatives of the *moderados.* Their administrative, educational, and financial measures and the formation of the Civil Guard were lasting achievements; but the generals could not stabilize their rule on the basis of their constitution of 1845, a conservative revision of 1837. The period was disturbed by a series of *progresista* military risings.

To the left of the *progresistas,* who were prepared to accept the monarchy if it gave them office, a Democratic Party developed; it was prepared to dethrone Isabella II, who was declared of age to rule in 1843. Never strong in numbers outside the towns, the Democrats radicalized politics. Orthodox *progresista* politicians were embarrassed by their extremist attitudes but could not neglect their potential role as urban revolutionaries.

It was not the Democrats but a group of discontented generals led by Leopoldo O'Donnell who successfully revolted in 1854. They were prepared to sacrifice the dynasty because the Queen and her mother favoured a rigid court conservatism that effectively excluded them from influence.

The rebellious military oligarchs were forced to call in civilian and radical support. This turned their pronunciamento into a mild revolution. Isabella survived only through Espartero's political timidity. Unprepared to accept the backing of the Democrats as the "George Washington of Spain," he accepted an alliance with O'Donnell, who was determined to arrest the drift to radicalism. In 1856 he broke with Espartero, defeated a demonstration in his favour, and dissolved the National Militia, the instrument of the left-wing Progressives. The radical thrust was thus defeated.

Economic expansion. The "revolutionary" period of 1854–56 saw no important constitutional change; but the further extension of disentailment and the new law for limited companies provided the legal structure for a rapid expansion of the economy. To promote this expansion, there were new injections of foreign credit—particularly French—and new banks. This capital made it possible to begin the railroad network that was to provide the transport infrastructure for a national market. The textile industry of Catalonia flourished, as a modern wool manufacture grew up; in the Basque Country, the second

pole of an industrial economy developed slowly around iron. Agriculture, still a dominant sector of the economy, expanded as the church and common lands provided new fields for the easiest of cash crops—wheat; the growth of such towns as Barcelona created a market for vegetables, wines, and fruit.

Expansion resulted in the classic expression of 19th-century liberalism—the haute bourgeoisie of finance and industry. Members of this new class ranged from solid Catalan manufacturers demanding protective tariffs to safeguard their gains, to daring speculators such as the railway financier Marqués de Salamanca, who took an active part in political life and the urbanization of Madrid. It also included successful generals ready to forget their humble origins. Together with the large landowners, these groups formed the oligarchy of liberalism.

O'Donnell's Liberal Union

The government that presided over this prosperity was O'Donnell's Liberal Union, which was an attempt to fuse all dynastic parties in a broad-based coalition. It provided a long period of stable government (1856–63), and had the Progressive politicians been less afraid of losing their left wing to the Democrats and had the Queen been willing to grant Progressives power, the dynasty might have survived. Instead, she excluded the Progressives and forced them, first to withdraw formally from political life, then to contemplate revolution. Their "sword," General Prim y Prats (a chemist's son and a striking example of the social mobility of the liberal army), was a resolute conspirator and the ablest of the political generals of the 19th century. When Isabella's court ministers alienated O'Donnell's followers, a powerful coalition was formed, and Prim dropped his alliance with the Democrats. A slump caused by bad harvests, a series of mediocre ultra-conservative governments, and a growth in democratic agitation among university intellectuals (whose main concern was the hold of the church over education) gave wide support to the military rising against Isabella. Her armies would not defend her, and she was forced to leave for France in September 1868.

THE REVOLUTION OF 1868 AND THE REPUBLIC OF 1873

The revolution that led to the dethronement of Isabella was the work of army oligarchs led by Francisco Serrano y Domínguez and Progressive conspirators behind Prim. The Democrats became active in setting up juntas after the revolution: for the most part they rapidly became Federal Republicans under the influence of the theories of the French anarchist Pierre-Joseph Proudhon as presented by their leader, Pí y Margall. The Democratic intellectuals' main contribution was to add a radical democratic content to the demands of the military oligarchy.

The generals were determined to keep the leadership of the revolution in their own hands by channelling it into a constitutional monarchy. Although they had to concede universal suffrage in the Constitution of 1869, they ruthlessly suppressed republican risings in the summer of that year. Their problem was to find a constitutional monarch.

Amadeus, duke of Aosta

Prim's attempt to persuade a Hohenzollern to accept the throne was opposed by France and set off the Franco-German War in 1870. In November 1870, Amadeus, duke of Aosta, was elected king, and Prim, the kingmaker, was assassinated the day Amadeus entered Madrid.

Amadeus attempted to rule as a constitutional monarch. Opposed both by Republicans and by Carlists, he could form no stable government from the "September coalition" of former conservative Liberal Unionists, the ex-Progressives, and the moderate Democrats—now called Radicals. Once Amadeus called the Radicals to power, the conservatives deserted the dynasty. Amadeus abdicated after an attack by the Radicals on the army in February 1873. The Cortes proclaimed Spain a republic.

The Republic of 1873 came into existence to fill the political vacuum created by Amadeus' abdication. The Republican Party was neither strong nor united. When the Republican leaders, on legal scruples, refused to declare for a *federal* republic, the provincial Federal extremists revolted.

This Cantonalist revolt was serious in Cartagena, Alcoy, and Málaga. The Republican leaders had allowed attacks on the army that had reduced it to impotence. To conservatives and men of order, the country seemed on the verge of total dissolution; the Carlists were immensely strengthened by the "excesses" of Cantonalists. Too late, Emilio Castelar y Ripoll, the last president of the republic, tried to recapture the loyalty of the army. In January 1874, Gen. Manuel Pavia y Rodríguez de Alburquerque drove the Republican deputies from the Cortes building in the hope of creating a government of order. Pavia turned power over to Gen. Francisco Serrano to form a coalition government.

General Serrano took over as president of a unitary republic. His main task was victory over the Carlists, now a strong force in northern Spain. In this he failed, and on December 29, 1874, a young brigadier, Arsenio Martínez Campos, "declared" for Alfonso XII, the son of Isabella.

There was no resistance. The extreme threat of anarchy in 1873 had resulted in a strong conservative reaction, strengthened by the religious policies pursued since 1868. The Constitution of 1869 for the first time had allowed complete freedom of religion. In spite of a total failure to create political stability, the Revolution of 1868 bequeathed to Spain the model of a modern secular state based on universal suffrage. On the extreme left these years saw the effective penetration of anarchism, especially in rural Andalusia and in industrial Catalonia, where the lower classes deserted a long tradition of political action via the Democratic and Republican parties and moderate unionism. Though anarchists were persecuted after 1873, the movement was kept alive by small groups of enthusiasts.

The Cuban revolt

The worst problem of the years 1868–75 was posed by the independence movement in Cuba, which, along with Puerto Rico, was the last possession of Spain in America. Cubans had long resented the failure to reform rule by captains general, to grant some autonomy, and to ease the economic sacrifices that were imposed by the Spanish tariff system. The revolt that began in October 1868 made great demands on Spain in men (100,000 by 1870) and money. The Ten Years' War (1868–78) made difficulties for all governments in power in Spain after 1868 and forced abandonment of the most popular of the pledges made by the rebels in 1868: the abolition of the arbitrary and socially selective recruitment system. Like the Carlist wars, the Cuban War tended to favour the monarchical reaction.

THE RESTORED MONARCHY, 1875–1923

Once the Carlists had been defeated and the Cubans had accepted the peace settlement of El Zanjón (1878), the restored monarchy provided the most stable government Spain had known since 1833. This stability was sustained by respectable economic growth.

Stability, 1875–98. The architect of the restoration itself and of the Constitution of 1876 was Cánovas del Castillo. A superb politician, Cánovas had hoped for a civilian restoration; he accepted Martínez Campos' coup but used the young Alfonso XII to keep the military out of politics.

The Canovite system

The Canovite system was artificial in that it required the contrived rotation in office (*turno pacífico*) of a Liberal and a Conservative party; this in turn demanded governmental control of elections, which were run by caciques, or local political bosses, who controlled votes in their districts. Only in this way could the government selected by the king and the politicians in Madrid obtain a parliamentary majority; extensive corruption and the use of administrative pressures on electors were considered the only ways to make the parliamentary system work in an underdeveloped society. This system survived the death of Alfonso XII (1885) and only began to falter in the 1890s, toward the end of his wife's regency. The Carlist threat weakened with defeat, and the majority of Republicans in Spain were domesticated and reconciled to the use of "legal" means.

"Without being a rich country," wrote an economist in the early 1880s, "Spain has become comfortably off." This prosperity, which was untroubled by the claims of organized labour, was the result of the demand for iron

ore after the invention of the Bessemer process (England and France invested heavily in mineral production), of the demand for Spanish wine after the devastations by phylloxera in France, and of the resumption of railway construction in Spain. The third largest wool industry in Europe grew up side by side with the older cotton mills in Catalonia. The boom did not break until the late 1880s, when an agricultural depression set in. A wave of economic pessimism preceded the political and intellectual reaction of 1898.

The loss of Cuba, Puerto Rico, and the Philippines in 1898 exposed the Spanish political system to severe criticism. No fiscal and political reform sufficient to satisfy Cuban demands could be effected within the framework of the monarchy, partly because of the pressure of the Spanish loyalist party in Cuba. A revolt in 1895 set off another costly war against Cuban guerrillas. The intervention of the United States could not be staved off by a last-minute grant of autonomy. Their humiliating and total naval defeat in 1898 became known to Spaniards as "the Disaster." Spain now lost the Philippines and the last of its possessions in the Americas at the very time when the great European powers were building their overseas empires.

War with the United States

Opposition movements, 1898–1923. Criticism of the restoration monarchy came from the Catalan and Basque regionalists, from a revived Republican Party, from the proletarian parties, from the army, from the more forward-looking of the Spanish politicians, and from the intellectuals.

Basque regionalism, though more akin in its ideas to extreme nationalist movements, was less a challenge than Catalan regionalism, which dominated Spanish politics until 1923. With its own Catalan language and a revived cultural tradition, it moved from a demand for protection of Catalan industry against "Castilian" free trade to a demand for political autonomy. The *Lliga Regionalista* (founded 1901), dominated by the Catalan industrialist Francesc Cambó i Batlle and the theoretician of Catalan nationalism, Prat de la Riba, demanded the end of the *turno* and a revival of regionalism within a genuine party system. Cambó wished to solve the Catalan question "within Spain"—*i.e.,* by legal means and in cooperation with monarchical politicians. The revival of Catalanism, however, set off a "Castilian" reaction in which moderate Catalans were accused of selfishness or of hiding separatist aims under "respectable" regionalism. In the 1907 election the united Catalan front, Solidaridad Catalana, defeated the parties of the system but then divided into a right (which accepted a solution within the monarchy) and a left (which was to drift to Republicanism). Cambó's cooperation with Madrid brought Catalonia no tangible concessions.

Republicanism, which had degenerated into local politicking and lived on its memories of 1873, was revived by the remarkable oratorical and organizational talents of Alejandro Lerroux, whose Radical Republican Party offered a program that appealed to the alienated working-class voter of Barcelona.

He was competing with a slow revival of anarchism, which veered between terrorism, educational propaganda, and union activity; the anarcho-syndicalist union, the Confederación Nacional del Trabajo (CNT), was founded in 1910. The Socialist movement with its union (the Unión General de Trabajadores, or UGT, founded 1888) was relatively weak except in the mining districts of the north and in Madrid, where it was dominated by its French-influenced founder, Pablo Iglesias. In 1909 the Socialists abandoned their boycott of "bourgeois" politics and allied themselves with the Republicans. This alliance was to give the party a political leverage in excess of its voting strength.

The Generation of '98

The intellectuals' protest embraced the writers of widely differing ideas collectively known as the Generation of '98. Joaquín Costa, a voluminous writer, was an especially harsh critic of *caciquismo;* he wanted a revived, effectively democratic, modernized Spain. His attempt to create a coalition of the "productive classes" against the political drones in the Unión Nacional failed. Miguel de Unamuno saw regeneration in terms of a return to "pure" Spanish values. All of the Generation of '98 distrusted politics as managed by professional politicians who, they said, were out of touch with the "real" Spain.

Among the politicians themselves, the conservative leaders Francisco Silvela and Antonio Maura and the democratic liberal José Canalejas sought to regenerate the system by widening the degree of political participation through "sincere" elections. They were opposed by the professional party members. Maura only succeeded in confusing the party structure by splitting the Conservative Party. The danger of "sincere" elections to the political establishment was revealed by the Republican victories in 1903.

Revolt in Morocco

The call up of troops for Morocco, where Spanish troops were engaged in operations protecting the Spanish coastal possessions, set off the Tragic Week of 1909 in Barcelona. Public order collapsed, and anarchists and Radical Republicans burned churches and convents. Maura was driven from office because Alfonso XIII (who ruled in his own right from 1902) accepted the Liberals' estimate of the harm Maura's firm repression would inflict on the monarchy. Rather than resist a Liberal Party that had allied with the Republican parties, the King held that the Liberals were a useful "lightning conductor," protecting the monarchy from the threat on the left. Ever since Maura's fall, the King's diagnosis had been challenged by conservatives.

World War I produced increased strains. Real wages fell, making the unions restive, and in 1917, junior officers formed juntas and struck for better conditions. The ensuing crisis was exploited by Catalan politicians, increasingly pressing for autonomy. The revolutionary coalition split up, and a general strike frightened Cambó and the Catalans, who threatened to call a national convention that would unite all critics of the monarchy. The formation of a national government under Maura ended the last serious attempt to regenerate the political system and to make it respond to reformist and Catalan demands. No subsequent government was strong enough to face the anarchist agitation in Catalonia and the Moroccan War.

Spain had been granted a protectorate in Morocco in 1912. In the effort to pacify it, economizing politicians were ready for compromise with the tribes, but the generals saw conquest as the only solution. A bid by Gen. Fernández Silvestre, reputedly backed by Alfonso XIII, for a crowning victory ended in the terrible massacre of Spanish troops at Annual in 1921. Opposition politicians were determined to expose the King's action and criticize the army.

Anarchist influences

World War I had given the anarcho-syndicalist movement great power. At the same time there grew a terrorist fringe, which the leaders of the CNT could not control. These leaders (Salvador Sequí and Angel Pestaña), though they shared the anarchist contempt for political action, wished to build unions powerful enough to challenge the employers by direct action. They mistrusted the libertarian tradition of spontaneous revolution as a means of toppling the bourgeois state. The great Barcelona strike of 1919 was the most impressive in Spanish history. When the employers' violent reaction discredited the moderates in the Confederación Nacional del Trabajo, it was followed by a wave of assassinations by gangsters employed by both the anarchists and the employers.

Thus, when Gen. Primo de Rivera staged his pronunciamento in September 1923, he could count on the support of the conservative classes fearful for social order. The Lliga, for instance, became more concerned about suppressing strikes than about Catalan autonomy, for which it had campaigned from 1915 to 1918. He could also count on the tacit alliance of Alfonso XIII, who was tired of politicians who could not provide him with effective governments.

PRIMO DE RIVERA (1923–30) AND THE SECOND REPUBLIC (1931–36)

Primo de Rivera. Primo de Rivera was a political improviser who believed his mission was to save Spain from the old politicians and to hand over government (after an interval of personal rule) to "clean" patriots. He failed to complete the process because his rule became increasingly

unpopular, especially among the intellectuals and Catalans. The September 1923 coup by which he had gained power had been widely welcomed in Catalonia, where, as captain general, Primo had listened sympathetically to Catalan demands. Soon afterward, however, Primo became a Spanish patriot and permitted an "anti-Catalan crusade." His followers' attempts to build up a political party (the Patriotic Union) to run a regenerated Spain and to provide it with an ideology collapsed.

At first he ruled via the army. In spite of initial quarrels with the African commanders, whom he forced to retreat in Morocco, the Military Directory was responsible for final victory in the protectorate. The Spanish, collaborating for the first time with the French, landed at Alhucemas (al-Hoceima) in September 1925 and defeated the most successful tribal leader, Abd el-Krim. By 1927 the whole of the protectorate was successfully occupied.

The Civil Directory (1925–30) was responsible for a thorough overhaul of local government and for an ambitious public works program to increase irrigation, hydraulic power, and road building. Primo's economic nationalism entailed strict protectionist policies and an attack on foreign oil monopolies. The complicated bureaucratic control of industry did not endear him to capitalists after 1926; on the other hand he collaborated successfully with the UGT while suppressing the CNT. The Civil Directory failed in its main task: to win sufficient political support in the National Assembly summoned for 1928 to facilitate a return to quasi-constitutional government.

Throughout his early years Primo was favoured by an economic expansion based on favourable terms of trade for Spanish exports. By 1929 the peseta began to fall in value in spite of desperate measures to save it. Economic recession alone would not have ruined the dictator, but he lost the support of both the army and the King. The army turned against him as a result of his attempts to abolish the privileges of the artillery and engineer corps. The King believed that student protests, the growing discontent in Catalonia, and the increasing conspiracies of the "old" politicians imperilled the dynasty. On January 28, 1930, he forced Primo's resignation.

Alfonso acted too late. His earlier support of the dictatorship ruined him in the eyes of the politicians and public. The weak governments of Gen. Dámaso Berenguer and Adm. Juan Bautista Aznar could barely keep order. At San Sebastián (August 17, 1930) an alliance of former liberal monarchists, Catalan politicians, and Republicans agreed to overthrow the monarchy. The failure of a Republican military rising at Jaca (December 12, 1930) saved them from establishing a republic by force. The municipal elections of April 12, 1931, proved that the great cities were overwhelmingly Republican. Rather than face civil war and street demonstrations in Madrid, Alfonso XIII left Spain.

Abdication of Alfonso XIII

The Second Republic. The history of the Second Republic falls into four distinct phases: (1) the Provisional Government, which lasted until the religious issue forced its resignation in October 1931; (2) the governments of the Left Republicans and Socialists, which ruled from October 1931 and were defeated in the elections of November 1933; (3) the conservative government of the Radical Republicans and the Catholic right from November 1933 to February 1936, punctuated by the revolution of October 1934, and that ended with the electoral victory of the Popular Front in February 1936; and (4) the government of the Popular Front and "the descent into violence" that culminated in the military rising of July 1936.

The Provisional Government was a coalition government, presided over by Alcalá Zamora, whose Catholicism reassured moderate opinion. The coalition included all the groups represented at San Sebastian: Lerroux's Radicals, the Catalan left, the Socialists, and the Left Republicans dominated by Manuel Azaña y Diaz.

The elections to the Constituent Cortes strengthened the Socialists and Left Republicans and thus upset the parliamentary balance between moderate Catholic Republicans and the left. It was the left that imprinted its views on the constitution, especially its religious clauses. The historically conditioned anti-clericalism had led the government to tolerate an outburst of church burning (May 1931). The Socialists and Left Republicans inserted in the constitution an attack on religious education and the regular orders, which forced the resignation of Alcalá Zamora and Miguel Maura, his minister of the interior.

This direct and, it would seem, ill-advised clash with Catholic sentiment was to provide a base for the construction of a party of the right devoted to the reversal of the church settlement. This party, the creation of the Catholic politician José María Gil Robles, became Acción Popular; it was to become the main component of the right-wing electoral grouping, the Confederación Española de Derechas Autónomas (CEDA). To the left its "accidentalism" (the doctrine that forms of government were irrelevant provided the church could fulfill its mission) was suspect.

The Acción Popular

From October 1931 the government, with Azaña as premier, was in the hands of Left Republicans and Socialists, with the Catholic right, the Basque Catholics, the Navarrese Carlists, and Lerroux's Radicals in opposition. Azaña aimed to create a modern democracy; labour legislation would be the work of the Socialists, with the UGT leader, Largo Caballero, as minister of labour.

In April 1931 there was a danger that Catalonia might declare its independence within a federal state. Azaña's greatest achievement was the settlement of the Catalan question. He overcame conservative Republican opposition to limited home rule under the Generalidad, which was controlled by the Catalan left (Esquerra) under Luis Companys. Largo Caballero's legislation provided labour with a strong negotiating position but could not, in itself, mitigate the mounting unemployment, which was particularly serious in the *latifundios* of the southwest. Since new machinery for the settlement of labour disputes was dominated by the UGT, it was opposed by the CNT, now influenced by the extreme revolutionary apoliticism of an anarchist group, the Federación Anarquista Ibérica (FAI). Violent strikes were frequent.

Sedition from the right came to a head in General Sanjurjo's pronunciamento in Seville (August 10, 1932). Politically more dangerous than Sanjurjo's abortive coup, however, were the steady growth of Gil Robles' Acción Popular and the Socialists' desertion of the Azaña coalition, as Largo Caballero wearied of cooperation with "bourgeois" parties. In the elections of November 1933, therefore, the left was divided and the right relatively united in the electoral union of the CEDA. Given an electoral law that favoured electoral coalitions, the CEDA and Lerroux's Radicals, now a respectable middle class party, triumphed. The newly elected Cortes was dominated by Lerroux's Radicals and the CEDA. Lerroux could not govern without the support of Gil Robles. With power within sight, Gil Robles accentuated his legalism, to the distaste of the militant monarchists among his supporters. Nevertheless, his party was regarded by the Left Republicans and Socialists as a Catholic brand of the Fascist trends now winning out in western Europe.

Conservative reaction

When CEDA entered Lerroux's government the Socialists staged a revolution. Revolutionary councils were set up in the mining districts of Asturias, where there was considerable destruction of property. In Barcelona the revolution was the work of Catalan nationalists, who believed autonomy was imperilled by the actions of the Madrid government in overruling an agrarian law passed by the Generalidad. Unsupported by the CNT, it was quickly suppressed.

The October Revolution of 1934 is the dividing point in the Second Republic. The Socialists, fearing the fate of their Austrian and German brothers, had revolted against a legal government and thereby established in the minds of the right the fear of "Red" rebellion. In the subsequent repression by the army lay the emotional origins of the Popular Front against "Fascism"—a re-creation of the Azaña coalition of Left Republicans and Socialists in order to fight the elections of February 1936.

The Popular Front won the election of February 1936 by a narrow majority. Spain had become polarized, and the division was to intensify.

The Popular Front

The Popular Front government was exclusively Repub-

lican. Under Largo Caballero, the left Socialists put increasing pressure on the government, using revolutionary language if not intending revolution. Largo Caballero's revolutionary rhetoric concealed his hope that the orthodox Republicans could be eased from power, leaving the field open to a pure Socialist government, which his followers chose to call, in Leninist language, the "dictatorship of the proletariat."

Just as the fears of the "Fascism" of the right justified the defensive reaction of the Socialists, so the right argued that the Republican government was a prisoner of the revolutionary left (they could point to a rapid growth of Communist influence). The Falange, founded by José Antonio Primo de Rivera, the son of the dictator, was a nationalist anti-Marxist grouping appealing to youth ready to engage in street affrays with the Socialist Youth. Conservatives rallied behind the right-wing National Front, which openly appealed to the military to save Spain from Marxism.

The army was the key factor; by the early summer a young officers' conspiracy was backed by Mola, Manuel Goded, and, finally, Francisco Franco. The murder of Calvo Sotelo with the connivance of government security forces was the final outrage for the right and the army.

THE CIVIL WAR

The rising of the military started in Morocco on July 17, 1936, and spread to the garrisons of metropolitan Spain in the following days. The Civil War took place because the rising was successful only in Old Castile, in Navarre, where Carlist support was decisive, and, of the larger towns, in Saragossa, Seville, Córdoba, Valladolid, and Cádiz. Galicia soon went over to the Nationalists, as did most of Andalusia. Catalonia and the Basque Provinces were loyal to the government because the Republic guaranteed their autonomy. In Madrid and Barcelona, the security forces, helped by the workers who were armed belatedly by the government, defeated the officers. Thus, in broadest terms, the Republic held the centre, the Levant, Catalonia, and the Basque industrial zones; the Nationalists held the food-producing areas. One consequence was to be an increasingly acute food shortage in the Republican zone.

The role of the workers in defeating the rising made their organizations the power in the Republican zone. The legal government was by-passed or totally supplanted by local committees and trade unions; the workers' militia replaced the dissolved army. In many parts of Spain a social revolution took place in July 1936: factories and farms were collectivized. The English novelist George Orwell described Barcelona, where the CNT was all-powerful, as "a town where the working class was in the saddle." The success of working class control, in terms of increased production, is difficult to estimate.

Orwell on Barcelona

This revolution was distasteful to the Left Republicans and to the Communist Party, which rapidly grew in number and in political influence because it controlled the supply of arms from the Soviet Union. In the name of an efficient war effort and the preservation of "bourgeois" elements in the Popular Front, the Communists pressed for a popular army and central government control. In September–November 1936, the CNT was brought into the government of Catalonia and into Largo Caballero's ministry in Madrid—an astonishing step for a movement that had consistently rejected "bourgeois" politics. The CNT militants did not approve the leaders' "surrender" and the dismantling of the militia-backed revolution.

A small Marxist revolutionary party, the Partido Obrero de Unificación Marxista (POUM), which rejected the Popular Front in favour of a workers' government, set off a rebellion in Barcelona in May 1937. The Communists, Republicans, and anti-Caballero Socialists used this as an excuse to oust Largo Caballero, who proved insufficiently pliable to Communist demands. The government led by the Socialist doctor Juan Negrín was a Republican–Socialist–Communist concern. The great unions, the UGT and CNT, were replaced by the political parties.

The Communists were correct in arguing that the committee–militia system was militarily ineffective. General Franco's army, ferried over from Morocco, cut through the militia and arrived before Madrid by November 1936. The successful resistance of the city, which was stiffened by the arrival of the International Brigades and Soviet arms, meant that the Civil War would be prolonged for two years.

Victory would go to the side with the best army, with unified political control, and with adequate arms supply. The core of the Nationalist army was the African army commanded by General Franco. Given the confused political control in Republican Spain, the secure military and political command of Franco (from October 1936) was decisive. In April 1937 he incorporated the Falange into a unified movement under his leadership.

Both sides sought help from abroad. The republic consistently hoped that France and Great Britain would allow them to acquire arms. Partly because of fear of a general war, partly because of domestic pressures, both powers backed non-intervention (*i.e.*, self-imposed restriction of arms supply by all powers). General Franco appealed immediately to Hitler in Germany and to Mussolini in Italy, which supplied aircraft early in the war. The Germans, in return for mineral concessions, supplied the Condor Legion (100 combat planes), and the Italians sent ground troops; both supplied tanks and artillery.

The Western democracies protested but did nothing. The Soviet Union alone responded to the breakdown of non-intervention by supplying arms to the Republican side. Soviet supplies were of great importance (tanks, aircraft, and a military mission) after October 1936. The Communist International also organized the International Brigades. In 1938, Soviet supplies dropped off, and the balance of arms supply was decisively in favour of the Nationalists. Once the Popular Army replaced the militia, the republic held Madrid and defeated two flanking attacks in the battles of Jarama (February 1937) and Guadalajara (March 1937), where the International Brigades decisively defeated a motorized Italian corps.

After his failure at Madrid, General Franco transferred his effort to the north, where the bombing of Guernica, on April 26, 1937, by German planes outraged public opinion in the democracies: by October 1937, General Franco had captured the industrial zone, shortened his front, and won a decisive advantage.

When General Franco concentrated again on Madrid the Republican army staged its most effective offensive in the winter Battle of Teruel (launched December 15, 1937). General Franco recovered Teruel, drove to the sea, and committed his one strategic error in deciding on the difficult attack on Valencia. To relieve Valencia the Republicans attacked across the Ebro (July 24, 1938); once more they failed to exploit the breakthrough, and the bloody battle exhausted the Popular Army.

The final Nationalist campaign in Catalonia was relatively easy. On the Republican side, the feasibility of continued resistance, which was supported by the Communists and Negrín, caused acute political divisions. On March 7, 1939, a civil war broke out in Madrid between Communists and anti-Communists. On March 28 the Nationalist forces entered a starving capital.

FRANCO'S SPAIN, 1939–75

The first decade of General Franco's government was harsh. As a result of the Civil War roughly 1,000,000 Spaniards were dead or had emigrated. Fierce political repression was matched by economic hardship. General Franco's alliance with the Axis powers brought diplomatic isolation from the Western democracies. After 1950, growing foreign investment and change in economic policy brought an increase in material prosperity and a diminution of opposition activities.

Recovery after 1939 was made difficult by the destruction caused by the Civil War (especially of railway rolling stock), by a severe loss of skilled labour, by a series of bad droughts (especially 1949), by restrictions on the import of capital goods imposed by the European war, and by misguided attempts at state-controlled industrial development within a protected economy. The national income dropped back to the levels of 1900, and real wages fell. These were the years of near famine, of the black market, and of rural misery and flight to the towns.

Franco's relations with the democracies

General Franco's sympathies lay openly with Germany and Italy, to whom he gave moral and material support. He nevertheless demanded a high price for his military cooperation against the Western Allies, on whom he was dependent for food and oil imports. When it appeared likely that the Allies would win the war, in 1943, General Franco reaffirmed Spain's nominal neutrality, without gaining their benevolence.

The declared hostility of the dominant great powers after 1945 and the exclusion of Spain from the United Nations gave the opposition in Spain new life. Don Juan, the heir of Alfonso XIII, presented himself as a democratic alternative. Valiant but futile guerrilla activities, inspired largely by the Communist Party (1944–48), were easily suppressed.

General Franco met these difficulties, the most severe of his regime, with confidence. The Fuero de los Españoles (July 1945), guaranteeing personal freedoms (provided no attack was made on the government), was an attempt to establish a more democratic image. More significant was his alliance with the church, which was given control of education, and his reduction of the power of the Falange (which had supplied a national Fascist ideology). The ostracism of Spain by the United Nations was skillfully turned into a means of rallying support for General Franco in the name of national unity.

General Franco's confidence came from his divination that, with the Cold War between the Western democracies and the Communist states, the United States could not sustain its hostility to Spain and that the Allies, while declaring for the democratic opposition, would not directly intervene to overthrow his regime. Hence the hopes of the opposition came to nothing. In 1953 an agreement with the United States gave General Franco considerable financial advantages in return for the establishment of four United States bases in Spain.

United States air and naval bases

Thus by 1953, Spain appeared to be a stable state. Internal political control remained in General Franco's hands, ensured by his mastery of the army and his ability to play off the groups that supported him against each other. In these ministerial changes the Falange steadily lost power to the technocrats of the Opus Dei (a lay Catholic organization), which broke with the economic nationalism of the Falange in favour of a "normal" capitalist system, with market mechanisms replacing state control.

The new policies seemed justified by their success, which was aided by a rapid growth of tourism and foreign investment. As in many countries that have seen an economic miracle, spectacular expansion (a growth rate of 7.4 percent between 1962 and 1966) brought problems of inflation and a wages–cost spiral. Investment went mainly into industry and some spectacular irrigation projects; the Spanish countryside remained poor and its productivity low. The rural poor of the south emigrated to the factories of Europe or to the cities of Spain.

While the new prosperity brought a degree of social mobility that was novel to Spanish society and satisfied the middle classes, rising prices entailed a revival of labour troubles. The workers became disillusioned with the "official" syndicates run by the Falange. They set up workers' commissions outside the official framework, and there were serious strikes, in spite of legislation that forbade them. Sections of the church were sensitive to these discontents. While the episcopate, on the whole, held to the view that the church should support the state, younger priests saw the long-term dangers of such an alliance. Thus they were sympathetic to the workers' commissions. An even more intractable problem was that of Basque nationalism, and, again, some of the Basque lower clergy were sympathetic to the nationalists. The nationalist movement developed a terrorist wing.

During the final decade of Franco's life, and against a background of increasing economic and political ferment, the Caudillo moved in slow, determined steps to prepare Spain for the transfer of power. On November 22, 1966, he presented the Cortes with a new Organic Law of the State that provided for the office of premier (*presidente del gobierno*) and direct election of one-sixth of the Cortes' membership. Supplementary laws passed in June 1967 gave the Falange the powers of a legislative upper chamber. Adm. Luis Carrero Blanco was named vice premier, Franco himself serving as premier as well as chief of state (*jefe del estado*). Instead of Don Juan, his son, Juan Carlos de Borbón y Borbón, was named by Franco and approved by the Cortes (July 22, 1969) as prince of Spain and Franco's successor. Exactly two years later it was announced that Juan Carlos would assume the powers of head of state should Franco fall ill or be absent from Spain. On July 18, 1972, a law was passed naming Carrero Blanco interim premier upon Franco's death or retirement; he was made premier on June 9, 1973, Franco remaining as chief of state. Carrero Blanco was assassinated on December 20, 1973, by Basque nationalists and was succeeded nine days later by Carlos Arias Navarro, a former minister of the interior.

In a speech in February 1974 the new premier promised liberalization of the political system. Strict measures to maintain law and order were taken, however, including the first execution (March 2) of a political extremist since 1963. Franco's health began to fail, and Juan Carlos assumed the powers of chief of state from July to September. On December 20 a decree granted the right within certain limits to form political associations (except a Communist party).

The year 1975 was a momentous one for Spain. Increased terrorist activity by the Basque extremist organization led to a state of emergency in the provinces of Guipúzcoa and Vizcaya in April, anti-terrorist legislation in August, and the execution, despite worldwide protest, of five terrorists on September 27. On October 30 Juan Carlos became interim chief of state. Franco died on November 20, and Juan Carlos became king of Spain two days later.

SPAIN SINCE 1975

The accession opened a new political era leading to constitutional reform and the full transition to democracy. In April 1976 plans for reforming the constitution were announced. In July, Arias Navarro was replaced as premier by Adolfo Suárez González, who appointed a new, democratic-minded Cabinet. Following a program of transition to democracy, the Cortes on November 18 approved the Political Reform Law, setting elections for a bicameral legislature for June 15, 1977. In preparation, an electoral law of universal suffrage was passed (March 15, 1977), the National Movement (Falange) was disbanded (April 1), and the Communist Party was legalized (April 9).

During the elections several major and regional parties emerged, and a minority government was formed by an alliance of smaller, centrist groups; called the Unión Centro Democrático (UCD; Union of the Democratic Centre), it was led by Suárez. The new Cortes was opened by Juan Carlos on July 22, 1977, and it embarked upon a program of reform.

A new constitution was approved by the Cortes in November 1978 and by the electorate in December. Taking effect on December 29, it proclaimed Spain a parliamentary monarchy, took away the official status of the Roman Catholic Church, and guaranteed free enterprise and human and civil rights. Suárez resigned as premier and leader of the UCD in January 1981. On February 23, after the Cortes failed to confirm his successor, Leopoldo Calvo Sotelo y Bustelo, members of the Civil Guard staged a military coup that was ended only by the direct intervention of Juan Carlos. Sotelo was then confirmed and took office. (R.Ca./Ed.)

In October 1982 the Spanish parliamentary elections marked a monumental break with the Franco legacy, as a socialist majority was elected in the Cortes Generales. The PSOE received 46 percent of the popular vote and won a solid majority in the Cortes. The UCD, victors of the 1977 and 1979 elections, along with Prime Minister Leopoldo Calvo and his Cabinet were swept out of office. The primary beneficiaries of the election, besides the PSOE and its leader, Felipe González, were King Juan Carlos and the Popular Alliance, led by Manuel Fraga Iribarne. (Ed.)

Separatism

One of the most pressing problems continuing to face the government was that of the separatist movements. Limited autonomy was granted to Catalonia and to the Basque

provinces in 1977; to the Balearic Islands, Castile–León (except for Madrid), and Estremadura in 1978; and to Andalusia and Galicia in 1980. By the early 1980s Catalonia, Galicia, and the Basque regions had elected regional parliaments. Tension, nonetheless, remained in the Basque region. The Basque terrorist organization, ETA, continued its policy of violence despite the central government's 10-point plan of 1983 to arrive at a peaceful settlement of the Basque problem and despite increased antiterrorist measures. The government did, however, achieve a breakthrough in 1984 in its efforts to control terrorism when France reversed its long-standing policy of granting asylum to ETA members.

Spain continued to follow a foreign policy that had been growing slowly more liberal during Franco's final years. The country had already divested itself of most of its colonial holdings, granting independence to Equatorial Guinea in 1968 and ceding Ifni to Morocco in 1969. In 1976 it ceded the Spanish Sahara to Morocco and Mauritania. Spain had begun commercial relations with the Communist countries by an agreement with Romania in 1967. Diplomatic activity had been extended to Latin America in 1971; a trade agreement was made with the Soviet Union in 1972; and formal diplomatic relations were established with East Germany and China in 1973. On January 1, 1986, after long negotiations, Spain gained admittance to the European Economic Community.

Andalusia

Andalusia (Spanish Andalucía) is a region with an area of 33,964 square miles (87,966 square kilometres), including most of Spain south of the Sierra Morena, corresponding roughly to the Roman province of Baetica and divided after 1833 into the eight provinces of Almería, Cádiz, Córdoba, Huelva, Jaén, Málaga, Sevilla, and Granada. The origins of the name are uncertain; scholars have connected it with the occupation of the country by the Vandals in the 5th century AD. The Arab form al-Andalus designated at various periods the whole peninsula, the area under Muslim rule, and the kingdoms of Seville, Córdoba, Jaén, and Granada. In 1981 the historic region of Andalusia became one of the 17 autonomous communities of Spain, including the present provinces of Almería, Málaga, Granada, Jaén, Córdoba, Sevilla, Huelva, and Cádiz.

PHYSICAL AND HUMAN GEOGRAPHY

Andalusia consists mostly of high, heavily eroded mountain chains and their foothills, broken in the west by the Guadalquivir depression and in the east by the Almería and Almanzora rivers. Settlement has been heaviest in the valleys and coastal plains and in the folds of the south-facing mountain spurs. The climate and fauna and flora, often varying considerably within a few miles from subtropical coastal type to alpine, correspond to those of certain parts of the North African littoral. Other shared features are flat-roofed houses, cave-dwelling communities, and the intensive cropping of irrigated hill terraces with the consequent proliferation of *minifundia* (small holdings), though stock-rearing *latifundia* are the rule in the plains. (K.Ga./Ed.)

Andalusia is one of the most distinctive major regions of the peninsula. Framed by the southern border of the Sierra Morena, the Campo do Montiel, the Murcian Steppes, and elsewhere by the sea, it is divided into two distinct sectors: the Guadalquivir Valley of Lower Andalusia, and the sub-Baetic and the Sistema Penibético of Upper Andalusia. Perhaps no other region of western Europe has had a richer cultural heritage, dating from the mineral exploitation and town life of the Tartessians and Romans. Of the major towns, almost all were Roman in origin and later intensely Arabicized. Compared with the rural peasantry of Castile, hard-working and resourceful, the Andalusian labourer is traditionally urban-minded and pleasure-loving. The economic strength of Andalusia has always been the balanced interests of mountain and plain, with complementary economies; thus the provinces of Sevilla and Granada tend to represent distinct interests.

The Andalusian Plain

Of the two, the Andalusian Plain is the more important, with a high population density around the city of Seville. Settlement is markedly nucleated, with the vast majority of the population living in large villages and towns. Significantly, the Guadalquivir Valley is the only extensive lowland in the peninsula that penetrates deeply into the interior from the coast. Its apex strikes 200 miles (320 kilometres) toward the northeast from the Gulf of Cádiz. From a width of about 100 miles (160 kilometres) at its mouth, it narrows to 60 miles (100 kilometres) at Seville and six miles (10 kilometres) at Ubeda, but to the south it is flanked by two other narrow depressions followed by the valleys of the Genil and Guadiana Menor. A marine trough until the late Quaternary, the Guadalquivir Valley contains fine sediments that have been carved into smoothly undulating relief, making it famed for its black soils. These are intensively cropped, with olives on the hill slopes. The marshes of Las Marismas and sand dunes of the Arenas Gordas are the only lands not utilized for agriculture. In Huelva, where cork forests and stock rearing are important, is a major afforestation scheme with eucalyptus forest, planted since 1940. Olive groves are very important in the other provinces; they cover a large proportion of the cultivated area of Jaén, Córdoba, and Sevilla; many have been planted since the 19th century. Vineyards are significant in the Condado of Huelva and Montilla in Córdoba. In the Campiña, most of the nation's cotton is grown. The chief towns are Seville and Huelva (both ports), Córdoba, and Jaén.

Upper Andalusia, though slightly smaller than the plain, is the dominant physical influence, bringing heavy rainfall on its southwestern flanks, and the source of the major tributaries of the Guadalquivir. Although the mountain ranges extend structurally for 500 miles (800 kilometres) from east-northeast to west-southwest and are 125 miles (200 kilometres) at their maximum width, they are much less compact than the Pyrenees. At their extremities they appear more like isolated mountain ranges emerging from a tangled relief of hills, plateaus, and plains. Termed the Sistema Penibético, the ranges can be divided into three zones: the sub-Baetic Mountains, which rise above the Andalusian Plain to 3,000–6,500 feet (910–2,000 metres) in three series of ranges; the central valleys and depressions traceable for about 110 miles (180 kilometres) between Antequera, Granada, and Baza; and the principal chain of Sierra Nevada. Rivers have trenched, deep valleys to the coast, and deforestation of the steep slopes has created new deltas.

In Cádiz as in the Andalusian Plain, *latifundia* (large landed estates) are an agrarian problem, with most of the province comprising estates of more than 620 acres (250 hectares) yet representing only a very small proportion of the total holdings. Family interests may form several great estates, the largest of which are under tree crops, especially olive groves. Specialized cultures such as the vineyards of Jerez de la Frontera and Málaga are in smaller holdings. Vegetables and cereals are irrigated in the intermontane basins of the Genil Valley, Arroyo de la Vega of Granada, Río de Guadix, and others. On the coast at Motril, Málaga, Torrox, Torre del Mar, and Adra sugarcane and bananas are grown. Tourism on the Costa del Sol is an important economic activity. Málaga, Granada, and Cádiz are the chief cities. (J.Ho.)

HISTORY

Andalusia's history was closely linked with that of the North African coast until the last decade of the 15th century, when the process of integration was partially suspended by the fall of Granada in 1492 to the monarchs of Castile and Aragon, who forbade their former Muslim subjects to communicate with Africa under pain of death, even after their conversion to Christianity. Both areas had been occupied successively by Punic, Roman, and Visigothic settlers; after the invasion of southern Spain from Tangier by Ṭāriq ibn Ziyād in 711, the Strait of Gibraltar virtually ceased to exist as a human frontier for the next eight centuries, even though political strife between

Spanish and African Muslim dynasties was often intense. In the 10th century the Caliphate of Córdoba drew its military strength largely from Berber mercenaries, just as Algiers in the 17th was garrisoned largely by deported Spanish Moriscos. Most of the distinguished figures of the Muslim period divided their lives between the two continents; for example, Averroës, the greatest of Spanish Muslim philosophers, who was born at Córdoba in 1126, was *qāḍī* of Seville and later of his native city, and, except for a few years of banishment, served after 1182 until his death as court physician in Marrakesh, where he did most of his writing.

Whereas the Andalusian contribution to North Africa in the medieval period was mainly cultural and artistic, the African Muslims repaid their coreligionists in Spain by reinvigorating their fighting power and religious zeal at times when discord and tolerance were weakening their resistance to the Christians. The invasions of Spain by the Almoravids in the 11th century and by the Almohads in the 12th prolonged the life of the petty but highly cultured Muslim principalities that arose from the ruins of the caliphate. These invasions also played a part as important as, though less direct than, that of the rivalry between the Christian monarchs in the birth of the Naṣrid sultanate of Granada in 1232. The defeat of the Marinids, one of the three great Berber groups, at the Salado (1340) and Palmones (1343) rivers, by Alfonso XI of Castile and Leon put an end to effective North African intervention in the peninsula; but the tide of the Christian reconquest of Spain was stemmed for a time by civil war in Castile, strife between crown and feudal nobility, and mutual distrust among the Christian princes.

Invasions by Almoravids and Almohads

For more than a century the Muslims who had thronged to Granada for asylum were saved by the slowing of the Christian advance. While their frontiers were the scene of a fluctuating guerrilla warfare which inspired the most colourful and moving of the Spanish ballads, their cities saw the revival of a score of fine crafts; Almería and Málaga traded with Italy and North Africa; the *vegas* and terraced slopes were cultivated to yield a wealth of fruits; the mulberry-planted mountainsides produced the finest silks in Europe; and even the poorest hillsides bore fast-growing crops of panic grass and millets. Above the thickly populated city of Granada itself, on an outlying spur of the Sierra Nevada, rose the fortress and palace of the Alhambra, flanked by the Generalife and other pleasure palaces, which fell into ruins soon after the reconquest.

Muslim institutions. The government of Muslim Spain, whether under the caliphs of Córdoba, the *ṭā'ifa* kings, or the sultans of Granada, was not radically different from that of the eastern caliphate. The office of ruler was nominally hereditary, though in practice he was frequently elected and deposed by military, aristocratic or merely local factions. A favourite of the ruler, or a military dictator who seized power, often took the title of ḥajib (chamberlain) and stood above the viziers (the ruler's delegates or ministers) who with the royal secretaries (kuttāb) formed the diwan or council of state. Local authority was delegated to civil and military governors called walis, each of whom administered a province or chief city, while on every frontier there was a military chief who enjoyed a large measure of independence. Armies consisted of paid mercenaries or were recruited on a tribal or clan basis and rewarded with the spoils of a raid; frontiers, however, were garrisoned by ascetic warrior sects, the Sufis, who corresponded to the military orders of the Christians.

Muslim law, which is canonical insofar as it derives ultimately from the Qur'ān, was administered by the *qāḍīs*, who were chosen from scholars versed in the traditions of Islām (the fakihs). As the office of *qāḍī* became increasingly onerous in Spain, criminal offenses were relegated to a special judge, the *sahib-al-shurtah,* while under the caliphate a magistrate residing in Córdoba, the *sahib-al-mazalim,* reviewed complaints against all public officials. In addition, most cities had a municipal justice, the *muhtasib* (Spanish *almotacén*), who directed the police, judged offenses against public morality, and retained after the reconquest his function of supervising markets, weights, and measures.

Administration of Muslim law

The income of the state was derived from the *zakah,* a tithe imposed originally on the incomes of individual Muslims, but later on the products of agriculture, industry, and commerce; from the capitation tax levied on non-Muslims, which declined after the expulsion of the Mozarabs; from rents on the state lands recorded in the chancellery registers, which became increasingly important; and from import and export duties, supervised by the officials of the revenue minister. In Granada under the Naṣrids the silk trade was an important source of revenue; silks could be bought and sold only in three marts, to which they were taken by elected deputies and stored until sold by the brokers. There was a variety of local taxes on consumer goods, public utilities, and irrigation, mostly devoted to defraying the personal expenses of the ruler's household. In addition, the pious bequeathed property to a public welfare fund that supported mosques, schools, leper houses, and lunatic asylums, provided maintenance for fakihs and students and ransoms for captives, and even served to repair roads, bridges, and defense works.

At the time of the reconquest, when Islāmic law was completely replaced by Roman and canon law, many administrative and fiscal institutions of the Muslims were guaranteed to them in their capitulations; in this way they were retained or copied by the Christians and survived until the advent of the Bourbon dynasty in Spain. This was especially true of municipal and guild regulations, which were often translated from the Arabic and incorporated in local *ordenanzas.*

Survival of Islāmic influence. While the most valuable contribution of Muslim Andalusia to the European heritage was in the realms of philosophy and literature, the most striking survivals of the Islāmic occupation to be seen in modern Spain are agricultural and domestic. Many of the crops grown in Andalusia were introduced by the Arabs (for example, sugarcane, apricots, and almonds—though two of the most characteristic features of the landscape, the maguey, or American aloe, and the prickly pear, come from the New World); and many of the elaborate irrigational constructions date from the Muslim period and have Arabic-derived names (*aljibe,* a well; *acequia,* a water channel; *noria,* a waterwheel). The traditional Andalusian house, though Roman in origin, owes many of its refinements to the Muslims. A spacious porch gives access to the central patio, decorated with blue tiles and horseshoe arches with stuccowork arabesques, in the centre of which a fountain plays among citron trees, flowering shrubs, and fragrant edgings of myrtle clipped in geometrical patterns. In summer, life revolves around the patio and the cool rooms leading off it; in winter the family moves upstairs to heavily carpeted rooms heated by a large round copper brazier standing in a polygonal surround of marquetry and burning, by a process of downward combustion, powdered charcoal made from olive stones. The house is covered by a flat roof and from the outside presents an unrevealing white facade broken only by a few small openings with elaborate wrought-iron grilles. Behind these the family lives in greater seclusion than is usual elsewhere in Europe, and guests other than kinsfolk are rarely invited. Modern Andalusian cooking obtains many of its ingredients from the New World; but the use of olive oil is associated primarily with the Muslims, for the Christians proved their faith by using lard until a comparatively recent date.

Much of what is accepted as typically Andalusian derives from periods before the Muslim conquest (as castanets and some flamenco dancing) or from later periods, being attributable to the influence of the New World, the Gypsies, the bandit and smuggler tradition of the 18th century, and the absentee landlords and political bosses of the 19th and 20th centuries. Perhaps the most lasting, though not the most immediately obvious, impress left by the Muslims on the Andalusian character is the gift for crystallizing the most fleeting emotion, aesthetic perception, or witty thought in improvised music and verse. Aragon

Aragon was a constituent kingdom of the Spanish monarchy after 1479. The historic Kingdom of Aragon was

roughly coextensive with the modern provinces of Huesca, Zaragoza, and Teruel and belonged to the Crown of Aragon, which also encompassed Catalonia, Valencia, and various French and Mediterranean territories. The economic, political, and cultural development of the Kingdom of Aragon lagged behind that of Catalonia and Valencia. In 1981 the historic region of Aragon became one of the 17 autonomous communities of Spain, including the provinces of Zaragoza, Huesca, and Teruel.

PHYSICAL AND HUMAN GEOGRAPHY

The north frontier of Aragon followed the Pyrenean water parting, from the peak of Anie (8,215 feet [2,504 metres]), the last of the great peaks toward the west, to the peak of the Aneto (11,168 feet [3,404 metres]) in the Maladetta group. Thus Aragon is backed by the western, or forward, echelon of the high Central Pyrenees, nearly to the point where the headwaters of the River Garonne separate it from the eastern. From this background of high peaks the descent to the lowlands of the Ebro is less rapid (average gradient 3½ in 100) than the descent toward the Garonne on the French side (seven in 100). The difference is due to the much greater development on the south side of topographical features parallel to the principal axis of the chain. Thus the River Aragon—finding at Jaca the soft marl that runs from east to west in a belt from Pamplona, in Navarre, to Boltaña—is diverted west and forms the broad valley of the Canal de Berdun; the influence of this belt is seen also in the course of the Cinca and of certain minor streams. East of Boltaña the rivers flow directly south, and the first of these, the Noguera Ribagorzana, gives the eastern boundary of Aragon. South of the belt of marl, a series of sierras—roughly aligned from west-north-west to east-south-east—of which the Sierra de Guara (6,791 feet [2,070 metres]) is the most important, runs from the River Aragon to the Sierra del Montsech (5,554 feet [1,693 metres]) in Catalonia; these sierras overlook the great, saucer-shaped central lowland on their south, across which runs the River Ebro. The heart of Aragon is this lowland and more strictly that part to which the descent from the crest of the Pyrenees is most obviously a descent by steps. The approaches to the defile by which the Ebro cuts its way from this enclosed basin through the Catalan coastal chain to the sea belong to Catalonia from Fayón downstream. The western boundary of Aragon runs more or less diagonally across the sierras bordering the central plateau so as to include within Aragon, in the south, the greater part of the sierra belt, while in the north the commanding Sierra del Moncayo (7,595 feet [2,315 metres]), immediately overlooking the Ebro lowland, forms an advanced bulwark of Castile. The descent from the central plateau is again by steps, and the border of Aragon is defined so as to cover the important structural depression, occupied in part by the River Jiloca, which runs from Calatayud, on the River Jalón, to Teruel. From the eastern limit of this depression the boundary runs to the Ebro at Fayón so as to include in Aragon the headwaters of the streams flowing to the Mediterranean. It is clear from the above that Aragon divides naturally into zones, parallel in the north to the Pyrenees and in the south to the border of the plateau. In the first zone, that of the high Pyrenean valleys, cultivated patches sustain scanty village populations; there is some mining—the cobalt mines are interesting—but the forest and the high summer pastures are the chief resources.

Topography

The next, the limestone zone to the south, includes picturesque scenic forms carved by the rivers; it is represented as high as the Pyrenean crest in the Monte Perdido (10,997 feet [3,352 metres]), one of the Three Sisters group. The zone is of no economic importance, but its strategic interest is obvious from the structure. Behind the protecting sierras to the south, Sierra di Guara, etc., beyond which the Muslims made no lasting conquest or impression, sprang up early in the Muslim period the countships of Aragon, with centre at Jaca, Sobrarbe, with centre at Ainsa, and Ribagorza, at first forming a single fief with Pallás. Until its establishment as an autonomous fief in 875, Ribagorza-Pallás was dependent on Toulouse through Cerdagne, and the influence of the easy Segre-Cerdagne pass across the Pyrenees extended as far westwards as the Ésera, the western boundary of Ribagorza. The separation of Pallás, the amalgamation (between 1034 and 1038) of Ribagorza with the western countships, which had always looked west to Navarre, and the declaration of Aragon as an independent kingdom (*c.* 1034) defined the boundaries of Upper Aragon as described above.

The lowland zone, which dips from an altitude of 1,640 feet (500 metres) to the Ebro (at 656 feet near Zaragoza) and rises again to the south toward the sierras, is by no means uniform. The frequency of local regional names, Monegros, Desierto de Calanda, Llano de Violada, indicates variations that express themselves sometimes in the nature of the soil (especially in the presence or absence of gypsum), but principally in the presence or absence of a non-brackish water supply. Huesca, in the north of the zone, on the old road from the coast by Lérida which, today as always, avoids the arid, waterless plateau of Los Monegros, was an important town long before Zaragoza, the natural centre of the lowlands. In the period following the final establishment by Augustus of Roman authority in the entire peninsula and with the new appreciation of the importance of the line of the Ebro as a baseline in strategical schemes envisaging the peninsula as a whole, Zaragoza became a most important nodal point of communications. Standing at the point of confluence with the Ebro of the Gallego valley, by which came the road from the Pyrenean pass of *Summus Portus,* and of the Huerva on the south, Zaragoza was also within 15 miles of the mouth of the Jalón, the entrance to the pass leading by the Sierra Ministra and the River Henares to the Tagus, and in Zaragoza was focussed the importance of the central lowland from which radiated all the routes to the interior of the peninsula. These advantages of site the city has always enjoyed, mutatis mutandis, in a degree corresponding with the degree of unification of the peninsular regions. The central lowland of Aragon had its most complete historical expression in the Muslim period as the kernel of the kingdom of Zaragoza. Not always able to maintain its independence of the Umayyads of Córdoba or of the Moroccan dynasties controlling the south, nor able always to control the north of its own area where the cities had climatic advantages and where Huesca had a much older tradition, the kingdom did not long survive the capture by Aragon of Monzón (1089) and of Huesca (1096); Zaragoza itself fell in 1118. The union of the enlarged kingdom of Aragon, now centred in Zaragoza, with the maritime state of Catalonia (1135) gave it a new Mediterranean outlook. The circumscription of Aragon by Castile both on the north, where the district of La Rioja and the plateau of Soria became finally Castilian, and on the south, where the conquest of Murcia for Castile drove a wedge between Valencia, held by the Aragonese, and the Muslims of Granada, forced eastward the expansion of Aragon and led to the foundation of the Aragonese empire.

Prominence of Zaragoza

The southern part of Aragon would form one single zone of hill country were it not for the strip of sheltered valleys along the line of the Jalón and of the depression marked by the towns of Calatayud, Daroca, and Teruel. With Albarracín, on the upper Guadalaviar, these towns formed the four communities that dominated the hill pastures for many centuries. The peach ripens in the valleys, where the irrigated lands are intensely cultivated; apart from these the sheep pastures on the hills are the principal resource.

The temperature of Lower Aragon is between that of Old Castile with its low mean winter temperatures and that of New Castile with its high mean summer temperatures. Northward from the Sierra de Guara the seasons are reduced more and more to long severe winters and short cool summers; in a lesser degree the same is true of the highlands of Aragon. The rainfall is small save on the Pyrenean front, and we note the approximate equality both of the winter and summer minima and of the spring and autumn maxima. The deficiency of the rainfall, which does not exceed 20 inches (500 millimetres) annually over the greater part of Aragon, and falls below 12 inches (300 millimetres) in the neighbourhood of Zaragoza, has made irrigation a prime necessity. Some of the more important canals are the Imperial canal with intake from the Ebro on

the right bank below Tudila and terminating at El Burgo, below Zaragoza; the Canal de Tauste, on the opposite side of the river; the Canal de Aragon y Cataluña, with intake from the Ésera near Olvena, the principal canal terminating near the junction of the Rivers Segre and Cinca. One of the larger reservoirs is that of La Peña, on the River Gallego. The Moneva reservoir, on the River Aguas, is one of the largest in southern Aragon. (Ed.)

HISTORY

The original kingdom was brought into existence by a testamentary act of Sancho III of Navarre in 1035. Sancho left to his third son, Ramiro, the then small Pyrenean county of Aragon, elevating it to an independent kingdom.

Early expansion of Aragon

To this mountain domain (which took its name from the river flowing through Jaca, its capital) Ramiro (1035–63) was soon able to add the counties of Sobrarbe and Ribagorza, to the east. All the counties had long been under Frankish influence, an important bearing on the character of some Aragonese institutions. By 1104 the kings of Aragon had doubled the size of the original kingdom by conquests southward toward the Ebro. Zaragoza, capital of the Almoravid kingdom of the same name, fell to Alfonso I of Aragon (1104–34) in 1118, and the occupation of the valleys of the Jalón and Júcar rivers, to the south of Zaragoza and the Ebro, soon followed. These conquests, involving the absorption into Aragon of large numbers of Mudéjar and Mozarab farmers and artisans, greatly altered the social complexion of the country. The pattern of future operations against the Moors was fixed by the Treaty of Cazorla, signed by Alfonso II of Aragon (1162–96) and Alfonso VIII of Castile in 1179, which divided those parts of Spain remaining in Muslim hands into two zones—one for each kingdom to reconquer.

In 1150 the ruler of Catalonia, Ramón Berenguer IV, count of Barcelona, married the heiress of the Kingdom of Aragon. Thus, until 1410, both countries came to be ruled by the Catalan house of Barcelona. The previous history of Catalonia, formerly the Frankish-dominated Spanish March, had been unlike that of Aragon. It possessed a unified legal code (in which feudal custom played a large part) and a written political constitution and was much more cosmopolitan and bourgeois in outlook than Aragon. Until 1412 Catalan influence dominated the union, with the Catalans tending to support the crown in its frequent constitutional struggles with the feudal Aragonese nobility. The union was of great value to the Catalans, who were able to devote themselves to commerce and maritime expansion, knowing that the financial and military responsibility of defending them from Castile would fall largely on the inhabitants of the Aragonese hinterland. Navarre, ruled by Aragon since 1076, became independent again in 1134; it once more came under the crown of Aragon in the reign of John II (king of Aragon from 1458 to 1479 and of Navarre from 1425).

At the time of their union, both Aragon and Catalonia had developed important territorial interests in southern France. These occupied much of the attention of the crown until Aragonese pretensions in France were finally abandoned in 1258. The only territory north of the Pyrenees that remained permanently attached to the Aragonese crown was the county of Roussillon. The occupation of the Balearic Islands took place in 1228 and the conquest of the rich Moorish kingdom of Valencia in 1238. Valencia, like the Balearics, was colonized by Catalans, though it retained a large Mudéjar population. It was administered as a separate kingdom of the crown of Aragon, with its own laws and parliament. Having thus completed the occupation of the Moorish territories allotted to Aragon by the Treaty of Cazorla, the Aragonese began expansion in the Mediterranean, made possible by the sea power of the Catalans. In 1282, after the Sicilian Vespers, Peter III (1276–85) was received by the Sicilians as their king, and thenceforward Sicily was ruled either directly by the kings of Aragon or by their relatives. Sardinia was incorporated into the Aragonese empire in 1320. A further accretion to Aragonese power came in 1442, when Alfonso V (1416–58) successfully concluded his long struggle to conquer the kingdom of Naples.

Between 1356 and 1369 Peter IV (1336–87) had been involved in a disastrous war with Castile. This war and its aftermath revealed that the powerful feudal nobles of Aragon tended to sympathize more with the Castilian magnates than with their own municipalist dynasty. Their chance came in 1412 when, after the extinction of the House of Barcelona in 1410, they procured the election of a a Castilian prince, Ferdinand of Trastámara, to the vacant throne against strong Catalan opposition. The final blow to Catalan supremacy came when Alfonso V of Aragon transferred his capital to Naples in 1443; though, later, the Catalans waged an unsuccessful civil war against Trastámaran rule. John II countered this resistance by arranging for his heir, Ferdinand, to marry Isabella, heiress of Henry IV of Castile. In 1479, therefore, on John's death, the countries of the Aragonese crown were united with Castile. Under this union the Aragonese countries retained their own political and administrative systems, despite certain modifications under Philip II, until the beginning of the 18th century, when, in consequence of the rebellion of the lands of the crown of Aragon during the War of the Spanish Succession, their constitutional privileges were abrogated by Philip V. As an administrative unit the old kingdom of Aragon proper survived until 1833, when the division of it into the three existing provinces took place. (P.E.R.)

Union with Castile

Asturias

Asturias once was a principality of Spain, created (1388) by John I of Leon and Castile when his eldest son Henry married the daughter of the Duke of Lancaster. The principality belonged to the eldest son of the sovereign; adminstratively the principality was chiefly merged in the province of Oviedo, to describe which Asturias still survives in popular usage as a regional term. In 1981 the historic region of Asturias became one of the 17 autonomous communities of Spain, including the province of Oviedo.

PHYSICAL AND HUMAN GEOGRAPHY

Clearly defined on three sides by mountain ranges, which make the district a rough oval, and on the fourth side by a long straight coastline, broken only by the projecting Cabo de Peñas, the Asturias are secluded from the rest of the peninsula and such outlook as they have is maritime. On the east the triple limestone massif of the Picos de Europa leaves only a narrow strip for passage to the coast of old Castile; on the south the Cantabrian mountains shut off the central plateau. On the west the lower Sierras de Rañadoiro and de Meira, running northeast to southwest, block the road to Galicia; between these sierras the boundary line of the Asturias runs without any special natural definition to the Ria de Rivadeo.

The abrupt descent from the Cantabrian crest in Peña Ubiña, brings down the rivers by steep courses set in deep valleys—in canyons, in the mountain limestone of the eastern Asturias—to the sea. A fan-shaped area drains to the Ria de Pravia by the converging Rivers Narcea and Nalón; the town of Pravia stands at the apex of the fan. Besides these rivers and their tributaries, the Navia and Sella are the only important streams. To the east of this fan, behind the coast between Avilés and Caravia, lies the area of successive marine invasions in geological times. To one of these invasions is due the natural trench that forms the central valley of the Asturias east of Oviedo and continues along the line of the old sea gulf narrowing out between the Picos de Europa and the Sierra de Cuera. This structural valley, neither the result of stream action nor occupied by any important stream, gives the principal interior line of communications in the Asturias. Along the coast the great Cantabrian platform, running from western Galicia to the mouth of the River Adour in France, is represented in the Asturias as elsewhere, by the gently rolling downs, 200 to 230 feet (61 to 70 metres) in height and cut usually in sheer cliffs toward the sea, into which the platform, segmented by the rivers from the interior, has been molded by the weather. Today the platform is thickly populated, and one single coastal road connects the long line of small towns set on successive

Relief

heights. The intervening *rias* are clogged with silt and afford no good harbours. The relief, of mountain, valley, and coastal platform, the coal supply, and the humidity of the climate determine jointly the character of the Asturias. The impenetrable Picos de Europa, in whose fastnesses the chamois still roams, sheltered the Christian nucleus of resistance to the Muslims, which developed into the Kingdom of Oviedo and Asturias. In the early stages of this resistance the term Asturias (derived from the original inhabitants, the Astures, whose territory extended westward from Ribudesella and as far as the Douro) covered loosely the Cantabrian territory held by the Christians; there were Asturias in the Liébana valley and as far east as Santander (Asturia de Sancto Anderio), and the name lingered long east of the Picos in the term Asturia de Santillana (Sancta Illana). But the important movement was westward along the central valley, in which Cangas de Onís and Oviedo (alternating with Pravia) were successive headquarters or capitals of the small Christian state. After the capital of the enlarged state had been tranferred to Leon by Ordono II (914–924), the isolation of the Asturias and of Galicia, both from each other and from the repopulated territory on the central plateau, contributed to the weakness and lack of homogeneity of the Kingdom of Leon. The mountain barrier between Leon and the Asturias made Oviedo at a later date a refuge for the Leonese king Bermudo II during the raid of Almanzor.

The coal of the Asturias lies in distinct groups of small basins; the town of Tineo is the centre for the most westerly group, but the comparatively thick beds of anthracite coal have been little exploited there for lack of means of communication. The most important group at present is the central; here the coal lies in a series of folds of the mountain limestone, cut by the Rivers Caudal and Nalón, on which Mieres and Langres are respectively the centres of exploitation. The more northerly basins of Arnas and Ferroñes supply a soft coal. The coals of the Asturian basins form a descending scale of hardness from north to south. Iron ore is also extracted in the Asturias. Zinc ores are mined in the Picos de Europa. The altitude at which the zinc is found, however, prevents operations in winter; the iron ores have a high percentage of silica; the coal seams are relatively thin and irregular and they dip steeply, so that the costs both of production and of transport are high. Thus the mineral resources of the Asturias have served to industrialize considerable tracts of country without bringing any high degree of prosperity. With a humid climate and a high rainfall nowhere less than 40 inches (1,000 millimetres) per annum, the Asturias are predominantly pastoral and the cow is the chief domestic animal. Horses and mules are bred on the Asturian pastures but they are not worked, except in the mines. The absence of a regular period of drought, together with favourable temperature conditions makes maize (corn) the chief cereal cultivated; the soils do not, however, favour the cultivator, and America and the mines attract labour more than the farm. The marked summer minimum of rainfall is sufficient to make ordinary summer irrigation desirable, but the typical Asturian irrigation is the winter flooding of lands by running water, partly to maintain the soil temperature and partly to secure the benefit of the fertilizing deposit of mud.

HISTORY

Asturias was from 718 to 910 the only independent Christian kingdom in the Iberian Peninsula. The kingdom was formed by a number of Visigothic nobles and officials who, after the Muslim invasion of Spain, retired to this area, as high mountain ranges to the east, south, and west made it a small and easily defended enclave. They elected Pelayo, a Visothic noble, as king and set up a capital at Cangas de Onís. The new kingdom managed to survive repeated attacks by the armies of the amirate of Córdoba and extended its frontiers to include Galicia and Cantabria before the end of the 8th century. The capital was transferred first to Pravia (*c.* 780) and thence, in the reign of Alfonso II (791–842), to a strategically sited new city constructed for the purpose at Oviedo. During the reign of Alfonso III (866–910) the frontiers of Asturias were pushed south to the line of the Duero from the Atlantic to Osma. By this time, the kings of Asturias, with the aid of Mozarab (Christian) immigrants from the amirate, commanded sufficient manpower to garrison and repopulate the areas south of the Asturian mountains. The kings made alliances with dissident Muslim leaders and sometimes established a modus vivendi with the amirs of Córdoba but always retained their independence. An important factor in building up a sense of national identity was the discovery, early in 9th century, of the supposed tomb of St. James at Padrón, in Galicia. The shrine subsequently established at Santiago de Compostela was soon to become the spiritual centre of the nation. By the 10th century the kingdom was too large to be effectively controlled from the mountain capital at Oviedo, and García I (909–914) made Leon his administrative centre in 910.

Visigothicism

Self-conscious Visigothicism was a feature of the Asturian kingdom, whose princes claimed direct descent from the Visigothic rulers of Spain and whose earliest chroniclers stressed the duty of the kingdom to proceed to the early and total reconquest of the whole peninsula. Church organization was reestablished on the Visigothic model, aided by the immigration of Mozarabic priests, and the many churches built in Asturias adhered closely to Visigothic architectural tradition. Similarly the secular administration of the Asturian kings continued, although in attenuated form, the system of the Visigothic rulers, and the *Forum judicum* remained the basis of Asturian law. Some Frankish influence is evident in the administration and in architecture, and there are traces of diplomatic contacts with Charlemagne and his successors, but, generally, the Asturian kingdom lived in total isolation from the rest of Christian Europe.

Asturias was created a principality by John I of Castile for his eldest son, Henry, in 1388. This principality survived during the existence of the Spanish monarchy as a title (in modern times purely honorific) borne by the sovereign's eldest son. (P.E.R./Ed.)

Balearic Islands

The Balearic Islands (Islas Baleares) is an archipelago of five islands, with a number of islets, in the western Mediterranean. The islands are located about 50 to 190 miles (80 to 300 kilometres) off the east coast of Spain, of which they form a province. The archipelago, which lies between 38°40″ and 40°6″ N, and 1°22″ and 4°25″ E, comprises two distinct groups. The eastern and larger group, the Balearics proper, contains the two principal islands, Majorca (Spanish Mallorca) and Minorca (Menorca), and the small island of Cabrera, south of Majorca. The western group, formerly known as the Pine Islands (Las Pitiusas; ancient Pityusae), comprises Ibiza (Iviza) and Formentera, with several islets. In 1981 the Balearic Islands became one of the 17 autonomous communities of Spain.

PHYSICAL AND HUMAN GEOGRAPHY

The land. The Balearics are, structurally, the continuation of the Andalusian Mountains, which end on the Spanish mainland at Cabo de la Nâo, a little more than 50 miles west of the Pityusae. They are the emergent portions of two submarine plateaus, which are separated from each other by a considerable marine depression. The seas separating Ibiza from Formentera and Majorca from Minorca are, however, relatively shallow, and a fall of the Mediterranean sea level of 300 feet (91 metres) would convert the Balearics into two islands. The edge of the northern submarine plateau is truncated abruptly by an east–west abyss more than 8,000 feet deep. Minorca's northwest–southeast axis lies obliquely to the direction of this fault zone; and the character and extent of the Palaeozoic formations of Devonian Age comprising the island suggest that Minorca is a remnant of the continental massif that formerly united Sardinia with Catalonia. The other islands of the Balearics are aligned on the southwest–northeast trend of the submarine plateaus and presumably are the expression of violent Alpine folding from the southeast. Rocks from Trias to Oligocene bear witness to these mountain-

building movements, older formations being brought up also as inliers.

The resultant sierra of northwest Majorca, parallel to the coast, rises in the Torrellas or Puig Mayor to 4,734 feet; a minor highland zone in the southeast reaches almost 2,000 feet; and the core of Ibiza is crowned by La Atalaya, 1,558 feet. The rugged and precipitous cliff coastlines of both northwest Ibiza and northwest Majorca, often referred to as their Costa Brava, occur where these zones of high relief are adjacent to the sea. Elsewhere in Majorca and Ibiza there are broad belts of lowland, often of fertile Miocene soils or alluvium, surrounded or interrupted by undulating hills, boulder-strewn and scarred by the courses of torrents, which in flood spread their debris on the piedmont zone. Formentera has a more monotonous relief, consisting of two tablelands (the higher, La Mola, 630 feet) mainly of Quaternary deposits connected by a narrow isthmus of alluvium. Minorca has a more worn terrain, the highest of its small hills, Monte Toro, in the north centre, reaching an elevation of only 1,174 feet. This northern monotonous stony plateau runs to the sea in a northeast coast of much more dislocated relief, which contains many bays and capes and the deep inlet of Mahón. A fairly well-marked depression separates this plateau from the low southern tableland with its gently rolling surface cut by broad ravines with fertile alluvial bottoms. Cabrera, separated by a five-mile-wide strait from Majorca, is a semi-arid contiuation of the larger island's eastern hills.

Climate

Within a general pattern of Mediterranean climate characterized by winter rain and summer drought, there are marked variations from one island to another, and within each island, dependent largely on relief and aspect. Minorca, having no protecting range of mountains, is colder and wetter in winter (25 inches [635 millimetres] annually), and feels the effects of hot summer winds more than the other islands. The average summer temperature is 75° F (24° C), and that of winter 50° F (10° C). In Majorca there are marked differences between the rainy cooler northern mountains and the protected remainder of the island, which has an average rainfall of less than 20 inches and rarely suffers gales. Ibiza, Cabrera, and Formentera are even drier, with an annual precipitation of less than 15 inches. In all the islands the period May–August is almost rainless, the number of rainy days being less than 80 annually. There are, therefore, no permanent streams but a great number of torrent courses and ravined gullies which are filled spasmodically. Snow rarely falls, although frosts are not uncommon in the period January–March. In the mountains of Majorca snow may lie for several weeks until the spring thaw. Daytime summer temperatures frequently reach 90° in June, July, and August, but these are moderated by sea breezes, and the evenings are usually cool and often in the 50° range even in midsummer.

Agricultural and pastoral use of the lowland areas and the construction of hillside terraces for arable farming have limited natural vegetation to the rocky hilly lands, ravines, and terrain impracticable for farming. The exposed northern areas of Minorca are either treeless or support only stunted specimens, but the sheltered southern gullies (barrancas) have some pine woods, pomegranate orchards and even semitropical vegetation on their slopes. In the other islands Aleppo and Stone pine and some holm oak occur where rainfall and soils are sufficient, but great areas are covered with Mediterranean scrub vegetation, which includes juniper, oleander, myrtle, and rock roses. This *garigue* was formerly the undergrowth of a forest cover. The prevailing arboriculture of Majorca and Ibiza has resulted in a two-tier cover of the fertile parts of those islands (*huertas*), as cereals and legumes are grown in the orchards and groves of almond, olive, carob bean, and fig trees. Artificial meadows of lucerne occur in the most easily irrigated areas.

The people. The vast majority of the population of the Balearics live in Majorca, a large proportion of all the islanders residing in Palma alone. Most of the Majorcans and Minorcans are town-dwellers, but the reverse is true of Ibiza and Formentera where the majority of the people live in rural settlements. Cabrera and Formentera are thinly populated. Ethnically the people reflect the rich variety of their historical antecedents. The larger towns contain a majority of folk of Catalan descent, with Jewish and Italian minorities, but the country districts show in their physical types important admixtures of Moorish, Phoenician, Greek, and even Nordic characteristics, and some families can trace their ancestry to Moorish-Catalan progenitors. There are also small numbers of returned emigrants, from the mainland, from France, and from Latin America, the latter known as *americanos*. Castilian is the language of the cities, but in rural areas a Catalan dialect, with many resemblances to Provençal French and with several Arabic infusions, is the common tongue spoken. Some Majorcans returned from France and residing in Sóller speak French; and some forms of speech introduced by the British still survive in Minorca.

The economy. All the islands together form a Spanish province, with Palma as its capital. The city is also the military, judicial, and ecclesiastical headquarters of the province.

Arboriculture is the traditional industry of Majorca and Ibiza, cereals, legumes, and animal fodder crops being grown among the almond, carob, bean, fig, olive, and apricot trees, either on the irrigated *huerta* lowlands or on the intensely terraced hillsides. Minorca is more important for pastoralism but also produces good crops of ranges. Stock raising is widespread in all the islands, small groups of sheep, goats, and pigs being cared for by the women and children. *Feixes,* or reclaimed lands, adjacent to Ibiza city, are important sources of market-garden produce. This rural economy is essentially peasant-operated, much of the domestic furniture, foodstuffs, local customs, and arts exhibiting distinct self-sufficient characteristics. Almonds, figs, and apricots are exported, and there is a considerable local production of wines, olive oil, butter, cheese, and poultry.

Agriculture

For centuries Ibiza has been an important manufacturer of sea salt. Fishing provides much food for the islanders, and some fish is exported to the mainland. Timber-cutting, charcoal-burning, and small glass, pottery, footwear, and foodstuffs factories complete the industrial fabric, but many of these occupations are complementary and secondary to agriculture, having a labour supply that fluctuates with the demands of the farmland.

The tourist industry is an important part of the economy of all the islands, many thousands of visitors, especially from Spain, France, Great Britain, and Germany, being attracted by the climatic, scenic, and historic merits of the Balearics. The construction of hotels, guest houses, and villas, the provision of services, and the making and sale of souvenirs, especially fine lace and embroidery, provide employment and income.

Sea communications are maintained principally through Barcelona, and air services link Majorca and Minorca with many west European cities. (G.J.B.)

HISTORY

Archaeological artifacts. The earliest historical records describe the inhabitants of the Balearic Islands as cave dwellers. Natural and partly artificial caves abound in the limestone rock and have produced the few simple flint implements and incised pottery that can be assigned to the beginning of the Bronze Age and are the earliest records of human activity. Subterranean methods of living persisted, and the walled settlements of the inhabitants largely consisted of windowless rooms. Megalithic hill forts crown some of the hills.

Talayots. The earliest and best known monuments are the talayots (towers). They are still numerous and were formerly much more so, especially in the intensively cultivated island of Majorca, where great numbers were destroyed, particularly on the plains adjoining the southeast coast of the island. They are chambered towers of stone, with either a round or a rectangular plan. They were roofed, generally with the aid of a central pillar composed of circular superimposed slabs, and faced with clay to produce a monolithic appearance.

The masonry of the round towers is very rough, the walls being composed of immense rugged blocks of hammer-dressed limestone; but the four-cornered talayots, which

are presumably later, show smaller masonry. Like the nuraghi of Sardinia, they served as fortified dwelling places; outbuildings are normally attached, and they are occasionally sited within villages enclosed by Cyclopean walls.

Taulas. With the talayots in Minorca are associated the so-called temples; these halls may well have been used for ceremonial purposes, but they certainly formed a normal element of the habitations associated with the talayots. Within the hall stands a taula (table), a rectangular slab of dressed stone that supports a second, horizontal, slab. These T-shaped taulas are central supports for roofing; there are often supplementary pillars between the taula and the outer wall and clay-covered pilasters against the wall and in the angles.

It seems certain that these most remarkable prehistoric remains in Majorca and Minorca are not likely to be much earlier than the middle of the 2nd millennium BC and represent a culture that continued with little change until Roman times.

Burial caves. Rock cut tombs and burial caves are found in many forms; those of the best known series, at San Vicente, on the northern extremity of Majorca, are cut into a sloping hillside. They resemble the burial grottoes of southern France near Arles and must indicate a common origin. Carvings in Majorcan caves confirm the relationship. Many caves of the same type, when sited on level ground, are approached by steps sunk in a trench, which was filled by blocking material to seal the tomb.

The *nau* grave

The *nau*, or *naveta* (Catalan, "ship"), so termed from its resemblance to an upturned boat, was also a type of grave. These are now found chiefly in Minorca and are elongated structures built, like the talayots, of immense closely fitted blocks of stone, with a rounded end and squared or slightly concave front; in this front face is a tiny door giving access from a forecourt through a passage to a long rectangular chamber roofed by large slabs. In the famous Nau d'Es Tudons the total length of the structure was about 60 feet, the width 24 feet, and the height about 25 feet. Structures of somewhat similar form in Majorca seem to have been used as dwellings.

Finds. Although the talayotic civilization seems to have continued without much modification, the position of the islands off the northern shore of the Mediterranean laid them open to continued influence from more eastern civilizations, as many finds attest. Important discoveries of bronze swords and single and double axes, antennae swords, heads and figures of bulls and other animals, small human figures from Sardinia or farther east, and many other objects bear witness to the foreign trade of the islanders over long periods of time. Local manufactures are represented by pots and shards. Most of the types seem to have persisted with little change until they are found mixed with Roman wares following the Roman occupation. (W.J.He./Ed.)

Invasions and occupations. There is historical evidence of at least 2,600 years of settlement, for the islands passed successively under the rule of Carthaginians, Romans, Vandals, Moors, and Spanish, all of whom have left their mark to some extent on the physical and cultural landscape. The islands are thus in many ways an epitome of Mediterranean insular history. Ibiza in particular was a strategic point, easily reached via the North African coast and providing a convenient base to raid the rich lands of Alicante, Valencia, and Majorca. Occupied for centuries by the Phoenicians and Carthaginians, Ibiza became a Roman colony in 123 BC. Under all these occupations its economic resources of lead, zinc, salt, foodstuffs, and purple dye (from marine mollusks) were sought by traders.

Founding of Palma

When the archipelago was conquered by Q. Caecilius Metellus in 123 BC, the largest city of the Balearics, Palma (the symbol of victory), was founded, and olive cultivation was introduced. Five centuries of peace, during which the islands supplied their new masters with Minorcan mules and the celebrated Balearic slingers, were broken by the arrival of the Vandals, who were followed by the troops of the Byzantine emperor Justinian. Though raided frequently both by Muslims and by Normans, the islands were not permanently conquered by the Caliphate of Córdoba until 903. The Moorish occupation led to many improvements in agriculture and irrigation, notably the introduction of windmills and waterwheels turned by animals, both devices being conspicuous features of the landscape today. James I of Aragon (the Conqueror) annexed Majorca and Ibiza in 1230–35, Minorca falling to his descendant Alfonso III in 1286. The islands formed a semiautonomous kingdom until 1349 and became a great base of medieval cartography and navigational science. Settlement was extended, agriculture was developed, and trade prospered.

In the War of the Spanish Succession the strategic value of the large landlocked harbour of Mahón attracted the attention of the participants, and its capture by the British in 1708 ushered in a century of dispute over its possession, which was not finally settled until the Spanish regained it in 1802 by the Peace of Amiens. In the Spanish Civil War (1936–38) points in the islands were seized by insurgent troops. Loyalist forces temporarily recaptured Ibiza, Formentera, and Minorca, the latter serving as an important base for their naval operations. (G.J.B./Ed.)

The Basque Provinces

The Basque Provinces (Provincias Vascongadas) are three small provinces, Guipúzcoa, Álava, and Vizcaya, that lie in north central Spain on the Bay of Biscay, adjoining the French border. In 1979 the three provinces formed the first autonomous community in Spain, the Basque Country (País Vasco). With an area of 2,803 square miles (7,261 square kilometres), approximately 90 miles (145 kilometres) wide from east to west and 45 miles (72 kilometres) from north to south, the Basque Country is one of the smaller autonomous communities of Spain. Isolated by the mountainous terrain, the Basques have maintained their linguistic and cultural uniqueness since the beginning of the Roman occupation in the 2nd century BC.

PHYSICAL AND HUMAN GEOGRAPHY

The Basque Provinces are bordered by France to the northeast, the provinces of Navarre to the east, La Rioja and Burgos to the south, Cantabria to the west, and the Bay of Biscay to the north. To the east the Pyrenees separate the Iberian Peninsula from the rest of the European continent and create a mountainous terrain that rapidly descends to the coast. To the south the Cantabrian Mountains run east–west through the provinces, separating the coast from the central plain of Álava and the provinces to the west. South of Álava's central plain lies the Ebro River, which defines the southern boundary of the province. Along the northern coast the Atlantic weather patterns prevail, characterized by heavy precipitation throughout the year, while in southern Álava, known as the Rioja Alavese, a warmer and drier climate permits the cultivation of both wine grapes and olives. Between the two regions lie the Cantabrian Mountains, which exhibit a more temperate climate.

Since the Spanish Civil War the Basque Provinces have undergone urbanization and heavy industrialization, with the result that the region around Bilbao, the capital of Vizcaya, has become the only significant rival to Barcelona as Spain's most industrialized area. With the subsequent depopulation of the rural areas, the traditional life of the Basques has changed dramatically since 1939.

The slopes of the Pyrenees were for centuries the domain of isolated farmers and shepherds. In the early 19th century, farmers began cultivating corn (maize) and potatoes after these two crops were imported from the United States. By the mid-20th century, cattle raising had largely supplanted sheep raising, and corn had become the primary crop. Wheat, barley, oats, and sugar beets are other principal crops. In the Rioja Alavese, situated at a lower elevation than the mountainous north, approximately one third of the the arable land is devoted to viticulture. The woodlands in the northern part of Álava are exploited for lumber, particularly oak. Vitoria, the provincial capital, is an industrial centre, where furniture, bicycles, and agricultural machinery are produced. Álava

The two coastal provinces, Guipúzcoa and Vizcaya, are heavily industrialized. During the 19th century, iron and

Bilbao

steel production was concentrated around Bilbao, where iron was locally mined and shipped from the upriver port to the sea via the estuary called the Ria de Bilbao. Steel production reached its peak in Bilbao in the 1960s, when more than half of Spain's steel was produced there. Bilbao is also a centre for the chemical and metallurgical industries. Because the city is the most important port in Spain, it is also a financial centre and the traditional heart of various maritime industries, notably fishing and shipbuilding and repair. Along the coast, fishing, which once provided the primary means of livelihood, is now a secondary industry. Shipbuilding, a traditional activity of the Basques that began before the defeat of the Spanish Armada in 1588, when Spain was the major European naval power, has remained an important industry along the northern coast. Besides Bilbao, other shipbuilding centres are located at Santander and Gijón, Oviedo. Near the French border, the cities of Santander and San Sebastián, the capital of Guipúzcoa, have little heavy industry and are the centre of the region's tourism.

Certain genetic traits, including distinctive blood-type concentrations and skeletal differences, have led scholars to hypothesize that the Basques are descendants of an ancient Iberian people. The question of Basque origin is complicated by the Basque language, which bears no relation to Indo-European languages or to the few ancient fragments of Iberian writing that still exist.

Traditional Basque life centres around the *caserio,* the farm that houses a single family. Sometimes a few families form a small village, but the rural Basques are generally isolated, making for a strong patrimonial family life. This isolation has also allowed the Basques to maintain cultural separateness from their Spanish and French neighbours. Urbanization has attracted much of the rural population to the large coastal industrial centres; greater Bilbao accounts for four-fifths of the population of the three provinces. Agricultural production has thus declined, and many small villages have been depopulated. The urban centres have also attracted Spanish people from other provinces, so the traditions of Basque life and language have remained vital chiefly in the ever-dwindling rural enclaves.

HISTORY

Before the Roman invasion, the Basques occupied a large area of northern Spain, extending to the eastern edge of the Pyrenees, and part of southern France. When the Romans colonized the region in the 2nd and 1st centuries BC, many Basques assimilated Roman culture and language. Only the western Basques, living in relative isolation in the mountainous area of the present-day Basque Provinces, retained their distinct ethnicity and continued to speak their own language.

After the Roman Empire fell, these western Basques resisted all subsequent invaders, including the Visigoths, the Franks, the Normans, and the Moors, and they invaded in turn southwestern France. Basque self-government was conducted by local officials who were either appointed or elected. Delegates from each province gathered annually at the celebrated oak in Guernica to modify the *fueros,* or body of laws, that governed all three provinces. Despite the provinces' later alliances with Castile and Navarre, their political independence and the *fueros* were recognized by Spain until the 19th century. Although the Basques were required to swear allegiance to the Spanish crown, taxation was voluntary, and collection was determined by the Basques themselves. Basques served in the Spanish Army but only under Basque officers and only for the defense of the country. Elections for all local and provincial offices were conducted by the Basques, and they were free to engage in trade with foreign powers.

Self-government

After the Kingdom of Navarre broke from Castile and Aragon in 1035, the Basques found themselves situated between rival kingdoms. The region remained the subject of dispute until the three provinces were annexed to the Castilian crown. Guipúzcoa was the first to be annexed, in 1280, followed by Álava in 1332 and Vizcaya in 1379.

Basque autonomy was revived for a short time at the end of the Republican era in 1936. Basque Nationalists supported the Republicans based in Vizcaya and Guipúzcoa in order to pursue their own goal of political autonomy. Several attempts were made to enact an autonomy statute between 1931 and 1937, but the effort was thwarted until 1936, when an autonomous government was organized in Bilbao, which was controlled by the Republicans. Bilbao fell to the Nationalist forces soon after, in June 1937, and the nine-month-old government fled to France and then to Barcelona, which remained a Republican stronghold until the end of the Civil War. Proscriptions against speaking the Basque language or teaching Basque history suppressed Basque nationalism during Franco's regime but fuelled the growth of the extremist Basque separatist organization, the ETA (Basque Euzkadi ta Azkatasuna; "Basque Homeland and Liberty"). After Franco's death and the establishment of the autonomous community, the País Vasco, some measure of political autonomy was granted to the region, but the ETA continued its violent campaign in support of complete separation and social reform. Canary Islands

The Canary Islands (Islas Canarias) is an archipelago in the Atlantic Ocean, between 27°39″ and 29°25″ N and 13°20″ and 18°12″ W. The minimum distance from the northwest African mainland is 67 miles (108 kilometres) between Fuerteventura and Cape Juby. In 1981 the Canary Islands, with the provinces of Santa Cruz de Tenerife and Las Palmas de Gran Canaria, became one of the 17 autonomous communities of Spain.

PHYSICAL AND HUMAN GEOGRAPHY

The land. Physically the Canaries fall into two groups: the western group includes Tenerife, Grand Canary, La Palma, Gomera, and Hierro and consists of isolated mountain peaks that rise from a deep ocean floor; the eastern group comprises Lanzarote, Fuerteventura, and six islets, surmounting a single submarine plateau less than 4,500 feet (1,400 metres) deep. After the researches of Christian Leopold von Buch in the early 19th century, the Canary

Islands, which are geologically associated with Madeira and the Azores, became classical ground to the student of volcanism. They are merely cones of ejection, formed by volcanic eruptions during and after the Tertiary Period. The lavas consist chiefly of basalts and trachytes.

The Canaries are situated at the eastern edge of a vast subtropical anticyclone and most of the year within the north-east trade wind. The trade wind blows strongly all summer but in winter may be interrupted by winds from between the west and southeast, occcasionally bringing hot, dusty weather and, rarely, locusts, from the mainland. In winter the passage of shallow depressions causes most of the archipelago's scanty rainfall. The climate is warm and dry. On the lower parts, February, the coolest month, has a mean temperature of 62° to 64° F (17° to 18° C), and August, the hottest month, has a mean temperature of 74° to 76° F (24° to 25° C), except in the eastern islands, which can be hot inland. Sunshine is abundant at all seasons, and rainfall, except on exposed parts of the western islands, is small and variable. The more populous districts have mean annual rainfalls of between six and 16 inches (150 and 400 millimetres), with about 50 to 60 rain days, but most of this falls in a few short, heavy storms in winter. The lower, eastern islands experience long droughts. Snow does not fall below about 3,000 feet (about 900 metres) and is unusual below 5,000 feet (1,500 metres). The Pico de Teide on Tenerife is often snowclad above 8,500 feet (2,600 metres) from November to April. This grand peak was the scene of a remarkable step in the progress of meteorology when in August 1856 the British astronomer Charles Piazzi Smyth (1819–1900) made two ascents that demonstrated the layering of the atmosphere in trade-wind areas.

Animal life

There were probably no indigenous mammals on the Canaries at the time of their discovery by Europeans. The dog, swine, goat, and sheep found there by the Spaniards had probably been introduced by earlier invading peoples from Africa. The ornithology is more interesting. About 220 species have been recorded, and, of these, 75 breed locally, and more than 40 are peculiar to this archipelago.

Of the 900 species of wild flowering plants found in the Canaries, just over 300 are indigenous. The latter show strong affinities with the vegetation of the Mediterranean and tropical East Africa and weak affinities with the vegetation of eastern Asia and the New World. The scanty rainfall and porous volcanic surfaces cause large tracts of the drier islands to be almost barren, yet the xerophytic plant life is of great interest, especially the cactuslike *Euphorbia,* of which about 25 species occur, and the famous dragon tree (*Dracaena draco*). The considerable height of the western islands, all exceeding 4,600 feet (1,400 metres), allows a wide range of subtropical and temperate plants to flourish. The following scheme for Tenerife illustrates the general zonal arrangement of vegetation with increase of altitude: (1) From sea level to 1,300 feet (400 metres) the climate resembles that of Egypt, and the characteristic plants of arid tracts are *Euphorbia* and *Sempervivum.* The better watered or irrigated lands yield crops such as bananas, oranges, coffee, dates, sugarcane, and tobacco. (2) From 1,300 to about 2,300 feet (700 metres) the climate resembles that of southern Italy, and the chief crops are wheat, barley, corn (maize), potatoes, and grapes. Where rainfall suffices, trees such as laurel, fig, walnut, almond, and eucalyptus thrive. (3) Between 2,300 and 4,000 feet (1,200 metres) is the main cloud layer, and the climate becomes appreciably cooler, except during southerly winds. Rather open formations and, in wetter places, quite dense stands of indigenous trees occur, including *Ardisia, Ilex, Rhamnus, Olea, Myrica,* and various species of laurel. (4) From 4,000 to about 6,000 feet (1,830 metres), athwart the normal edge of the cloud layer, the Canary pine (*Pinus canariensis*) is dominant, but tree heaths are fairly common. (5) Between 6,000 and 8,500 feet (2,600 metres), or above the cloud layer, the tree growth is replaced, first, by a narrow belt where *escobón* (*Cytisus proliferus*) and the gorselike *codeso* (Adenocarpus viscosus) provide important fodder supplies, and, then, by a wide zone where the pumice- and lava-strewn slopes are dotted with *retama,* a dark-green broom that bears white and pink flowers. (6) Above about 8,500 feet (2,600 metres) snow lies for many months, and vegetation is almost absent.

Social conditions

The people. The Guanches, who occupied the islands at the time of the Spanish invasion, no longer exist as a separate race. The present inhabitants, or Canarios, are scarcely distinguishable from the people of Spain. Spanish is the only language in use, and Spanish customs are stoutly maintained. Since 1900, when 80 percent of the Canarios could neither read nor write, education has progressed rapidly. Good schools are numerous, and there is a university (founded 1701) at La Laguna, Tenerife. The staple diet of many of the poorer people is composed of fish, potatoes, and *go fio,* which usually consists of corn or wheat roasted, salted, ground, and kneaded with water or milk.

In 1927 rivalry between the two chief ports, Las Palmas de Gran Canaria and Santa Cruz de Tenerife, caused the archipelago to be divided into two provinces. Appropriate civil and military provincial officials reside in both capitals. In addition, each of the seven main islands of the archipelago has its own council (*cabildo insular*) under a deputy civil governor. Roman Catholicism is the official religion; La Laguna and Las Palmas are episcopal sees in the archbishopric of Seville.

The economy. Because of the mild temperatures and richness of the volcanic soils, agriculture in the Canaries is usually profitable and varied. Until 1853 wine formed the staple product. In that year a grape disease caused by phylloxera (a plant louse) attacked the vineyards, and viticulture was soon largely replaced by cochineal production.

The cochineal insect, introduced in 1825, thrived on a local cactus. The boom imparted a lasting benefit to Canarian agriculture, as landowners undertook elaborate terracing and in places even broke up lava streams to expose the ancient soil buried beneath. The cochineal industry declined (because of competition from synthetic dyes) in the late 19th century in favour of the cultivation of sugarcane and later of bananas, tomatoes, potatoes, and various other vegetables and fruits. Potatoes, tomatoes, and bananas have become the main cash crops. Cuttlefish, sardines, mackerel, and anchovy are caught locally.

The Canaries lie athwart trade routes from Europe to South Africa and to Central and South America. Tourism, which is the chief industry, has grown rapidly on the five largest islands. The islands are connected by steamship services. Each of the two capital cities has an international airport and also maintains air services to Fuerteventura, Lanzarote, and La Palma.

HISTORY

The Romans learned of the Canaries through Juba, king of Mauretania, whose account of an expedition to the islands, made about 40 BC, was preserved by Plutarch and the elder Pliny. The latter mentions "Canaria, so called from the multitude of dogs [*canes*] of great size." Hierro, then the most westerly place known, was chosen in about AD 150 by Ptolemy for the prime meridian of longitude, and until the late 18th century some navigators continued to reckon from this line. In 1402 Gadifer de la Salle and Jean de Béthencourt sailed from La Rochelle and soon occupied Lanzarote. Béthencourt went to Cádiz for reinforcements and returned in 1404 with the title of king, which he had secured from Henry III of Castile. Thereupon he completed the conquest of Fuerteventura and Hierro, and in December 1406 he returned to Europe, leaving his nephew Maciot in charge of the islands. Eight years of misrule followed before Queen Catherine of Castile intervened. Between 1420 and 1460 a force sent by Prince Henry of Portugal subdued Gomera.

Spanish sovereignty

In 1479 the Treaty of Alcáçovas recognized Spanish sovereignty, and the bitter conquest of the three more populous islands then began. In 1483 the few hundred surviving Guanche warriors on Grand Canary surrendered; La Palma was finally conquered in 1491 and Tenerife in 1496. The islands were used by Columbus on his first transatlantic voyage and became an indispensable Spanish base on sea routes to America.

In 1833–34 the islands were linked by submarine cable to Europe and America. In 1936 Gen. Francisco Franco

used the Canaries as the first base of the Nationalist revolution, going from there to Spanish Morocco.

Castile

The name Castile refers to the central region of Spain, which occupies more than one-quarter of the area of peninsular Spain. Castile represents the limits reached at the end of the Middle Ages by the Kingdom of Castile proper and by the Moorish Kingdom of Toledo, which had been annexed to the Castilian crown at the end of the 11th century. The former is known as Old Castile (Castilla la Vieja). After the Middle Ages the name New Castile (Castilla la Nueva) was given to the former Kingdom of Toledo. The Sierra de Guadarrama forms the approximate dividing line between the two.

Between 1981 and 1983 Castile formed five autonomous communities. The historic region of Old Castile formed three autonomous communities. The largest part of the region became the autonomous community of Castile-León, which includes the modern provinces of Ávila, Soria, Valladolid, Burgos, León, Salamanca, Zamora, Palencia, and Segovia. The province of Santander, which lies north of the Cantabrian Mountains, became the autonomous community of Cantabria. The province of Logroño became the autonomous community of La Rioja. The region of New Castile formed two autonomous communities, Madrid and Castile-La Mancha, the latter comprising the modern provinces of Toledo, Ciudad Real, Cuenca, and Guadalajara.

PHYSICAL AND HUMAN GEOGRAPHY

Castile extends for about 300 miles (480 kilometres) from north to south and 160 miles from east to west. It consists of a vast central plateau, with an average altitude of about 2,500 feet (760 metres). This plateau has a natural frontier of high mountains on all sides, except on the borders of León and Murcia; it is also bisected by the Sierra de Guadarrama and Sierra de Grédos, which extend in a southwesterly direction across the central districts and form the dividing line between Old and New Castile. Geographically it also includes the high plains of León, toward the northwest, and of Murcia on the southeast. The existing frontier is marked on the north by the Cantabrian Mountains; on the east by the Sierra de la Demanda with its offshoots and by the Serrania de Cuenca; on the south by the Sierra Morena; and on the west by minor ranges that link the three more or less parallel chains of the Sierra de Grédos, Sierra de Guadalupe, and Sierra Morena. Three great rivers, the Douro, the Tagus, and Guadiana, flow westward into Portugal and finally reach the Atlantic; while the Ebro, which rises in the north of the kingdom, skirts the northeastern frontier on its way to the Mediterranean.

The climate of Old Castile is healthful but liable to severe cold and heat. Snow falls early and lies late in the mountains, and there is a heavy rainfall in the northwest. New Castile has a still more rigorous climate, for although the mean annual temperature is about 59° F (15° C), the summer heat in the valleys is peculiarly oppressive, and the highlands are swept by scorching or icy gales, laden with dust. The rainfall rarely exceeds 10 inches (254 millimetres) in a year.

Soil conditions in the central plateau

In both the Castiles the central plateau has a naturally fertile soil, but drought is common, owing to the insufficient volume of the rivers and the failure of the Spaniards to extend the fine system of irrigation that the Moors originated. Certain districts, indeed, in which a layer of heavy loam underlies the porous and friable surface, are able to retain the moisture that elsewhere is absorbed. Such land is found in Palencia and in the Mesa de Ocaña, where it yields abundant crops; and many of the northern mountains are well wooded. But vast tracts of land are useless except as pasture for sheep, and even the sheep are driven by the severe winters to migrate yearly into Extremadura. The normal Castilian landscape is an arid and sterile steppe, with scarcely a tree or spring of water; many of the villages are built of sunburnt unbaked bricks, which share the dusty brownish-gray tint of the soil. Especially characteristic is the great plain of La Mancha.

HISTORY

The name Castile—probably meaning "land of castles"—is first found in 800, when it was applied to a small district at the foot of the Cantabrian Mountains in the extreme north of the modern province of Burgos. This territory expanded during the 9th century but remained broken up into petty counties, whose rulers were nominated by the kings of Asturias and Leon, until these counties were united by Fernán González (932–970), the first count of all Castile. He contrived to make the new county hereditary in his family and thus secured a measure of autonomy for it under the kings of Leon. In the time of Fernán González the capital of the county was established at Burgos, where it was to remain, and expansion southward into Moorish territory occurred. Under counts García Fernández (*c.* 970–1005) and Sancho García (1005–17) the territory of Castile reached as far as the Douro (Spanish Duero) River. Relations with the kings of Leon, still nominally suzerains of Castile, were frequently bad.

The urge toward independence shown by the counts and people of Castile from the beginning has been variously explained. It seems likely that the regions conquered by the counts of Castile from the Moors were generally repopulated by emigrants from Cantabria, who had scarcely been affected by Arabic culture and custom, whereas in Leon there was a large immigration of Mozarabs from the Moorish areas further south, thus establishing marked social differences between the two regions. The country of Castile rejected the ancient Visigothic legal code (*Forum Judicum*), the basis of Leonese law, in preference for local customary law. Small, free proprietors were prominent among its people, and a considerable number of minor nobles (*infanzones*), rather than the traditional magnate families of Leon, made up the Castilian nobility. Later, however, the Castilians came to think of themselves as truer representatives than the Leonese of the Visigothic tradition.

The Visigothic tradition

In 1029 Castile lost its autonomy and passed into the hands of Sancho III (the Great) of Navarre. On his death (1035) he left it, as a kingdom, to his son, Ferdinand I. Under Ferdinand it was first united with Leon (1037–65), though the seniority of Leon in the partnership was still recognized. Castile was again united with Leon (1072–1157) under Alfonso VI and Alfonso VII, but thereafter the two kingdoms once more separated. The political and military hegemony of Castile over Leon was established by Alfonso VIII of Castile (1158–1214) who, in 1188, forced the king of Leon to do homage to him. By now, Castilian rule extended far south of the Tagus River and eastward to the modern frontiers of Aragon. The Leonese kings, however, never accepted the claims made by Castile to suzerainty, and Alfonso IX of Leon refused, in consequence, to support Alfonso VIII in his wars against the Almohads. Castilian pursuit of political hegemony over Leon, therefore, partially weakened the Christian front against the Muslims. In 1230 Ferdinand III, already king of Castile, succeeded to the Leonese throne, and both crowns were finally united under Castilian leadership.

An attempt by Castile to annex Portugal by force in 1383–85 failed, but a Castilian prince, Ferdinand of Trastámara, was successfully placed on the Aragonese throne, partly as a result of Castilian financial support and military force, in 1412. This move foreshadowed the personal union of the two crowns under Ferdinand and Isabella. The Kingdom of Navarre was annexed by Castile in 1515.

Castilian political hegemony in Spain

Castilian political hegemony in Spain was an accomplished fact from the middle of the 12th century, and the chanceries of European courts in the later Middle Ages frequently identify Castile with Hispania. The final conquest of most of Andalusia was carried out by Castilian armies in the time of Ferdinand III. The literary language of Spain after its unification was the Castilian vernacular, and the centre of political and administrative power since then has always been in Castile. Nevertheless, opposition to the political hegemony of Castile from the other regions, which enjoyed complete or partial independence in

the Middle Ages, has always remained strong and is still a live political issue, especially since the centres of modern industrial strength in Spain are now largely outside Castile, which, for geographic reasons, is an economically backward area. It has been claimed that medieval Castile was, in all respects, a more progressive kingdom than its neighbours, with a more developed sense of the unity and destiny of Spain. Some of these claims seem exaggerated. The real reason for the dominating part that Castile has played in Spanish history may well have been the superior martial spirit and military organization of its people.

Catalonia

Catalonia (Spanish Cataluña; Catalan Catalunya) is an autonomous community of Spain comprising the four modern provinces of Barcelona, Gerona, Lérida, and Tarragona, with an area of 12,328 square miles (31,929 square kilometres). It is the richest and most highly industrialized part of the country. Formerly a principality of the crown of Aragon, Catalonia has always played an important role in the history of the Iberian Peninsula and since the 17th century has been the centre of a separatist movement often dominating Spanish affairs.

PHYSICAL AND HUMAN GEOGRAPHY

Catalonia occupies a triangular area in the northeastern corner of Spain, bordered by France and Andorra in the north, by Aragon in the west, by Valencia in the south, and by the Mediterranean in the east. A mountainous zone, with more than one-third of its population concentrated in the city of Barcelona, Catalonia is cut off by mountains to the south and west; consequently for much of its history the region has exhibited closer ties with southern France than with the rest of Spain. Catalan, the native language, is spoken also in Roussillon, north of the Pyrenees, and is quite different from Castilian Spanish.

The coast, which is partly sandy, partly rocky, extends about 240 miles (190 kilometres); its chief harbours are those of the capital, Barcelona, of Mataró, of Rosas, and of Tarragona. The surface is much broken by spurs of the Pyrenees, the direction of which is generally south. Running southwest to northeast, and united on the north with one of the offsets of the Pyrenees, is the range of the Sierra Llena, which bisects Catalonia and forms its central watershed. The principal rivers are the Ter, the Llobrégat, and the Ebro, which all run into the Mediterranean. None of them is navigable. The climate, in spite of frequent mists and rains, sudden changes of temperature, and occasional great midday heat, is healthful and favourable to vegetation. The dwarf palm, orange, lime, and olive grow in the warmer tracts; and on the higher grounds the thorn apple, pomegranate, myrtle, esparto, and heaths flourish. There is much woodland, but meadows and pastures are rare. Corn, millet, rye, flax, licorice, and fruits of all sorts—especially nuts, almonds, oranges, figs, walnuts, and chestnuts—are produced. Wheat sufficient for one-fourth of the population is grown, and the vine is extensively cultivated. Few cattle but numbers of sheep, goats, and swine are reared. Game is plentiful, and the fisheries on the coast are excellent. The wines are for the most part rough and strong, though some are very good, especially when matured. They are much used to adulterate those of the Porto region of Portugal or, after undergoing the blending operation termed *compage,* are passed off as Bordeaux wines in France. The best of them, *priorato,* is chiefly known in England, under the disguise of second- or third-rate port; it was much used in the military hospitals of America during the Civil War.

The Catalonians are known for their national pride and strong revolutionary spirit. They are distinct in origin from the other inhabitants of Spain, from whom they differ in their dialect and costume. In their great energy and their love of enterprise they resemble the Basques. Irrigation, careful husbandry, and railroad communications have much developed the resources of their country, in themselves excellent; and there are many manufacturing towns and industrial establishments.

HISTORY

Catalonia was one of the first Roman possessions in Spain, forming the northeastern portion of Hispania Tarraconensis. Occupied during the 5th century by the Goths, it was taken by the Moors in 712, but Charlemagne began the reconquest later in the 8th century, establishing the March of Gothia as a Frankish outpost. Gerona was taken in 785 and Barcelona in 801. This part of Catalonia was then incorporated into the kingdom of the west Franks, but Frankish suzerainty over Catalonia became only nominal and was completely rejected during the reign of Count Borrell (died 991). From 1137, when Count Ramón Berenguer IV was betrothed to Petronila, queen of Aragon, Catalonia and Aragon were united under the same ruler. In the 13th and 14th centuries Catalonia monopolized the trade of the western Mediterranean, and Catalan mercenaries intervened decisively in Italy and Greece. Catalan interests, which differed widely from those of Aragon, dominated the union until 1420, when the male line of the counts of Barcelona became extinct. Dissatisfaction in Catalonia with the new Trastâmara dynasty increased after 1412 until, during the reign of John II, it developed into a full-scale, but unsuccessful, rebellion (1462–72).

Incorporation into the kingdom of the west Franks

During the 16th century, after the marriage of John II's son Ferdinand with Isabella of Castile had brought about the unification of Spain, Catalonia was relegated to a position of secondary importance in Spanish affairs. The Turks seriously interfered with trade in the western Mediterranean, on which Catalan prosperity depended; and the exploitation of Spanish America was reserved for Castile. By the 17th century the conflict of interests between Catalonia and Castile combined with the decline of the Spanish monarchy's prestige to produce the first of those separatist movements by which the history of Catalonia has since been characterized.

The trouble was caused by an economic crisis during the reign of Philip IV. To raise funds, the crown wanted to impose on the whole of Spain a degree of fiscal and administrative unity incompatible with the maintenance of the *fueros* of the lands of the crown of Aragon. The Catalans were determined to resist such efforts of centralization and regarded the shortage of money as due to waste caused by inefficiency at Madrid and rash expenditure on foreign wars. The deadlock was unresolved when, in 1635, war broke out between Spain and France. This aggravated the King's financial position and led to the billeting in Catalonia of "foreign" Castilian troops, whose behaviour initiated a secessionist revolt (June 1640). The rebellious Catalans placed themselves under the protection of the French king Louis XIII, and civil war ensued in which French support was mainly responsible for keeping the Catalan insurgents in the field. The fighting did not end until 1659 when, by the Treaty of the Pyrenees, Philip IV came to terms with the French.

In 1705, again motivated largely by a desire to ensure preservation of its *fueros,* Catalonia, together with Aragon and Valencia, declared its support for the archduke Charles in the War of the Spanish Succession. In 1714, however, Catalonia was completely subjugated by Philip V's forces, and its constitution and privileges were abrogated. Catalonia subsequently lost nearly all its previous autonomy, but it gained by the encouragement given by the Bourbons to industrial development, while the termination of Castile's monopoly of the trade with Spanish America provided a fresh impulse for Catalan commerce and shipping.

Catalan separatism reemerged in the 19th century in rural areas in the support given to Carlism and in the towns in the demands of the manufacturers for high tariffs against British and French competition. The Catalan resurgence, however, really began with the literary Renaixensa of the 1850s. This, at first, involved little more than competitions between Catalan poets and reviving medieval festivals such as the Jocs Florals, but during the 1860s, more serious efforts were made to revive the use of Catalan (then only spoken in rural areas) as a living language, including the establishment of a Catalan newspaper and a theatre for Catalan plays. Catalan nationalism became a serious political force after 1876, when the defeat of the Carlists led the church to transfer its support to the new,

Reemergence of Catalan separatism

rising movement for regional autonomy. It then became a predominantly right-wing movement.

The loss of Cuba in 1898, a dramatic revelation of Spain's political and economic decline, served to revive Catalonian separatism. The electoral victory won in 1901 by the new party, the Lliga Regionalista, showed that Catalan nationalism was politically a force of consequence, and the struggle for autonomy commenced in earnest. By 1913 a slight degree of home rule had been obtained under the *ley de mancomunidades,* but this measure was repealed 10 years later by Primo de Rivera, who attacked all manifestations of Catalan separatism. Primo de Rivera's policy led to the formation of a left-wing coalition party, the Esquerra Republicana, led by Francesc Macià. The Esquerra won a sweeping victory in the municipal elections of April 1931, and two days later Macià proclaimed a Catalan republic. Thereafter a compromise was worked out with the central republic established at Madrid, and in September 1932 the statute of autonomy for Catalonia was passed by the constituent Cortes. Catalonia played a prominent part in the history of the second republic in Spain and in the civil war of 1936–39. The nationalist victory in 1939 meant the loss of autonomy, and Gen. Francisco Franco's government adopted a repressive policy toward Catalan nationalism. Conversely, Catalonia was the most notable centre of opposition to Franco.

The establishment of democratic rule under the constitutional monarchy of Juan Carlos did not decrease Catalonia's desire for autonomy, and in September 1977 limited autonomy was granted to Catalonia. On October 25, 1979, autonomy was ratified by a regional plebiscite, thereby creating the autonomous community of Catalonia.

Extremadura

Extremadura (Estremadura) is a region of western Spain, once economically important because of its rich winter pastures. Extremadura comprises the provinces of Cáceres and Badajoz, with an area of 16,062 square miles (41,600 square kilometres). It is to be distinguished from the Portuguese province of Estremadura, which occupies the central coastal region of Portugal. In 1981 Extremadura became one of the 17 autonomous communities of Spain.

PHYSICAL AND HUMAN GEOGRAPHY

Extremadura is bounded on the north by León and Old Castile, east by New Castile, south by Andalusia, and west by the Portuguese provinces of Beira and Alentejo, which separate it from Portuguese Estremadura. Extremadura consists mainly of a tableland separated from León and Old Castile by the lofty Sierra de Gredos, the plateau of Béjar, and the Sierra de Gata, which form an almost continuous barrier along the northern frontier, with summits ranging from 6,000 to more than 8,500 feet (1,830 to 2,590 metres) in altitude. On the south the comparatively low range of the Sierra Morena constitutes the frontier of Andalusia; on the east and west there is a still more gradual transition to the plateau of New Castile and the central plains of Portugal. The tableland of Extremadura is itself bisected from east to west by a line of mountains, the Sierras of San Pedro, Montánchez, and Guadalupe (4,000–6,000 feet), which separate its northern half, drained by the Tagus River, from its southern half, drained by the Guadiana. The Tagus and Guadiana flow from east to west through a monotonous country, often almost uninhabited and covered with a thin growth of shrubs and grass. A characteristic feature of this tableland is the vast heaths of gum cistus and lavender. The climate in summer is hot but not unhealthful, except in the swamps, which occur along the Guadiana. Sheep farming is the most important of Extremaduran industries. Immense herds of swine are bred and constitute a great source of food to the inhabitants, the pork, bacon, and hams being in high esteem. The beech, oak, and chestnut woods afford an abundance of food for swine, and there are numerous plantations of olive, cork, and fruit trees.

Tableland

In character and physical type, the people of this region are less easily classified than those of other Spanish provinces. Their failure to develop a distinctive local type of character and civilization is perhaps the result of the adverse economic history of their country. The two great waterways that form the natural outlet for Extremaduran commerce flow to the Atlantic through a foreign and, for centuries, a hostile territory.

HISTORY

Historically, this name—popularly supposed to derive from Latin *terra extrema et dura*—was given during static periods of the Christian reconquest of the Iberian Peninsula to whatever then happened to be the zones bordering on Moorish territory. Thus in the 10th and 11th centuries the border approximated to the line of the Duero, or Douro, River from Soria in the east to the Atlantic Coast near Coimbra. Then, during the reign of Alfonso VI of Leon and Castile, the name Extremadura was transferred (*c.* 1086) to a newly conquered region to the south, which included Salamanca, Segovia, and Ávila. Leon, following its southern expansion between 1157 and 1230, also had a province called Extremadura which stretched southward from Ciudad Rodrigo to beyond Badajoz. In the 12th and early 13th centuries, therefore, both Leon and Castile possessed Extremaduran provinces administered as separate entities by each kingdom. Later in the reign of Ferdinand III of Castile and Leon this separate administration was abandoned, and, from the later Middle Ages, the term was applied to a region only slightly larger than the combined area of the two modern provinces.

Galicia

Galicia (the ancient Gallaecia or Callaecia) is a former captaincy-general and a former kingdom, countship, and province in the northwestern angle of Spain. Galicia is bounded on the north by the Bay of Biscay, east by León and Asturias, south by Portugal, and west by the Atlantic Ocean. It has an area of 11,256 square miles (29,153 square kilometres). In 1833 Galicia was divided for administrative purposes into the provinces of La Coruña, Lugo, Orense, and Pontevedra. In 1981 the historic region of Galicia became one of the 17 autonomous communities of Spain, retaining its four provinces.

PHYSICAL AND HUMAN GEOGRAPHY

The highland north of the headwaters of the Miño forms the sole connecting link between the Cantabrians properly so called and the mountains of central and western Galicia. The average elevation of the province is considerable, and the maximum height (6,593 feet [2,009 metres]) is reached in the Peña Trevinca on the eastern border of Orense.

The principal river is the Miño (Portuguese Minho; Latin Minius; so named, it is said, from the minium, or vermillion, found in its bed). Rising near Mondoñedo, within 25 miles (40 kilometres) of the northern coast, the Miño enters the Atlantic near the port of Guardia, after a course of 170 miles south and southwest. Of its numerous affluents the most important is the Sil. Other rivers include the Tambre, the Ulla, and the Lerez, or Ler, which falls into the Atlantic by estuaries, or *rias,* called, respectively, Ria de Muros y Noya, Ria de Arosa, and Ria de Pontevedra.

According to Eratosthenes (276–196 BC) the entire population of the peninsula was at one time called Galatae. The region properly called Gallaecia, bounded on the south by Douro and on the east by the Navia, was first entered by the Roman legions under Decius Junius Brutus in 137–136 BC, but the final subjugation cannot be placed earlier than the time of Augustus (31 BC–AD 14).

The coastline of Galicia, extending to about 240 miles, is bold and deeply indented, presenting a large number of secure harbours. The Eo, which bounds Galicia on the east, has a deep estuary, the Rivadeo, or Ribadeo, which is a good harbour. Vivero Bay and the Ria del Barquero y Váres are of a similar character, while the harbour of Ferrol is an important naval station. On the opposite side of Betanzos Bay is the great port of Corunna, or Coruña. The principal port on the western coast is formed by the deep and sheltered Bay of Vigo, but there are also good roadsteads at Corcubion, at Marin, and at Carril.

Features of the coastline

The rainfall is exceptionally heavy, and snow lies on some of the high ground for a considerable portion of the year. Much timber is grown on the highlands, and the rich valley pastures support large herds of cattle and swine. In the lowland districts good crops of corn, wheat, barley, oats, and rye, as well as of turnips and potatoes, are obtained. The *dehesas,* or moorlands, abound in game, and fish are plentiful in all the streams. The mineral resources of the province, which are considerable, were known to some extent to the ancients. Strabo (*c.* 63 BC–AD 21) speaks of its gold and tin, and Pliny (AD 23–79) mentions the *gemma Gallaica,* a precious stone. Galicia is also remarkable for the number of its sulfur and other warm springs, the most important of which are those at Lugo and Orense.

HISTORY

In the Middle Ages Galicia was one of the constituent kingdoms of the crown of Castile. Its name is derived from the Gallaeci, who lived there when the region was conquered by the Roman legions *c.* 137 BC. The Gallaeci were probably not Iberians. Some historians consider that the region was heavily settled by Celts, but this has been disputed. In Roman and Visigothic times Galicia stretched south to the Douro and eastward to beyond the city of León. From *c.* 410 it was an independent kingdom under the Suebi until 585 when the latter were finally destroyed by Leovigild. After 711 its population was greatly increased by an influx of Visigothic refugee settlers who were able to establish themselves in its river basins. The language of Galicia is closely related to Portuguese, and the existence of a separate Galician-Portuguese language can be discerned by the early 11th century. By the 13th century there was a flourishing tradition of lyric poetry in Galicia, and, as a result, Galician-Portuguese became the language even of Castilian lyric poets until late in the 14th century.

Despite its clear ethnic, linguistic, and geographic differences from the rest of Spain, and its remoteness from the centre, Galicia rarely sought political independence. As a result of Alfonso III's division of his kingdom, it was ruled by Ordoño II as king (910–914), by Sancho I as a refugee (926–929), and by García, son of Ferdinand I, as king (1065–71). After 1369 it was unwilling to accept the usurpation of Henry II of Trastámara and, for a time, seemed disposed to accept Ferdinand of Portugal as king. Probably the possession of the national shrine of St. James of Compostela (Santiago de Compostela) from the 9th century attached the Galicians, for religious and economic reasons, firmly to the central kingdoms. In modern times there has been a revival of interest in the Galician language and culture. (P.E.R./Ed.)

León

León is a traditional region of Spain. In 1981 León became one of the provinces of the autonomous community of Castile-León.

PHYSICAL AND HUMAN GEOGRAPHY

In the northern part of the province is the high Cantabrian range, the highest peak of which is the Torre Cerredo (8,688 feet [2,648 metres]). This part of the province also contains the passes of Tarna, San Glorio, Pontón, and Pajares, which have links with Santander and Asturias. The natural regions are El Bierzo, a lowland where mining has replaced agriculture; La Montaña, comprising the judicial districts of Murias, Vecilla, and Riaño; and La Meseta, a dry desert with fertile strips, such as that along the Órbigo River. The climate is extreme continental. The main catchment area is the basin of the Esla, a tributary of the Duero (Douro), in which is situated the large dam at Ricobayo. Tributaries of the Esla are the Cea, Porma, Bernesga, and Órbigo. The second most important river basin is that of the Sil, which runs through Bierzo. Other rivers are the Sella and the Cares.

The main crops are cereals, flax, and hops, León being the most important producer of hops in Spain. Timber resources include oak, beech, and chestnut. Cattle, donkeys, and sheep are bred. There are deposits of anthracite, iron, bituminous coal, and mica; Ponferrada is a great coal- and iron-mining area. The considerable mineral resources offer prospects for industrial development. Chemical factories have been established for the manufacture of antibiotics.

The city of León

The city of León is the capital of the province and is located on the Bernesga, 83 miles (134 kilometres) north-northwest of Valladolid by road. It is on the Madrid–Oviedo road and railway; there are other railway lines to La Coruña and to Bilbao. It developed from the camp of the Roman seventh legion, its modern name being a corruption of the Latin *legio.* A monumental city with a wealth of artistic interest, it attracts large numbers of tourists. Especially remarkable are the fine Gothic cathedral, noteworthy for its stained-glass windows known as the Pulchra Leonina, the Romanesque collegiate church of San Isidoro, and the Renaissance-style church of San Marcos. After recapture from the Muslims, León became the capital of the Kingdom of Asturias and Leon in the 10th century when García I transferred his court there from Oviedo. An important market town on the pilgrimage route to Santiago, León exercised considerable political, cultural, and economic influence during the Middle Ages. The street names of the old part of the city recall the offices and structure of the medieval town. The economic life of the city declined in the 16th century and did not revive until the 19th with the development of mining. By the mid-20th century León was resurgent, with a new city and increasing industrialization.

HISTORY

In the later Middle Ages, the Kingdom of Leon covered the area of the modern provinces of León, Palencia, Valladolid, Zamora, and Salamanca, together with the Asturian province of Oviedo. The medieval kings of Leon also ruled Galicia and as much of the county of Portugal as had been reconquered before that country achieved independence in 1140. They were, in name at least, suzerains of the county of Castile until 1035. The group of dialects spoken and written in medieval Leon (Asturo-Leonese) were clearly demarcated from the language of Castile. Today these dialects survive strongly only in Asturias and, to some extent, in rural León as far south as Zamora. There is a popular literature and music of folktales, ballads, and other songs.

The rise of the medieval Leonese kingdom began with García I (909–914), who set up his court on the site of the former Roman permanent camp of the Legio VII Gemina. The period of Leonese hegemony in Christian Spain nominally lasted until the death of Alfonso VII (1157), but it had, long before, been seriously undermined by the conquests of Sancho the Great (1000–35) of Navarre and by the elevation, on his death, of Castile from county to kingdom. During the whole of the 10th century, when the Caliphate of Córdoba was at its most powerful, Leon lost ground in the struggle with the Moors, and its kings often had to accept a de facto submission to the caliphs. Leon, however, had inherited from the Asturian monarchy a strong attachment to Visigothic tradition, and its rulers, sometimes taking the title of emperor or king of all Spain, tried to further the Reconquest wherever possible. The second period in Leonese history runs from 1157 to 1230, when the kingdom was ruled, in separation from Castile, by its own kings Ferdinand II (1157–88) and Alfonso IX (1188–1230). Relations with Castile were rarely friendly, but Leon was stable during this time and won notable victories over the Moors in Leonese Extremadura. After the final union with Castile (1230), Leonese political and administrative institutions were, for a time, maintained, and the records of the Cortes show that some sense of the separate identity of Leon survived into the first half of the 14th century. In modern times, however, the revival of separatist feelings in various parts of Spain has awakened no response in Leon, now a predominantly agricultural and rather backward region.

Final union with Castile (1230)

During the first century of its existence there was a large influx of Mozarabic immigrants into Leon. These introduced strong Arabic linguistic and cultural influences into the kingdom. Modern Spanish historiography—concerned often to justify medieval Castilian separatism—has tended

to portray medieval Leon as an archaizing, Byzantine type of state overready to compromise with the Moors. The evidence for this is not wholly convincing. Leon successfully bore the brunt of the caliphate's attacks and seems to have been the first peninsular kingdom to evolve popular parliamentary institutions. (P.E.R./M.B.F./Ed.)

Murcia

PHYSICAL AND HUMAN GEOGRAPHY

Murcia is part of the ancient kingdom of Murcia, made up of Albacete and Murcia, and in 1981 it became one of the 17 autonomous communities of Spain. It is situated mainly in the Penibetic mountain (Sistema Penibético) region. The Segura forms the basis for irrigation in the Murcian plain; its principal tributary is the Guadalentin. On the coast lies the Mar Menor, a large saltwater lagoon of 66 square miles (170 square kilometres). National highways and railways cross the province. It is an important producer of lemons and oranges. Other crops include esparto, hemp, cotton, saffron, and olives. There are rich deposits of zinc, lead, and sulfur; copper and tin are also mined. There is a large oil refinery at Escombreras on the coast. Other industries include the manufacture of chemicals and vegetable canning. Ports include the naval base at Cartagena, with the Bazan shipyards, and the fishing port at Mazarrón. There is a paratroop training base at Alcantarilla. Main towns include Lorca, Yecla, Cieza, and Caravaca.

The town of Murcia

The town of Murcia, the seat of a bishopric, is situated at the confluence of the Segura and Guadalentín (Sangonera) rivers, in a rich and fertile area known as the *huerta.* The Segura divides the city in two, the more important part lying on the left bank. The cathedral (Sta. Maria) dates from the 14th to 16th century but was restored in the 18th. It contains the fine chapel of the Vélez family (1507). In the Ermita de Jesús are the majority of the Passion sculptures of Francisco Salcillo; they attract many visitors during Holy Week. The University of Murcia was founded in 1915.

Murcia is a communications centre and an agricultural trade centre for citrus fruits, almonds, cereals, olive oil, and pepper cultivated in the *huerta.* The silk industry, which dates from Moorish times, is still carried on; manufactures of woollen, linen, and cotton goods, saltpetre, flour, leather, aluminum products, furniture, and hats have been established.

HISTORY

There was a town at Murcia before the Roman occupation of southern Spain in the 3rd century BC, but its name then, and during the Roman rule, is unknown. Its name is first mentioned in the histories and chronicles of the Muslims, and, according to the Arab geographer Yaqut, it was founded in 825 by the Umayyad amir of Córdoba, ʿAbd ar-Raḥmān II, who made it the capital of the province. After the fall of the Caliphate of Córdoba in 1031, it came under the control of Almería, and then of Valencia, until in 1063 its ruler, ʿAbd ar-Raḥmān ben Ṭāhir, declared himself independent.

The kingdom's very complicated history is consistent in representing a nationalistic interpretation of Islām. The ruler ʿAbd ar-Raḥmān ben Ṭāhir declared himself independent in 1063, though to preserve the fiction of the religious unity of the caliphate he took the title not of king (*malik*) but of minister (*hachib*). An attempt by the ruler of the *ṭāʾifa* (petty kingdom) of Seville to annex Murcia in 1079 failed because of a rebellion by the ruler's own vizier. For about 10 years thereafter Murcia played an intermediary role between the Almoravids and the Castilians, but in the end religious sympathies inclined it toward the former. The Almoravid caliph Yūsuf ibn Tāshufīn, who brought the quarrelling *ṭāʾifa*s under his control, took possession of Murcia in 1092, incorporating it into his empire.

The Almoravids imposed a completely military regime, which provoked discontent. In 1144 a former king of Zaragoza, Abu Ch'afar ben Hud (Zafadola), started a rising that became general. Involved internal struggles led Murcia to submit to Zafadola's authority, exercised by one of his lieutenants, Abd Allah ben Iyad, who administered the territory as a kingdom. Iyad contrived to unite Valencia and Murcia in a single kingdom after Zafadola's death. In 1147 Iyad was succeeded by Mohammed ben Mardanish. For 20 years, Mardanish led the struggle against a new invading force from North Africa, the Almohads. But a family quarrel, begun in 1168, led to the downfall of the kingdom, and, on dying, Mardanish recommended that his sons submit to the Almohads. In spite of this, Murcia retained an autonomous administrative system; it was conserved by the Castilians when they took possession of the territory, almost without a struggle, in 1243.

Navarre

Navarre (Navarra) is a traditional region of northern Spain. Originally formed by the Basques into a kingdom in the 9th century, it was not annexed to the Spanish crown until 1512. Under the Nationalist government it enjoyed a limited economic autonomy. In the remote districts, Lower and Upper Navarrese (Basque subdialects) and Navarro (Aragonese dialect) are still spoken. Navarre is one of the 17 autonomous communities of Spain and consists of Navarra province. It is bounded by the French Pyrenees to the north, Guipúzcoa province to the northwest, Álava and Logroño to the west, Zaragoza (Saragossa) to the south and southeast, and the Aragonese province of Huesca to the east.

PHYSICAL AND HUMAN GEOGRAPHY

Navarre has a great variety of scenery as it stretches from the western Pyrenees to the Ebro steppes. A tripartite division is clear: the Pyrenean sector, the central basins and hills, the southern plateaus and steppes. The Pyrenean sector consists of a tangled relief of forested mountains and well-watered valleys. The ranges consist largely of sandstones with rounded and more subdued relief (seldom exceeding 4,000 feet [1,200 metres]) than the central Pyrenees. The chief Pyrenean road pass is the Col de Roncesvalles (Puerto de Ibañeta; 3,468 feet), with two others to the northwest, the Puertos de Maya (Otsondo) and de Vera. The region is largely drained by the Bidasoa, an Atlantic stream. The lower basin, called Cinco Villas, has a relatively dense population in scattered hamlets. Iron workings have encouraged small metallurgical industries at Vera and Elizondo, linked by a narrow-gauge railway to Irún; but the dense stands of timber and pastoralism are the main sources of wealth.

The central depression, now utilized by the railway from Vitoria to Pamplona and then by a narrow-gauge line to Sangüesa on the Aragón river, has played a vital role in Navarrese history. It has united the diverse Pyrenean valleys and focussed commerce on the provincial capital, Pamplona. In this climatically transitional zone, cereal cultivation mingles with forest lands and stock rearing, and settlements become more nucleated into villages.

The southern half of Navarre consists essentially of foothills and steppes through which the valleys of the Ega, Arga, and Aragón run centripetally to the Ebro. The position of Tudela near the confluence of these valleys explains its role as a regional market town. The landscape is more arid and monotonous, with cultivation of cereals and large nucleated settlements; *e.g.,* Estella and Tafalla. Las Bárdenas on the southeastern borders is true steppe.

HISTORY

The Kingdom of Navarre

The Kingdom of Navarre was formed out of a part of the territory occupied by the Vascones (*i.e.,* the Basques and Gascons), who lived on the southern slope of the western Pyrenees and part of the shore of the Bay of Biscay. In the course of the 6th century there was a considerable emigration of Basques to the north of the Pyrenees. The cause is supposed to have been the pressure put upon them by the attacks of the Visigoth kings in Spain. The name of Navarre is derived by etymologists from *nava,* a flat valley surrounded by hills, and *erri,* a region or country. It began to appear as the name of part of Vasconia toward the end of the Visigoth epoch in Spain in the 7th

century. Its early history is more than obscure. The first historic king of Navarre was Sancho Garcés, who ruled at Pamplona in the early years of the 10th century. Under him and his immediate successors, Navarre reached the height of its power and its extension. When the kingdom was at its height it included all the modern province of the name: the northern slope of the western Pyrenees called by the Spaniards the Ultrapuertos ("country beyond the passes"), and now known as French Navarre; the Basque Provinces; the Bureba, the valley between the Basque Mountains and the Montes de Oca to the north of Burgos; the Rioja and Tarazona in the upper valley of the Ebro. In the 12th century the kings of Castile gradually annexed the Rioja and Álava. About the year 1200 Alfonso VIII of Castile annexed the other two Basque provinces, Biscay (Vizcaya) and Guipúzcoa. Tarazona remained in possession of Aragon. After 1234 Navarre, though the crown was claimed by the kings of Aragon, passed by marriage to a succession of French rulers. In 1516 Spanish Navarre was finally annexed by Ferdinand the Catholic. French Navarre survived as an independent kingdom until it was united to the crown of France by Henry IV, founder of the Bourbon dynasty. From 1510 until 1833, when it was fully incorporated with Spain, Navarre was a viceroyalty.

The whole kingdom was mountainous except for the Tudela salient in the southeast, where the dry plains called Las Bárdenas provided an important grazing region. Though Navarre at an early date ceased to have a frontier with the Moors, a considerable Moorish population lived there, notably in Tudela. The Navarrese Moors were allowed to serve in the army and also provided a source of skilled artisans. Large Jewish aljamas (congregations) existed in the chief towns and were protected by the Navarrese kings when persecution became serious elsewhere. Another important element were the *francos*—mostly French and Gascon immigrants—who inhabited separate quarters in Pamplona and other towns. Their relations with the native Navarrese were often strained.

Despite its small size in the later Middle Ages, Navarre had an important part in international politics, not only because of its rulers' involvement in French affairs but also because it controlled the main pass into Spain in the western Pyrenees and was a buffer state between Gascony, Castile, and Aragon. The chief pilgrim roads from the north to Santiago de Compostela thus traversed it. From its earliest days to 1234, after which a succession of French dynasties ruled Navarre, the kingdom's history fell within a wholly Spanish context and was closely associated with that of Aragon. Afterward strong French political and institutional influences can be detected.

The route to Santiago de Compostela

Pamplona was Moorish territory after 711, but the Basque magnates of the region early achieved some degree of autonomy and (*c.* 798) one of them, Iñigo Arista, established himself as an independent ruler there and, for a time, accepted Frankish suzerainty. By the time of García Iñíguez (*c.* 860–880) this dynasty was strong enough to assume regal titles and to establish diplomatic and family relations with Asturias. Under Sancho Garcés (905–925) the rulers of Pamplona extended their dominions south of the Ebro, capturing Nájera and much of La Rioja. By a combination of diplomatic dexterity and military strength the kingdom survived, relatively unscathed, the heyday of the caliphate in the 10th century. During the reign of Sancho III the Great (1005–35), the Navarrese were able to establish a brief hegemony over all Christian Spain. Sancho's empire was, however, short-lived, and in 1076 Sancho Ramírez of Aragon (1063–94) occupied Pamplona.

Until 1134 Navarre was then ruled by the Aragonese crown. It recovered its independence when the Navarrese proclaimed García V the Restorer (1134–50) as king. An entirely new orientation was given to Navarrese history in 1234 when Sancho VII (1194–1234) was succeeded by his nephew, Theobald I (1234–53), count of Champagne, and a succession of French rulers with important possessions in France ruled the kingdom. Historically the most famous of these French rulers was Charles II the Bad (1349–87), count of Évreux, under whom Navarre became internationally of great importance because of the King's involvement in French politics and the spread of the Hundred Years' War to the kingdoms of the Iberian Peninsula. Charles himself had ambitions to recover for his kingdom the territories in Spain that had belonged to Sancho the Great. He has been criticized for the brazen way in which he constantly altered Navarrese foreign policy to meet rapidly changing foreign pressures. Charles managed, however, to retain the loyalty of his subjects and to preserve the independence of Navarre.

The reign of Charles III (1387–1425) was relatively tranquil, but John II of Aragon became ruler of Navarre by marriage (1425–79), and the kingdom was then the scene, for years, of civil war among his supporters, those of his son and heir, Charles, prince of Viana, and other factions favouring union with France or with Castile. In 1484 the throne passed to John II of Albret, but independence had now become impossible due to Navarre's position between two major, mutually hostile states, France and Spain. In 1512 Ferdinand the Catholic occupied the Spanish portion of Navarre, which was formally annexed to the Castilian crown in 1516 but retained its status, institutions, and law as an independent kingdom until the 1800s.

In the later Middle Ages Navarre was divided administratively into five *merindades*—La Ribera (Tudela), Sangüesa, Pamplona (La Montaña), Estella, and Allién Puertos; in the last the functions of royal *merinao* were carried out by the *castelán* of St. Jean-Pied-de-Port. Under the *merinos* were the *sozmerinos* and, in the towns, the *bailes.* The chief military officer of the kingdom was the *alférez.* The treasury was partly modelled on the French system under a *recibidor general* or *tesorero,* with *recibidores* in each *merindad.* The somewhat ambiguous international status of Navarre was reflected in its coinage; apart from local currency, French, Gascon, and Aragonese money circulated freely. The law was based on the *Fuero General de Navarra* (a body of customary law built up before 1155) but much modified in different localities by local *fueros.* Efforts by some of Navarre's French rulers to undermine customary law were effectively resisted. In the 14th century one-sixth of the whole population claimed *hidalguía* (noble descent) and the tax exemption that went with it. The Corte General of Navarre controlled, in theory, not only extraordinary subsidies but also ordinary taxation. Since, however, it was the king's prerogative to decide who should be summoned and when, the Navarrese parliament had little real power. Ecclesiastical jurisdiction in Navarre was complicated, the bishops of Dax and Bayonne (in Gascony), Tarazona (Aragon), and Calahorra (Castile) having, or claiming, authority over outlying regions. Shortage of manpower was a constant concern from a military point of view; the earliest *fueros* had not contemplated the existence of a formal army at all. Later the defense of the kingdom rested on a large number of small castles. To increase reserves in war the later kings (notably Charles II) enlisted large numbers of foreign knights and their retinues as *mesnaderos.* Navarrese culture in the late Middle Ages was much influenced by the pilgrim route, and French influences were naturally predominant.

Valencia

Valencia was the name of an ancient kingdom in Spain. When the kingdom was incorporated into Aragon in 1238, it included the provinces of Castellón de la Plana, Valencia, and Alicante. Located on the eastern coast of Spain, the kingdom was bounded on the north by Catalonia, on the west by Aragon and New Castile, and on the south by Murcia. The modern province of Valencia has an area of 4,156 square miles (10,763 square kilometres). In 1982 Valencia, along with the provinces of Alicante and Castellón, became the Spanish autonomous region of Comunidad Valenciana.

PHYSICAL AND HUMAN GEOGRAPHY

The inhabitants are of very mixed race, owing to the successive occupation of the country by Iberians, Greeks, Carthaginians, Romans, Visigoths, and Moors. Their dialect resembles Catalan but is softer and contains a larger percentage of Arabic words.

The elaborate irrigation works and system of intensive agriculture, which have made the *huertas* ("gardens") of Valencia famous, were initiated by the Moors, as were the Elche date groves, Alicante vineyards, and Valencia orange plantations. The coast is skirted by considerable stretches of sand dune, and by a series of these the lagoon called the Albufera de Valencia is separated from the Mediterranean.

Principal rivers

The principal rivers are the Guadalaviar, or Turia, and the Júcar.

The *vegas* ("plains") have an exceptionally fine, almost subtropical climate. In their low-lying portions rice is the favourite crop; elsewhere wheat, corn, and all kinds of fruit are raised; the mulberry is cultivated for silk; and wine and oil are produced. Esparto grass is grown in the less fertile areas. The fishing industry is considerable, and there are manufactures of silk, carpets, and tapestry, woollen, hemp, and linen fabrics, glass, pottery, and leather; there are also iron foundries, distilleries, cooperages, and oil refineries. The coast railway from Barcelona traverses the province. Valencia is the capital and principal seaport.

The province centres on the coastal plain of the Gulf of Valencia. It is limited to the south by the mountains of northern Alicante and less clearly to the north by the watershed of the Turia drainage. Westward, the interior plateaus rise in a series of faulted steps, representing the edge of the Meseta, trenched by the gorges of the middle course of the Júcar River and its tributary the Cabriel. The Turia follows a structural depression providing an easy route into Aragon, via the Teruel corridor. Much of the interior is wild, sparsely populated country, opening out onto the lower and richer lands of Requeña and Liria. The coastal plain (1,244 square miles [3,222 square kilometres]) is the largest in eastern Spain, and more than three-quarters of the province's wealth and most of its population are concentrated in this area.

With an average rainfall of only 14–15 inches (335–380 millimetres) the plain would be substeppe but for the irrigation works developed by the Moors and expanded over the centuries. Broadly speaking, there are three major systems of irrigation: the Vega of Valencia, under horticulture and watered by the Turia; the Ribera, irrigated from the Júcar since the Middle Ages and extended several times chiefly for orange groves and rice; and the bordering hill lands, irrigated by pump for orange growing. Near the coast, south of the city of Valencia, the lagoon La Albufera has been reclaimed for rice cultivation.

Besides the city of Valencia and its suburbs—Burjasót, Paterna, Manises, and Mislata—the other chief towns are Alcira, Carcagente, Játiva, Onteniente, Sueca, Cullera, Gandia, Oliva, Algemesi, Tabernes de Valldigna, Torrente, and Sagunto, concentrated mostly in the south of the plain.

HISTORY

The Kingdom of Valencia was a Muslim principality, independent at intervals from 1010 to 1238. When Umayyad power disintegrated in the reign of Hisham II, Valencia was ruled first by two irrigation officials, then by the slave general Labib, and subsequently by Abd al-Aziz al-Manṣūr (1021–61). Stabilized by the protection of the Hammudite caliphs of Córdoba and by friendship with Christian princes, his reign marks a period of peace and prosperity. His successor, however, a minor, 'Abd al-Malik (1061–65), was attacked by Ferdinand I of Castile and Leon, who failed to capture Valencia but inflicted such a defeat on its defenders that they sought protection from al-Ma'mūn, the ruler of Toledo. Al-Ma'mūn deposed the minor, and from 1065 to 1075 Valencia formed part of his domains.

Leadership of Abū Bakr

The effeminacy of al-Kadir, al-Ma'mūn's successor, permitted the Valencians to reassert their independence under the leadership of the Toledan governor, Abū Bakr, who allied himself with Alfonso VI of Leon and Castile. But when the latter took Toledo in 1085, he installed al-Kadir as puppet ruler in Valencia with mercenary support. The following year when the mercenaries were recalled to stem the Almoravids, al-Kadir was left defenseless before his hostile subjects. Several potentates manoeuvred to depose him. The Count of Barcelona, allied with the Muslim ruler of Zaragoza, besieged Valencia (1089). To forestall them Alfonso offered the spoils of the city to the freebooter Rodrigo Díaz de Vivar, the Cid. On his approach the siege was lifted, but the Cid found it more politic to exact protection money from al-Kadir than to occupy the city. This was forced on him when the Valencians assassinated al-Kadir in 1092 and constituted themselves as a republic under Almoravid protection. The Cid ruled Valencia from 1094 to his death in 1099. When his widow was forced to relinquish the kingdom to the Almoravids in 1102, the Christians burned the city before evacuating it.

For the next 30 years Valencia was ruled by Almoravid governors, but in the confused period that preceded the arrival of the Almohads the city again recovered a measure of independence. The Valencians admitted as their overlords several ephemeral Murcian princelings, until the Valencian Ibn Mardanish seized control of both kingdoms in 1147. This prince, of Spanish origins, aroused popular opposition in Valencia by his alliances with the Christians, and in 1151 the Valencians, with Almohad support, revolted against him. The kingdom remained in the hands of local rulers, vassals of the Almohads, until it fell to James I of Aragon on September 28, 1238.

Physical and human geography. *General works:* The *Anuario Estadístico de España,* which is published annually by the Spanish government, contains general statistical information about the country. The *Enciclopedia Universal Ilustrada Europeo-Americana,* 70 vol. (1908–30; supplements, 1930–), provides detailed information about Spain, its regions, and its towns, especially in vol. 21, *España,* and under "España" in the supplements. PASCUAL MADOZ, *Diccionario geográfico-estadístico-histórico de España y sus posesiones de ultramar,* 16 vol. (1846–50), is still a valuable reference book despite the many years since its original publication. STEPHEN CLISSOLD, *Spain* (1969), and MATILDE MOLINER RUIZ, *España y los españoles* (1968), are informative books about the country and its regions; Spanish history is also treated.

The land: General information about Iberian geography may be found in books about the Mediterranean area, especially JAMES MCINTOSH HOUSTON, *The Western Mediterranean World: An Introduction to Its Regional Landscapes* (1964). MANUEL DE TERAN (ed.), *Geografía de España y Portugal* (1952–67), is the most complete work on the subject. J. VILA VALENTI, *La Península ibérica* (1968; new ed., 1978), gives a good, concise description of the country. HERMANN LAUTENSACH, *Iberische Halbinsel* (1964), constitutes a comprehensive geography of the Iberian Peninsula. WILLIAM BAYNE FISHER and HOWARD BOWEN-JONES, *Spain: An Introductory Geography* (1966), is a general manual. ADOLPH SCHULTEN, *Iberische Landeskunde. Geographie des antiken Spanien,* 2 vol. (1955–57), is an exhaustive scholarly work on the geography of the Iberian Peninsula in early historic times.

The people: The FUNDACION FOESSA, *Informe sociológico sobre la situación social de España* (1970), is a detailed survey of Spanish society, with extensive statistical information; it is periodically updated by *Síntesis actualizada.* JOSE CAZORLA, *Estratificación Social en España* (1973), is a discussion of classes in Spanish society. JUAN VELARDE FUERTES, *Economía y sociedad de la transition* (1978), is a discussion of Spain's economy and society in the years following the Franco regime. The most complete work on Spain's social structure is AMANDO DE MIGUEL, *Manual de estructura social de España* (1974). JULIO CARO BAROJA, *Los pueblos de España. Ensayo de etnología* (1946), is a well-documented account of the development of the Spanish people, from prehistoric times to present-day ethnological regions.

The economy: A general survey in English of the Spanish economy before the late 1970s is GEORGE HILLS, "Spain Under Franco: The Economic 'Miracle' 1959–67," in his *Spain* (1970). For the period of transition to democracy, see JOSE L. GARCIA DELGADO and JULIO SEGURA, *Reformismo y crisis económica* (1977); and RAMON TAMAMES, *Estructura Económica de España* (1980). The Organisation for Economic Co-operation and Development publishes occasional economic surveys of Spain in several languages, which contain much basic information. RODNEY H. MILLS, *The Spanish "Miracle": Growth and Change in the Spanish Economy, 1959 to mid-1965* (1966), is a staff economic study for the Board of Governors of the Federal Reserve System. RICHARD HUMBERT, *Spain* (1970), is published by the United States Bureau of International Commerce.

Transportation: *Las Obras Públicas* (annual), an account of the activities of the Ministry of Public Works for the year;

JOSE IGNACIO RAMOS TORRES and MARCOS MARTIN BLANCO, *El Transporte en España: Organización y magnitudes económicas* (1966), a study of the Spanish transportation system, with emphasis on economic and legal aspects; COMISARIA DEL (II) PLAN DE DESARROLLO ECONOMICO Y SOCIAL, *Transportes* (1967), an official analysis of the evolution, problems, objectives, investments, and operations of the Transport Division.

Administration and social conditions: *Anuario Político Español* (annual), a nonofficial publication, political in nature, that examines social and economic questions; OSCAR ALZAGA, *La constitución Española de 1978* (1978), an explanation of the basic principles of the Spanish constitution; *Informe económico* ("Economic Report"), a general review of the economy issued annually by the Bank of Bilbao; JOSE ANTONIO CARMONA GUILLEN, *Estructura electoral local de España* (1979), a description of Spain's local electoral structure; RAMON MARTIN MATEO, *Manual de derecho administrativo* (1980), a complete summary of the Spanish system of administration; RAUL MORODO, *Los partidos políticos en España* (1979), a description of Spain's political parties; for information on the formation of autonomous communities in Spain, see MINISTRY OF CULTURE, *Cultura Española y autonomías* (1980); MANUEL GARCIA PELAYO, *El tema de las nacionalidades* (1979); JOSE F. History. The principal bibliographical guide to Spanish history is BENITO SANCHEZ ALONSO, *Fuentes de la historia española e hispanoamericana,* 3rd ed., 3 vol. (1952). LUIS G. DE VALDEAVELLANO, *Historia de España,* vol. 1 (1952), is the best general history, but it extends so far only to 1212. The most comprehensive work eventually will be the collaborative *Historia de España* under the editorial direction of RAMON MENENDEZ PIDAL, of which five volumes have thus far appeared. Among the most important interpretive works is AMERICO CASTRO, *España en su historia* (1948; Eng. trans., *The Spaniards: An Introduction to Their History,* rev. ed., 1971), which centres on his thesis emphasizing the medieval interaction of Christians, Muslims, and Jews. CLAUDIO SANCHEZ-ALBORNOZ has taken sharp issue with Castro in his *España, un enigma histórico,* 2 vol. (1956). RAMON MENENDEZ PIDAL, *Historia de España,* vol. 1 (1947; Eng. trans., *The Spaniards in Their History,* 1950), is a judicious essay on the formation of the Spanish character. A highly readable and provocative overview of the trends of Spanish history is given by JAIME VICENS VIVES in his *Aproximación a la historia de España,* 5th ed. (1962; Eng. trans., *Approaches to the History of Spain,* 2nd ed. rev., 1970).

Ancient Spain: For prehistoric Spain, see LUIS PERICOT GARCIA, *La España primitiva* (1950); or ANTONIO GARCIA Y BELLIDO, *La península ibérica en los comienzos de su historia* (1953). GARCIA Y BELLIDO is also the author of works on the Carthaginians and Greeks in Spain: *Fenicios y Carthagineses en occidente* (1942) and *Hispania Graeca,* 3 vol. (1948). A useful work in English on the Roman period is C.H.V. SUTHERLAND, *The Romans in Spain, 217 B.C.–A.D. 117* (1939).

Medieval Christian Spain: In addition to the general works cited above, the following may be helpful: LUIS G. DE VALDEAVELLANO, *Curso de historia de las instituciones españolas. De los orígines al final de la edad media* (1968), an excellent survey of medieval institutions; ALFONSO GARCIA GALLO, *Manual de historia del derecho español,* 3rd ed. rev., 2 vol. (1967), especially valuable for its collection of documents relating to government and law. A useful work on its subject is JAIME VICENS VIVES, *Manual de historia económica de España,* 5th ed. (1967; Eng. trans., *An Economic History of Spain,* 1969). E.A. THOMPSON, *The Goths in Spain* (1969), is an informative study of the Visigothic kingdom. YITZHAK BAER, *A History of the Jews in Christian Spain,* 2 vol. (1961; originally published in Hebrew, 1959), treats one of the principal elements in medieval society and makes use of a wealth of sources. A classic work delineating the life of the Cid and placing him in the context of the 11th century is RAMON MENENDEZ PIDAL, *El Cid en la historia* (1921; Eng. trans., *The Cid and His Spain,* 1934). ROBERT I. BURNS, *The Crusader Kingdom of Valencia,* 2 vol. (1967), is a useful study of the settlement of Valencia after the Christian reconquest. See also EDWARD JAMES (ed.), *Visigothic Spain* (1980), a collection of essays.

Muslim Spain: The best work in English is W. MONTGOMERY WATT, *A History of Islamic Spain* (1965); see also E. LEVI-PROVENCAL, *Histoire de l'Espagne musulmane,* 2nd ed., 3 vol. (1950), and *L'Espagne musulmane au Xe siècle* (1932).

1479–1700: JOHN H. ELLIOTT, *Imperial Spain, 1469–1716* (1963), is the only single work covering precisely this period. JOHN LYNCH, *Spain Under the Habsburgs,* 2 vol. (1964–69), is based on modern research, especially in economic history. ROGER B. MERRIMAN, *The Rise of the Spanish Empire in the Old World and in the New,* vol. 2–4 (1918–34), covers the period from the Catholic Kings to Philip II. It is still useful as the most detailed political history of the period. The last volume, on Philip II, is especially good. ANTONIO DOMINGUEZ ORTIZ, *Crisis y decadencia de la España de los Austrias* (1969; Eng. trans., *The Golden Age of Spain, 1516–1659,* 1971), is a synthesis by one of the most distinguished contemporary Spanish scholars. HELMUT G. KOENIGSBERGER, *The Habsburgs and Europe, 1516–1660* (1971), attempts to view Spanish history in the perspective of European history. FERNAND BRAUDEL, *La Méditerranée et le monde méditerranéen à l'époque de Philippe II,* 2nd ed., 2 vol. (1966; Eng. trans. of vol. 1, *The Mediterranean and the Mediterranean World in the Age of Philip II,* 1972), is an economic and historical geography of the Mediterranean basin during the 16th century, in which Spain plays a central role. This book has become a classic since it first appeared (1949) and has been the basis for all further work on the period and area. WILLIAM H. PRESCOTT, *History of the Reign of Ferdinand and Isabella the Catholic,* 3 vol. (1838, many later editions), is still the fullest and most readable account in English. J.M. BATISTA I ROCA, "The Hispanic Kingdoms and the Catholic Kings," *The New Cambridge Modern History,* vol. 1 (1957), is an excellent short modern account. HENRY C. LEA, *A History of the Inquisition of Spain,* 4 vol. (1906–07), is still the fullest, and a very fair, account. PAUL J. HAUBEN (ed.), *The Spanish Inquisition* (1969), prints short extracts from authors with different viewpoints. JOSEPH PEREZ, *La révolution des "comunidades" de Castile, 1520–1521* (1970), is the most detailed account of the Comunero revolt. GARRETT MATTINGLY, *The Defeat of the Spanish Armada* (U.S. title, *The Armada;* 1959), is outstanding. JOHN H. ELLIOTT, *The Revolt of the Catalans: A Study in the Decline of Spain, 1598–1640* (1963), is the definitive work on this subject. JOHN H. PARRY, *The Spanish Seaborne Empire* (1966), is an excellent introduction to this subject. See also R.A. STRADLING, *Europe and the Decline of Spain: A Study of the Spanish System, 1580–1720* (1981); DAVID HOWARTH, *The Voyage of the Armada* (1981), an account from the Spanish perspective.

Spain since 1700: An informative introduction to the problems of modern Spain is GERALD BRENAN, *The Spanish Labyrinth,* 2nd ed. (1950). For an outline of political, economic, and social developments, see RAYMOND CARR, *Spain: 1808–1939* (1966). SALVADOR DE MADARIAGA, *Spain* (1958), is a stimulating general study by a liberal Spaniard. See also HENRY KAMEN, *The War of Succession in Spain, 1700–15* (1969). The reign of Charles III is covered by RICHARD HERR in *The Eighteenth Century Revolution in Spain* (1958). PIERRE VILAR, *La Catalogne dans l'Espagne moderne,* 3 vol. (1962), is a masterly treatment of late 18th-century Catalonia. EARL J. HAMILTON, *War and Prices in Spain, 1651–1800* (1947), is a study of the economy. ROBERT SOUTHEY, *History of the Peninsular War,* 3 vol. (1823–32), is still useful. For the army in politics, see ERIC CHRISTIANSEN, *The Origins of Military Power in Spain, 1800–1854* (1967); and STANLEY G. PAYNE, *Politics and the Military in Modern Spain* (1967). For mid-century politics see V.G. KIERNAN, *The Revolution of 1854 in Spanish History* (1966); and for the history of the republic, see C.A.M. HENNESSY, *The Federal Republic in Spain* (1962). ANTONIO RAMOS OLIVEIRA, *Politics, Economics and Men of Modern Spain, 1808–1946* (1946), is a useful guide. The best introduction is M. FERNANDEZ ALMAGRO, *Historia política de la España contemporánea* (1956). A Centre Left account of the republic is GABRIEL JACKSON, *The Spanish Republic and the Civil War, 1931–39* (1965). An excellent study of the politics of the Right is RICHARD ROBINSON, *The Origins of Franco's Spain* (1970). The history of the Civil War is fully treated in HUGH THOMAS, *The Spanish Civil War* (1961; rev. ed., 1977). For the internal history of the republic, BURNETT BOLLOTEN, *The Grand Camouflage* (1968), is excellent. The politics of Nationalist Spain are treated in STANLEY G. PAYNE, *Falange: A History of Spanish Fascism* (1961). For the development of the Franco régime, see J.W.D. TRYTHALL, *Franco: A Biography* (U.S. title, *El Caudillo: A Political Biography of Franco,* 1970); and GEORGE HILLS, *Franco: The Man and His Nation* (1967). For developments since 1975, see J. AMODIA, *Franco's Political Legacy* (1977), and F. GONZALEZ NAVARRO, *La nueva ley fundamental para la reforma política* (1976). Spanish Literature

The literature of Spain falls into three divisions according to language: Castilian, Catalan, and Galician. This article provides a brief historical account of the development of each of these three literatures and treats specifically the development of major genres. For a survey of the literature of the former Spanish colonies in the Americas, see LATIN-AMERICAN LITERATURE.

Although literature in the vernacular was not written until the medieval period, Spain had already made considerable contributions to literature. The two Senecas, Lucan, Martial, Quintilian, and Prudentius are among writers in Latin who lived in, or were born in, Spain before the separation of the Romance languages. For their writings, see LATIN LITERATURE. Later, the writings of Spanish Muslims and Jews form an important branch of Arabic and Hebrew literature.

Castilian literature

MEDIEVAL PERIOD

The origins of vernacular writing. By the time of the Muslim invasion (beginning in 711), the Latin spoken in the Iberian Peninsula was in the process of transformation into Romance. The 10th-century glosses to Latin texts in manuscripts belonging to the monasteries of San Millán de la Cogolla and Silos, in La Rioja, reveal traces of a vernacular already substantially developed. The earliest texts in Mozarabic (the Romance dialect of Spaniards living under the Muslims) were recovered from Hebrew and from Arabic *muwashshaḥs* (poems in strophic form, with subjects such as panegyrics on love), the last strophe of which was the *markaz* (theme stanza). They provide evidence of a popular poetry that may have begun as early as the 10th century and explain much in the traditional Spanish lyric types (*e.g.*, the *villancico,* "carol") of the later Middle Ages and Renaissance. The *markaz* was generally a woman's love song, and the motif, in Romance, was a cry of passion on which the whole poem was based.

The rise of heroic poetry. The earliest surviving monument of Spanish literature, and one of its most distinctive masterpieces, was the *Poema* (or *Cantar*) *de mío Cid* ("Song of My Cid"), an epic poem of the mid-12th century (the existing manuscript is an imperfect copy of 1307). It tells of the fall from and restoration to royal favour of a Castilian noble, Rodrigo Díaz de Vivar (*c.* 1043–99), known by the Arabic title *sidi,* "lord." The setting and personages, the topographical detail, the realistic tone and treatment, and the proximity in time of the poet to his hero have led to the acceptance of historical authenticity as a characteristic of the poem and of the Castilian epic in general. The last two of the three sections were, however, wholly imaginative, and the mere six lines given to the Cid's taking of Valencia from the Muslims make it clear that the scale of values is subjective and that the work is essentially poetic in conception. It won fame, nevertheless, as a popular embodiment of the Castilian character and lived on in epic, chronicle, ballad, and drama. The only other surviving epic text, a fanciful *Cantar de Rodrigo* ("Song of Rodrigo"), tells of the Cid's early manhood, from which the later legend of the Cid took shape. Frequent allusions in vernacular chronicles to the heroic narratives of minstrels make it clear that many narrative poems must have been lost. The chroniclers accepted these as historically authentic and "prosified" them, so that themes and even fragments of text can be reconstructed. Heroic narratives about which some information is available include *Los siete infantes de Lara* ("The Seven Princes of Lara"), *El cerco de Zamora* ("The Siege of Zamora"), *Bernardo del Carpio,* and others treating themes integral to the feudal history of Castile that were closer to a remote Visigothic past than to any French epic.

Epic poem of the Cid

The beginnings of prose. A major influence on prose was exercised by Arabic. Oriental learning came to Spain with the capture (1085) of Toledo from the Muslims. The city became a centre of translation from Oriental languages. An anonymous translation from Arabic (1251) of the "beast fable" *Kalīlah wa Dimnah* was the first example of storytelling in Spanish. An Oriental romance of the Seven Sages, known as the *Sendebar,* was translated likewise through Arabic, and other collections of Eastern stories soon followed.

Alfonso the Wise. The middle of the 12th century saw the recovery of Córdoba, Valencia, and Seville by the Christians. A more propitious intellectual atmosphere resulted in the founding of universities, and under Alfonso X of Castile and Leon (reigned 1252–84) literature achieved prestige. Alfonso, in whose chancery Castilian replaced Latin, could be described as the father of Castilian prose. His vast enterprises of translation and compilation aimed at fusing all knowledge—classical, Oriental, Hebrew, and Christian—in the vernacular. The works, often under his personal editorship, included the great legal code Las Siete Partidas (Eng. trans., *The Seven Divisions of Law*), a mine of information on the life of the time, and compilations from Arabic sources such as treatises on astronomy, on

The *Crónica general* and the *General estoria*

the magical properties of precious stones, and on games, especially chess. With the *Crónica general,* a vast history of Spain, and the *General estoria,* an attempt at a universal history from the creation, Alfonso founded Spanish historiography. The former, carried by Alfonso to AD 711 and completed by his son Sancho IV, was the most influential single work of the Spanish Middle Ages. Himself a poet, Alfonso made one of the greatest collections of medieval poetry and music, the *Cantigas de Santa María* ("Songs to the Virgin"), in Galician, the then accepted language for lyric.

Learned narrative poetry. A new school of poetry, indebted to France and linked with the monastery and a literate public, became known as the *mester de clerecía* ("craft of the clergy"). Adapting the French Alexandrine in the "fourfold way"—*i.e.,* four-line single-rhyme stanza with a 14-syllable line—it dealt with religious, didactic, or pseudo-historical matter. It was best exemplified in Gonzalo de Berceo (*c.* 1195–*c.* 1268), the earliest Spanish poet known by name, who versified in the vernacular the lives of saints, miracles of the Virgin, and other devotional themes with an ingenuous candour and an accumulation of picturesque and affectionately observed detail.

The 14th century. The period of translation and compilation was succeeded by one of brilliant original creation, best represented in the prose of Alfonso's nephew Juan Manuel and in the poetry of Juan Ruiz, archpriest of Hita. Juan Manuel's *Libro de los enxiemplos del conde Lucanor et de Patronio* (*Count Lucanor: or, The Fifty Pleasant Stories of Patronio*), a collection of 50 moral tales, still drew on Arabic sources, but its individuality places it high in the beginnings of Spanish fiction.

Under the influence of the Arthurian, or Breton, cycle, which had been circulating in translation, there had appeared (*c.* 1305) the first Spanish romance of chivalry and the first Spanish novel, *El caballero Cifar* ("The Knight Cifar"), on the theme of St. Eustace, the Roman general miraculously converted to Christianity. About the same time the *Amadís de Gaula,* a chivalric romance related to the Arthurian cycle, the oldest known version of which was written in Spanish by Garci Rodríguez (or Ordóñez) de Montalvo, was circulating and was destined to hold the imagination throughout the 16th century through its sentimental idealism, lyrical atmosphere, and supernatural adventure.

The works of Juan Ruiz

Juan Ruiz was the most intensely alert and individual of early poets. His *Libro de buen amor* (1330, expanded 1343; "Book of Good Love"), a collection of disparate elements—Ovid, Aesop, the 12th-century Latin *Pamphilus de amore,* and the liturgy—suggested a Muslim way of thinking in the mingling of eroticism with devotion and an invitation to the reader to interpret for himself equivocal teachings. His Trotaconventos, ancestress of Celestina, was the first great character in Spanish literature. The Alexandrine metre he handled with new vigour and plasticity, and the text was interspersed with religious, pastoral-farcical, amorous, or satirical lyrics of great metrical variety.

More exotic elements occurred in the verse *Proverbios morales* (*c.* 1355) of Santob de Carrión de los Condes and in an Aragonese version of the story of Joseph, based on the Qur'ān and written in Arabic characters, which was the chief example of "barbarian" literature in Spanish. The *Proverbios* of Santob introduced the grave sententiousness of Hebrew poetry with its extreme aphoristic concision; Santob's sources were the Old Testament, the Talmud, and the Hebrew poet and Arabic philosopher Ibn Gabirol.

Pedro López de Ayala dominated the poetry and prose of the later 1300s with his *Rimado de palacio* ("Poem of Palace Life"), the last major relic of the "fourfold-way," and his chronicles of Peter I, Henry II of Trastamara, John I, and Henry III of Castile, which stimulated the writing of personal, contemporary history; an early humanist, he translated and imitated Livy and Boccaccio, Boethius, St. Gregory, and St. Isidore.

Italian influence on Castilian poetry

The 15th century. The early 15th century witnessed a renewal of poetry under Italian influence. The contrast was strong during the reign of John II between the anarchy of feudalism in its death throes and the cultivation of polite letters, which was becoming a mark of birth and breeding. Collections of poems such as the *Cancionero de Baena* ("Songbook of Baena") made for the King by Juan Alfonso de Baena (a converted Jew and a poet), containing 583 poems by 55 poets from the highest nobles to the humblest versifiers, showed not merely the decadence of the Galician-Portuguese troubadour but also the stirrings of more intellectual poetry using symbol, allegory, and classical allusion in the treatment of moral, philosophical, or political themes. Francisco Imperial, a Genoese settled in Seville and a leader of the new poetry, drew on Dante, while the Marqués de Santillana, poet, scholar, soldier, and statesman, collected masterpieces of foreign literatures and stimulated translation. His *Proemio e carta al condestable de Portugal* (1449; "Preface and Letter to the Constable of Portugal"), the earliest work of literary history and criticism in Spanish, drew on his reading in contemporary foreign languages and translated classics. Imperial had already sought to acclimatize the Italian hendecasyllable. Santillana's sonnets in the "Italian style" marked the beginnings of the formal enrichment of Spanish poetry. His role as precursor is still acknowledged, though the sonnets and long poems, which reflected his Italian-influenced training, are neglected in favour of his charming rustic songs of native inspiration.

Santillana's contribution

Juan de Mena's vast allegorical poem of the drama of history past, present, and future (*El laberinto de fortuna,* 1444; "The Labyrinth of Fortune"), a more conscious attempt to rival Dante, was weighed down by pedantry and over-Latinization of syntax and vocabulary.

An outstanding anonymous poem of the early part of the 15th century, the *Danza de la muerte* ("Dance of Death"), was the finest example of a theme then popular with poets, painters, and composers. Related to the earlier *Danse macabre* at Paris but written with greater satiric force, it introduced characters (*e.g.,* a rabbi) not included in the French cycle. It presented a cross section of society in the form of a dialogue between Death and his protesting victims and, although not intended for dramatic presentation, formed the basis for later drama.

THE ERA OF THE RENAISSANCE

The beginning of the Siglo de Oro. The unification of Spain in 1479 and Columbus' discovery of the New World (1492), following the introduction of printing (1474) and concurrent with the cultural traffic with Italy (Naples had been a dependency of Aragon since 1443), may be taken as opening the era of the Renaissance in Spain. In this period—known as the Siglo de Oro or "Golden Age"—Spanish literature reflected the wealth of new experience born of overseas adventure and the detached questioning attitude to the rediscovered norms of classical authority. The early Spanish humanists included the first grammarians and lexicographers of any Romance tongue. Juan Luis Vives, the brothers Juan and Alfonso de Valdés, and others were followers of Erasmus, whose writings circulated in translation from 1536 and whose influence was seen in the Counter-Reformation figure of St. Ignatius of Loyola, founder of the Society of Jesus, and later in a religious writer and poet, Fray Luis de León.

The masterpiece of the early Renaissance is the *Comedia de Calixto y Melibea* (1499), a novel in dialogue form published anonymously but attributed to a converted Jew, Fernando de Rojas. The dominant character, a procuress called Celestina, depicted with a realism unsurpassed in Spanish letters, gave this work the title by which it is most commonly known, *La Celestina.* The analysis of passion and the dramatic conflict that its pursuit involved were worked out with such psychological intensity as to make this the first masterpiece of Spanish prose and Spain's first realistic novel.

The significance of *La Celestina*

Poetry. Spanish ballads, or *romances,* link medieval heroic epic to 20th-century poetry and drama; they lie at the heart of the national consciousness; and their expansion and capacity for survival, from Salonika to Chile and from the Low Countries to North Africa, reflect the far-flung boundaries of Spain's prestige in its age of greatness. The earliest datable *romances* (mid-15th century) treated of frontier incidents or lyrical themes. The ballads on medieval heroic themes had importance because

they formed everyman's source book on national history and character. Traditional ballads were collected in the Antwerp *Cancionero de romances* ("Ballad Songbook") and in the *Silva de varios romances* ("Miscellany of Various Ballads"), both *c.* 1550, and thereafter repeatedly. Soon the form (octosyllabic, alternate lines having a single assonance throughout) was exploited for lyrical purposes by the most famous poets of the age, and it has remained the chosen medium for popular narrative verse.

The earlier attempt to Italianize Spanish poetry had failed because Spanish language and verse techniques were still incapable of sustaining the burden. The Catalan Juan Boscán Almogáver, reintroducing Italian metres (see below *Catalan literature*), prepared the way for a much greater poet, Garcilaso de la Vega, with whom the lyric was reborn. To his mastery of poetic technique derived from medieval and classical poets he added an intense personal note in the use of characteristic Renaissance themes. His short poems, elegies, and sonnets largely determined the course of lyric poetry throughout the Siglo de Oro.

The rebirth of the lyric

Fray Luis de León, adopting some of Garcilaso's verse techniques, typified the "Salamanca school," with its emphasis on content rather than form. The poet and critic Fernando de Herrera headed a contrasting school of Seville, which, deriving equally from Garcilaso, was concerned rather with subtleties of refined sentiment; in a quartet of remarkable odes he gave vibrant expression to topical heroic themes. A defense of the short native metres was reinforced by the aforementioned traditional ballad collections (*romanceros*) and by the evolving drama.

For epic poetry the models were Ariosto and Tasso, but the themes and heroes were those of overseas conquest and expansion or defense of the empire and the faith. Alonso de Ercilla y Zúñiga came nearest to real achievement with his *Araucana* (published 1569–90), telling of native resistance to the Spanish conquest of Chile. Another typical example of the attempt at epic is Lope de Vega's *Dragontea* (1598), a verse history of Sir Francis Drake's last voyage and death.

Early drama. The origins of drama in Spain are to be sought, as elsewhere, in the church. The *Auto de los reyes magos* ("Play of the Three Wise Kings"), an incomplete play of an Epiphany cycle, is the only surviving text of medieval Spanish drama. The characterization of the Magi and of Herod and his advisers was realistic, and the medley of metres foreshadowed one aspect of later development of the drama in Spain.

A reference in King Alfonso X's legal code suggested also the existence of some form of secular drama in the 13th century, but no texts have survived. These *juegos* (short satiric entertainments given by traveling players) were the forerunners of the short plays and interludes—*pasos, entremeses, sainetes*—that formed one of Spain's main contributions to dramatic genres.

The dramas of Juan del Encina

Juan del Encina marked the emancipation of the drama from ecclesiastical ties by performances for a noble patron. His *Cancionero* (1496; "Songbook") contains pastoral-religious dramatic dialogues in a rustic dialect, but he soon turned to secular themes or vivid farce. Some of his plays showed a conception of drama changed by his long stay in Italy, in which native medievalism was transformed into Renaissance experimentation. Encina's Portuguese disciple Gil Vicente, a court poet at Lisbon who also wrote in Castilian, showed a great advance in naturalness of dialogue, acuteness of observation, and sense of situation.

The emergence of the drama from court to marketplace and the creation of a public were largely the work of Lope de Rueda, who toured Spain with his modest troupe and a repertoire of his own composition. His four prose comedies were clumsy, but the 10 *pasos* (comic interludes between the acts of longer plays) showed his dramatic merits, and he had the distinction of fathering the one-act play, which may be regarded as the most vital and popular dramatic form in Spain.

The first dramatist to realize the possibilities of the ballads in the theatre was Juan de la Cueva. His comedies and tragedies were mostly taken from classical antiquity, but in *Los siete infantes de Lara* ("The Seven Princes of Lara"), *El reto de Zamora* ("The Challenge of Zamora"), and *La libertad de España por Bernardo del Carpio* ("The Liberation of Spain by Bernardo del Carpio"), all published in 1588, he turned to early heroic stories already familiar in ballad; and thus, although not an accomplished dramatist, he helped to found a "national" drama.

Prose. *Historical writing.* Prose before the Counter-Reformation produced some notable dialogues, especially Alfonso de Valdés' *Diálogo de Mercurio y Carón* (1528; "Dialogue Between Mercury and Charon"). His brother Juan wrote a *Diálogo de la lengua* ("Dialogue About the Language") of great critical value. History continued to be cultivated, patriotism waxing higher as Spain's greatness cast its shadow over Europe; its last flowering was seen in Juan de Mariana's own translation into Spanish (from 1601) of his Latin history of Spain, which marked the triumph of the vernacular for all literary purposes.

The landmarks in historical writing, however, came from the New World and showed the transmitting of vital experience into literature with a vividness unknown in Spain. Columbus' letters and accounts of his voyages, the letters and accounts to Charles V of Hernán Cortés, and many other narratives by more humble conquistadores ("conquerors") opened up new horizons to the reader and, in the attempt to capture exotic landscapes in words, enlarged the resources of the language. The most engaging of such writings was the *Historia verdadera de la conquista de la Nueva España* (1632; *True History of the Conquest of New Spain*) by the explorer Bernal Díaz del Castillo. Bartolomé de Las Casas, the "Apostle of the Indies," wrote a *Brevísima relación de la destrucción de las Indias* (published 1552; "Very Brief Account of the Destruction of the Indies"; Eng. trans., *The Tears of the Indians*), criticizing Spanish colonial policy and the ill-treatment of the native population, which gave rise among Spain's enemies to the famous *leyenda negra,* or "black legend."

Narratives by the explorers

The novel. Popular taste in the novel was dominated for a century by the progeny of the medieval courtly romance *Amadís de Gaula.* These interminable romances kept alive certain ideals of medieval chivalry, but, having lost touch with life at every point, they represented pure escapism and in due course evoked such literary reactions as the pastoral novel. Naturalized from Italy and filled with nostalgia for an arcadian golden age, its shepherds were courtiers and poets who, like the knights-errant of chivalric romance, turned their backs on reality.

A more positive reaction was in the picaresque novel initiated in 1554 with the anonymous *Lazarillo de Tormes.* This genre, native to Spain and influential elsewhere, had as its hero a picaro ("rogue"), essentially an antihero, living by his wits and concerned only with staying alive, who, passing from master to master, depicted life from underneath. Important in guiding fiction back to direct observation of life, the picaresque formula contributed little to the development of the novel as an art form.

Miguel de Cervantes, the preeminent figure in Spanish literature, produced in *Don Quixote* (part 1, 1605; part 2, 1615) the prototype of the modern novel. Nominally a satire on the moribund chivalric romance, Cervantes' conception allowed the presentation of reality on two levels: the "poetic truth" of Don Quixote and the "historic truth" of his squire, Sancho Panza. In the constant interaction of these rarely compatible attitudes, Cervantes revealed the novel's scope as a philosophical commentary on existence, and in the interplay of the two characters he established psychological realism in contrast with the static characterization of previous fiction. In the *Novelas ejemplares* (1613; "Exemplary Tales"), Cervantes particularized his claim to be the first to write *novelas* (short stories in the Italian manner) in Spanish by differentiating between those that interest by the action and those whose merit lies in the mode of telling.

Don Quixote

Mystical writings. The great period of Spanish mysticism coincided with the Counter-Reformation, though it had antecedents, particularly in the expatriate Spanish Jew León Hebreo, whose *Dialoghi di amore* (1535; "The Dialogues of Love"), written in Italian, exercised a profound influence on 16th-century and later Spanish thought. The literary importance of the mystics derives from the fact that in trying to transcend limitations of language they

liberated previously untapped resources of expression. In the writings of St. Teresa of Ávila, notably in her autobiography and letters, there were the gifts of a great novelist in embryo. In his prose as in his poetry, Fray Luis de León showed passionate devotion, sincerity, and profound feeling for nature in a style of singular purity. St. John of the Cross achieved preeminence through three poems expressing in exalted style the experience of mystic union.

The dramatic art of Lope de Vega

Later drama. The drama achieved its true splendour in the genius of Lope de Vega (in full, Lope Félix de Vega Carpio). Its manifesto was Lope's own treatise, *Arte nuevo de hacer comedias en este tiempo* (1609; "New Art of Writing Plays at This Time"), which rejected the Neoclassical "rules," opted for a blend of comedy and tragedy and metrical variety, and made public opinion the arbiter of good taste. The new *comedia* ("drama") was a "social" drama, ringing changes on the triple foundation of society: respect for crown, church, and the human personality, the last symbolized in the "point of honour" that Lope commended as the best theme of all. This was a matter of convention, "honour" being equivalent more or less to reputation. It was a drama less of character than of action and intrigue, which rarely grasped the essence of tragedy. What the great Spanish playwrights did possess was a remarkable sense of stagecraft and the ability to make the most intricate plot gripping.

Lope, who claimed authorship of more than 1,800 *comedias,* towered over his contemporaries. He had an unerring sense of what could move an audience to respond to a reflection on the stage of some of the ingredients of its country's greatness. Through Lope the drama became "national" in the truest sense. The two main categories of his work are the native historical and the *capa y espada* ("cloak-and-sword") plays of contemporary manners. Lope ransacked the literary past for heroic themes, chosen to illustrate aspects of the national character or of that social solidarity on which Spain rested.

The cloak-and-sword play, which dominated drama after Lope, was pure diversion, with much use of disguise, falling in and out of love, false alarms about honour, and a duplication of the plot by the humorous lackey and the lady's maid. It gave pleasure by its dexterity, sparkling dialogue, and entanglements in relations between the sexes and showed the pleasures of the moment in an irresponsible world.

The works of Tirso de Molina

The greatest of Lope's immediate successors was Tirso de Molina (pseudonym of Gabriel Téllez), whose *Burlador de Sevilla* (1630; "The Trickster of Seville") presented the Don Juan legend on stage for the first time. *La prudencia en la mujer* (1634; "Prudence in Woman") figured among the greatest of Spanish historical dramas, as did *El condenado por desconfiado* (1635; *The Doubter Damned*) among the theological, while Tirso's cloak-and-sword comedies were among the liveliest of the type. Mexican-born Juan Ruiz de Alarcón y Mendoza struck a distinctive note. His 20 plays were sober, studied, and imbued with serious moral purpose, and his *Verdad sospechosa* (1634; "The Truth Suspected") inspired the great French dramatist Pierre Corneille's *Menteur.* Corneille's famous *Le Cid* similarly had its source in the conflict between love and honour posed in *Las mocedades del Cid* ("The Youthful Exploits of the Cid") by Guillén de Castro y Bellvís.

Culteranismo and conceptismo. In poetry and prose the early 17th century in Spain was marked by the rise and spread of two interrelated stylistic movements. That known as *culteranismo,* the high-flown style of which Luis de Góngora y Argote was archpriest, resumed attempts to ennoble the language by re-Latinizing it. This process was not only carried to extremes in vocabulary, syntax, and word order, but expression was garbed in classical myth and allusion and complicated by every subtlety of metaphor. It was an attempt to achieve a poetry that, if rediscovered after hundreds of years, could be still fresh through the immortality of its Latinism. His example (*Soledades* [1613; "Solitudes"]) invited many untalented imitations. The other stylistic movement, *conceptismo,* played on ideas as *culteranismo* did on language. Aiming always at the semblance of profundity, the style was concise and epigrammatic and thus belonged to prose, especially satire, since it was much concerned with stripping appearances from reality. Its best outlet was the essay. Francisco Gómez de Quevedo y Villegas, the greatest satirist of his age and one of Spain's masters of language, was, in *Sueños* (1627; "Dreams"), an outstanding exponent. Baltasar Gracián y Morales reduced its refinement to an exact code in his *Agudeza y arte de ingenio* ("The Conceit, a Treatise on Style"), as he also tried to codify in a series of treatises the art of living. Gracián was certainly a thinker, and his allegorical novel *El criticón* (*The Critick*) was a pessimistic interpretation of life as a "daily dying."

The plays of Calderón. Pedro Calderón de la Barca adapted Lope de Vega's formula for producing a tightly structured drama in which formal artistry and poetic texture are closely wedded to depth of theme and unity of dramatic purpose. One of the world's outstanding dramatists, Calderón wrote plays that were as effective in the public playhouses as in the newly built court theatre of Buen Retiro. The elaborate stage techniques of the latter enabled Calderón to excel in mythological drama (*La estatua de Prometeo* [1669; "The Statue of Prometheus"]) and contribute to the rise of a type of musical comedy known as the zarzuela (*El jardín de Falerina* [1648; "The Garden of Falerina"]). Calderón was a fertile creator, and his numerous secular plays encompassed both comedy and tragedy. In his best comedies, the conventions of intrigue and suspense are modified to create a subtle critique of urban mores and generally accepted values, astride the joy of laughter and the foreboding of eventual tragedy (*La dama duende* [1629; *The Phantom Lady*]). His tragedies probe deeply into the human predicament, exploring problems of personal and collective guilt (*Las tres justicias en una* [*c.* 1637; *Three Judgments at a Blow*]), the bathos of limited vision and lack of communication (*El pintor de su deshonra* [*c.* 1645; *The Painter of His Own Dishonour*]), the destructiveness of certain social codes (*El médico de su honra* [1635; *The Surgeon of His Honour*]), and the clash between the constructive nature of reason and the destructive violence of self-centred passion (*La hija del aire* [1653; "The Daughter of the Air"]). Some of his best known plays are more appropriately classified as high drama, offering a positive though never simplistic vision. *El alcalde de Zalamea* (*c.* 1640; *The Mayor of Zalamea*), for example, rejects the supremacy of social honour and points to the inner nature of man's true worth and dignity. Philosophical problems of determinism and free will are vividly dramatized in *La vida es sueño* (1635; *Life Is a Dream*), in which the escape route from the confusion of life is shown to lie in an awareness of reality and self-knowledge.

Calderón's exploration and critique of natural values has its otherworldly counterpart in his overtly religious plays, whether in the mold of the Jesuit drama with its emphasis on conversion (*El mágico prodigioso* [1637; *The Wonder-Working Magician*]) and heroic saintliness (*El príncipe constante* [1629; *The Constant Prince*]) or in the medieval tradition of morality plays that he brought to a peak of artistic perfection in his *autos sacramentales.* These liturgical plays use formal abstractions and symbols in order to expound the specific drama of the human fall and Christian redemption, and they range in their artistry from the immediate metaphorical appeal of *El gran teatro del mundo* (*c.* 1635; *The Great Theatre of the World*) to the increasingly elaborate patterns of his later productions (*La nave del mercader* [1674; "The Merchant's Ship"]).

Calderón's *autos sacramentales*

After Calderón's death Spanish drama lay dead for 100 years. *Culteranismo* and *conceptismo,* though symptoms rather than causes of decline, played their part in stifling imaginative literature, and by the close of the century little remained of its former greatness.

THE 18TH CENTURY

With the establishment of the Bourbon dynasty after the War of the Spanish Succession (1701–14), renewal of the country's intellectual life began. Numerous academies were created, the most influential being the Real Academia de la Lengua Española (now the Real Academia Española), founded in 1713 to maintain the purity of the language. Men of letters began again to study abroad and discovered

how far Spain had deviated from the intellectual course of western Europe. A new spirit of inquiry into the national heritage caused scholars to go back and unearth forgotten medieval literature. Gregorio Mayáns y Siscar wrote the first biographical study of Cervantes. A church historian, Enrique Flórez, embarking on a vast historical enterprise, *España sagrada,* helped resurrect the whole cultural background of medieval Christian Spain. Landmarks of even greater importance were the publication of the 12th-century epic *Poema de mío Cid,* the works of Gonzalo de Berceo, and Juan Ruiz' *Libro de buen amor,* all for the first time. From all this there resulted a debate between old and new that waged throughout the middle decades of the century, compelled both sides to reason out their positions, and marked the birth of a new critical approach to literature. Two names stand out: Ignacio de Luzán Claramunt, whose work on poetics launched the great Neoclassical polemic in Spain, and Benito Jerónimo Feijóo y Montenegro, a Benedictine monk who, in assailing error, prejudice, and superstition wherever he found them, made a monumental contribution to the intellectual emancipation of Spain. Imaginative prose produced the *Noches lúgubres* (published 1789–90; "Sad Nights") of José Cadalso Vázquez, looking forward to Romanticism, and the *Fray Gerundio* (1758) of José Francisco de Isla, a satire looking back to the picaresque novel.

First publication of the *Cid*

Poetry, moribund for nearly 100 years, raised a timid head in a small group at Salamanca, led by Diego González, which toward 1775 turned for inspiration to Fray Luis de León, just as two decades later a group at Seville sought to revive the glories of Herrera. Juan Meléndez Valdés, who learned to think from the English philosopher John Locke and to feel from the English poet Edward Young, best exemplified the combination of new influences at work. A conscious artificer rather than a great poet, he helped poetry through the painful apprenticeship necessary to its rehabilitation.

In drama, the second half of the century saw a great battle over the Neoclassical "rules" (meaning chiefly the unities of place, time, and action). *La Raquel* (1778), by Vicente Antonio García de la Huerta Muñoz, showed the capabilities of the reformist school. It fell to Ramón de la Cruz to bridge the gap by his resurrection of the earlier *paso* (one-act prose skit) and longer *entremeses* (interludes) of Lope de Rueda, Cervantes, and Luis Quiñones de Benavente. Based on satirical observation of the Madrid scene, his one-act sketches did not transgress the unities or offend the purist; at the same time they delighted the public and brought the drama back to commenting on life and society. Leandro Fernández de Moratín applied the lesson to the full-length play and produced comedies imbued with deep social seriousness which were yet good theatre. His dialogue in *La comedia nueva* (1792; "The New Comedy") and in *El sí de las niñas* (1806; *The Maiden's Consent*) ranks among the best prose of the 18th century.

THE 19TH CENTURY

The Romantic movement. Literature in Spain in the first third of the 19th century was still affected by the Napoleonic Wars and their long aftermath. Many liberals driven into exile by Ferdinand VII after 1823 sought refuge in France; and, when they returned to Spain after his death in 1833, they had been so influenced by French Romanticism that this date has been taken as the beginning of the Romantic movement in Spain. The ground had been prepared in Cádiz from 1814 onward in a debate initiated by a German, Johann Niklaus Böhl von Faber, on literary values; in Barcelona with the founding in 1823 of a review, *El europeo;* and in Madrid with Agustín Durán's essay in 1828 on the drama of the Siglo de Oro and his *Colección de romances antiguos* (1828–32). Romanticism in Spain was, in many respects, a return to the spirit of its own earlier classics. The formal characteristics of Spanish Romantic drama—mingling of genres, rejection of the unities, metrical variety—had characterized the drama of Lope de Vega and his contemporaries, who had, moreover, treated many of its themes.

Influence of French Romanticism

The movement arrived in Spain a generation later than elsewhere and had a short life. It never became a school or had a particular leader. José de Espronceda was the one Romantic who lived his Romanticism. His *Estudiante de Salamanca* (appeared in two parts, 1836 and 1837; "Student of Salamanca"), *Canciones* (1840; "Songs"), and an unfinished work, *El diablo mundo* (1840; "The Devilish World"), were the only subjective lyrics of value that the period produced, and they marked a milestone in the development of poetic form. A play, *Don Álvaro o la fuerza del sino* (1835; "Don Alvaro; or, The Force of Destiny"), by Ángel de Saavedra, duque de Rivas, and the preface, by the critic Antonio Alcalá Galiano, to Saavedra's narrative poem *El moro expósito* (1834; "The Foundling Moor"), came nearest to expressing a philosophy of Romanticism.

Three poets revealed how one of Romanticism's concerns was liberation of the individual personality. Gustavo Adolfo Bécquer, in 76 *Rimas* (published 1871; "Rhymes"), expressed his own tortured emotions; Ramón de Campoamor y Campoosorio wrote *Doloras* (1845; "Sufferings"), *Pequeños poemas* (1871; "Little Poems"), and *Humoradas* (new poetic forms of his invention, published in 1886), attempting to bring poetry back into the realm of ideas; and Gaspar Núñez de Arce wrote *Gritos del combate* (1875; "Combat Cries"), patriotic, declamatory exhortations defending democracy.

Costumbrismo. *Costumbrismo* was a movement that started earlier than Romanticism and flourished at the same time. It concerned realistic prose writing, often within a narrative framework. Both the *cuadro de costumbres* and the *artículo de costumbres* were short literary sketches on customs, manners, or character, but the *cuadro* inclined to description for its own sake, whereas the *artículo* was more critical and satirical. *Cartas de un pobrecito holgazán* (1820; "Letters from a Poor Idler"), by Sebastián de Miñano, was probably the first work of this kind, but the most important were by Mariano José de Larra, outstanding prose writer and most critical mind of his age, who dissected society pitilessly in *Artículos* (1835–37); by Ramón de Mesonero Romanos, whose *Escenas matritenses* (1836–42; "Scenes of Madrid") gave a vivid picture of contemporary life; and by Serafín Estébanez Calderón, who portrayed the manners, folklore, and history of Andalusia in *Escenas andaluzas* (1847; "Andalusian Sketches"). These writings and other similar pieces, with their realistic and regional elements, helped to prepare for a revival of the novel.

Realistic prose writing

Revival of the Spanish novel. For more than two centuries the novel, with which Spain had made its greatest contribution to literature, had been almost extinct. The first novels of the revival were more interesting for powers of observation and description (a continuation of *costumbrismo*) than for imaginative or narrative quality. A woman novelist, Fernán Caballero, determined the technique of observation that was to rehabilitate the novel in *La gaviota* (1849; *The Seagull*). In 1874 the great period of the regional novel began with *El sombrero de tres picos* (*The Three-Cornered Hat*), a sparkling tale of peasant malice by Pedro Antonio de Alarcón. Although local Realism prevailed too in Juan Valera's novels, they were also remarkable for their psychological insight and notes of cultured detachment. The greatest regional writer was José María de Pereda, whose Realism was a powerful re-creation of nature as the abiding reality, more important than the individual. *Sotileza* (1884; "Subtlety") and *Peñas arriba* (1893; "Up the Mountains") revealed his support for traditional values of religion, family, and country life. An attempt by Emilia, condesa de Pardo Bazán, in her novels of Galicia, *Los pazos de Ulloa* (1886; *The Son of a Bondwoman*) and *La madre naturaleza* (1887; "Mother Nature"), to combine a Spanish Christian outlook with French Naturalism made clear their incompatibility, and in later novels she returned to a genuinely Spanish Realism. Armando Palacio Valdés was the novelist of Asturias.

Besides this cult of regionalism, the fecundity in the novel of Benito Pérez Galdós created a world in itself. After living through one of the most turbulent chapters in Spanish history, he imaginatively re-created its antecedents, beginning with the war against Napoleon. The 46 novels of his *Episodios nacionales* (1873–79 and 1898–1912) embraced

The novels of Pérez Galdós

70 years of the country's story and taught generations of Spaniards much of what history they knew.

Postromantic drama. The drama, disoriented after a brief Romantic efflorescence, produced few outstanding works. Manuel Tamayo y Baus achieved fame by an isolated work, *Un drama nuevo* (1867; *A New Drama*), in which the characters are members of Shakespeare's company of actors (including Shakespeare himself). Adelardo López de Ayala pilloried bourgeois vices in *El tejado de vidrio* (1857; "The Glass Roof") and *Consuelo* (1870). The 1904 Nobel Prize for Literature set a seal on José Echegaray y Eizaguirre, whose 63 plays fall into two main groups. In the first, drama became melodrama with a constant striving after effect and a basic falsity of character, passion, and situation alike. The second comprised a serious, often tragic, drama of social problems. Joaquín Dicenta brought the drama nearer to earth with an unpleasantly realistic study of working-class conditions in *Juan José* (performed 1895).

THE MODERN PERIOD

The Generation of '98. For more than two decades before 1900, a mood of seething political and social analysis developed in Spain that gave in Ángel Ganivet's *Idearium español* (1897; *Spain, an Interpretation*) one of the most searching analyses of the Spanish character ever written. The imperial cycle, begun in 1492, ended in ignominy with the Spanish–American War of 1898, and thinking Spaniards embarked on a diagnosis of their country's ills and an attempt to shock the national mentality out of its *abulia,* or "lack of will." The novel was injected with a new seriousness of purpose, and the critical, psychological, and philosophical essay rose to new importance. Novelists and essayists constituted what Azorín (pseudonym of José Martínez Ruiz) called the Generation of '98, a group that regained respect for Spanish letters abroad.

Unamuno's analyses of the national problem

Miguel de Unamuno, who dominated the literary scene for a generation, studied the national problem acutely in the five essays in *En torno al casticismo* (1895; "On Spanish Purism") and in the *Vida de Don Quijote y Sancho* (1905; *The Life of Don Quixote and Sancho*). He examined the problem of immortality in his most important work, *Del sentimiento trágico de la vida* (1913; *The Tragic Sense of Life in Men and Peoples*). A provocative rather than a systematic thinker, he aimed at sowing spiritual disquiet. The novel was to him a medium for discussion of the fundamentals of personality; his own include *Niebla* (1914; *Mist*), *Abel Sánchez* (1917; Eng. trans., *Abel Sánchez*), and *Tres novelas ejemplares y un prólogo* (1920; "Three Cautionary Tales and a Prologue").

Azorín concerned himself with the reinterpretation of earlier literary values and of the Spanish countryside in, for example, *El alma castellana* (1900; "The Castilian Soul"), *La ruta de Don Quijote* (1905; "Don Quixote's Route"), and *Clásicos y modernos* (1913). An artist in criticism and a finely sensitive miniaturist, he contributed powerfully to the deflation of the rhetoric that had vitiated much 19th-century writing. A philosopher, José Ortega y Gasset, developed themes from criticism and psychology (*Meditaciones del Quijote* [1914; "Meditations on Quixote"]) to national problems (*La España invertebrada* [1921; *Invertebrate Spain*]), then to international (*El tema de nuestro tiempo* [1923; *The Modern Theme*] and *La rebelión de las masas* [1929; *The Revolt of the Masses*]).

Pío Baroja repudiated tradition, religion, and the cult of the individual and advocated social action. *La raza* ("The Race"), *La lucha por la vida* (1904; "The Struggle for Life"), and *Agonías de nuestro tiempo* (1926; "Agonies of Our Time") were fiercely vigorous attempts to arouse discontent with material conditions. As vigorous but possessing greater narrative skill was Vicente Blasco Ibáñez, who wrote on contemporary social problems from the standpoint of an anarchist, as in *La bodega* (1905; *The Wine Vault*) and *La horda* (1905; *The Mob*). He won international renown with *Los cuatro jinetes del apocalipsis* (1916; *The Four Horsemen of the Apocalypse*), a novel of World War I.

Novecentistas

The term *novecentistas* is applied to writers of the early 20th century who sought to renew intellectual and aesthetic standards after the passionate involvement of their immediate predecessors.

The novel. In Ramón Pérez de Ayala, the novel was at once a polished art form and a forum for philosophical discussion. *Belarmino y Apolonio* (1921; *Belarmino and Apolonio*), a projection of the old debate between faith and reason, made its characters almost symbolic, as did *Tigre Juan* (1926; *Tiger Juan*), on the traditional theme of honour. Gabriel Miró's perfect descriptive prose retarded the action of his novels, but he remained a supreme artist in words. The novel as a literary form fell under the influence of Ortega y Gasset, who in *La deshumanización del arte* (1925; *The Dehumanization of Art*) propounded principles of a pure, depersonalized art. Analyzing the novel as an art form, he predicted its decline. In the following decade Benjamín Jarnés and others attempted, without complete success, to apply a technique of pure art to the novel; Jarnés' works were outstanding examples of the Surrealist novel in Spain.

The Spanish Civil War (1936–39) drove into political exile some promising novelists whose narrative art matured abroad. Max Aub analyzed the civil conflict in an artistically and thematically impressive cycle of novels entitled *El laberinto mágico* (1943–68; "The Magic Labyrinth"). Ramón José Sender, whose pre-Civil War novels had been realistic and overtly sociopolitical, developed an interest in the mysterious and irrational. While his trilogy *Crónica del alba* (1942–66; "Chronicle of the Dawn") dwelt on the Civil War in a realistic manner, his magic, myth-dominated world of *Epitalamio del prieto Trinidad* (1942; *Dark Wedding*) or *Las criaturas saturnianas* (1968; "Saturnine Beings") pointed toward more universal concerns. Francisco Ayala abandoned his youthful aestheticism to cultivate Spanish and human themes in short stories and novels (*e.g., Muertes de perro* [1958; *Death as a Way of Life*]) of multiple perspective and complex narrative techniques.

In the aftermath of the Civil War the narrative in Spain went into a relative decline, only occasionally arrested by such successes as the psychologically perceptive *La familia de Pascual Duarte* (1942; *The Family of Pascual Duarte*) of Camilo José Cela. This novel created a vogue for a form of harsh, sordid, unsentimental realism known as *tremendismo.* Always wedded to literary experimentation, Cela attempted more ambitious technical heights in his later novel *La colmena* (1951; *The Hive*), which provides a panorama of Madrid society during the post-Civil War period.

Cela and *tremendismo*

The sociopolitical trauma of the civil conflict with its cultural and economic uncertainty fostered a return of outmoded forms of Realism. Conventional reading was provided by such craftsmen as Juan Antonio de Zunzunegui and Ignacio Agustí. José María Gironella was more ambitious in his controversial epic trilogy on the Civil War: *Los cipreses creen en Dios* (1953; *The Cypresses Believe in God*), *Un millón de muertos* (1961; *The Million Dead*); and *Ha estallado la paz* (1966; *Peace After War*). Miguel Delibes conveyed a critical concern for a society whose natural values are under constant threat. Greater technical advance and thematic originality are evinced in his *Cinco horas con Mario* (1966; "Five Hours with Mario"), a powerful novel constructed almost entirely with interior monologue. During the 1950s a starker form of Social Realism became the dominant manner in the work of a group of competent, committed novelists (Ana María Matute, Rafael Sánchez Ferlosio, the brothers Juan and Luis Goytisolo, Jesús Fernández Santos, Juan García Hortelano, Carmen Martín Gaite, Ignacio Aldecoa, Jesús López Pacheco, Daniel Sueiro, and Elena Quiroga). The finest novel produced by a member of this group was Ferlosio's *El Jarama* (1956; "The Jarama"; Eng. trans., *The One Day of the Week*), in which the monotonous existence of urban youth is vividly re-created in the aimless conversations of the characters. By the 1960s, this form of direct, unadventurous Realism was a spent force. Luis Martín-Santos was the first to break the mold with his epoch-making *Tiempo de silencio* (1962; *Time of Silence*), in which the familiar topic of life in post-Civil War Spain was subjected to the elaboration of conscious artistry. Juan

New form of Social Realism

Goytisolo, whose early novels had been firmly anchored in Social Realism, ventured into increased introspectiveness and revolutionary experimentation with structure and language in his *Señas de identidad* (1966; *Marks of Identity*). In the same line of promising innovation is Juan Benet Goita, whose *Volverás a Región* (1967; "You Will Return to Región") combined density of form with myth and allegory.

Drama. With the new century, drama achieved renewed vigour under the stimulus of Jacinto Benavente y Martínez, a prolific playwright noted for his craftsmanship and wit. A social satirist preoccupied with ethics, Benavente stopped short of alienating the sympathies of his devoted upper-class public, as, for example, in *Los intereses creados* (1907; *The Bonds of Interest*). The bourgeois drama of Benavente and others shared some of its success with the poetic, nostalgic drama of Eduardo Marquina, and with the so-called *género chico*—*i.e.*, genre consisting of light dramatic or operatic one-act playlets. The popular, costumbrista setting of the latter dissolved into amusing inanities in the hands of the brothers Serafín and Joaquín Álvarez Quintero while reaching a more serious level in some of the satirical pieces of Carlos Arniches.

A most original, innovative playwright of the 1920s was Ramón María del Valle-Inclán, who attempted, without much success, to shake the theatre out of its bourgeois complacency and artistic mediocrity. In his dramatic productions, he inveighed against hypocrisy and corrupt values in poignant, taut scenes of mordant irony. *Luces de Bohemia* (1920; *Bohemian Lights*) illustrates both the theory and practice of *esperpento*, an aesthetic formula that sought to depict reality through a deliberately exaggerated mimesis of its grotesqueness. Also concerned with the renovation of the stage, Jacinto Grau added tragic dignity to his pessimistic view of an absurd reality in *El señor de Pigmalión* (1921).

García Lorca's drama

Federico García Lorca stood far above his contemporaries. His drama was poetic in more than the usual sense, presenting elemental passions with an intensity that made the characters poetic symbols of man's tragic impotence to arrest his fate. His dramatic poetry was modern yet traditional, personal yet universal, Surrealist yet childlike. His plays *Bodas de sangre* (1933; *Blood Wedding*), *Yerma* (1934; Eng. trans., *Yerma*), and *La casa de Bernarda Alba* (1936; *The House of Bernarda Alba*) depicted extremes of passion involving the traditional Spanish theme of honour.

Rafael Alberti's contribution to the movement of dramatic reform was characterized by an imaginative adaptation of classical forms of Spanish drama (*El hombre deshabitado* [1931; "The Uninhabited Man"], a modern allegorical *auto* in the manner of Calderón) and by the creation of poetic, fatalistic myths out of the realism of popular themes and folk motifs.

The renovation attempted by Valle-Inclán, Grau, Lorca, and Alberti had little effect on the commercial theatre and came to an abrupt end with the outbreak of the Civil War. Though there has been no lack of skillful playwrights to provide politically acceptable entertainment (Edgar Neville, José López Rubio, Víctor Ruiz Iriarte, and Alfonso Paso) or on occasion more soul-searching drama (Alejandro Casona and Joaquín Calvo Sotelo), no great dramatist has emerged since the mid-1940s. A figure of some importance, however, is Antonio Buero Vallejo, who has had some success in revitalizing the theatre. Subtle and imaginative, he uses myth, history, and contemporary life as dramatic metaphors in his exploration and critique of society—*En la ardiente oscuridad* (1950; "In the Burning Darkness"); *La tejedora de sueños* (1952; *The Dream Weaver*); and *Un soñador para un pueblo* (1958; "A Dreamer for a People"). Alfonso Sastre has rejected this formula in favour of a more direct, committed approach to social problems. The relaxation of censorship in the 1960s awoke an interest in the Theatre of the Absurd, its main exponent in Spain being Fernando Arrabal.

Modernismo

Poetry. Rubén Darío, Latin America's greatest poet, took *modernismo* to Spain in 1892. In general, Modernism was a reaction against 19th-century bourgeois materialism and a search for other and more specifically aesthetic values of life. Darío's Modernism greatly enriched the musical resources of Spanish verse, notably by a daring use of new rhythms and metres.

Modernism heralded a brilliant period for Spanish poetry that lasted for more than half a century. A new deeply introspective, aesthetically beautiful poetry emerged, and it proved to be truly cosmopolitan in its concern with the human condition without ceasing to respond to its Spanish circumstance and literary tradition. Antonio Machado explored memory through recurrent symbols of multiple evocation, the dimly drawn boundaries of dream and reality, time past and present, searching for permanency in the duration of consciousness. A consummate creator of introspective poems in *Soledades* (1903, augmented in 1907; "Solitudes"), Machado turned outward in *Campos de Castilla* (1912, augmented in 1917; "Fields of Castile") to produce powerful poems on the state of the country and the character of its people. Anguished by transient reality, Juan Ramón Jiménez sought salvation in an absorbing, manic dedication to *poesía desnuda* ("naked poetry"). In quest of a Platonic absolute, his measured, exact poetry reflected an increasing exultation in the mystical discovery of transcendence within the immanence of self and physical reality that he never totally forsook. Jiménez' voluminous output—*Rimas* (1902; "Rhymes"); *Sonetos espirituales* (1914–15; "Spiritual Sonnets"); *Diario de un poeta recién casado* (1917; "Diary of a Poet Recently Married"); and *Animal de fondo* (1947; "Animal of the Depth")—speaks of a lifetime spent in the pursuit of poetry and its modes of expression.

The *poesía desnuda* of Juan Ramón Jiménez

A group of outstanding poets, known collectively as the Generation of 1927, made its presence felt during the 1920s and '30s and for some decades thereafter. Following the lead of Machado and Jiménez, they took inspiration from the past (ballads, traditional songs, lyrics, and Góngora's poetry) as well as from the immediate, often ephemeral present (Surrealism and other "-isms") to produce well-integrated and intensely personal poetry. Images, free from the shackles of strict reason and logic, became central to the act of poetic creation.

Among the leading members of the group was Federico García Lorca. In every respect, Lorca was a poet of fundamentals whose work demonstrated the starkness of feeling and effect characteristic of the traditional song and ballad forms. In *Romancero gitano* (1928; *The Gypsy Ballads*), he created an illusion of popular poetry with a sophisticated use of myth and symbolic imagery that conveyed to the reader a mysterious, ambivalent vision of nature. Symbols and metaphors, always central to Lorca's poetry, approach the hermetic in *Poeta en Nueva York* (1940; *Poet in New York*), a Surrealist record of urban inhumanity and rootlessness written in 1929–30 at the time of his visit to the United States. Pedro Salinas sought "pure" poetry in a reduction of content and a heightened sensitivity to language. A profoundly personal experience of love in *La voz a ti debida* (1934; "The Voice Inspired by You"; Eng. trans., *Truth of Two and Other Poems*) leads to an exploration of the subtle interrelation between the solidity of external reality and the fleeting world of subjective perception.

Jorge Guillén's sustained poetic effort is contained in *Cántico* (1928; *Cántico: A Selection*). This work, organically enlarged in successive editions, is a disciplined hymn to the marvels of everyday reality. Guillén had the rare gift of transmuting sense impressions and emotions into conceptual and structural patterns while enhancing the humanity of the experience. Always alert to impending chaos, his later works (*Clamor* [1957–63; "Clamour"] and *Homenaje* [1967; "Homage"]) displayed a keener awareness of suffering and disorder.

Aleixandre and Alberti

Vicente Aleixandre, another prominent member of the Generation of 1927, attained maturity in the controlled creation of myth after a formless dabbling in the subconscious. In *La destrucción o el amor* (1935; "Destruction or Love"), he penetrated into human despair and cosmic violence. Similar to Lorca, Rafael Alberti began writing poetry by drawing on popular forms and folk elements. His playful poetry of *Marinero en tierra* (1925; "Sailor on Land"), however, soon gave way to the stylistic complexities of *Cal y canto* (1927; "Lime and Stone") and the

sombre introspective mood of *Sobre los ángeles* (1929; *Concerning the Angels*), a controlled masterpiece born out of personal crisis. The poetry of Luis Cernuda, as suggested by the title of his collected works *La realidad y el deseo* (first published 1936; "Reality and Desire"), dwells on the gulf between harsh reality and a personal world of ideal aspirations. The tension, melancholy, and sense of alienation resulting from the unbridgeable gap between these realms pervades much of Cernuda's poetry.

Other poets worthy of mention in this brilliant period of Spanish poetry are Gerardo Diego, Dámaso Alonso, Emilio Prados, and Manuel Altolaguirre. The younger Miguel Hernández, whose promise was cut short by a tragic death, bridged the gap between the Generation of 1927 and the new wave of post-Civil War poets.

The Civil War and its traumatic aftermath resulted in an abandonment of pure poetry, already signaled in the 1930s, for a simpler approach to the problem of poetic communication. Discipline of form, devotion to clarity through direct imagery, and reduced lexis were stressed and the social and human content increased, though not always in an overtly political fashion. The contemporary period has yielded many notable names—Leopoldo Panero, Luis Rosales, Luis Vivanco, Gabriel Celaya, Blas de Otero, Vicente Gaos, José Ángel Valente, Claudio Rodríquez, among others—but no truly great voice has yet emerged in the second half of the century.

New directions in poetry

Catalan literature

The Catalan language is a branch of peninsular rather than of southern Gallo-Romance. It shows, nonetheless, many traces of kinship with Provençal, and the literature in its origins used the Occitan language (*langue d'oc*, the dialects of Old French spoken south of the Loire River) and the poetic forms cultivated by troubadours north of the Pyrenees.

MEDIEVAL PERIOD

Poetry. The early Catalan troubadours Guillem de Bergadà, Hug de Mataplana, Guillem de Cervera, and others were genuine Provençal poets. About 100 years later, in the late 14th century, Provençal influence apparently lessened, and poets turned to northern France for inspiration. They took over the long French narratives on romance themes such as the Arthurian cycle and used the *noves rimades* metre, a sequence of octosyllabic rhymed couplets. Several poets working in this tradition carried the new interest in the *langue d'oïl* (the dialects of Old French spoken north of the Loire) to the extent of incorporating passages of French poetry in their poems.

The great period of Catalan poetry

The great period of Catalan poetry was the 15th century, after John I of Aragon had established in 1393 a poetic academy in Barcelona on the model of the academy in Toulouse with *jocs florals* ("floral games," or poetry congresses), including literary competitions. This royal encouragement continued under Martin I and Ferdinand I and helped to emancipate the literary style from foreign influences. As the century advanced, Valencia emerged as a new focus of literary activity: a school of poetry developing there was noted for its characteristic use of eight-line decasyllabic verses with crossed, or "chained," rhymes and final four-line refrain, illustrating a turning away from French models and a new inspiration from Italy. The *cants d'amor* and *cants de mort* ("songs of love" and "songs of death") by Ausiàs March contained the finest verses ever written in Catalan, exerted influence in 16th-century Castile, and continue to influence modern Catalan poets. Jaume Roig's *Lo spill o llibre de les dones* (*c.* 1460; "The Mirror or Book of Women") was very different—a caustic satire on woman, written in more than 16,000 four-syllable lines, portraying contemporary Valencian life vividly. Johan Roiç de Corella, a Valencian lyricist, was perhaps the best representative of the Renaissance.

After the union of Aragon with Castile, the Castilian language predominated throughout Spain, spelling a long eclipse of Catalan literature. Nevertheless, Juan Boscán Almogáver inaugurated a new Castilian school of poetry, and Castilians regard him as a landmark in the history of their Renaissance; by the time Boscán's works were published (1543), Catalan poetry had been dead for 50 years.

Prose. Though the oldest document (the text of an oath by a bishop of Urgel) dates from *c.* 1100, literary prose did not begin until the end of the 13th century. It was written in the everyday speech found in charters from the time of James I's accession to the Aragonese throne in 1213; four great chronicles that survive represent the peak of medieval Catalan prose. The anonymous *Llibre dels feyts del rey en Jacme* ("Book of the Deeds of King James"), compiled after James I's death in 1276, and Ramon Muntaner's account of the Grand Catalan Company's expedition to the Morea in southern Greece and of James II's conquest of Sardinia were distinguished by skill of narration and quality of language. Bernat Desclot's chronicle deals with the reign of Peter I the Great; though the account of Peter IV the Ceremonious is ascribed to Bernat Desclot, it was planned and revised by the King himself.

The works of Ramon Llull

Ramon Llull was unequaled in his encyclopaedic production, in Catalan, Arabic, and Latin, covering every branch of medieval knowledge and thought. His exhaustive theological treatise *Llibre de contemplació en Déu* (*c.* 1272; "Book of the Contemplation of God") began Catalonia's golden age of literature, providing incidentally a mine of information on contemporary society. The *Llibre d'Evast e Blanquerna* (*c.* 1284; *Blanquerna; a Thirteenth Century Romance*) founded Catalan fiction. It included the *Llibre d'amic e amat* (*Book of the Lover and the Beloved*), a masterpiece of mysticism, while his *Fèlix* (*c.* 1288) and *Llibre de l'orde de cauaylería* (between 1275 and 1281; *The Book of the Order of Chivalry*) were instructive works in a narrative framework.

Bernat Metge began the "classical age" by translating Boccaccio's story of Griselda from Petrarch's Latin version and, clothing his scholastic learning with poetic imagination, achieved the stylistic masterpiece of Catalan prose. The chivalric romance *Tirant lo Blanc* (*c.* 1460) by Joanot Martorell was notable of its kind for the theme, drawn from Muntaner, of the real adventures of the Catalans in the Middle East. The anonymous late 14th-century *Curial e Güelfa* draws on Desclot and is the only other Catalan romance in this vein.

The beginnings of drama were represented by a 15th-century Assumption play, *Misteri d'Elch,* which is still performed annually at Elche on the Feast of the Assumption.

DECLINE: 16TH–18TH CENTURY

With the loss of political independence, literary and linguistic independence was also lost, and Catalan fell to the level of a patois, kept alive only in the countryside and in the pulpit. The 16th century furnishes a single poet worthy of the name: Pere Serafí, some of whose *Cants d'amor* (1565), written in imitation of Ausiàs March but less obscure, are graceful enough to merit remembrance. In prose, only scholars, chiefly antiquaries and historians, still wrote in Catalan. Forty years of research and abundant documentation give interest to the *Crònica universal del principat de Cathalunya,* a history of the Catalan kingdom, of Jeroni Pujadas, of which only the first part (1609) is in Catalan. Thereafter, the eclipse was almost complete. Catalan remained only as the language of folk song and ballad; in these—first collected in the *Romancerillo catalán* (1853; "Little Collection of Catalan Ballads") by Manuel Milà i Fontanals, the historian who played a considerable part in the Catalan revival—it lived on until the reawakening.

THE RENAIXENSA AND AFTER

In 1814 appeared the *Gramática y apologia de la llengua cathalana* ("Grammar and Apology of the Catalan Language") of Josep Pau Ballot i Torres, a forerunner of the literary and linguistic renascence (Renaixensa) that marked the Romantic period in Catalonia. The pioneers, however, saw the inadequacies of the ancient language for the expression of spiritual and intellectual ideas. The Institut d'Estudis Catalans, founded in Barcelona in 1907, has played a notable part in the deliberate enrichment and purifying of Catalan as a vehicle for contemporary thought.

Bonaventura Carles Aribau's patriotic *Oda a la pátria*

Major Romantic poets

(1832; "Ode to the Fatherland") and the poems of Joaquim Rubió i Ors and Victor Balaguer prepared the way for the mysticism of Jacintó Verdaguer Santaló, a great epic poet (*L'Atlántida* [1877], *Canigó* [1886]). Miguel Costa i Llobera cultivated a classical perfection of form. In Joan Maragall i Gorina, Catalonia found its first great modern poet who, in spiritual quality, exerted a powerful influence on later poets.

The foundations of modern Catalan prose were laid by the critical writings of Rubió i Ors, Francisco Pi i Margall, one of the four presidents of the Spanish Republic of 1873, and Josep Torras i Bages (*La tradició catalana* [1892; "The Catalan Tradition"]). One of the best and most influential writers in prose was the essayist Eugeni d'Ors (pseudonym "Xenius"), whose philosophical novel *La ben plantada* (1911; "Firmly Rooted") was one of the most notable works in modern Catalan literature.

Catalan dramatists have produced plays of considerable originality. Àngel Guimerà achieved a European reputation with *Terra baixa* (1896; "Lowlands"), which inspired a German and a French opera and was widely translated. The many social dramas of Ignasi Iglésias, inspired by the early works of Gerhart Hauptmann, included one near-masterpiece, *Els Vells* (1903). Adrià Gual, author of several works of fantasy, did his best work as director of the Teatre Intim, founded in Barcelona in 1898, which familiarized the public with the great drama of all countries and ages.

Further development of modern Catalan literature was delayed by the dictatorship (1923–30) of Miguel Primo de Rivera, who banned the use of any language other than Castilian, and by the Civil War of 1936–39. Many Catalan men of letters fled abroad, and those who remained found the political climate hardly conducive to productive literary activity.

Conditions in Catalonia improved only slightly during the postwar years as the government of Gen. Francisco Franco adopted a generally repressive policy toward Catalan culture. Although some Catalan writers chose to ignore the prevailing realities and cultivated what could be construed as a literature of artistic escape, the most influential poets of the period, Salvador Espriu and Pere Quart (pseudonym of Joan Oliver), began writing poetry that dealt with social issues in a decidedly Realistic mode. Other recent Catalan authors of note, such as the prose writers Mercè Rodoreda and Josep Maria Espinàs, also have largely grounded their works in contemporary social life.

Galician literature

Medieval poetry. Galician is closely related to Portuguese, and there is no separating the two languages in the three great repositories of medieval verse, the 14th-century *Cancioneiro* ("Songbook") *da Ajuda, Cancioneiro da Vaticana,* and *Colocci-Brancuti.* Indigenous lyric origins were overlaid by Provençal influence, and a dominance of emotion over thought identified Galician with subjective lyricism, so that for over a century Castilian poets made it their medium for lyrics. Of 116 names in the *Cancioneiro da Vaticana,* 75 have been tentatively identified as Galician; none achieved particular individuality. Macías El Enamorado (flourished mid-14th century) was the last Galician troubadour; Galicians thereafter wrote in Castilian, and, though there were echoes of their tradition, the Renaissance and Castilian political hegemony finally ended Galician literature until the 19th century.

The modern revival. The Romantic movement, like the Peninsular War, revived local feeling and interest in things Galician but not in the language. The *xogos froraes* ("floral games," or poetry congresses; an equivalent of Catalan and Provençal *jocs florals*) of 1861, with the first dictionary (1863) and first grammar (1864) of Galician, marked a change. Francisco Añón y Paz was the first notable poet in the resurrected idiom, his most stirring notes being love of country and of freedom. Rosalía de Castro, the greatest name in Galician literature, identified herself with the spirit and people of the Galician countryside in *Cantares gallegos* (1863; "Galician Songs"); her *Follas novas* (1880; "New Leaves"), introspective to the verge of despair, reflected deep personal sorrows. Eduardo Pondal y Abente, a bard of a dimly sensed heroic past, was concerned with nature and Celtic mythology. Valentín Lamas Carvajal has been remembered as the voice of the peasant.

Rosalía de Castro

Prose showed no comparable achievement. Aurelio Ribalta, Manuel Lugrís Freire, and Heraclio Pérez Placer wrote short stories but were overshadowed by novelists of stature—Emilia, condesa de Pardo Bazán, and Rosalía de Castro—who chose to write for a larger public in Castilian.

The 20th century has produced, especially since 1920, a continuing abundance of Galician poets, not yet sufficiently differentiated, who underline the identification of Galician literature with a markedly poetic regional temperament and language.

Speech

While many animals possess voices of various types and inflections, man has learned to modulate his voice by articulating the laryngeal tone into audible oral speech. Vocal sound in itself is meaningless, until the conventional codes of a language have been learned, ordinarily first from the mother, then from other family members, and finally in school. "Sick," for example, means "ill" in English, while *sic* means "so" or "thus" in Latin. The difference between speech and language is one of application. Speech is the oral, audible expression of human language while talking. Writing and reading represent the use of human language through graphic symbols. The Morse code, naval flag signals, smoke signals of American Indians, African drum languages, and the almost extinct whistle language of the Pyrenees are all examples of special language usage without the need for oral speech. Each of these language systems has its own mode of transmission (electronic equipment, light, and air) and each is limited by darkness, distance, obstacles, etc.

Man became characteristically human when he learned to speak, perhaps 1,000,000 or more years ago, although the exact time will probably never be known. The ability to use symbolic and abstract spoken language is so far specifically human, though psychologists who have investigated the possibility of teaching spoken language to chimpanzees raised like human children in the family home have had results that, while limited, suggested that great affection and intensive training can teach a nonhuman some primitive beginnings of symbolic verbal behaviour (*e.g.*, sounds resembling "mama").

Man differs from the higher animals in several respects: he makes no mechanical use of his mouth in food gathering or tool making, and thus has freed his oral cavity for such activities as verbal articulation. He has developed manual dexterity, the preferred use of one leading and dominant hand for skilled manipulation, drawing, and (later) writing. Preferred laterality (left or right) of hand, foot, eye, face muscles, tongue, and even ears is linked to the development of a distinctively human (known in no other animal) dominance of one brain hemisphere over the other in speech learning. Many nerve pathways from either side of the brain cross to the other side of the body. Thus, the human brain became ready for specialized language function in the dominant hemisphere of the brain, usually the left hemisphere. It may be inferred that language had as its precursors such phenomena as tool making and cerebral dominance. Conversely, it would seem that prehistoric relics of fire, tools, weapons, and utensils indicate that the makers of such artifacts must have possessed some form of language. All human culture (and its propagation) appears to depend on some form of language to serve as the vehicle for teaching, persuasion, and tradition. Indeed, cultural impoverishment is observed in those with little or no language and speech: deaf-mutes, the mentally retarded, or the abnormally isolated. Without special instruction, learning is greatly impeded in deaf children, despite the potential for great intelligence that may be present.

The phonetics of speech

ARTICULATORY PHONETICS

The traditional method of describing speech sounds is in terms of the movements of the vocal organs that produce them. The main structures that are important in the production of speech are the lungs and the respiratory system, together with the vocal organs shown in Figure 1. The airstream from the lungs passes between the vocal cords, which are two small muscular folds located in the larynx at the top of the windpipe. The space between the vocal cords is known as the glottis. If the vocal cords are apart, as they are normally when breathing out, the air from the lungs will have a relatively free passage into the pharynx (see Figure 1) and the mouth. But if the vocal cords are adjusted so that there is a narrow passage between them, the airstream will cause them to be sucked together. As soon as they are together there will be no flow of air, and the pressure below them will be built up until they are blown apart again. The flow of air between them will then cause them to be sucked together again, and the vibratory cycle will continue. Sounds produced when the vocal cords are vibrating are said to be voiced, as opposed to those in which the vocal cords are apart, which are said to be voiceless.

Voiced and voiceless sounds

The air passages above the vocal cords are known collectively as the vocal tract. For phonetic purposes they may be divided into the oral tract within the mouth and the pharynx, and the nasal tract within the nose. Many speech sounds are characterized by movements of the lower articulators—*i.e.*, the tongue or the lower lip—toward the upper articulators within the oral tract. The upper surface includes several important structures from the point of view of speech production, such as the upper lip and the upper teeth; Figure 1 illustrates most of the terms that are commonly used. The alveolar ridge is a small protu-

berance just behind the upper front teeth that can easily be felt with the tongue. The major part of the roof of the mouth is formed by the hard palate in the front, and the soft palate or velum at the back. The soft palate is a muscular flap that can be raised so as to shut off the nasal tract and prevent air from going out through the nose. When it is raised so that the soft palate is pressed against the back wall of the pharynx there is said to be a velic closure. At the lower end of the soft palate is a small hanging appendage known as the uvula.

As may be seen from Figure 1, there are also specific names for different parts of the tongue. The tip and blade are the most mobile parts. Behind the blade is the so-called front of the tongue; it is actually the forward part of the body of the tongue and lies underneath the hard palate when the tongue is at rest. The remainder of the body of the tongue may be divided into the centre, which is partly beneath the hard palate and partly beneath the soft palate; the back, which is beneath the soft palate; and the root, which is opposite the back wall of the pharynx.

The major division in speech sounds is that between vowels and consonants. Phoneticians have found it difficult to give a precise definition of the articulatory distinction between these two classes of sounds. Most authorities would agree that a vowel is a sound that is produced without any major constrictions in the vocal tract, so that there is a relatively free passage for the air. It is also syllabic. This description is unsatisfactory in that no adequate definition of the notion syllabic has yet been formulated.

Consonants. In the formation of consonants, the airstream through the vocal tract is obstructed in some way. Consonants can be classified according to the place and manner of this obstruction. Some of the possible places of articulation are indicated by the arrows going from one of the lower articulators to one of the upper articulators in Figure 1. The principal terms that are required in the description of English articulation, and the structures of the vocal tract that they involve are: bilabial, the two lips; dental, tongue tip or blade and the upper front teeth; alveolar, tongue tip or blade and the teeth ridge; retroflex, tongue tip and the back part of the teeth ridge; palato-alveolar, tongue blade and the back part of the teeth ridge; palatal, front of tongue and hard palate; and velar, back of tongue and soft palate. The additional places of articulation shown in Figure 1 are required in the description of other languages. Note that the terms for the various places of articulation denote both the portion of the lower articulators (*i.e.*, lower lip and tongue) and the portion of the upper articulatory structures that are involved. Thus velar denotes a sound in which the back of the tongue and the soft palate are involved, and retroflex implies a sound involving the tip of the tongue and the back part of the alveolar ridge. If it is necessary to distinguish between sounds made with the tip of the tongue and those made with the blade, the terms apical (tip) and laminal (blade) may be used.

Classification of consonants

There are six basic manners of articulation that can be used at these places of articulation: stop, fricative, approximant, trill, tap, and lateral.

Stops. Stops involve closure of the articulators to obstruct the airstream. This manner of articulation can be considered in terms of nasal and oral stops. If the soft palate is down so that air can still go out through the nose, there is said to be a nasal stop. Sounds of this kind occur at the beginning of the words *my* and *nigh*. If, in addition to the articulatory closure in the mouth, the soft palate is raised so that the nasal tract is blocked off, then the airstream will be completely obstructed, the pressure in the mouth will be built up, and an oral stop will be formed. When the articulators open the airstream will be released with a plosive quality. This kind of sound occurs in the consonants in the words *pie, tie, kye, buy, die,* and *guy*. Many authorities refer to these two articulations as nasals, meaning nasal stops (closure of the articulators in the oral tract), and stops, meaning oral stops (raising of the soft palate to form a velic closure).

Fricatives. A fricative sound involves the close approximation of two articulators, so that the airstream is partially obstructed and a turbulent airflow is produced. The mechanisms used in the production of these sounds may be compared to the physical forces involved when the wind "whistles" round a corner. Examples are the initial sounds in the words *fie, thigh, sigh* and *shy*. Some authorities divide fricatives into slit and grooved fricatives, or rill and flat fricatives, depending on the shape of the constriction in the mouth required to produce them. Other authorities divide fricatives into sibilants, as in *sigh* and *shy*, and nonsibilants, as in *fie* and *thigh*. This division is based on acoustic criteria (see below).

Varieties of fricatives

Approximants. Approximants are produced when one articulator approaches another but does not make the vocal tract so narrow that a turbulent airstream results. The terms frictionless continuant, semivowel, and glide are sometimes used for some of the sounds made with this manner of articulation. The consonants in the words *we* and *you* are examples of approximants.

Trills. A trill results when an articulator is held loosely fairly close to another articulator, so that it is set into vibration by the airstream. The tongue tip and blade, the uvula, and the lips are the only articulators than can be used in this way. Tongue tip trills occur in some forms of Scottish English in words such as *rye* and *ire*. Uvular trills are comparatively rare but are used in some dialects of French, but not Parisian French. Trills of the lips are even rarer but do occur in a few African languages.

Taps. A tap is produced if one articulator is thrown against another, as when the loosely held tongue tip makes a single tap against the upper teeth or the alveolar ridge. The consonant in the middle of a word such as *letter* or *Betty* is often made in this way in American English. The term flap is also used to describe these sounds, but some authorities make a distinction between taps as defined here and flaps, in which the tip of the tongue is raised up and back and then strikes the alveolar ridge as it returns to a position behind the lower front teeth. Some languages—*e.g.*, Hausa, the principal language of Northern Nigeria—distinguish between words containing a flap and words containing a tap. The distinction between a trill and a tap is used in Spanish to distinguish between words such as *perro,* meaning "dog," and *pero,* meaning "but."

Laterals. When the airstream is obstructed in the midline of the oral tract, and there is incomplete closure between one or both sides of the tongue and the roof of the mouth, the resulting sound is classified as a lateral. The sounds at the beginning and end of the word *lull* are laterals in most forms of American English.

Affricates

The production of many sounds involves more than one of these six basic manners of articulation. The sounds at the beginning and end of the word *church* are stops combined with fricatives. The articulators—tongue tip or blade, and alveolar ridge—come together for the stop, and then, instead of coming fully apart, they separate only slightly so that a fricative is made at the same place of articulation. This kind of combination is called an affricate. Lateral articulations may also occur in combination with other manners of articulation. The laterals in a word such as *lull* might more properly be called lateral approximants, in that the airstream passes out freely between the sides of the tongue and the roof of the mouth without a turbulent airstream being produced. But in some sounds in other languages the sides of the tongue are closer to the roof of the mouth and a lateral fricative occurs; an example is the sound spelled *ll* in Welsh words such as *llan* "church" and the name *Lluellyn.*

Secondary articulations. When an approximant articulation occurs at the same time as another articulation is being made at a different place in the vocal tract, the approximant is said to form a secondary articulation. There are special terms for some of these possibilities. Added lip rounding is called labialization; it occurs in the formation of several English sounds—*e.g.,* during the pronunciation of the palato-alveolar fricative at the beginning of the word *shoe.* Raising of the front of the tongue while simultaneously making another articulation elsewhere in the vocal tract is called palatalization. It is the distinguishing characteristic of the soft consonants in Russian and also occurs, to a lesser extent, in English; *e.g.,* in the first consonant in the word *leaf.* Raising of the back of the tongue to form a secondary articulation is called velarization; it occurs in the last consonant in the word *feel,* which therefore does not contain the same sounds as those in the reverse order in the word *leaf.* Retracting of the root of the tongue while making another articulation is called pharyngealization; it occurs in Arabic in what are called emphatic consonants.

States of the glottis

The states of the glottis, places of articulation, and manners of articulation discussed above are sufficient to distinguish between the major contrasts among the consonants of English and many other languages. But additional possibilities have to be taken into account in a more detailed description of English, or in descriptions of several other languages. Among these possibilities are variations in the timing of the states of the glottis. In addition to the contrast between the voiced and voiceless states of the glottis that occur during an articulation, there may be variations in the state of the glottis during the release of the articulation. Thus both the *p* in *pin* and that in *spin* are voiceless bilabial stops, but they differ in that the glottis remains in a voiceless position for a short time after the release of the bilabial stop in *pin,* whereas in *spin* the voicing starts as soon as the lips come apart. When there is a period of voicelessness during the release of an articulation, the sound is said to be aspirated. The main difference between the consonants in *pea* and *bee,* when these words are said in isolation, is not that the one is voiceless and the other voiced, but that the first is aspirated and the second is unaspirated. Some languages distinguish between both voiced–voiceless and aspirated–unaspirated sounds. Thus Thai has contrasts between voiceless aspirated stops, voiceless unaspirated stops, and voiced unaspirated stops.

Several languages use more than just the voiced and voiceless states of the glottis. In Hindi and many of the other languages of India, some sounds are produced while the vocal cords are vibrating for part of their length but are apart, so that a considerable amount of air escapes between them at one end. This phenomenon is known as breathy voice, or murmur. Other languages have sounds in which the vocal cords are held tightly together so that only part of their length can vibrate. This kind of sound, which is usually very low pitched, is sometimes called creaky voice, or vocal fry. It is used to make contrasts between consonants in several American Indian languages. An additional glottal state that is widely used—*e.g.,* in the Austronesian (Malayo–Polynesian) languages of the Philippines—is a glottal stop, a tight closure of the two vocal cords. This articulation also occurs in many forms of English as the usual pronunciation of *t* in words such as *bitten* and *fatten.*

Types of airstream. In English, all sounds are produced with an airstream caused by the expiration of the air from the lungs. This is known as a pulmonic airstream. Other mechanisms for producing an airstream also occur. If there is a glottal stop and the closed glottis is moved rapidly upward or downward it can act like a piston pushing or pulling the air in the pharynx. This is the glottalic airstream mechanism. When there is an upward movement of the closed glottis the resulting sound is called an ejective. Amharic, the national language of Ethiopia, uses this mechanism to produce both ejective stops and fricatives, which contrast with the more usual stops and fricatives made with a pulmonic airstream mechanism. A downward movement of the glottis is used in the production of implosive sounds, which occur in many American Indian, African, and other languages. The use of movements of the tongue to suck air into the mouth is known as the velaric airstream mechanism; it occurs in the production of clicks, which are regular speech sounds in many languages of southern Africa.

Factors in consonant description

To summarize, a consonant may be described by reference to seven factors: (1) state of the glottis, (2) secondary articulation (if any), (3) place of articulation, (4) type of airstream, (5) central or lateral articulation, (6) velic closure—oral or nasal, and (7) manner of articulation. Thus the consonant at the beginning of the word *swim* is a (1) voiceless, (2) labialized, (3) alveolar, (4) pulmonic, (5) central, (6) oral, (7) fricative. Unless a specific statement is made to the contrary, consonants are usually presumed to have a pulmonic airstream and no secondary articulation, and it is also assumed that they are not laterals or nasals. Consequently, points 2, 4, 5, and 6 are often disregarded and a three-term description—*e.g.,* voiceless alveolar fricative is sufficient.

Vowels. Vowels traditionally have been specified in terms of the position of the highest point of the tongue and the position of the lips. Figure 2 shows these positions for eight different vowels. The highest point of the tongue is in the front of the mouth for the vowels in *heed, hid, head,* and *had.* Accordingly, these vowels are classified as front vowels, whereas the vowels in *hod, hawed, hood,* and *who'd* are classified as back vowels. The tongue is highest in the vowels in *heed* and *who'd,* which are therefore called high, or close, vowels, and lowest in the vowels in *had* and *hod,* which are called low, or open, vowels. The height of the tongue for the vowels in the other words is between these two extremes, and they are therefore called midvowels. Lip positions may be described as being rounded, as in *who'd,* or unrounded or spread, as in *heed.*

The specification of vowels in terms of the position of the highest point of the tongue is not entirely satisfactory for a number of reasons. In the first place, it disregards the fact that the shape of the tongue as a whole is very different in front vowels and in back vowels. Second, although the height of the tongue in front vowels varies by approximately equal amounts for what are called equidistant steps in vowel quality, this is just not factually true

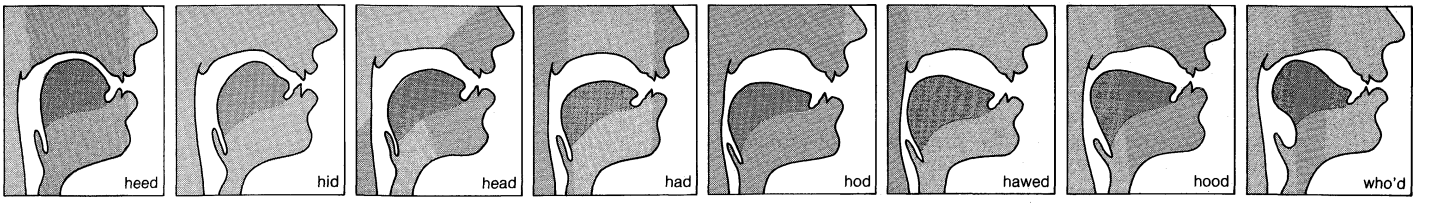

Figure 2: Tongue position for several vowel sounds.

in descriptions of back vowels. Third, the width of the pharynx varies considerably, and to some extent independently of the height of the tongue, in different vowels.

Tenseness and laxness

Some authorities use terms such as tense and lax to describe the degree of tension in the tongue muscles, particularly those muscles responsible for the bunching up of the tongue lengthways. Other authorities use the term tense to specify a greater degree of muscular activity, resulting in a greater deformation of the tongue from its neutral position. Tense vowels are longer than the corresponding lax vowels. The vowels in *heed* and *hayed* are tense, whereas those in *hid* and *head* are lax.

In many languages there is a strong tendency for front vowels to have spread lip positions, and back vowels to have lip rounding. As will be seen in the next section, this results in vowels that are acoustically maximally distinct. But many languages—*e.g.*, French and German—have front rounded vowels. Thus French has a contrast between a high front unrounded vowel in *vie,* "life," and a high front rounded vowel with a very similar tongue position in *vu,* "seen," as well as a high back rounded vowel in *vous,* "you." Unrounded back vowels also occur—*e.g.*, in Vietnamese.

Nasalized vowels, in which the soft palate is lowered so that part of the airstream goes out through the nose, occur in many languages. French distinguishes between several nasalized vowels and vowels made with similar tongue positions but with the soft palate raised. Low vowels in many forms of English are often nasalized, especially when they occur between nasal consonants, as in *man.*

Cardinal vowels

Because of the difficulty of observing the precise tongue positions that occur in vowels, a set of eight vowels known as the cardinal vowels has been devised to act as reference points. This set of vowels is defined partly in articulatory and partly in auditory terms. Cardinal vowel number one is defined as the highest and farthest front tongue position that can be made without producing a fricative sound; cardinal vowel number five is defined as the lowest and farthest back vowel. Cardinal vowels two, three, and four are a series of front vowels that form auditorily equidistant steps between cardinal vowels one and five; and cardinal vowels six, seven, and eight are a series of back vowels with the same sized auditory steps as in the front vowel series. Phoneticians who have been trained in the cardinal vowel system are able to make precise descriptions of the vowels of any language in terms of these reference points.

Suprasegmentals. Vowels and consonants can be considered to be the segments of which speech is composed. Together they form syllables, which in turn make up utterances. Superimposed on the syllables there are other features that are known as suprasegmentals. These include variations in stress (accent) and pitch (tone and intonation). Variations in length are also usually considered to be suprasegmental features, although they can affect single segments as well as whole syllables. All of the suprasegmental features are characterized by the fact that they must be described in relation to other items in the same utterance. It is the relative values of the pitch, length, or degree of stress of an item that are significant. The absolute values are never linguistically important, although they may be of importance paralinguistically, in that they convey information about the age and sex of the speaker, his emotional state, and his attitude.

Many languages—*e.g.*, Finnish and Estonian—use length distinctions, so that they have long and short vowels; a slightly smaller number of languages, among them Luganda (the language spoken by the largest tribe in Uganda) and Japanese, also have long and short consonants. In most languages segments followed by voiced consonants are longer than those followed by voiceless consonants. Thus the vowel in *cad* before the voiced *d* is much longer than that in *cat* before the voiceless *t*. Variations in stress are caused by an increase in the activity of the respiratory muscles, so that a greater amount of air is pushed out of the lungs, and in the activity of the laryngeal muscles, resulting in significant changes in pitch. In English, stress has a grammatical function, distinguishing between nouns and verbs, such as *an insult* versus *to insult*. It can also be used for contrastive emphasis, as in *I want a RED pen, not a black one.*

Pitch and intonation

Variations in laryngeal activity can occur independently of stress changes. The resulting pitch changes can affect the meaning of the sentence as a whole, or the meaning of the individual words. Pitch pattern is known as intonation. In English the meaning of a sentence such as *That's a cat* can be changed from a statement to a question by the substitution of a mainly rising for a mainly falling intonation. Pitch patterns that affect the meanings of individual words are known as tones and are common in many languages. In Chinese, for example, a syllable that is transliterated as *ma* means "mother" when said on a high tone, "hemp" on a midrising tone, "horse" on the falling-rising tone, and "scold" on a high-falling tone.

ACOUSTIC PHONETICS

Speech sounds consist of small variations in air pressure that can be sensed by the ear. Like other sounds, speech sounds can be divided into two major classes—those that have periodic wave forms (*i.e.*, regular fluctuations in air pressure) and those that do not. The first class consists of all the voiced sounds, because the vibrations of the vocal cords produce regular pulses of air pressure.

From a listener's point of view, sounds may be said to vary in pitch, loudness, and quality. The pitch of a sound with a periodic wave form—*i.e.*, a voiced sound—is determined by its fundamental frequency, or rate of repetition of the cycles of air pressure. For a speaker with a bass voice, the fundamental frequency will probably be between 75 and 150 cycles per second. Cycles per second are also called hertz (Hz); this is the standard term for the unit in frequency measurements. A soprano may have a speaking voice in which the vocal cords vibrate to produce a fundamental frequency of over 400 hertz. The relative loudness of a voiced sound is largely dependent on the amplitude of the pulses of air pressure produced by the vibrating vocal cords. Pulses of air with a larger amplitude have a larger increase in air pressure.

Fundamental frequency

The quality of a sound is determined by the smaller variations in air pressure that are superimposed on the major variations that recur at the fundamental frequency. These smaller variations in air pressure correspond to the overtones that occur above the fundamental frequency. Each time the vocal cords open and close there is a pulse of air from the lungs. These pulses act like sharp taps on the air in the vocal tract, which is accordingly set into vibration in a way that is determined by its size and shape. In a vowel sound, the air in the vocal tract vibrates at three or four frequencies simultaneously. These frequencies are the resonant frequencies of that particular vocal tract shape. Irrespective of the fundamental frequency that is determined by the rate of vibration of the vocal cords, the air in the vocal tract will resonate at these three or four overtone frequencies as long as the position of the vocal organs remains the same. In this way a vowel has its own characteristic auditory quality, which is the result of the specific variations in air pressure caused by the superimposing of the vocal tract shape on the fundamental frequency produced by the vocal cords.

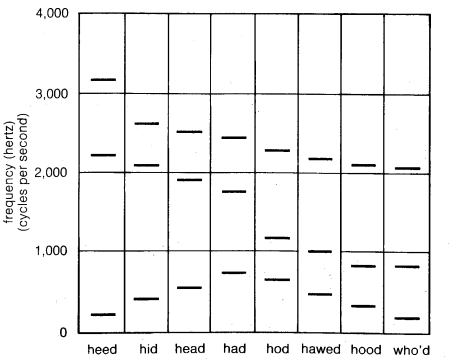

Figure 3: Schematic spectrogram showing frequencies of the first three formants of the vowels in similar English words.

Vowel formants. The resonant frequencies of the vocal tract are known as the formants. The frequencies of the first three formants of the vowels in the words *heed, hid, head, had, hod, hawed, hood,* and *who'd* are shown in Figure 3. Comparison with Figure 2 shows that there are no simple relationships between actual tongue positions and formant frequencies. There is, however, a good inverse correlation between one of the labels used to describe the tongue position and the frequency of the first, or lowest, formant. This formant is lowest in the so-called high vowels, and highest in the so-called low vowels. When phoneticians describe vowels as high or low, they probably are actually specifying the inverse of the frequency of the first formant.

Most people cannot hear the pitches of the individual formants in normal speech. In whispered speech, however, there are no regular variations in air pressure produced by the vocal cords, and the higher resonances of the vocal tract are more clearly audible. It is quite easy to hear the falling pitch of the second formant when whispering the series of words *heed, hid, head, had, hod, hawed, hood, who'd.* Conversely, the auditory effect of the second and higher formants is lessened when speaking in a creaky voice. Under such conditions, it is possible to hear the rise in pitch of the first formant during the first four of these words, and the fall in pitch during the last.

Consonant formants. Voiced consonants such as nasals and laterals also have specific vocal tract shapes that are characterized by the frequencies of the formants. They differ from vowels in that in their production the vocal tract is not a single tube. There is a side branch formed when the nasal tract is coupled in with the oral tract, or, in the case of laterals, when the oral tract itself is obstructed in the centre. The effect of these side branches is that the relative amplitudes of the formants are altered; it is as if one or more of the possible superimposed variations in air pressure had been lessened because it had been trapped in the cavity formed at the side. Nasals and laterals can therefore be specified in terms of their formant frequencies, just like vowels. But in a complete specification of these consonants the relative amplitudes of the formants also have to be given, because they are not completely predictable.

Other voiced consonants such as stops and approximants (semivowels) are more like vowels in that they can be characterized in part by the resonant frequencies—the formants—of their vocal tract shapes. They differ from vowels in that during a voiced stop closure there is very little acoustic energy, and during the release phase of a stop and the entire articulation of a semivowel the vocal tract shapes are changing comparatively rapidly. These transitional movements can be specified acoustically in terms of the movements of the formant frequencies.

Pitch of voiceless sounds

Voiceless sounds do not have a periodic wave form with a well-defined fundamental frequency. Nevertheless, some sensations of pitch accompany the variations in air pressure caused by the turbulent airflow that occurs during a voiceless fricative, or in the release phase of a voiceless stop. This is because the pressure variations are far from random. During the first consonant in *sea* these have a tendency to be at a higher centre frequency, and hence a higher pitch, than in the pronunciation of the first consonant in *she.* There is also a difference in the average amplitude of the wave form in different voiceless sounds. All voiceless sounds have much less energy—*i.e.,* a smaller amplitude—than voiced sounds pronounced with the same degree of effort. Other things being equal, the fricatives in *sin* and *shin* have more amplitude—*i.e.,* are louder—than those in *thin* and *fin.*

In summary, speech sounds are fairly well defined by nine acoustic factors. The first three factors include the frequencies of the first three formants; these are responsible for the major part of the information in speech. Characterizing the vocal tract shape, these formant frequencies specify vowels, nasals, laterals, and the transitional movements in voiced consonants. The frequencies of the fourth and higher formants do not vary significantly. The fourth factor is the fundamental frequency—roughly speaking, the pitch—of the larynx pulse in voiced sounds, and the fifth, the amplitude—roughly speaking, the loudness—of the larynx pulse. These last two factors account for suprasegmental information; *e.g.,* variations in stress and intonation. They also distinguish between voiced and voiceless sounds, in that the latter have no larynx pulse amplitude. The centre frequency of the high-frequency hissing noises in voiceless sounds constitutes the sixth acoustic factor, and the seventh is the amplitude of these high-frequency noises. These two factors characterize the major differences among voiceless sounds. In more accurate descriptions it would be necessary to specify more than just the centre frequency of the noise in fricative sounds. The eighth and ninth factors include the amplitudes of the second and third formants relative to the first formant; the amplitudes of the formants as a whole are determined by the larynx pulse amplitude. These latter factors are the least important in that they convey only supplementary information about nasals and laterals.

Instruments for acoustic phonetics. The principal instrument used in acoustic phonetic studies is the sound spectrograph. This device gives a visible record of any kind of sound. A spectrographic analysis of the phrase *speech pictures* is shown in Figure 4. The time of occurrence of each item is given on the horizontal scale. The vertical scale shows the frequency components at each moment

Sound spectrograph

in time, the amplitude of the components being shown by the darkness of the mark. (Figure 3 diagrams the formant frequencies in a set of English vowels in the same way and might be regarded as a schematic spectrogram.) In the phrase *speech pictures* the first consonant has a comparatively random distribution of energy, but, as Figure 4 shows, it is mainly in the higher frequencies. The second consonant is a voiceless stop, which produces a short gap in the pattern. The next segment, the first vowel, has four formants that appear as dark bars with centre frequencies of 300, 2,000, 2,700, and 3,400 hertz. Each of the other segments has its own distinctive pattern.

Much information has also been gained from the use of speech synthesizers, which are instruments that take specifications of speech in terms of the acoustic factors summarized above and generate the corresponding sounds. Some speech synthesizers use electronic signal generators and amplifiers; others use digital computers to calculate the values of the required sound waves. Good synthetic speech is hard to distinguish from high-quality recordings of natural speech. The principal value of a speech synthesizer is its precisely controllable "voice" that an experimenter can vary in a systematic way to determine the perceptual effects of different acoustic specifications.

LINGUISTIC PHONETICS

Phonetics is part of linguistics in that one of the main aims of phonetics is to determine the categories that can

Relation of phonetics to linguistics

be used in explanatory description of languages. One way of looking at the grammar of a language is to consider it to be a set of statements that explains the relation between the meanings of all possible sentences in a language and the sounds of which they are composed. In this view, a grammar may be divided into three parts: the syntactic component, which is a set of rules describing the ways in which words may form sentences; the lexicon, which is a list of all the words and the categories to which they belong; and the phonological component, which is a set of rules that relates phonetic descriptions of sentences to the syntactic and lexical descriptions.

Phonological rules. In the lexicon of a language, each word is represented in its underlying, or basic, form, which discounts all of the alternations in pronunciation that are predictable by phonological rules. For example, there are phonological rules that will account for the variations in the placement of stress and the alternations of vowel quality that occur in sets of words such as *harmOny, harmOnic, harmOnious* and *melOdy, melOdic, melOdious.* The rules that predict the pronunciation of the capitalized *O*'s are general, rather than specific for each word, and the grammar should state such rules so that the regularities are revealed. Accordingly, each of these words must be entered in the lexicon in a way that represents simply its underlying form, and that allows the alternations that occur to be generated by phonological rules. The underlying form is known as the phonemic—sometimes morphophonemic, or phonological—representation of the word. The phonemes of a language are the segments that contrast in the underlying forms. American English may be said to have at least 13 vowel phonemes, which contrast in the underlying forms of words such as *bate, bat, beat, bet, bite, bit, bout, but, boat, dot, bought, balm,* and *boy.* Some authorities consider that there are additional vowel phonemes exemplified in the words *bush* and *beaut(y)*, but others believe that these can be derived from the same underlying vowel as that in the word *bud.* Phonemes are traditionally written between slanting lines, as /P/, /M/, or /L/.

The variants of phonemes that occur in phonetic representations of sentences are known as allophones. They may be considered to be generated as a result of applying the phonological rules to the phonemes in underlying forms. For example, there is a phonological rule of English that says that a voiceless stop such as /P/ is aspirated when it occurs at the beginning of a word (*e.g.,* in *pin*), but when it occurs after a voiceless alveolar fricative (*i.e.,* after/s/), it is unaspirated (*e.g.,* in *spin*). Thus the underlying phoneme /P/ has an aspirated and an unaspirated allophone, in addition to other allophones that are generated as a result of other rules that apply in other circumstances. Allophones are conventionally written inside brackets—*e.g.,* [p] or aspirated [p^h].

Classes of phonemes

In stating phonological rules it is necessary to refer to classes of phonemes. Consider part of the rule for the formation of the plural in English: there is an extra vowel in the suffix if the word ends in the same sound as occurs at the end of *horse, maze, fish, rouge, church,* or *judge.* The plural forms of words of this kind are one syllable longer than the singular forms. The phonological rules of English could simply list the phonemes that behave in the same way in the rules for plural formation; the rules for the possessive forms of nouns and for the 3rd person singular of the present tense of verbs are similar in this respect. The rules are more explanatory, however, if they show that these phonemes behave in a similar way because they form a natural class, or set, whose members are defined by a common property. In the case of these plural forms, the phonemes are all, and only, those that have a high-frequency fricative component; they may be called the sibilant, or strident, phonemes.

Other phonological rules that refer to the natural classes of phonemes have already been mentioned. The rule concerning voiceless stops' being aspirated in some circumstances and unaspirated in others refers to the subset of phonemes that are both voiceless sounds and stops. Similarly, the variations in vowel length in *cat* and *cad* can be expressed with reference to the set of phonemes that are vowels, and also to the set that comprises both voiceless sounds and stops.

Features. Each of the phonemes that appears in the lexicon of a language may be classified in terms of a set of phonetic properties, or features. Phoneticians and linguists have been trying to develop a set of features that is sufficient to classify the phonemes in each of the languages of the world. A set of features of this kind would constitute the phonetic capabilities of man. To be descriptively adequate from a linguistic point of view, the set of features must be able to provide a different representation for each of the words that is phonologically distinct in a language; and if the feature set is to have any explanatory power it must also be able to classify phonemes into appropriate natural classes as required in the phonological rules of each language.

In the earlier work on feature sets, emphasis was placed on the fact that features were the smallest discrete components of language. Not much attention was paid to their role in classifying phonemes into the natural classes required in phonological rules. Instead, they were considered to be the units to which a listener attends when listening to speech. Features were justified by reference to their role in distinguishing phonemes in minimal sets of words such as *bill, pill, fill, mill, dill, sill, kill.*

Jakobson, Fant, and Halle features. As a result of studying the phonemic contrasts within a number of languages, Roman Jakobson, Gunnar Fant, and Morris Halle concluded in 1951 that segmental phonemes could be characterized in terms of 12 distinctive features. All of the features were binary, in the sense that a phoneme either had, or did not have, the phonetic attributes of the feature. Thus phonemes could be classified as being consonantal or not, voiced or not, nasal or not, and so on. In 1968, Noam Chomsky and Morris Halle stated that nearer 30 features are needed for a proper description of the phonetic, and linguistic, capabilities of man. In agreement with Jakobson, they claimed that each feature functions as a binary opposition that can be given the value of plus or minus in classifying the phonemes in underlying forms. But they suggested that the features may require more precise systematic phonetic specifications.

Binary quality of features

Chomsky–Halle features. Some of the binary features proposed by Chomsky and Halle are listed in Table 1. The first group comprises major class features, because these features are required for dividing sounds into classes such as vowels, consonants, and semivowels. There are several problems in giving satisfactory definitions of the phonetic properties of these features, but there is no doubt that binary oppositions of this kind are needed for describing phonological patterns.

The next group, the manner of articulation features, includes continuant/noncontinuant (in which noncontinuant is exactly equivalent to the notion of stop as defined above), and delayed release (the comparatively slow parting of the articulators that occurs in an affricate). The source features refer to the action of the vocal cords (voice) or to fricative noise mechanisms (strident).

The cavity features include nasal and lateral, which are used in the same sense as they were in the section on articulatory phonetics, and the features that determine the place of articulation of consonants and the quality of vowels. The most important features specifying the place of articulation of consonants are anterior, made in the

front of the mouth, and coronal, made with the tip or blade of the tongue raised toward the teeth or teeth ridge. These two features can be used to specify four places of articulation: bilabial (+anterior, −coronal); dental, or alveolar (+anterior, +coronal); postalveolar, or palato-alveolar (−anterior, +coronal); velar (−anterior, −coronal). There is still some disagreement concerning whether consonantal places of articulation are specified appropriately by binary oppositions of this kind.

Vowels and binary features

There is even more disagreement over the advisability of describing vowels in terms of binary features. Chomsky and Halle use the features high/nonhigh and low/nonlow to specify the height of the tongue, midtongue positions being considered to be simply those that are -high, -low; the feature back/nonback is employed to specify the front/back distinctions among vowels. But these three features can be combined to specify only six basic tongue positions: high front, high back, midfront, midback, low front, and low back. It is true that each of these possibilities can have tense/nontense (lax) variants and rounded/nonrounded (spread) variants. But the Chomsky–Halle feature system does not permit the specification within underlying forms of central vowels, nor of more than three degrees of tongue height. Moreover, their binary oppositions of vowel height do not make it clear that the difference between low vowels and midvowels is the same as that between midvowels and high vowels.

Table 2 shows the feature composition of a number of segments that occur in English. The phonetic symbols at the top of each column are used with the values discussed in the following section.

PHONETIC TRANSCRIPTION

There are many different kinds of phonetic transcription. In some circumstances a phonetic symbol can be simply an abbreviation for a phonetic description. The symbol [s] may then be regarded as exactly equivalent to the phrase "voiceless, alveolar, fricative." When a linguist tries to describe an unknown language he begins by writing it down using symbols in this way. Later, when he has learned about the function of sounds and the underlying forms in the language, he might make a more systematic transcription, known as a broad transcription, in which each phoneme is represented by a simple symbol.

Occasionally it is convenient to use a transcription in which some of the allophones are represented by specific symbols, or some of the phonemes are designated by the symbols for a more restricted set of categories. If, for example, the transcription were to be used in teaching pronunciation, the difference between the aspirated and unaspirated allophones of /p/ might be represented by transcribing *pan* as [pʰan] and *span* as [span]; or the vowel phoneme in each of these words might be designated by the more specific symbol [æ], which represents a low

Narrow transcription

The most widely used set of symbols is that of the International Phonetic Association (IPA). The latest version of the IPA chart is shown in Table 3. In general, the consonants have the same values as the corresponding letters in many European languages; the vowel symbols have similar values to the corresponding letters in a language such as Italian.

EXPERIMENTAL PHONETICS

Experimental phonetics employs the methods of investigation commonly used in other disciplines—*e.g.*, physics, physiology, and psychology—for measuring the physical and physiological dimensions of speech sounds and their perceptual characteristics. The sound spectrograph and speech synthesizers were mentioned in the section on acoustic phonetics. Other techniques include the use of X-rays; air-pressure and air-flow recording; palatography, a method of registering the contacts between the tongue and the roof of the mouth; and cinematography. All of these techniques have been used for studying the actions of the vocal organs.

Much of the work in experimental phonetics has been directed toward obtaining more accurate descriptions of the sounds that characterize different languages. There have also been several studies aimed at determining the relative importance of different features in signalling contrasts between sounds. But experimental phoneticians are probably most concerned with trying to discover the central cerebral processes involved in speech.

One issue of this kind that has been extensively discussed is the so-called motor theory of speech perception. There is a great deal of evidence that the way in which people speak greatly influences their perception of what is said to them. For example, speakers of Spanish cannot pronounce the different vowels in words such as *ship* and *sheep* in English. These people also have difficulty in hearing the difference between these two vowels. But when they have learned, by trial and error methods, to say them correctly, then they can easily hear the difference. Similarly, using synthetic speech stimuli it is possible to make a series of consonant sounds that go by acoustically equidistant steps from [b] through [d] to [g]. When listeners hear these synthetic sounds they do not consider the steps between them to be auditorily equidistant. The steps that correspond to the large articulatory movements between the consonants are heard as being much larger than the equal size acoustic steps that do not correspond to articulatory movements occurring in the listener's speech. Facts such as these have led some phoneticians to believe that the perception of speech is structured more in motor—articulatory—terms than in acoustic terms. Other phoneticians have claimed that the evidence does not really distinguish between these two possibilities but demonstrates simply that the perception of speech is structured in terms of linguistic categories.

Motor theory of speech perception

Another major problem is the size of the units that are involved in the perception of speech. Some authorities have claimed that a listener distinguishes between words by making a series of binary decisions concerning the features in each segment that he hears. Others hold that the listener takes in information in much larger temporal pieces and perhaps processes speech in terms of units of at least the size of a syllable. All authorities agree on the importance of context in the processing of information. Speech conveys information in a redundant way. Experiments have shown that a listener need attend to only a part of the information presented to him in order to understand all that is being said.

Perception and size of speech units

A related problem is that of the temporal structure of speech production. There may be very little structure, and a speaker may simply time the movements of his vocal organs by allowing each gesture to run its course before starting on the next one. Alternatively, he may impose a hierarchical structure on the gestures by requiring, for instance, each major stress in a sentence to occur at some predetermined moment, and the articulatory movements to be speeded up or slowed down depending on the number of movements that have to occur before the major stress. There is some evidence in favour of this latter possibility as a result of experiments in which a speaker is asked to say a given phrase first slowly and then fast. When he is speaking at a rate that is twice as fast as some other rate, then the interval between the major stresses is about halved. But the duration of each segment is not halved. The consonants are only slightly reduced in length, whereas the vowels are considerably shortened. Some authorities have used the results of experiments of this kind to argue that the stress group is the major unit in the temporal organization of speech.

The physiology of speech

THE REGULATORS

Respiratory mechanisms. Human speech is served by a bellows-like respiratory activator, which furnishes the driving energy in the form of an airstream; a phonating sound generator in the larynx (low in the throat) to transform the energy; a sound-molding resonator in the pharynx (higher in the throat), where the individual voice pattern is shaped; and a speech-forming articulator in the oral cavity (mouth). Normally, but not necessarily, the four structures function in close coordination. Audible speech without any voice is possible during toneless whisper; there can be phonation without oral articulation as in some aspects of yodeling that depend on pharyngeal and laryngeal changes. Silent articulation without breath and voice may be used for lipreading.

An early achievement in experimental phonetics at about the end of the 19th century was a description of the differences between quiet breathing and phonic (speaking) respiration. An individual typically breathes approximately 18 to 20 times per minute during rest and much more frequently during periods of strenuous effort. Quiet respiration at rest as well as deep respiration during physical exertion are characterized by symmetry and synchrony of inhalation (inspiration) and exhalation (expiration). Inspiration and expiration are equally long, equally deep, and transport the same amount of air during the same period of time, approximately half a litre (one pint) of air per breath at rest in most adults. Recordings (made with a device called a pneumograph) of respiratory movements during rest depict a curve in which peaks are followed by valleys in fairly regular alternation.

Differences between quiet breathing and phonic respiration

Phonic respiration is different; inhalation is much deeper than it is during rest and much more rapid. After one takes this deep breath (one or two litres of air), phonic exhalation proceeds slowly and fairly regularly for as long as the spoken utterance lasts. Trained speakers and singers are able to phonate on one breath for at least 30 seconds, often for as much as 45 seconds, and exceptionally up to one minute. The period during which one can hold a tone on one breath with moderate effort is called the maximum phonation time; this potential depends on such factors as body physiology, state of health, age, body size, physical training, and the competence of the laryngeal voice generator—that is, the ability of the glottis (the vocal cords and the opening between them) to convert the moving energy of the breath stream into audible sound. A marked reduction in phonation time is characteristic of all the laryngeal diseases and disorders that weaken the precision of glottal closure, in which the cords (vocal folds) come close together, for phonation.

Respiratory movements when one is awake and asleep, at rest and at work, silent and speaking are under constant regulation by the nervous system. Specific respiratory centres within the brain stem regulate the details of respiratory mechanics according to the body needs of the moment. Conversely, the impact of emotions is heard immediately in the manner in which respiration drives the phonic generator; the timid voice of fear, the barking voice of fury, the feeble monotony of melancholy, or the raucous vehemence during agitation are examples. Conversely, many organic diseases of the nervous system or of the breathing

mechanism are projected in the sound of the sufferer's voice. Some forms of nervous system disease make the voice sound tremulous; the voice of the asthmatic sounds laboured and short winded; certain types of disease affecting a part of the brain called the cerebellum cause respiration to be forced and strained so that the voice becomes extremely low and grunting. Such observations have led to the traditional practice of prescribing that vocal education begin with exercises in proper breathing.

Types of breathing

The mechanism of phonic breathing involves three types of respiration: (1) predominantly pectoral breathing (chiefly by elevation of the chest), (2) predominantly abdominal breathing (through marked movements of the abdominal wall), (3) optimal combination of both (with widening of the lower chest). The female uses upper chest respiration predominantly, the male relies primarily on abdominal breathing. Many voice coaches stress the ideal of a mixture of pectoral (chest) and abdominal breathing for economy of movement. Any exaggeration of one particular breathing habit is impractical and may damage the voice.

Brain functions. The question of what the brain does to make the mouth speak or the hand write is still incompletely understood despite a rapidly growing number of studies by specialists in many sciences, including neurology, psychology, psycholinguistics, neurophysiology, aphasiology, speech pathology, cybernetics, and others. A basic understanding, however, has emerged from such study.

The limbic system

In evolution, one of the oldest structures in the brain is the so-called limbic system, which evolved as part of the olfactory (smell) sense. It traverses both hemispheres in a front to back direction, connecting many vitally important brain centres as if it were a basic mainline for the distribution of energy and information. The limbic system involves the so-called reticular activating system (structures in the brain stem), which represents the chief brain mechanism of arousal, such as from sleep or from rest to activity. In man, all activities of thinking and moving (as expressed by speaking or writing) require the guidance of the brain cortex.

In contrast to animals, man possesses several language centres in the dominant brain hemisphere (on the left side in a clearly right-handed person). It was previously believed that left-handers had their dominant hemisphere on the right side, but recent findings tend to show that many left-handed persons have the language centres more equally developed in both hemispheres or that the left side of the brain is indeed dominant. The foot of the third frontal convolution of the brain cortex, called Broca's area, is involved with motor elaboration of all movements for expressive language. Its destruction through disease or injury causes expressive aphasia, the inability to speak or write (see Figure 5). The posterior third of the upper temporal convolution represents Wernicke's area of receptive speech comprehension. Damage to this area produces receptive aphasia, the inability to understand what is spoken or written as if the patient had never known that language.

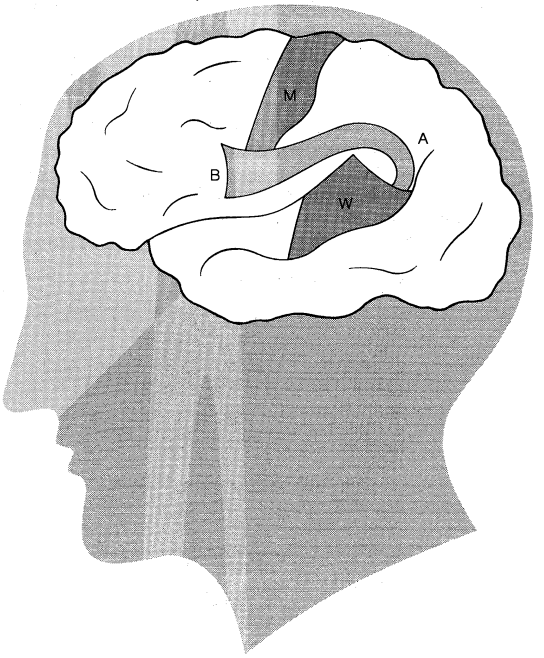

Figure 5: Lateral surface of left hemisphere of brain. B, Broca's area; M, motor cortex; W, Wernicke's area; A, arcuate fasciculus.

Broca's area surrounds and serves to regulate the function of other brain parts that initiate the complex patterns of bodily movement (somatomotor function) necessary for the performance of a given motor act. Swallowing is an inborn reflex (present at birth) in the somatomotor area for mouth, throat, and larynx. From these cells in the motor cortex of the brain emerge fibres that connect eventually with the cranial and spinal nerves that control the muscles of oral speech.

In the opposite direction, fibres from the inner ear have a first relay station in the so-called acoustic nuclei of the brain stem. From here the impulses from the ear ascend, via various regulating relay stations for the acoustic reflexes and directional hearing, to the cortical projection of the auditory fibres on the upper surface of the superior temporal convolution (on each side of the brain cortex). This is the cortical hearing centre where the effects of sound stimuli seem to become conscious and understandable. Surrounding this audito-sensory area of initial crude recognition, the inner and outer auditopsychic regions spread over the remainder of the temporal lobe of the brain, where sound signals of all kinds appear to be remembered, comprehended, and fully appreciated. Wernicke's area (the posterior part of the outer auditopsychic region) appears to be uniquely important for the comprehension of speech sounds.

The integrity of these language areas in the cortex seems insufficient for the smooth production and reception of language. The cortical centres are interconnected with various subcortical areas (deeper within the brain) such as those for emotional integration in the thalamus and for the coordination of movements in the cerebellum (hindbrain).

Feedback mechanisms

All creatures regulate their performance instantaneously comparing it with what it was intended to be through so-called feedback mechanisms involving the nervous system. Auditory feedback through the ear, for example, informs the speaker about the pitch, volume, and inflection of his voice, the accuracy of articulation, the selection of the appropriate words, and other audible features of his utterance. Another feedback system through the proprioceptive sense (represented by sensory structures within muscles, tendons, joints, and other moving parts) provides continual information on the position of these parts. Limitations of these systems curtail the quality of speech as observed in pathologic examples (deafness, paralysis, underdevelopment).

THE STRUCTURE OF THE LARYNX

The morphology (structure) of the larynx is studied according to the cartilages, muscles, nerves, blood vessels, and membranes of which it is composed.

Cartilages of the larynx. The frame or skeleton of the larynx is composed of several cartilages, three single and three pairs. Single cartilages are the shield-shaped thyroid in front, whose prominence forms the "Adam's apple" in the male; the cricoid cartilage below, which resembles a signet ring and connects the thyroid to the trachea or windpipe; and the leaf-shaped epiglottis, or laryngeal lid, on top. Among the paired cartilages are the two arytenoids, which ride on the cricoid plate and move the vocal cords sideways; the two corniculate cartilages of Santorini on top of the arytenoids; and the two cuneiform cartilages of Wrisberg. The cartilages are held together by ligaments and membranes, particularly around their joints. The larynx is connected below to the uppermost ring of the trachea (see Figure 6), while above it is connected by the thyrohyoid ligaments to the hyoid bone beneath the tongue. Most of the laryngeal cartilages ossify (turn to bone) to variable degrees with age under the influence of masculinizing hormones. This fact is an important sign in the X-ray diagnosis of certain vocal disorders. If a man

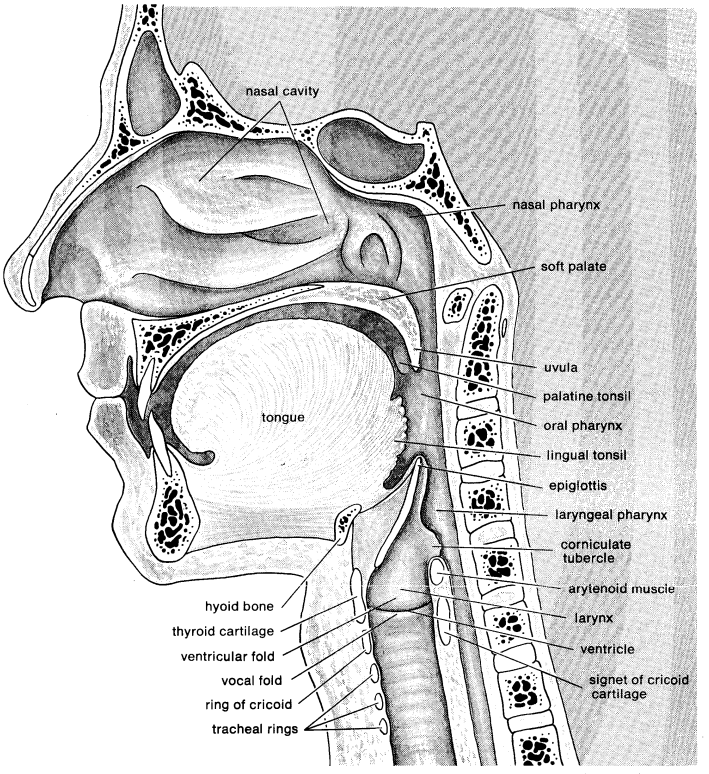

Figure 6: Sagittal section of head and neck.

shows less ossification than is normal for his age, he may be deficient in male hormones; this may also account for an effeminate sound in his voice. Conversely, when a woman shows increased laryngeal ossification, she may suffer from virilizing hormones, which might also explain any lowering and roughening in her voice.

Laryngeal muscles. There are two types of laryngeal muscles, the external (extrinsic) ones, which move the larynx as a whole, and the internal (intrinsic) ones, which move the vocal folds to shape the glottis. It is helpful to remember that the anatomical names of most such muscles are derived from their origin on one structure to their insertion on another.

The extrinsic muscles comprise the thyropharyngeus, which extends from the posterior border of the thyroid cartilage to the pharyngeal constrictor muscle, and the cricopharyngeus, which extends from the cricoid cartilage to the lower portion of the pharynx and the opening of the esophagus (the food tube that connects the mouth and the stomach). This cricopharyngeus muscle aids in the closing of the esophagus whenever it is not open for swallowing. Under the influence of emotional tension, the cricopharyngeus muscle may go into a spasm, which leads to a painful sensation of tightening in the throat that is usually described as a "lump in the throat." A disorder of this sort (which was previously referred to as globus hystericus) is now believed to be a sensation of cricopharyngeus spasm from emotional tension or imbalance as the result of excessive activity of the autonomic (involuntary) nervous system.

"Lump in the throat"

Extrinsic muscles. Although it is situated outside the laryngeal cartilages, the short cricothyroid muscle, a triangular muscle between the respective two cartilages, is traditionally discussed among the intrinsic (internal) muscles. Whenever this muscle contracts, the cricoid and thyroid cartilages are brought together anteriorly. This moves the anterior (forward) insertion of the vocal cords inside the thyroid wing forward, while their posterior (backward) insertion on the arytenoid cartilages is shifted backward. From this rotation results a marked elongation of the vocal folds clearly visible on X-ray films. This stretching action is the chief mechanism for raising the pitch of the sound generated and thus for the differentiation of vocal registers (*e.g.*, chest voice, falsetto). For embryologic reasons, the cricothyroid is the only laryngeal muscle that has its own nerve supply from the superior laryngeal nerve, a high branch of the vagus nerve (which issues from the brain stem). All other laryngeal muscles are innervated by the recurrent or inferior (low) laryngeal nerve, a low branch of the vagus nerve. This fact is important in the diagnosis of laryngeal paralysis because the resulting immobilization of the vocal cord and the remaining vocal function depend on the type of paralysis; *i.e.*, whether only the high or the low nerve or both of the laryngeal nerves are paralyzed on one side.

Intrinsic muscles. The intrinsic muscles include all of the following. The thyroarytenoid muscle extends from the inside of the anterior edge of the thyroid cartilage to the anterior vocal process of the arytenoid cartilage. This muscle may be separated into two portions, an internal part within the vocal cord and an external part between the vocal cord and the wing of the thyroid cartilage. For the most part, the fibres run parallel with the vocal cord. When they contract, they shorten the cord, make it thick, and round its edge. The external portion assists in bringing the vocal cords together, thus making glottal closure more tight.

The cricoarytenoids are two muscle pairs: one lateral pair (to the side) and one posterior pair (backward). These two pairs of muscles have an antagonistic (opposing) action. The posterior cricoarytenoids are the muscles of inspiration that open the glottis. They arise from the posterior surface of the cricoid plate and are attached, in an upward, forward, and outward direction, to the lateral muscular process of the arytenoid cartilage. When these muscles contract, they rotate the arytenoid outward, thus opening the glottis. The lateral cricoarytenoids belong among the muscles of expiration, the adductor group. They arise from the lateral ring of the cricoid cartilage and insert into the muscular process of the arytenoid in an upward and backward direction. Contraction of the lateral cricoarytenoids rotates the arytenoid cartilages inward so that the vocal folds are brought together.

The cricoarytenoid muscles

The two sides of the interarytenoid muscle are blended into one single mass, which extends from the muscular process of one arytenoid to that of the other. The action of this muscle is to pull together the posterior aspect of the arytenoid cartilages, thus closing the posterior portion of the cartilaginous glottis between the vocal processes of the arytenoids.

A fold from the top of the arytenoid to the lateral margin of the epiglottis on each side is supported by a bilateral band of muscle, the aryepiglotticus muscle. This semicircular structure aids in narrowing the laryngeal vestibule by pulling the arytenoids together and the epiglottis down. This is another example of the sphincter action ("valve" function) of all adducting laryngeal muscles that bring the vocal cords together. This sphincter action, by tightening of its closure, is the basis for all laryngeal protection. When this primitive sphincter mechanism intrudes into the refined coordination of phonation, it constricts the voice and causes the throaty quality of retracted resonance. This primitive, protective mechanism is at the root of many functional voice disorders. Moreover, the constricting sphincter action by many muscles is very strong

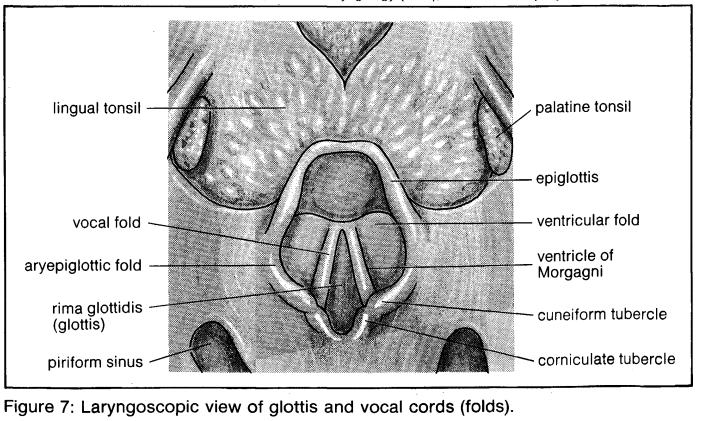

Figure 7: Laryngoscopic view of glottis and vocal cords (folds).

because it is opposed by only one muscle, the abducting posterior cricoarytenoid.

Vocal cords. The two true vocal cords (or folds) represent the chief mechanism of the larynx in its function as a valve for opening the airway for breathing and to close it during swallowing (see Figure 7). The vocal cords are supported by the thyroarytenoid ligaments, which extend from the vocal process of the arytenoid cartilages forward to the inside angle of the thyroid wings. This anterior insertion occurs on two closely adjacent points, the anterior commissure. The thyroarytenoid ligament is composed of elastic fibres that support the medial or free margin of the vocal cords.

The inner cavity of the larynx is covered by a continuous mucous membrane, which closely follows the outlines of all structures. Immediately above and slightly lateral to the vocal cords, the membrane expands into lateral excavations, one ventricle of Morgagni on each side. This recess opens anteriorly into a still smaller cavity, the laryngeal saccule or appendix. As the mucous membrane emerges again from the upper surface of each ventricle, it creates a second fold on each side—the ventricular fold, or false cord. These two ventricular folds are parallel to the vocal cords but slightly lateral to them so that the vocal cords remain uncovered when inspected with a mirror. The false cords close tightly during each sphincter action for swallowing; when this primitive mechanism is used for phonation, it causes the severe hoarseness of false-cord voice (ventricular dysphonia).

False vocal cords

The mucous membrane ascends on each side from the margins of the ventricular folds of the upper border of the laryngeal vestibule, forming the aryepiglottic folds. These folds extend from the apex of the arytenoids to the lateral margin of the epiglottis. Laterally from this ring enclosing the laryngeal vestibule, the mucous membrane descends downward to cover the upper-outer aspects of the larynx where the mucous membrane blends with the mucous lining of the piriform sinus of each side. These pear-shaped recesses mark the beginning of the entrance of the pharyngeal foodway into the esophagus.

The mucous membrane of the larynx consists of respiratory epithelium made up of ciliated columnar cells. Ciliated cells are so named because they bear hairlike projections that continuously undulate upward toward the oral cavity, moving mucus and polluting substances out of the airways. The true vocal cords, however, are exceptional in that they are covered by stratified squamous epithelium (squamous cells are flat or scalelike) as found in the alimentary tract. The arrangement is functional, since the vocal cords have to bear considerable mechanical strain during their rapid vibration for phonation, which occurs during many hours of the day. The transition from the respiratory to the stratified epithelium above and below the vocal cords is marked by superior and inferior arcuate (arched) lines. Unfortunately, such transitional epithelium also has the drawback of being easily disturbed by chronic irritation, which is one reason why the large majority of laryngeal cancers begin on the vocal cords. The mucous membrane of the larynx contains numerous mucous glands in all areas covered by respiratory epithelium, excepting again the vocal cords. These glands are especially numerous over the epiglottis and in the ventricles of Morgagni. The mucus secreted by these glands serves as a lubricant for the mucous membrane and prevents its drying in the constant airstream.

The vocal cords also mark the division of the larynx into an upper and lower compartment. These divisions reflect the development of the larynx from several embryonal components called branchial arches. The supraglottic portion differs from the one beneath the vocal cords in that the upper portion is innervated sensorially by the superior laryngeal nerve and the lower (infraglottic) portion by the recurrent (or inferior) laryngeal nerve. The lymphatics (*i.e.*, the vessels for the lymph flow) from the upper portion drain in an upward lateral direction, while the lower lymphatics drain in a lateral downward direction.

The space between the vocal cords is called rima glottidis, glottal chink, or simply glottis (Greek for tongue). When the vocal cords are separated (abducted) for respiration, the glottis assumes a triangular shape with the apex at the anterior commissure. During phonation, the vocal cords are brought together (adducted or approximated), so that they lie more or less parallel to each other. The glottis is the origin of voice, although not in the form of a "fluttering tongue" as the Greeks believed.

The vocal cords vary greatly in dimension, the variance depending on the size of the entire larynx, which in turn depends on age, sex, body size, and body type. Before puberty, the larynx of boys and girls is about equally small. During puberty, the male larynx grows considerably under the influence of the male hormones so that eventually it is approximately one-third larger than the female larynx. The larynx and the vocal cords thus reflect body size. In tall, heavy males the vocal cords may be as long as 25 millimetres (one inch), representing the low-pitched instrument of a bass voice. A high-pitched tenor voice is produced by vocal cords of the same length as in a low-voiced female contralto. The highest female voices are produced by the shortest vocal cords (14 millimetres), which are not much longer than the infantile vocal cords before puberty (10–12 millimetres). The larynx is, among other things, a musical instrument that follows the physical laws of acoustics fairly closely.

Dimensions of the vocal cords

Substitutes for the larynx. A growing number of middle-aged or older patients have had their larynx removed (laryngectomy) because of cancer. Laryngectomy requires the suturing of the remaining trachea into a hole above the sternum (breastbone), creating a permanent tracheal stoma (or aperture) through which the air enters and leaves the lungs. The oral cavity is reconnected directly to the esophagus. Having lost his pulmonary activator (air from the lungs) and laryngeal sound generator, such an alaryngeal patient is without a voice (aphonic) and becomes effectively speechless; the faint smacking noises made by the remaining oral structures for articulation are practically unintelligible. This type of pseudo-whispering through buccal (mouth) speech is discouraged to help the patient later relearn useful speech on his own. A frequently successful method of rehabilitation for such alaryngeal aphonia is the development of what is called esophageal or belching voice.

Alaryngeal aphonia

Esophageal voice. Some European birds and other animals can produce a voice in which air is actively aspirated into the esophagus and then eructated (belched), as many people can do without practice. The sound generator is formed by the upper esophageal sphincter (the cricopharyngeus muscle in man). As a replacement for vocal cord function, the substitute esophageal voice is very low in pitch, usually about 60 cycles per second in humans. Training usually elevates this grunting pitch to about 80 or 100 cycles.

Esophageal voice in man has been reported in the literature since at least 1841 when such a case was presented before the Academy of Sciences in Paris. After the perfection of the laryngectomy procedure at the end of the 19th century, systematic instruction in esophageal (belching) phonation was elaborated, and the principles of this vicarious phonation were explored. Laryngectomized persons in many countries often congregate socially in "Lost Cord Clubs" and exchange solutions of problems stemming from the alaryngeal condition.

Artificial larynx. Approximately one-third of all laryngectomized persons are unable to learn esophageal phonation for various reasons, such as age, general health, hearing loss, illiteracy, linguistic barriers, rural residence, or other social reasons. These persons, however, can use an artificial larynx to substitute for the vocal carrier wave of articulation. Numerous mechanical and pneumatic models have been invented, but the modern electric larynx is most serviceable. It consists of a plastic case about the size of a flashlight, containing ordinary batteries, a buzzing sound source, and a vibrating head that is held against the throat to let the sound enter the pharynx through the skin. Ordinary articulation thus becomes easily audible and intelligible. Other models lead the sound waves through a tube into the mouth or are encased in a special upper dental plate. More recent efforts aim at surgically inserting an electric sound source directly into the neck

tissues to produce a more natural sound resembling that of normal speech.

THEORY OF VOICE PRODUCTION

Myoelastic theory

The physical production of voice has been explained for a long time by the myoelastic or aerodynamic theory, as follows: when the vocal cords are brought into the closed position of phonation by the adducting muscles, a coordinated expiratory effort sets in. Air in the lungs, compressed by the expiratory effort, is driven upward through the trachea against the undersurface of the vocal cords. As soon as the subglottic pressure has risen sufficiently to overcome the closing effort of the vocal cords, the glottis is burst open, a puff of air escapes, the subglottic pressure is reduced, and the elasticity of the glottis together with the effect of the moving air causes the adducted cords to snap shut. The subglottic pressure rises again and the entire cycle is repeated. These cycles of exploding air puffs occur as frequently as the physical interaction of the subglottic pressure with the glottic resistance permits. The latter is determined by the tension of the vocal cords and their closing force. The number of these cycles per second is small for tones of low pitch and much greater for high tones, as will be explained later. The resulting laryngeal fundamental tone thus varies greatly in audible pitch.

According to the myoelastic theory, the production of laryngeal voice is a mechanical phenomenon directed by aerodynamic principles and muscular coordination. The vocal cords vibrate purely passively in the blowing airstream and are merely maintained in their position of phonation by the adducting muscles as these are activated by the laryngeal nerves. This vibration is not an active phenomenon like the whirring of the wings of a flying insect. Evidence for the myoelastic theory can be demonstrated in various ways. High-speed motion pictures of the vocal cords have been made, photographing their vibration at the rate of 4,000 or more frames per second. When such a picture is then projected at regular film speeds of 16 or 24 frames per second, the available film length is greatly extended in duration so that each of the hundreds of vocal-cord vibrations per second can be seen in ultraslow motion. A tone of 250 cycles per second (cps or Hz), for example, filmed at 4,000 frames and played back at 16 frames per second will permit each of the 250 vibrations to be seen for one second. Other evidence supporting the myoelastic theory is found in observations such as the fact that a nearly normal voice can be produced despite bilateral (on both sides) vocal-cord paralysis.

Vocal registers. *The basic registers.* For many centuries the so-called vocal registers were well known to the classical masters of the bel canto style of singing, the basic registers being called chest voice, midvoice, and head voice. These terms are derived from observations, for example, that in the low-chest register the resonances are felt chiefly over the chest. When sitting on a wooden bench with a large male, one can feel the vibrations of his low voice being transmitted through the back of the bench. In the high head voice, the vibrations are felt chiefly over the skull. The practice of singing is based on several artistic subdivisions in both sexes, depending on factors as discussed below. Other vocal phenomena may be heard below and above normal register limits, such as extra low tones, the "vocal fry."

Transition between vocal registers

The natural transition between two adjacent registers may be compared to the gearshift of a car. The same absolute vehicle speed can be maintained by driving either with the engine turning fast while in low gear or with fewer engine revolutions in the next higher gear. The register mechanism of the human voice is quite similar in this respect. Where the registers overlap, a series of transitional tones may be sung with either of the adjacent registers. These tones of the same fundamental frequency, sound level, and basic sound category in different vocal registers have recently been defined as isoparametric tones. In the untrained male voice, the transition between the midvoice and the high falsetto sounds abrupt; this so-called register break is similar to the noisy gearshift in a run-down truck. One aim of vocal education is to teach smoothly equalized register transitions.

Loud phonation of any given tone shifts its register mechanism toward the next lower register; for example, a crescendo falsetto tone grows into loud head voice. Conversely, soft intonation raises the mechanism to the next higher type, as when a loud head tone fades into soft falsetto. This phenomenon is the physiologic basis of *messa di voce,* the technique of swelling tones. Thus, the characteristic mechanism of each register represents a continuum of intralaryngeal adjustments. In the male voice, the gradual and overlapping transitions of phonic function may be aligned as follows: low chest tones, loud–soft; transition; middle register, loud–soft; transition; loud head voice–soft artistic falsetto–thin natural falsetto. X-ray studies can show the difference between the loud male head voice and the soft male falsetto. The former employs the midvoice mechanism, the latter the falsetto mechanism. In the female voice, the two lower registers behave similarly, while head voice can be only loud or soft and may be followed by a fourth register, the flageolet or whistle register of the highest coloratura sopranos. The Italian term falsetto simply means false soprano, as in a castrato (castrated) singer. Hence, the normal female cannot have a falsetto voice.

Studies of register differences. Studies devoted to the problem of voice register may be divided into two groups: observations of the visible laryngeal mechanism and studies of the audible register differences.

Studies of the visible laryngeal mechanism for the production of different registers began with the laryngoscope. Modern laryngostroboscopes employ the oscillating light of a high-power fluorescent light source that is monitored by the laryngeal vibrations through a throat microphone. Such devices, when they flash on and off at just the right rate, make the vocal cord movements appear much slower than they actually are, so that the observer perceives a slow-motion pattern. High-speed cinematography (moviemaking) has elucidated many details of vocal cord function for the various registers. Radioscopic (X-ray) methods were introduced only a few years after the discovery of X-rays in 1895. Among these, lateral (from the side) radioscopy of the larynx reveals the mechanism of vocal cord tension; frontal X-ray films demonstrate the typical configuration of the vocal cords for each register. Mechanical recordings of the respiratory movements of the chest, originally with rubber belts and lately with electronic strain gauges, disclose the breathing patterns for the various registers. Breath support (*appoggio*) of singing instruction can be demonstrated through such recordings, as well as by radiography of the chest. Aerodynamic measurements of pressure, flow rate, and volume of the air exhaled during specific phonic tasks have produced additional details. Electromyography (study of muscle currents) involving the insertion of needle electrodes into certain laryngeal muscles permits the isolated recording of finely coordinated muscular effort during the singing in various registers.

Differences in sound-wave patterns

A second group of investigations concerns audible register differences as an acoustic phenomenon. Electroacoustic analysis demonstrates the specific sound-wave patterns (harmonic spectra) of each register. In general, the full chest voice is rich in higher harmonics, whereas the thin falsetto voice is composed chiefly of sound-wave energy distribution near the vocal fundamental (the relatively narrow band of wave frequencies that characterizes any particular voice). The subjective impressions of singers during the production of an ascending scale reflect the voluntary techniques of vocal breath control, such as with respiratory support (*appoggio*). Positioning of the larynx, suitable shaping of the pharyngo-oral resonator (vocal tract), proper placement of the tongue, and the specific tension of the soft palate belong among the learned techniques of register equalization. Definite vibrations may be felt in the thorax, in the area of the hard palate, or above the nose. These subjectively felt resonances depend on bone conduction of the laryngeal sound. Very little has as yet been done regarding the subjective evaluation of voice registers by listening judges. These perceptual factors are still little understood, but it appears that multiple acoustic perceptions operate in voice-register judgment.

It is clear that the vocal registers represent a continuum of

laryngeal adjustments in response to different respiratory-mechanical requirements necessary for the production of the individual frequency range. The poles of these adjustments at the opposites of chest voice and male falsetto voice illustrate the chief differences, as shown in Table 4; the midvoice occupies an intermediate position.

Vocal attributes. *Vocal frequency.* The voice has various attributes; these are chiefly frequency, harmonic structure, and intensity. The immediate result of vocal cord vibration is the fundamental tone of the voice, which determines its pitch. In physical terms, the frequency of vibration as the foremost vocal attribute corresponds to the number of air puffs per second, counted as cycles per second (cps or Hz). This frequency is determined by both stable and variable factors. The stable determinants of the individual voice range depend on the laryngeal dimensions as related to sex, age, and body type. The smaller a larynx, the higher its pitch range. Within this individually fixed range, variables that influence the pitch of a given phonation include: tension of the cord, force of glottal closure indicated by the glottal resistance, and expiratory air pressure. Growing tension of the cricothyroid muscle (as the external vocal cord tensor) increases the vocal pitch, and vice-versa. Increased glottal closure and expiratory effort add to this tensing effect under certain circumstances. For example, 100 vibrations per second produce a low chest tone of a low male voice, while 1,000 are close to the "high C" of a female soprano. An average vocal range normally encompasses two musical octaves (*e.g.,* 100 to 400 vibrations per second); trained singers may reach three or more octaves.

Voice types. Musical practice for centuries has recognized six basic voice types: bass, baritone, and tenor in the male, in contrast to contralto, mezzo-soprano, and soprano in the female. Sex, therefore, is one of the first determinants of voice type in the two categories. Body type and general physical constitution represent the second determinant of the individual voice type because the laryngeal dimensions vary in fairly strict conformity to whether the body type is large or husky or frail or small. A tall, athletic male usually has a large, spacious larynx. Repeated observations show that short, dainty females tend to have a small and delicately built larynx. The intermediate voice types of the male baritone and the female mezzo-soprano usually represent the corresponding intermediate body types. The art of singing recognizes additional subdivisions. The voice of a basso profundo is extremely low and heavy. The lyric tenor possesses a high, light, and flexible voice. Still higher and lighter is the counter tenor (as used in singing oratorios) who is the male counterpart of the highest female voice found in the extra high and light coloratura soprano. The dramatic voices employed in the Wagnerian operas represent intermediate forms between a male tenor (or high baritone) and a heroically masculine body type. The female dramatic soprano is usually heavily built; her strong mezzo-soprano voice can produce the high soprano tones.

The registers are related to voice types. As a general rule, the low voices possess a large range of chest voice with a much smaller range of head voice. The reverse holds for the high voice types, while baritone and mezzo-soprano assume an intermediate position. In the normal individual and the well-trained singer in particular, the midvoice encompasses one musical octave. As a further rule of thumb, the traditional and optimal transition tones follow a fairly stable and general pattern. As summarized in Figure 8, the three female voice types usually show the first transition from chest to midvoice at the tones d^1, e^1, and f^1, above middle c^1, respectively. The second transition between midvoice and head register in the three female voice types is almost precisely one octave higher. An extra-low contralto voice may prefer to shift the two transitions at

slightly lower frequencies, whereas a very high coloratura soprano may prefer the two shifts a semitone (halftone) higher. The two transition tones of the three male voice types are situated almost precisely one octave lower than the respective six female transition tones. It should not be overlooked that the specific features in male voices sound approximately one octave lower than in the female voices of corresponding type. This octave phenomenon stems from the larger dimension of the adult male larynx. (The musical custom of writing the tenor part on the soprano stave in contrast to the correct notation of bass and baritone in the bass clef is a misleading tradition that derives from an old custom of four-part writing, for the tenor always sounds one octave lower than the soprano.)

Vocal ranges. As shown in Figure 8, the individual ranges of the singing voice extend from about 80 cycles per second in the low bass to about 1,050 cycles per second in the "high C" of the soprano (all values are approximated). The lowest note of serious musical literature is a low D with 73 cycles per second at the end of Osmin's aria in Mozart's *Abduction from the Seraglio,* and the highest is a high f^3 with almost 1,400 cycles per second sung by the Queen of the Night in Mozart's *Magic Flute.* Exceptionally high soprano tones are no longer sung with vocal cord vibration but are produced in the flageolet (or whistle) register simply by whistling through the narrow elliptical slit between the overtensed and motionless vocal cords. When citing the exceptional vocalistic feats of singers from the classical bel canto era, it should not be overlooked that musical pitch has been rising markedly since those days. Concert pitch is presently standardized at 440 cycles per second for the international tuning tone a^1. In the last half of the 18th century, the reference tone was at least one semitone lower.

Harmonic structure. A second attribute of vocal sound, harmonic structure, depends on the wave form produced by the vibrating vocal cords. Like any musical instrument, the human voice is not a pure tone (as produced by a tuning fork); rather, it is composed of a fundamental tone (or frequency of vibration) and a series of higher frequencies called upper harmonics, usually corresponding to a simple mathematical ratio of harmonics, which is 1:2:3:4:5, etc. Thus, if a vocal fundamental has a frequency of 100 cycles per second, the second harmonic will be at 200, the third at 300, and so on. As long as the harmonics are precise multiples of the fundamental, the voice will sound clear and pleasant. If nonharmonic components are added (giving an irregular ratio), increasing degrees of roughness, harshness, or hoarseness will be perceived in relation to the intensity of the noise components in the frequency spectrum.

Modulation of vocal tone

The primary laryngeal tone composed of its fundamental and harmonics is radiated into the supraglottic vocal tract (above the glottis). The cavities formed by the pharynx, nasopharynx, nose, and oral cavity represent resonators. Since they are variable in size and shape through the movements of the pharyngeal musculature, the palatal valve, and the tongue in particular, the individual sizes of the supraglottic resonating chambers can be varied in countless degrees. The shaping of the vocal tract thus determines the modulation of the voice through resonance and damping. As a general rule, a long and wide vocal tract enhances the lower harmonics, producing a full, dark, and resonant voice. Conversely, shortening and narrowing of the vocal tract leads to higher resonances with lightening of the voice and the perceptual attributes ranging from shrill and strident to constricted and guttural.

Vocal styles. These types of vocal resonance may be illustrated with a continual series of vocal practices that have been studied through physiologic and electroacoustic analysis. This perceptual series begins with the full, loud, and sonorous sound during the natural vocalizations for laughing, yawning, and yodelling. The rich higher harmonics responsible for the perceptual qualities of these vocalizations are produced by a maximally lowered larynx and greatly widened resonator. At the next step is the sonorous and full sound of so-called covered singing in the German opera style. Rich in higher harmonics (or overtones), this vocal style is performed with lowered larynx, elevated epiglottis, and widened throat cavity. A large group of open or uncovered singing styles lying in the centre of the series extends from the extremely uncovered, flat, and "white" openness of, for example, Spanish flamenco singing, over the flat style of popular singing, to the brightness of Italian bel canto. Approaching the other pole of the series, the large group of functional voice disorders results from constricted resonance of the vocal tract. It is typical of these hyperkinetic (overactive) vocal disorders that the voice is produced with marked laryngeal elevation, constriction of the laryngeal vestibule, and often with pronounced elementary sphincter action of the larynx. The extreme end of this functional series is characterized by the use of the larynx as a primitive sphincter organ as employed in ventriloquism. The maximally elevated and constricted larynx within a very narrow throat cavity produces the high-pitched, thin, muffled, and weak quality of ventriloquism, which is characterized by great reduction of the higher harmonics.

Use of the larynx in ventriloquism

Individual voice quality. Apart from the variable influences of the vocal tract on the momentary vocal resonance according to training and intention, the supraglottic resonator exerts a constant influence on the vocal quality by shaping its individual characteristics. Just as human faces differ in almost endless variations, the configuration of the supraglottic structures is also highly characteristic, having, in fact, been called the "inner face." The anatomical shape and the physiologic flexibility of the vocal tract serve to mold the individual vocal personality in at least two ways: by its inborn shape and by the learned behaviour of using it for communication. Any individual's mother tongue shapes his articulatory behaviour into certain patterns, which remain audible in all languages that he learns after puberty and constitute one aspect of the so-called foreign accent. It often is easy to recognize a speaker over the telephone after having listened to his voice a few times without necessarily having met him in person. The ability to recognize a given speaker solely by the quality and inflection of his voice is the basis of efforts to produce "voice prints" that should be as unmistakably identifying as fingerprints are.

Intensity. Vocal intensity, the third major vocal attribute, depends primarily on the amplitude of vocal cord vibrations and thus on the pressure of the subglottic airstream. The greater the expiratory effort, the greater the vocal volume. Another component of vocal intensity is the radiating efficiency of the sound generator and its superimposed resonator. The larynx has been compared to the physical shape of a horn. This construction is most efficient in acoustical practice, as seen in the shape of wind instruments, car horns, sirens, loudspeakers, etc. A well-shaped, wide, and flexible vocal tract enhances the projective potential of the voice. Conversely, a morphologically narrow, pathologically constricted, or emotionally tightened throat produces a muffled, constricted sound with poor carrying power.

Laughing and yawning

The inborn automatic reflexes of laughing and yawning illustrate the resonator action of the vocal organ. Together with a widely opened mouth, flat tongue, elevated palate, and maximally widened pharynx, the larynx assumes a lowered position with maximally elevated epiglottis. This configuration is ideal for the unimpeded radiation of the vocal cord vibrations so that the resulting sound is loud and bright, with a gaily ringing quality; it is the sound of happy laughter. The opposite is present with the painfully tight-throated, choked sobbing of someone crying in despair.

Singing and speaking. A major difference between singing and speaking is psychological in nature. Singing as a physiological performance is exhibited by the majority of human beings who have what seems to be an inborn musical sense that depends on appropriate development of their highest cortical (brain) centres for audition. Although the art of singing in a particular artistic style typically demands formal study, the untrained use of the voice for self-expression through singing develops spontaneously in late childhood and during the period following vocal maturation. Singing involves the use of inherited neural mechanisms that are regulated in part by deeper,

subcortical (below the cortex) brain centres, particularly those related to emotional activity. Singing serves many as a way of emotional relief and is related to the social activities of human play. Although song among humans is not as intimately related to sexual propagation as it is in certain animals (*e.g.*, birds), people are still influenced by such sensual stimuli as love songs and madrigals, as well as ceremonial and religious performances.

The practice of spontaneous singing and of artistic song satisfies emotional needs, but it may not always communicate in a clear ideational sense. When a brain stroke causes aphasia (loss of language for communication), for example, the singing voice often remains normal or at least better preserved, so that some aphasics who cannot say a word can sing with good articulation. This observation has been used to explain that disorders causing aphasia may damage other brain areas than those used for singing. Another example is the severe stutterer who can sing or whisper with fluency. The same dichotomy of communicative speech and declamatory singing is often seen in cases of spastic dysphonia (a peculiar, grave voice disorder without demonstrable brain damage that causes a painfully choked and halting manner of speaking, while singing usually remains undisturbed).

Perceptual differences between speaking and singing

In the perceptual category, the principal differences between speaking and singing concern the rhythmic patterns. Speaking uses gliding vocal inflections with rapid pitch variations as well as frequent and abrupt intensity modifications for syllabic accentuation. The rhythmical pattern of stresses, unstressed syllables, and breathing pauses is dictated by the meaning of the sentence. The so-called prosodic features of speech (*i.e.*, its melodic inflections) follow the general, regional, and dialectal rules of a given language. In this sense, the essence of speaking is its continual flexibility, variability, and adaptability.

Singing differs from speaking in the following respects. The melody is followed in precise and discrete steps over customary musical intervals, which commonly are not smaller than semitones in Western music, though quarter and eighth tones are frequently used in Oriental and African music. The vowels are prolonged because they carry the melody. The rhythm of the fixed tonal steps follows the pattern prescribed by the composer and long notes may be sustained for special effects.

Exceptions to these general rules are found in the portamento, a gliding change between two pitch levels, of Western song, used sparingly as an embellishment. Parlando singing is a speaking type of song, used in the recitativo of Italian opera style. In these intentionally communicative preludes to formal arias—because they tell most of the story—the rhythm of the spoken word is incorporated into the melody, which, in turn, to a certain degree, follows the prosodic vocal inflection.

The melodic inflection of speech communicates considerable meaning in certain languages, such as in Africa and China. This problem of linguistic tonality, or word melody, requires the appropriate individual selection of various rising, sustained, or falling intervals to express the full meaning of a word. Chinese words are monosyllabic, and their multiple meanings cannot be understood without the appropriate prosodic inflection by the "tones" of the particular dialect. If Chinese is spoken without vocal inflection, such as when whispering, intelligibility is reduced by at least one-third.

SYNTHETIC PRODUCTION OF SPEECH SOUNDS

The essence of speech and its artificial re-creation has fascinated scientists for several centuries. Although some of the earlier speaking machines represented simple circus tricks or plain fraud, an Austrian amateur phonetician, in 1791, published a book describing a pneumomechanical device for the production of artificial speech sounds.

Speech synthesizers. A number of electronic speech synthesizers have been constructed in various phonetic laboratories in the latter half of the 20th century. Some of these are named the "Coder," "Voder," and "Vocoder," which are abbreviations for longer names (*e.g.*, "Voder" standing for Voice Operation Demonstrator). In essence, they are electrical analogues of the human vocal tract. Appropriately arranged electric circuits produce a voicelike tone, a modulator of the harmonic components of this fundamental tone, and a hissing-noise generator to produce the sibilant and other unvoiced consonant sounds. Resonating circuits furnish the energy concentrations within certain frequency areas to simulate the characteristic formants of each speech sound. The resulting speechlike sounds are highly controllable and amazingly natural as long as they are produced as continuants. For example, it is possible to imitate the various subtypes of the hard U.S. sound for R (as in "car") by moving a few levers or knobs. Difficulties become greater when many other attributes of fluent speech are to be imitated, such as coarticulation of adjacent sounds, fluctuating nasalization, and other segment features and transients of connected articulation. Speech synthesizers have, nevertheless, made a contribution to the study of the various physical characteristics that contribute to the perception and recognition of speech sounds.

Speech recognizers

The counterpart of speech synthesizers is the speech recognizer, a device that receives speech signals through a microphone or phono-optical device, analyzes the acoustic components, and transforms the signals into graphic symbols by typing them on paper. Modern models may incorporate computers to store some of the information that permits the device directly to type from dictation. Early models had great difficulties with the correct spelling of homophonous words (those that sound alike but differ in spelling and meaning) such as "to, too, two" or "threw, through, thru." Human transcribers usually have no difficulty with these distinctions because they listen to major parts of the sentence to recognize each word from the context and general situation. The computerized machines developed in the 1970s, however, had to be programmed for each detailed aspect of speech recognition that people normally learn through many years of general schooling and specialized training. Moreover, the machines could be effective only for very limited vocabularies and had to be adjusted to each individual speaker.

The pathology of speech

THE STUDY OF SPEECH DISORDERS

Prevalence of speech disorders. A comprehensive evaluation of knowledge and research in speech and hearing, published in 1969 by a section of the U.S. Public Health Service, under the title *Human Communication and Its Disorders—An Overview,* revealed that approximately 9,000,000 Americans were reported to have hearing impairments of handicapping magnitude; another 2,000,000 were said to suffer from central processing disorders from neurologic disease; and 10,000,000 to have speech disorders. The cost of coping with these problems was about $500,000,000 per year, while the annual deficit in earning power among such impaired persons approximated nearly $2,000,000,000. The same report estimated the prevalence of various speech disorders in the United States as shown in Table 5. The disorders of articulation among young children were numerically most frequent.

No data in similar detail are available from other countries; however, from experience in Germany, Austria, and other Central European countries, it may be said that

Table 5: Estimated Prevalence of Speech Defects in the United States

type of speech problem	ages 5–21 years		all ages	
	percent	number	percent	number

the incidence and prevalence of speech disorders follow similar patterns among other Western nations. Certain deviations from these trends are equally typical. The incidence of cleft palate is very high among American Indians, while it is much lower among Negroes than in Caucasians. Stuttering is more frequent in northern countries, such as in Scandinavia, than it is in southern regions—*e.g.*, Italy. Similar trends have been noted in the Far East. Nonorganic, functional, or emotional disorders of voice and speech reflect psychological tensions exerted by the environment. For such reasons, vocal nodules (growths on the vocal cords), contact ulcer, vocal fatigue, etc., occur with greater incidence in metropolitan areas and are conspicuously less frequent in rural regions.

Classification of speech disorders. In accordance with physiological considerations, disorders of communication are first classified into disorders of voice and phonic respiration, disorders of articulated speech, and disorders of language. It has been known for a long time that the majority of communication disorders are not caused by local lesions of the teeth, tongue, vocal cords, or regulating brain centres. Since these predominant disorders of voice and speech develop from derangements of the underlying physiological functions of breathing, use of the voice, speaking habits, or emotional disorders, this group has been labelled as functional. The remainder of the communication disorders with clearly recognizable structural abnormalities in the total speech mechanism has been termed organic.

Interaction of functional and organic disorders

While this empirical grouping has certain implications for the selection of the appropriate treatment, it is not satisfactory because organic structure and living function can never be separated. Certain functional disorders of the voice caused by its habitual abuse may very well lead to secondary structural changes, such as the growths (polyps and nodules) of the vocal cords, which develop as a result of vocal abuse. On the other hand, all of the obviously organic and structural lesions, such as loss of the tongue from accident or surgery, almost inevitably will be followed by emotional and other psychological reactions. In this case, the functional components are of secondary nature but to a great extent will influence the total picture of disturbance, including the patient's ability to adjust to his limitation, to relearn a new mode of appropriate function, and to make the best of his condition.

Within these major groups, the various types of communication disorders have for a long time, and in most parts of the world, been described by the listener's perceptual impression. Most languages employ specific words for the various types of abnormal speech, such as stuttering, stammering, cluttering, mumbling, lisping, whispering, and many others. The problem with such subjective and symptomatic labels is the fact that they try to define the final, audible result, the recognizable phenomenon, and not by any means the underlying basis. This general human tendency to describe disorders of communication by what the listener hears is analogous to the attempts of early medicine to classify diseases by the patient's symptoms that the diagnosing physician could see or hear or feel or perhaps smell. Before the great discoveries of the 19th century had erected a logical basis for medical pathology, the various diseases were classified as numerous types of fevers, congestions, dyscrasias, etc. Thus, malaria was originally thought to be caused by the evil emanations (miasma) of the bad air (*mal aria*) near swamps until it was recognized to be caused by a blood parasite transmitted by the mosquito.

The various approaches of medical, psychiatric, psychological, educational, behavioral, and other schools of speech pathology have made great advances in the recent past and better systems of classification continue to be proposed. They aim at grouping the observable symptoms of speech disorders according to the underlying origins instead of the listener's subjective impressions. While this is relatively easy in the case of language loss from, for example, a brain stroke because the destroyed brain areas can be identified at autopsy, it is more difficult in the case of the large group of so-called functional speech disorders for two reasons: first, they are definitely not caused by gross, easily visible organic lesions, and, second, many functional disorders are outgrown through maturation or appropriate learning (laboratory study of the involved tissues in such cases would reveal no detectable lesions). It is hoped that refined methods of study in the areas of both "functional" psychology and "organic" neurophysiology will eventually reveal the structural bases for the prevalent disorders of voice and speech.

Treatment and rehabilitation. The selection of methods in the medical treatment or educational rehabilitation of communication disorders depends primarily on the underlying basis for the disturbance. Any case of chronic hoarseness should be evaluated first by a laryngologist to establish a precise diagnosis. This is particularly important in the older age groups in which an incipient laryngeal cancer is often overlooked because the patient does not pay attention to his deteriorating voice. The prognosis of all cancers becomes rapidly poorer the longer the disease remains unrecognized. As soon as disease of the larynx is excluded as a cause of the vocal complaint, vocal rehabilitation by a competent speech pathologist should be considered.

Treatment by appropriate specialists

Malformations, diseases, or injuries of the peripheral speech mechanism are treated by appropriate specialists; the plastic surgeon repairs a cleft of the palate; the neurologist and internist treat the stroke patient until he has recovered sufficiently to be referred for re-education of his language abilities. The pediatrician treats the child with mental retardation, while the geneticist counsels the family regarding the possible inheritance of the disorder and its future avoidance. Deafness or severe hearing loss in early childhood is a typical cause for severe delay of language development and should be promptly recognized through appropriate examination by the ear surgeon (otologist) and hearing specialist (audiologist). Cases of childhood autism (withdrawal, severe eccentricities) or early schizophrenia are now being recognized with increasing frequency by speech pathologists, child psychiatrists, pediatricians, and clinical psychologists. This multitude of various professional interests in the recognition and rehabilitation of such exceptional children is well served by the coordination of these efforts in the modern team approach. But again, the largest group of disorders of voice and speech has causes other than these grossly organic lesions. They belong within the province of speech rehabilitation by experts in speech pathology and other functional practitioners.

Development of speech correction. That mankind has been troubled by speech afflictions since the beginning of recorded history can be gleaned from numerous remarks in the books of the Bible. Further, many scientific and medical writers from the time of antiquity to the Middle Ages reported observations of speech and voice disorders. The recommended remedies merely reflected the inadequacies of the philosophical or empirical notions of their times. Scientifically oriented speech pathology originated in Germany during the latter part of the 19th century, following closely the development of otolaryngology. Three names stand out in this respect: C.L. Merkel (*Anthropophonik;* 1857), Adolph Kussmaul (*The Disorders of Speech;* 1877), and Hermann Gutzmann, Sr., who became the first professor of speech pathology at the University of Berlin Medical School around 1900.

Experimental phonetics

During the same time, the new science of experimental phonetics was developed by Jean-Pierre Rousselot in Paris, who promptly recognized the great contributions that experimental phonetics could make to the study of normal and disturbed speech. This close collaboration of medical speech pathology with experimental phonetics has remained typical for the European continent where speech correction is customarily carried out under the direction of physicians in the ear, nose, and throat departments of the university hospitals. The designation of speech and voice pathology as logopedics and phoniatrics with its medical orientation subsequently reached many other civilized nations, notably in Japan and on the South American continent. The national organizations in most of these areas are now represented in the International Association of Logopedics and Phoniatrics, which was founded in Vienna in 1924.

The evolution of speech correction in the Anglo-Saxon countries followed a different trend. Although Great Britain has had a long tradition in general and experimental phonetics, its College of Speech Therapists was organized as an examining and supervisory body in 1945. Similar organizations followed in other areas of the British Commonwealth.

American speech pathology elected a different way. The American Speech and Hearing Association (ASHA), founded in 1925 in New York City, became the organizing, examining, and supervisory body for a rapidly growing membership, which surpassed 12,000 by 1970. More than 200 colleges and universities in the United States, many accredited by ASHA, offer degrees in speech pathology and audiology, some including work at the doctoral level. The large majority of ASHA members hold the master's degree and work as speech clinicians in the public school systems. A smaller number with master's degrees and a still smaller number with doctoral degrees staff the more than 300 clinics that deal with communication disorders and that are usually affiliated with hospitals, colleges, universities, and occasionally with civic organizations.

Soviet Russian speech correction originally followed the developments of European logopedics and phoniatrics and is now directed by the Department of Logopedics in the Government Institute of Defectology of the Academy of Pedagogical Sciences in Moscow. One facet of speech pathology in the U.S.S.R. is its emphasis on Pavlovian theory (conditioning and retraining) and intensive use of neuropsychiatric methods, including pharmacology, sleep therapy, and other intensive treatment programs during hospitalization. Similar trends operate in the eastern European countries under Russian influence, such as in Czechoslovakia, where the first independent medical department of logopedics and phoniatrics was organized at the Faculty of Medicine of Charles University in Prague.

MAJOR TYPES OF SPEECH DISORDERS

Voice disorders. In international terminology, disorders of the voice are described as dysphonia. Depending on the underlying cause, the various types of dysphonia are subdivided by the specifying adjective. Thus, a vocal disorder stemming from paralysis of the larynx is a paralytic dysphonia; injury (trauma) of the larynx may produce traumatic dysphonia; endocrine dysphonia reflects the voice changes resulting from disease of the various endocrine glands such as the pituitary. The various dysphonias of clearly organic origin from systemic disease (*e.g.,* muscular, nervous, or degenerative disease afflicting the entire body) or from local laryngeal changes differ in their visible symptomatology, as well as in the perceptual impression produced by the abnormal voice. Nevertheless, it has not yet been possible to define the acoustical alterations in the vocal spectrum that would allow a clear and objective differentiation among the subjective graduations of an abnormal voice as hoarse, harsh, husky, breathy, grating, gravelly, gritty, etc.

Because a large group of dysphonias have no visible laryngeal causes, they are grouped as nonorganic. Two main types of these so-called functional voice disorders may be distinguished: the habitual dysphonias that arise from faulty speaking habits and the psychogenic dysphonias that stem from emotional causes. Both of these types of dysphonia again occur in two basic subtypes, the hyperkinetic (overactive) and the hypokinetic (underactive) since emotional disorders interfere with voluntary vocal function by either causing excessive or depressed physiological activity. In the hyperkinetic disorders, the highly coordinated patterns of phonation regress to the primitive, forceful, and exaggerated sphincter action of the larynx as seen during gagging. The result is hyperkinetic dysphonia, the gratingly harsh vocal disorder due to excessive muscular action in a constricted larynx. In the second subtype, the movements for phonation regress even more deeply to the original function of respiration; the sluggish larynx remains more or less open, and the glottis is incompletely closed for phonation, leading to hypokinetic dysphonia with subdued, breathy huskiness.

Emotional causes

Disorders of language development. The most frequent speech disorders are those that disturb the child's acquisition or learning of language. While those concerned with modern terminology are striving for an improved classification according to the etiologic (causative) factors, it is still customary to classify these disorders on the basis of the complaint: absence of speech, baby talk, poorly intelligible articulation, lisping, etc. Recent studies of large numbers of children with such developmental language disorders have shown that at least two chief classes of these disorders may be distinguished: general language disability from genetic factors with a familial (inherited) pattern chiefly from the paternal side, and acquired language disorders due to damage sustained before, during, or shortly after birth (*i.e.,* perinatally).

These latter perinatal damages encompass the gamut of toxic, infectious, traumatic, nutritional, hormonal, and other damages that may hurt the growing fetus or young infant. Major and minor birth injury is not an infrequent factor. Hereditary factors also encompass a great variety of genetically predetermined influences, including familial tendency to exhibit slow language development, lesser endowment in the brain area for language, inferior function in the highest brain areas of auditory performance without organic damage to the ears, slow maturation of motor function (including clumsiness and deviation from normal cerebral dominance), and other signs of delayed cerebral growth. Additional environmental causes include poor language patterns used by the family, parental neglect, emotional maladjustment, general weakness from prolonged disease, as well as various socioeconomic, cultural, and other psychological influences.

While some otherwise perfectly normal children, particularly boys, may not elect to begin talking until age three, making good progress in every respect from then on, the absence of speech after age two may be caused by any of the conditions mentioned thus far and would appear to merit prompt investigation. If an organic cause can be detected, the symptomatic description of delayed language development then yields to a specific etiologic (causal) diagnosis. Although it is best to describe the absence of speech in early childhood as simply delayed language development, some American investigators tend to refer to this condition as congenital (present at birth) aphasia, a term rejected by most European scholars who argue that there cannot be an inborn or early acquired aphasia before a language has been learned.

Many children encounter unusual difficulties in mastering the patterns of articulation of their mother tongue and are said to manifest articulatory immaturity (infantile dyslalia). If no organic cause can be found, the probable cause may be delayed maturation of psychomotor skills.

Marked delays of language development are often followed by a period of inability to learn the rules of grammar and syntax at the usual age (dysgrammatism). Though this is often a sign of inherited language disability, it may reflect mental retardation or other types of brain damage.

Some children who have suffered such laboured language development may then go through a period of retarded reading and writing disability, a condition often defined as dyslexia. Again, there are two chief varieties: the primary or developmental reading and writing disability due to constitutional (organic) and hereditary factors, and a large secondary group of symptomatic reading disorders acquired through any of the influences that retard language development in general, including troubles with vision. Practically all investigators agree that primary or developmental dyslexia shows a marked hereditary tendency (is familial) and is typically associated with other disorders of psychomotor development, deviation from the prevalent right handedness, and poor function in the auditory area in the brain, often associated with lack of musical talent. Primary dyslexia is significantly associated with other developmental speech disorders.

Reading and writing disability

Articulatory disorders. *Cluttering.* Those who have followed large numbers of children with language disabilities for a long time are impressed by the fact that these various manifestations of an underlying developmental disorder often terminate in a peculiar impediment of speech that has been well known to European speech pathologists for

many years but is not yet fully recognized in American speech literature: cluttering (or tachyphemia), the hasty, sloppy, erratic, stumbling, jerky, and poorly intelligible speech that may somewhat resemble stuttering (see below) but differs from it markedly in that the clutterer is usually unaware of it, remains unconcerned, and does not seem to fear speaking situations. Its association with other past or persistent signs of subnormal language development also differentiates congenital cluttering from emotional stuttering. Experts are strikingly unanimous in stressing the hereditary nature of cluttering.

Lisping. Although lisping belongs among the articulatory disorders and usually has the same causes as articulatory disorders (dyslalia) in general, it differs from other disorders of articulation in several respects. For one, lisping occurs in various varieties: with the tongue tip protruding between the front teeth, with a slurping noise in the cheek pouch, with the tongue too far back along the palatal midline, with excessive tongue pressure against the teeth; in several snorting and nasal subtypes, as well as through substitute hissing deep in the throat or even within the larynx, such as in cleft-palate speech. Moreover, the causes of lisping include a diverse group of particular conditions: abnormal number or position of teeth; imitation of other lispers; deficiency of palatal closure; slight hearing loss in the high frequencies; as well as several psychologic causes, such as effeminate affectation, infantile mannerisms, or mental disturbance. Lisping is less easily outgrown than the other infantile dyslalias and may persist into adult life if not corrected.

Causes of lisping

Stuttering, or stammering. Academically known as dysphemia, what is called stuttering in the United States is usually named stammering in Great Britain. While everyone seems to know what stuttering sounds like, experts do not agree about what really causes it. In the age groups after puberty, stuttering is the most frequent and conspicuous type of disturbed speech encountered. This is one reason why among the studies dealing with speech pathology in the world literature those devoted to stuttering are the largest single group. Despite numerous and intensive studies of the problem, findings and conclusions are far from unanimous. A great number of theories have been proposed to explain the origin and nature of stuttering, which range from the premise that subtle physical disturbances in the nervous system (so-called neurogenic asynchronies) are responsible to the opinion that psychological maladjustment alone is to blame. The report issued by the U.S. Public Health Service (see above *Prevalence of speech disorders*) concludes that "stuttering remains an enigma while illustrating the type of disorder which does not have either a clean-cut organic cause or a clearly habitual basis."

Research findings indicate (as is the case with many developmental speech disorders, particularly language disability, articulatory disorders, reading disability, and cluttering) that trouble with stuttering affects the male sex at least four times more frequently than the female. Hereditary predisposition has been noted in many studies of large groups of stutterers, with evidence for an inherited tendency found among as many as 40 percent of the stutterers studied. Some experts insist that stuttering is not a single disease entity but that it comprises several types of the disorder with different causes. According to such views, the familial occurrence of stuttering represents a combination of the stuttering symptom with a cluttering tendency that is inherited. Although imitation of another stutterer may form the basis for acquiring the habit, purely psychological explanations that stress parental attitudes in training their children fail to reveal why many stutterers have siblings (brothers or sisters) with perfectly normal speech.

Treatment of stuttering

The treatment of stuttering is difficult and often demands much skill and responsibility on the part of the therapist. The possibility of some specific medical cure seems remote at the present time. Even the most advanced methods of modern psychiatry have failed to produce superior results in treatment. For a time it was hoped that new psychopharmacological drugs (*e.g.,* tranquillizers) might facilitate and accelerate recovery from stuttering, but these efforts have been disappointing thus far. The typical program of management in this disorder is a strict program of psychotherapy (talking freely with a psychiatrist or psychologist so as to reduce emotional problems) supported by various applications of learning theory or behavioral theory (in retraining the stutterer) and other techniques depending on the therapist's position. It is widely agreed that the patient must acquire a better adjustment to the problems of his life and that he needs to develop a technique for controlling his symptoms and fears. Prognosis (predicted outcome of treatment) thus is held to depend greatly on the patient's motivation and perseverance. It is interesting to note that experienced investigators no longer aspire to a "cure" of stuttering through an etiologic (causal) approach. Instead of focussing on underlying causes, they aim at making the patient "symptom-free" via symptomatic therapy.

Prevention of stuttering may be aided through parent counselling. The normal, immature speech of many children is characterized by various nonfluencies; these include hesitations, syllable repetition, groping for the right word, and vocalizations between words such as "ah-ah." Some misguided parents castigate these normal signs of developing speech with various admonitions and, even worse, try to forbid the nonfluencies by mislabelling them as stuttering. In some children, this parental interference associates normal nonfluency with feelings of insecurity and fear, tending to make the child become a real stutterer. Much research has been devoted to this probable etiology for one type of stuttering; its elimination through parental guidance indeed has been reported to help in reducing the number of stutterers.

Dysphasia and aphasia. Dysphasia means the partial or total loss of language as a result of lesions in those parts of the brain that are directly related to language function. Stroke in elderly patients and head injury in younger ones are typical causes. Aphasia is seen most frequently when the left side of the brain is afflicted, as evidenced by paralysis of the right arm and leg. Evidence indicates that the left hemisphere is dominant in all right-handed individuals and in some left-handers as well. Some experts even believe that the left brain hemisphere is dominant for language in most individuals regardless of handedness and that dominance of the right brain is exceptional in some left-handers. According to other opinions, dominance for language is more evenly distributed in both hemispheres in left-handed persons. As explained before, two major brain areas are recognized as intimately associated with language function: Broca's area in the third frontal convolution and Wernicke's area in the posterior third of the upper temporal convolution. The angular gyrus at the junction of the temporal (side), parietal (top), and occipital (back) lobes of the brain is believed to be related to graphic language as used for reading and writing.

Aphasiology, the science of aphasic language loss, is studied by neurologists, neurosurgeons, some phoniatrists, certain speech pathologists, as well as some psychologists and linguists. This diversity of research background accounts, in part, for the great diversity in theoretical approaches to aphasia. Numerous classification schemes that have been proposed vary from simple groupings into a few main types of aphasia to complicated systems with many forms and subtypes of aphasic disturbances. Similar to research in stuttering, the literature on aphasia is exceptionally large and growing.

The phenomenon of aphasia

The essence of aphasia is the loss of memory for the meaning of language and its production. Thus, in the predominantly expressive or motor forms, the patient can no longer remember the intricate patterns for articulation; he can no longer form a word in speaking or writing, even though he may know what he wants to express. In the predominantly receptive or sensory forms, the patient can talk freely, sometimes excessively and incessantly (logorrhea), although with numerous errors and meaningless clichés, but he no longer comprehends what is said to him or what he tries to read. Those who recover from receptive forms of the disorder are likely to explain that during their aphasia spoken language sounded like an unintelligible, alien tongue. The degree to which there is combination of expressive and receptive symptoms varies greatly with

the type and extent of brain lesion. There may be total loss of all language functions (global aphasia) to slight residual errors or misunderstandings when the brain damage is only slight or temporary. A major complication of aphasia is the frequent association with right hemiplegia, in which the paralyzed hand is no longer serviceable for writing. Retraining of the left hand for writing may then become necessary.

Management of aphasia has two goals: one, the physical recovery of the patient through treatment by the internist, neurologist, and possibly brain surgeon, and two, the re-education of the brain functions that remain, the aim being to help the patient relearn some use of language under the guidance of the speech pathologist. The better the recovery from the brain lesion, the more chances there are of prompt and complete return of language. When the brain losses are permanent, the patient must relearn each word, sentence, and phrase like the young child, albeit in a more cumbersome manner, apparently using brain parts that still function. He is repeatedly shown the picture of an object along with its printed name; these words are spoken to him by his teacher over and over in the hope that he will learn to repeat the word or phrase until he can say it spontaneously. Words that are relevant to the patient's everyday life are emphasized first with due consideration for his interests and past occupation; later he may advance to the use of abstract concepts and of higher levels of language. Various types of automated training programs are available, including a simple playback device that shows an inserted card with a picture on it, the name of the pictured object printed next to it, and the audible word recorded on a strip of magnetic tape. Devices of this type enable the patient to practice at his own pace.

Symptomatic speech disorders. Under this heading may be summarized various types of communication disorders that develop on the basis of known structural lesions or metabolic disturbances. Etiologic classifications group these impediments according to the types of organic diseases, as well as in respect to the afflicted effector organs (such as the tongue). Disturbed speech from lesions in the various parts of the nervous system is known as dysarthria. Mental retardation usually limits the development of linguistic ability to the same extent as it does intellectual capacity; this language disorder has been described as dyslogia. Mental disturbances can also manifest themselves in linguistic symptoms, such as in the peculiar (dysphrenic) mode of speech among sufferers of schizophrenia. Hearing loss dating from early childhood leads to a typical distortion of the speech pattern for which various names have been coined, such as audiogenic dyslalia. Visible defects in such oral articulators as the lips and teeth limit the mechanics of articulation and thus reduce the quality and intelligibility of speech; such speech problems are known collectively as dysglossia.

Dysarthria. Damage to those parts of the nervous system that regulate the actions of voice and speech cause distinctive alterations of the speech pattern. The most important disorder of this type is cerebral palsy from brain injury before, during, or soon after birth. The majority of cerebral palsy victims retain normal intelligence, but are handicapped by distortions of voluntary movements, including those for speaking. Just as walking may be stilted and jerky and arm movements crude and uncontrolled, the patterns of voice and speech will reflect the same distortions. Great advances in rehabilitation have been achieved in the recent past, such as with the well-known Bobath method, which is based on learned suppression of primitive reflexes.

Effects of cerebral palsy

Shaking palsy. Another type of dysarthria is observed in cases of Parkinson's disease. This affliction of the nervous system makes body movements either excessively rigid or tremulously repetitive, such as with the so-called "pill-rolling" sign of hand tremor. Voice and speech reflect the same patterns, sometimes appearing as the first obvious symptoms of the disease. Brain surgery is used in an attempt to improve these abnormal body movements, often with good general results, although speech may be little improved or even made worse. Neurologists also are collecting observations on promising drug treatments for Parkinson's disease, such as with L-Dopa.

When a neurologic disease damages the bulbar nuclei (in the brain stem) of the nerves innervating the organs for speech, the effect of bulbar dysarthria is heard. In severe cases, voice may be reduced to a faint grunting, while articulation deteriorates into mumbling or total muteness. Chorea, another neural disorder manifested in sudden jerky movements of the entire body, may be associated with bizarre, explosive disruptions of the speech flow. Cerebellar dysarthria results from disease of the brain part called the cerebellum (which regulates fine motor coordination), leading to various disorganizations of speech including a "drunken" (ataxic) quality.

Mental retardation. Major advances in the science of inheritance (genetics) and in biochemistry have clarified a number of inborn metabolic causes of many types of mental retardation (see BEHAVIOUR, INNATE FACTORS IN HUMAN). Some of these forms of retardation can be avoided through genetic counselling of prospective parents or prevented by prompt treatment following early diagnosis. (In some cases a change in diet is effective.) Improved prenatal care may reduce the size of another group of mentally retarded individuals whose problem stems from brain damage sustained during fetal life before birth. The number of unknown causes in other cases of retardation is still considerable, however.

Management of the mental retardate

The total management of the mentally retarded child concerns a large group of specialists: pediatrician, geneticist, clinical psychologist, audiologist and speech pathologist, and special educators in institutions for such children. Following classification on the basis of a level of educability, the child undergoes a composite training program geared to his capabilities. Intensive training in language usage not only tends to improve his communication skills but also forms a bridge to increased general learning. There has been recent stress on the not infrequent combination of mental retardation with hearing loss; in such cases, the audiologist prescribes a hearing aid and auditory training to improve the receptive aspects of communication.

Language and mental disorder. Expert analysis of the bizarre speech patterns associated with certain psychiatric disturbances is of primary diagnostic significance. If a mute child persists in stereotyped rituals and strange behaviour, a diagnosis of childhood autism is likely to be made. Some experts distinguish this from a similar disorder called childhood schizophrenia, in which previously good general and linguistic development falls apart in association with similarly bizarre behaviour. In adolescence, a sudden change of voice to a shrill falsetto or weird chanting may herald the outbreak of juvenile schizophrenic disease. Infantile lisping, strange distortions of articulation, and various eccentricities in verbal expression are other signs of schizophrasic speech in the adult schizophrenic. Linguistic study may help the psychiatrist in analyzing the patient's ways of thinking and to provide a measure of the sufferer's progress under therapy. Great therapeutic stress is placed on establishing contact with the autistic child by eliciting from him some sort of communication. Language is felt to be one of the best bridges to break open the closed inner world of such children.

Speech of the hard of hearing. Hearing loss that dates from childhood hinders the normal development of language because the most important sensory portal for speech learning remains deficient. Such children learn to say the sounds of speech as they hear them; that is, in a muffled, distorted, or even inaudible fashion. The articulatory disorder (audiogenic dyslalia) usually reflects the measured (audiometric) pattern of hearing loss. If sound waves at high frequencies cannot be heard, speech sounds with formants in that high-frequency region will be affected. The hissing sibilants contain the highest formants and are therefore most typically disturbed by high-frequency hearing loss. The lower frequencies that can still be heard limit the audible formants to this residual range, which transposes the normal formant patterns into the abnormally lowered frequency band. As a result, a sharp hissing S is spoken as a muted Sh, and the light vowels are transformed into their darker counterparts (for example,

the word "set" may be pronounced as "shot" or "shöd" as if it were German).

The voice reflects analogous changes. In the case of conductive hearing loss (in which neural structures for hearing are intact), the patient hears himself well through the bones of his skull but cannot hear others. Because his bone conduction remains good, his voice will sound loud to him and he tends to keep it subdued. The opposite occurs with neural (or perceptive) hearing loss in which there is nerve dysfunction. In this case, the patient hears his own voice as poorly as that of others, and he tends to talk in an overloud and screeching voice.

Correction of audiogenic dyslalia may be possible through early fitting of a suitable hearing aid, intensive auditory training, and speech exercises aided by audiovisual playback devices (auditory trainers, tape recorders, visible speech devices, etc.).

Deaf-mutism

Profound or total deafness going back to early childhood without special training inevitably leads to deaf-mutism, the absence of oral language development as a direct result of deafness. Deaf-mute children have traditionally been educated in special schools for the deaf, where the oral method (showing how to shape the oral structures for each speech sound) of teaching speech has competed with the older manual method of allowing the deaf to communicate through their own gestural or finger spelling. Recent advances in training include the liberal use of amplification devices (*e.g.,* group hearing aids) in all school situations as well as the earliest possible fitting of hearing aids following definite diagnosis. This can be accomplished even when the patient cannot communicate that he hears (*e.g.,* in very young babies) through such methods as recording brain-wave patterns in response to measured sound stimulation (EEG response audiometry).

Speech impediments from defective articulators. Dysglossic (from defective oral structures) disorders in articulation have interested mankind for the longest time; the biblical and poetical interchange of the words for "tongue" and "speech" in many languages has kept alive the assumption that speech originates within the fleshy tongue. For the same reason, the popular term tongue-tied still persists to refer to an abnormally immobile tongue and some assumed resulting limitation of linguistic ability. Even the academic designation of the science of languages as "linguistic" is traditionally based on the Latin word *lingua* for tongue.

Tongue-tie. In practice, the condition of a true tongue-tie (ankyloglossia) occurs only rarely and is quite easily corrected through a simple operation. Even when the shortened band beneath the tongue tip is permitted to persist, very little speech disturbance, if any, is audible in such persons. The only limitation of articulation to be expected is the decreased ability to protrude the tongue tip between the teeth for the English Th and the trilling lingual R in southern German, Latin, and Slavic languages. In any event, a true tongue-tie never causes stuttering, lisping, or any other of the major speech disorders.

Loss of tongue. Major defects of the tongue from paralysis, injury, or surgery reduce the articulation of the lingual sounds to the same extent that the tongue's mobility is visibly limited. Spontaneous compensation is usually quite prompt, depending on the patient's general linguistic talent. One exception is complete bilateral (both sides) paralysis of the tongue, which causes a very severe disorder of chewing and swallowing as well as severe limitation of speech intelligibility. The total loss of the tongue (true aglossia) from injury or surgery is often amazingly well compensated. Patients can learn to use residual portions of a tongue stump as well as other oral structures to substitute for the missing tongue; indeed, some persons without a tongue have relearned to speak so well that the listener would not suspect its absence.

Nasal speech. Several types of nasal speech are not easily diagnosed; even specialized physicians are often not fully aware of the differences.

Increased nasal resonance leads to open nasality (hypernasal speech), affecting all oral speech sounds that should not be nasal. Organic causes impair the accuracy of palatal occlusion during emission of the nonnasal sounds. Among these are paralysis, congenital malformation, injury, or defects of the palate. The functional causes of palatal sluggishness include imitation, faulty speech habits, dialectal influences, hearing loss, mental retardation, or psychiatric disorders.

Decreased nasal resonance

Decreased nasal resonance produces closed nasality (hyponasal speech), which muffles the three nasal resonants (M, N, and Ng). The best known organic causes are an acute cold, hay fever, large adenoids, as well as all other nasal diseases that obstruct the airway. Functional causes are less frequent, in the form of a rare, faulty speech habit; occasionally the problem comes from mental retardation or from severe language disability.

Mixed nasality poses a serious problem; it stems from the combination of one cause of open nasality with another of closed nasality (one may be of organic type and the other functional, or both may be organic). A typical combination is the open nasality from paralysis (paresis) of the palate (or its congenital deficiency) combined with closed nasality from obstruction of the nasopharynx by adenoids. The resulting mixed nasality causes the nasal resonants to sound muffled and subdued, while careful testing reveals slight open nasality on all oral sounds.

Treatment of nasal speech is unlikely to be successful without prudent balancing of all factors involved. This responsibility rests primarily with the diagnosing otolaryngologist or phoniatrist. The complaint of "talking through the nose" should never warrant a tonsil and adenoid operation without complete evaluation. If this were done in the example cited just above, removal of the obstructing adenoids would alleviate only the closed nasality, while making the open component more severe with marked deterioration of the patient's speech. This dilemma is often present when adenoids cause chronic middle-ear disease with hearing loss, while the palate is incompetent, as from a slight congenital malformation or paresis. In such case, the patient's general health and his hearing must be weighed against the possibility of making his speech worse.

Cleft palate speech. This type of organic dysglossia has also been named rhinoglossia (Greek *rhin, rhis:* "nose") because it is an organic cause of excessively nasal speech. Clefts of the lip, upper jaw, and hard and soft palate occur in various types and combinations. Cleft palate is a congenital (present at birth) malformation that develops for various reasons during the early weeks of embryonic life. The causes may be grouped as follows: inheritance in some cases; embryonal damage from various environmental causes in others; while still other cases of cleft palate are part of a syndrome of general or multiple malformation, which may again be hereditary, the result of chromosomal aberrations, or of environmental origin. Genetic influences are inferred from evidence that North American Indians (Montana) show a high incidence of cleft palate, but Negroes (as on the island of Jamaica) show an unusually low incidence.

Mechanism of cleft palate disorder

The speech disorder in cleft palate cases is complex. As a direct, mechanical result of the absent velopharyngeal (soft palate-pharynx) closure, voiced sounds assume an abnormal nasal quality from the unusual resonance of the nasal chambers. The influence of nasality on the perceptual and acoustic characteristics of the speech sounds has been discussed earlier. A second component is a mechanical limitation in articulating plosive sounds (*e.g.,* P) because the necessary intra-oral pressure cannot be achieved. For the same reason, the sibilant sounds (*e.g.,* S) are greatly distorted because the articulating air escapes through the nose before it can produce the characteristic hissing noise at one of the places of constriction. The child with an unrepaired cleft palate seems unconsciously to attempt to overcome these mechanical limitations in several ways. He tries to constrict the nostrils through facial grimaces, and he attempts to increase the expiratory air pressure. He also succumbs to the "law of centripetal regression of articulation"; that is, he shifts the articulation of the oral sounds below the point of deficient palatal occlusion, down into the pharynx or even the larynx. It is easy to demonstrate by X-ray fluoroscopy how the larynx becomes constricted during each plosive or sibilant sound in such cases.

These mechanical limitations of articulation in cleft

palate lead to secondary modifications of behaviour. Linguistic ability is retarded through general limitation of speech learning; emotional reactions to the handicap may complicate the clinical picture; a vicious circle is thus established, which in turn impedes the sufferer's general intellectual and special linguistic development.

Other coincidental disorders complicate the pattern of cleft-palate speech. Many cleft-palate patients also suffer from middle-ear infection, and the resulting hearing loss may add the component of audiogenic dyslalia. In other cases, the structural malformation may be complicated by mental retardation. Coincidental genetic factors may aggravate the speech problem when the syndrome of familial (neurally inherited) language disability is superimposed. In such cases, the mechanical speech disorder of rhinoglossia becomes complicated by the additional signs of delayed speech development, articulatory dyspraxia, dysgrammatism, reading and writing disability, etc. This combination is evident in some cases following the successful surgical correction of the palatal deficiency. Although the nasality is promptly alleviated in such cases, the various speech disorders from language disability may persist, since they have nothing directly to do with the previous cleft palate.

Treatment of cleft palate

Management of cleft palate is the task of a well-coordinated team. The plastic surgeon closes the palatal deficiency, the psychologist analyzes the intellectual endowment, the speech pathologist corrects the various components of disordered speech, the audiologist determines coincidental hearing loss, and the otolaryngologist cares for the health of nose and ears. Tonsils and adenoids may be diseased, leading to the frequent complication of middle-ear infection with hearing loss. This condition may require removal of tonsils and adenoids to preserve hearing. A dilemma is then created; removal of tonsils and adenoids is generally contra-indicated in cases of deficient palatal closure because this operation increases the degree of open nasality. The child's welfare then should be carefully considered in order to avoid any harm.

When surgical repair is not feasible, the palatal defect may be covered by a special prosthetic plate (obturator) similar to false dental appliances. This technique has been known for many centuries, and various models of obturators have been constructed in the course of time. Cleft-palate care therefore includes the services of a prosthodontist (who makes false teeth) for the optimal construction of such appliances. If worn by children, obturators should be regularly altered to maintain continuous fit as the patient grows.

Well-organized centres for the management of cleft palate are able to offer excellent care so that the speech impediment can be ideally or almost completely corrected in many cases. The problem of cleft palate thus demonstrates once more that human speech requires complex detailed study of its normal functions and manifold approaches for the correction of its imperfections. Sponges: Phylum Porifera

The sponges, which constitute the phylum Porifera, are among the most primitive multicellular animals. They number approximately 5,000 described species and inhabit all seas, where they occur attached to surfaces from the intertidal zone to depths of 8,500 metres (29,000 feet) or more. One family, the Spongillidae, is found in fresh water. Adult sponges lack a definite nervous system and do not show conspicuous movements of body parts.

GENERAL FEATURES

Early naturalists regarded the sponges as plants because of their frequent branching form and their lack of obvious movement. The animal nature of sponges, first described in 1755, was confirmed in 1765 after observations of their water currents and the movement of their openings. In structure, function, and development, sponges are distinct from other animals. Many zoologists regard sponges as occupying an isolated position in the animal kingdom and classify them in the subkingdom Parazoa; on the other hand, sponges are sometimes considered relatives of another invertebrate animal group, the coelenterates.

The phylum Porifera may be divided into three classes on the basis of the composition of the skeletal elements—the Calcispongiae and Hyalospongiae include about 20 percent of the known species of sponges; the remainder are placed in the class Demospongiae (see Figure 1).

Importance. The soft elastic skeletal frameworks of certain species of the Demospongiae—*e.g., Spongia officinalis, Hippospongia communis, S. zimocca, S. graminea*—have been familiar household items since ancient times. In ancient Greece and Rome, sponges were used to apply paint, as mops, and by soldiers as substitutes for drinking vessels. During the Middle Ages, burned sponge was reputed to have therapeutic value in the treatment of various diseases. Natural sponges now are used mostly in arts and crafts such as pottery and jewelry making, painting and decorating, and in surgical medicine. Synthetic sponges have largely replaced natural ones for household use.

Commercial value

The living sponge is a mass of cells and fibres, its interior permeated by an intricate system of canals that open as holes of various sizes through the tough dark brown or black skin, which may be hairy from fibre ends that pierce it. Only after it has been completely cleaned of its millions of living cells does a sponge resemble the sponge of commerce; *i.e.,* a soft and elastic spongin skeletal framework. Commercially valuable sponges, which may be found from tidal level to a depth of about 200 feet, usually are harvested by hooking or harpooning in shallow waters, by skin diving or by deepwater fishing. Although the most valuable sponges are found in the eastern Mediterranean area, they also are harvested off the west coast of Florida and the Florida Keys, in the West Indies, off Mexico and Belize, and, to a limited extent, off the Philippines. Because they have the ability to regenerate lost parts, sponges can be cultivated from small fragments.

Sponges are valuable from a scientific point of view because of their unusual cellular organization (the cells do not form tissues such as those found in other animals), their ability to regenerate lost parts, and their biochemical features (they have many compounds not known in other animals). Sponges comprise an important part of the organisms that live in the depths of the sea (benthos) and may be associated with other organisms; *e.g.,* many types of animals live in sponges.

Size range and diversity of structure and colour. Most sponges are a few centimetres in size, but some urn-shaped or shapeless ones are less than a centimetre (0.4 inch); others, shaped like vases, tubes, or branches, may be one to two metres (3.3–6.6 feet) tall, and broad rounded masses may be one to two metres in diameter. Size within a species may vary with age, environmental conditions, and food supply.

The external appearance of sponges is variable. They may appear bushy or treelike and have fingerlike projections. Some, particularly in the class Demospongiae, are shapeless, or amorphous, masses that form thin encrustations on objects or are cushion shaped. A few Demospongiae have well-defined spherical shapes as in *Tethya aurantium,* the sea orange; others may be cup- or fan-shaped. Calcispongiae of the genus *Scypha* are shaped like tubular sacs, with an opening (osculum) at the tip. Members of

the Hyalospongiae are erect or cylindrical, with a stalklike base.

Colour among sponges is variable. Deep-water sponges usually show a neutral colour, drab or brownish; shallow-water sponges, frequently brightly coloured, range from red, yellow, and orange to violet and occasionally black.

Effects of symbionts

Most Calcispongiae are white. Some sponges (*e.g.,* the Spongillidae) are often greenish because green algae live in a symbiotic relationship within them; others are violet or pinkish, because they harbour symbiotic blue-green algae. These symbionts endow the sponges with colour as long as light is available; the sponges become white in the dark when no photosynthesis occurs and the algal pigments utilized in photosynthesis are no longer produced. Another variable character in sponges is consistency, which may range from the soft and viscous state of some encrusting species to the hard stonelike quality of the genus *Petrosia.* In addition, the surface of a sponge may be smooth, velvety, rough with protruding skeletal elements called spicules, or conulose (*i.e.,* provided with conical protrusions called conuli).

Distribution and abundance. The Porifera are present at all water depths, from the tidal zone to the deepest regions (abyss). They occur at all latitudes and are particularly abundant in Antarctic waters. Calcispongiae and Demospongiae are found mainly on the rocky bottoms of the continental shelf; the Hyalospongiae are characteristic of the deepest muddy bottoms of oceans and seas. In some environments, sponges are the dominating organisms; sometimes they cover wide areas, especially on rocky overhangs and in the caves of the littoral, or shore, zone. A restricted number of species are adapted to brackish waters; and members of the family Spongillidae (class Demospongiae) populate the fresh waters of rivers and lakes.

NATURAL HISTORY

Life cycle. Most sponges reproduce sexually, although asexual reproduction may occur. Sponges are generally hermaphroditic (male and female germ cells in one animal); sometimes dichogamy, in which male and female germ cells develop at different times in the same animals, occurs.

Sexual reproduction. The fertilization of an egg by a spermatozoan is peculiar in sponges in that a spermatozoan, after its release from a sponge, is carried by the water current until it is captured by a specialized cell called a choanocyte, or collar cell, in another sponge; the choanocyte transforms into an amoeba-shaped cell called a carrier cell, which gives up the spermatozoan to an egg, lying near a chamber formed by choanocytes and containing long lashlike appendages called flagella.

Types of larvae

Development of the embryo may occur in one of several ways characteristic of the different groups; as a result, more than one type of larva is found. The characteristic larva of the Calcispongiae and of some Demospongiae (*e.g., Oscarella*), called an amphiblastula, is oval in shape and has a cavity in the middle; the front half of the larva consists of cylindrical, flagellated cells, the other half of round cells without flagella. The larva swims with the flagellated portion forward. The amphiblastula is preceded by a stage (stomoblastula) in which the central cavity of a hollow mass of cells (blastula) opens outward and is surrounded by round granular cells (macromere), which are distinguished from other cells with flagella (micromere). The most common larval form among the Demospongiae is called a parenchymella; it is solid and compact, with an outer layer of flagellated cells and an inner mass of cells.

A larva swims for a period of time that may vary from a few hours to a few days before it descends to find a surface suitable for attachment. After attachment, the larva undergoes developmental changes (metamorphosis) becoming a young individual called an olynthus in the Calcispongiae, a rhagon in the Demospongiae; the young individual gradually develops into an adult sponge. The metamorphosis following larval attachment involves changes in the relative positions and functions of larval cells. In one larval type (parenchymella), the flagellated outer cells become the collar cells (choanocytes) of the interior of the adult sponge; the interior cells of the larva give rise, in the adult, to the cell layer (pinacoderm) and the different cells (*e.g.,* archaeocytes, collencytes) found in the amorphous substance (mesohyl) that fills the sponge. In the amphiblastula, the choanocytes are derived from the forward flagellated region; the other cells and the mesohyl are derived from the posterior half.

The sexual maturation of sponges is connected with the temperature of the water in which they live. In the temperate regions, maturation occurs mainly from spring to autumn; sometimes two distinct periods of reproduction occur, one in spring, the other in autumn. Some sponges mature at any time of the year; *e.g., Scypha,* formerly called *Sycon.* Tropical sponges also apparently mature any time throughout the year. Sponges for the most part bear living young (*i.e.,* are viviparous); the larvae are released through the canals of the excurrent (outgoing) water system and an opening (osculum) also involved in that system. A few sponges (*e.g., Cliona* and *Tethya*) lay eggs (*i.e.,* are oviparous).

The life-span of sponges is not well known; the small encrusting forms probably live about a year, disappearing during a season unfavourable to their survival; small fragments of an individual, however, may persist and reproduce new individuals in the next season. The large species have a much longer life-span; bath sponges (*Spongia, Hippospongia*), for example, attain a commercially desirable size after seven years and may live as long as 20 years.

Asexual reproduction. Asexual reproduction also occurs in sponges in various ways; the best known method is called gemmulation. Gemmulation begins when aggregates of cells, mostly archaeocytes, which, when they become laden with reserve food granules, are called thesocytes, become isolated at the surface of a sponge and are then called gemmules. These are expelled from the adult sponge and, in some marine species, serve as a normal reproductive process or, sometimes, as a means to carry the sponges over periods of unfavourable conditions when the adults degenerate; *e.g.,* drought, temperature extremes.

Gemmules

The freshwater Spongillidae undergo a slightly different gemmulation. Gemmules consist of aggregates of archaeocytes laden with reserve granules; in addition, however, they are surrounded by protective membranes formed by the archaeocytes. The protective covering is generally reinforced by spicules, which vary in shape according to the species and are useful in classification. Freshwater sponge gemmules allow a species to survive unfavourable conditions in a state in which vital activities are almost completely suspended. In cold regions, gemmulation occurs in winter, and the inactive gemmules are said to hibernate; in warm regions, gemmulation occurs in summer, and the gemmules are said to estivate. In spring or autumn when favourable conditions return, the gemmules germinate, their archaeocytes emerge through an opening (micropyle), the various cellular types differentiate, and a new sponge grows. Other methods of asexual reproduction include formation of stolons (rootlike extensions) and fragmentation of individuals.

Regeneration. The extraordinary capacity of sponges to regenerate is manifested not only by restoration of damaged or lost parts but also by complete regeneration of an adult from fragments or even single cells. Sponge cells may be separated by mechanical methods (*e.g.,* squeezing a piece of sponge through fine silk cloth) or by chemical methods (*e.g.,* elimination of calcium and magnesium from seawater). Dissociated cells settle, migrate, and form active aggregates in which the archaeocytes play an important role. In order for small aggregates of cells to form larger aggregates, the cells must generally become attached to a surface, where they flatten and develop an envelope of special cells (pinacocytes); this is called the diamorph stage. Reconstitution of the choanocyte chambers and of the canal system follow soon afterward, resulting in a young sponge that is functional and able to grow. It is generally believed that the reconstitution process, even if it involves cell division, is not comparable with embryonic development, because the various types of dissociated cells participate in the formation of the new sponge by sorting and rearranging themselves, rather than by differentiating from primitive cell types. Regeneration in sponges is of

theoretical interest in connection with certain cell properties; *e.g.,* adhesion, sorting out, and movement.

During unfavourable conditions, sponges are reduced to small fragments that may consist only of masses of archaeocytes covered by layers of pinacocytes. A complete sponge forms from these fragments when favourable conditions return.

Individuality of sponges

The regenerative abilities of sponges, their lack of a central coordinating organ (brain), and the peculiar migratory ability of cells within the organisms combine to make it somewhat difficult to define the individuality of a sponge. Various attempts to establish whether sponges are individuals or colonies have failed to solve the problem, and, thus far, no completely satisfactory criterion for defining a sponge has been found. Zoologists involved in the study of sponges empirically define a sponge individual as a mass that is enveloped by a common ectoderm, *i.e.,* by a common cellular layer.

Ecology. Most Porifera, very sensitive to a wide range of ecological factors, are difficult to raise under laboratory conditions. Few species (*e.g., Hymeniacidon sanguinea*) are able to tolerate long periods of emersion and variations in such physical factors as light, temperature, and salinity.

Habitats. Light is a limiting factor for the survival of most sponges in a given habitat. Littoral-dwelling sponges generally develop in caves, on shadowed walls, or under small shelters such as those provided by crevices. Some species, mainly in the tropics, however, are covered by a metre or less of water and thus are almost completely exposed to irradiation from the sun. Symbiotic relationships between algae and sponges usually occur in strongly illuminated zones; the algae may act as a protective device because they deposit pigments in the superficial cell layers of the sponge. In some sponges (*e.g., Petrosia ficiformis*), colour is related to the number of symbionts; in a cave, for example, sponges gradually change from intensely coloured specimens to light-coloured, sometimes white, ones in the depth of the cave where the number of algae decreases.

Porifera of the family Clionidae (class Demospongiae) live in galleries they excavate in shells of mollusks, in corals, in limestone, and in other calcareous materials. The boring activities of clionids are accomplished by the excavation, possibly involving both chemical and mechanical action, of numerous, small chips of calcium carbonate. Cytoplasmic projections and films put out by sponge cells in contact with a calcareous surface apparently come into intimate contact with the calcium carbonate, resulting in the removal of particles of relatively uniform size. Clionid sponges weaken limestone breakwaters and coral reefs, making them more easily subject to further abrasion by waves. In addition, they weaken oystershells.

Attachment to a surface

Although most sponges settle and grow on hard or rocky surfaces, some anchor to a firm object on soft bottoms, on sand, on mud, or on debris. Unattached sponges are rare. Different species may compete for a surface, and superposition of one species on another sometimes occurs; the presence of a rich population of different species on the same surface may help them to survive by the modifications each contributes to the environmental microclimate surrounding them, thereby providing protection against extreme fluctuations of physical factors such as temperature and light.

Associations with other organisms. The Porifera often grow on or near other organisms, sometimes killing those they cover; the sessile (attached) barnacle *Balanus,* for example, may be killed in this way. In other cases, associations may provide advantages to both organisms, particularly those between sponges and crustaceans. Some crustaceans, mainly crabs, use sponges for camouflage by removing a piece of a living sponge and holding it against their carapace (shell); the best known example of this type of mutualistic association is that of the sponge *Suberites domuncula* and hermit crabs, which live in the shells of gastropod mollusks. The advantage to the sponge is that it is carried by the mollusk; the hermit crab gains protection not only by living in the shell of the mollusk but also through the disagreeable smell and taste of the sponge, which discourages attack by fishes and other enemies.

Various plants and animals may live on the surface of a sponge or inside its canals and cavities. In some cases the associations are specific; *e.g.,* the coral *Parazoanthus axinellae* grows on the sponge *Axinella.* The organisms that live in the cavities of sponges include crustaceans, nematode and polychaete worms, ophiuroid echinoderms (brittle stars), and bivalve mollusks; some inhabit a sponge for occasional shelter or nourishment, others establish more intimate associations as parasites or predators. Young shrimps of the genus *Spongicola* penetrate certain sponges of the class Calcispongiae, live in them in pairs, and presumably are trapped for life in the rigid skeleton of the sponge; the Japanese consider these shrimps a symbol of matrimonial faithfulness. The number of organisms that live within a single sponge may be very high; thousands of organisms of various species, for example, may be found in *Spheciospongia vesparia,* a Caribbean sponge.

Some organisms that live on (called epibionts) and in (called endobionts) sponges act as parasites. Cyclopoid copepods are the most important parasites of marine sponges; in fact, some genera of these crustaceans have become modified as a consequence of their parasitic existence. Freshwater sponges also are attacked by parasites such as rotifers and mites, which lay eggs in them; larvae of the neuropteran insect family Sisyridae (spongillaflies) live in, and feed upon, freshwater sponges. In general, sponges are protected from predators by their disagreeable taste and smell and by their hard skeletal elements (spicules). In some cases, however, sponges are eaten by other organisms; *e.g.,* mollusks—gastropods such as snails and nudibranch slugs, prosobranchs such as *Patella* and *Littorina,* and chitons—some crustaceans, and some fishes (especially on coral reefs).

Algal associations

The most important symbiotic associations of sponges occur with single-celled and multicellular algae. The algae may live in the surface layers of the sponge, inside the cells, or among them. The sponge protects the algae from enemies, from unfavourable environmental conditions, and from their own metabolic waste products; the sponge uses the algae as a source of oxygen, as a mechanism for eliminating its products of metabolism, as a screen against sunlight, and as a food source (consuming both algal waste products and dying algae). Sponges of the freshwater Spongillidae and various species of marine littoral sponges consume dying green and blue-green algae respectively. The algae, which provide the Spongillidae with their characteristic green colour, may be transmitted through the gemmules. In some boring clionid sponges (*Cliona viridis*) of the class Demospongiae, some single-celled brown algae are constantly present. The marine sponges may also harbour multicellular blue-green algae (*e.g., Oscillatoria*), red (Rhodophyceae) and green (Chlorphyceae) algae. Red and green algae sometimes provide skeletal support for certain sponges.

Diseases of sponges. Sponges may be attacked by diseases of epidemic character, the agents of which are not well known. The commercial sponges of the West Indies once were nearly completely destroyed by a fungus-like microorganism; other sponges were not damaged.

FORM AND FUNCTION

The Porifera are unusual animals in that they lack definite organs to carry out their various functions. The most important structure is the system of canals and chambers, called a water-current system, through which water circulates to bring food to the sponge.

Water-current system. The essential elements of the water-current system include the pores, or ostia, through which water enters the sponge (incurrent system); the choanocytes, or collar cells, which are flagellated cells that capture food; and the oscula, openings through which water is expelled (excurrent system). Three types of water-current systems of increasingly complex structure may be distinguished by the arrangement of choanocytes and the development of canals—ascon, sycon, and leucon (Figure 2). The simplest, or ascon, type, found only in certain primitive genera of Calcispongiae (*e.g., Leucosolenia*), is characterized by an arrangement of choanocytes around a central cavity that directly communicates with the os-

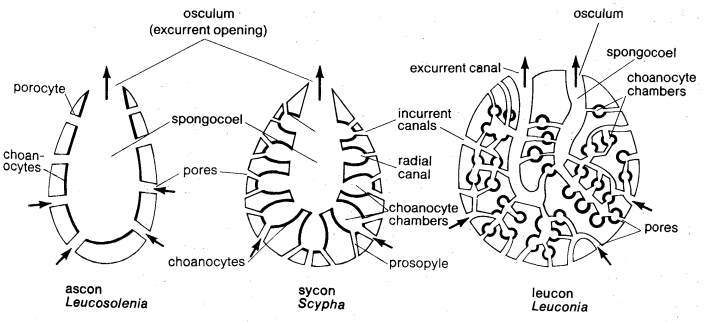

Figure 2: Water current systems in calcareous sponges. Arrows indicate the direction of water flow.

culum. The walls of these sponges are thin, lack canals, and are perforated by pores, which actually are openings through cells (porocytes). The sycon type of water-current system, found also in Calcispongiae is at first characterized by choanocytes that surround fingerlike projections called radial canals of the sponge wall. Water enters the radial canals directly through pores, makes its way into the central cavity, or spongocoel, and leaves by way of an osculum. In most syconoid sponges (*e.g., Scypha*) the radial canals are bordered by incurrent canals through which passes the water entering the pores; other openings (prosopyles) allow water into the choanocytes, from which it passes directly into the internal cavity and out of it through the osculum. In the leucon type, which is found in the more advanced Calcispongiae and in the other classes (Demospongiae and Hyalospongiae), the radial canals are replaced by numerous small flagellated chambers in which the choanocytes are localized; the chambers, scattered throughout the body of the sponge, have pores through which water passes into a complex system of incurrent canals, then into a spongocoel (internal cavity) by way of excurrent canals. Water enters very small pores found among the cells (pinacocytes), which line the outer surface of the sponge. After passing through a system of incurrent canals and cavities, also lined with pinacocytes, the water reaches the flagellated chambers, enters them through openings (prosopyles), and leaves through other openings (apopyles). The water is expelled through the osculum after passing through a system of excurrent canals and cavities lined with pinacocytes. During the development of many sponges, a simpler water current system (rhagon) precedes the leucon type. The rhagon type is characterized by reduced excurrent canals and by a large central cavity. In some Demospongiae the body is organized in two parts, an external ectosome without choanocytes, and an internal choanosome with choanocytes.

Leucon water-current system

Cell types. The sponges lack a well-defined organization of tissues. Single layers of cells line the outer surface of the body and the internal cavities; other cells, both motile and fixed, and fibres occur in an amorphous substance (mesohyl), gelatinous in nature. It has not been possible thus far to identify with certainty similarities of origin (homologies) between the various types of sponge cells and those of higher animals. Each type of sponge cell performs particular functions; the cells either may gather in certain areas of the sponge or form layers and membranes. They are easily modified, both in form and function, during larval development and during adult life. Furthermore, they have a remarkable ability to migrate and to transform from one cell type to another, although the mechanisms involved are not known. Three principal types of cells may be distinguished—choanocytes, archaeocytes, and pinacocytes–collencytes (Figure 3).

Choanocytes and archaeocytes. The choanocytes are provided with a flagellum, which is surrounded by a collar composed of cytoplasm. The main function of the flagellum apparently is to produce the water current, that of the collar is to capture food particles.

The archaeocytes, which are scattered in the mesohyl, have remarkable potentialities for transformation into various cell types, especially in the Demospongiae. Some persist and reproduce during the life of the sponge without specializing, thus forming an embryonic reserve from which other cellular types may be derived; others become specialized to carry out particular functions. Archaeocytes, often called amoebocytes, are amoeboid cells (*i.e.,* they have the ability to move); their cytoplasm contains large quantities of ribonucleic acid (RNA), and their large nuclei contain small bodies known as nucleoli. Amoebocytes function in regeneration and in transportation of food particles acquired at the choanocytes throughout the body of the sponge. During this distribution process, they carry granules consisting of various substances. Depending on the nature of the substance, amoebocytes may be known by several names; *e.g.,* granulocytes, thesocytes. Amoebocytes laden with various pigments (carotenoids and melanin, sometimes contained in algal symbionts) confer various colours to the sponge.

The archaeocytes may be important in sexual reproduction, if, as is postulated, male and female reproductive cells are derived from them. This role is disputed, however, since in some cases, mainly in the Calcispongiae, reproductive cells, particularly those of the male, are derived from choanocytes.

Pinacocytes, collencytes, and other cell types. Pinacocytes (Figure 3) form the pinacoderm, a single cell layer found on the body surface and lining the canals. Various types of pinacocytes occur—basipinacocytes are in contact with the surface to which the sponge is attached, exopinacocytes are found on the surface of the sponge, and endopinacocytes line the canals. Pinacocytes are flattened cells containing many granules; capable of contracting, pinacocytes may cause a reduction in the volume of the sponge if it is disturbed. In the Calcispongiae, the outer surface of the body also contains flattened granular cells called porocytes because they contain the pores needed to allow water into the sponge. The porocytes can contract, thus closing the pores during unfavourable environmental conditions.

The collencytes, found in the mesohyl, secrete fibres and often form a net in the cytoplasm. The mesohyl of sponges contains other types of cells (lophocytes, sclerocytes, myocytes) believed to be derived from archaeocytes. Lophocytes, similar to but larger than collencytes, have long cytoplasmic processes at one end, giving them the appearance of a comet; they apparently secrete fibres (spongin) that form skeletal material. The sclerocytes, or scleroblasts, which also produce skeletal material, are clas-

sified according to the chemical nature of the spicules; calcoblasts secrete calcareous spicules, silicoblasts siliceous (glasslike) ones. The myocytes are elongated, contractile cells, particularly abundant near the oscula, where they control their expansion and contraction. The presence of nerve cells in sponges is a matter of dispute; the general opinion, however, is that none exist, not even in a primitive form.

Skeleton. The skeleton of sponges is of great taxonomic significance. It may be mineral in nature (calcareous or siliceous) or composed of protein and other components (spongin, see Figure 4). The mineral skeleton is formed for the most part by units called spicules, either scattered throughout the sponge or united to form fibres; spicules are classified as megascleres, which function in support, and microscleres, which function in protection and also aid in support.

Spicule types

Mineral skeletons. Calcareous spicules, characteristic of the Calcispongiae, are composed chiefly of calcium carbonate in crystalline forms; *e.g.,* calcite, aragonite. Most calcareous spicules have one axis (monoaxon), which is usually pointed at both ends; these spicules are called oxeas. Triaxons have three rays and are called triacts; tetraxons have four rays and are called tetracts. Figure 4 shows spicule types.

Siliceous spicules, found in the Demospongiae and in the Hyalospongiae, are made essentially of silicic acid; they also contain some water, a small quantity of other compounds containing sodium, potassium, iron, and chlorine, and a small quantity of organic matter, called spiculin, which forms an axial fibre. The spicules of the Hyalospongiae are variable in form and often have remarkable dimensions. Characteristic spicules of the Hyalospongiae are triaxon forms with three orthogonal axes (that is, six rays); this form is called hexactine, and the class is also known as the Hexactinellida. The spicules are connected in a continuous network, and after the death of the sponge and the loss of its soft parts, the skeleton that remains has a delicate glass texture; *e.g.,* the Venus basket, *Euplectella.* Bundles of large spicules form stalks that allow members of the Hyalospongiae to attach to the muddy bottoms of the deeper parts of the ocean in which they generally live. In the genus *Monoraphis,* the stalk is one enormous spicule that may attain a length of two or three metres (6.6–10 feet) and a thickness of approximately one centimetre (0.4 inch).

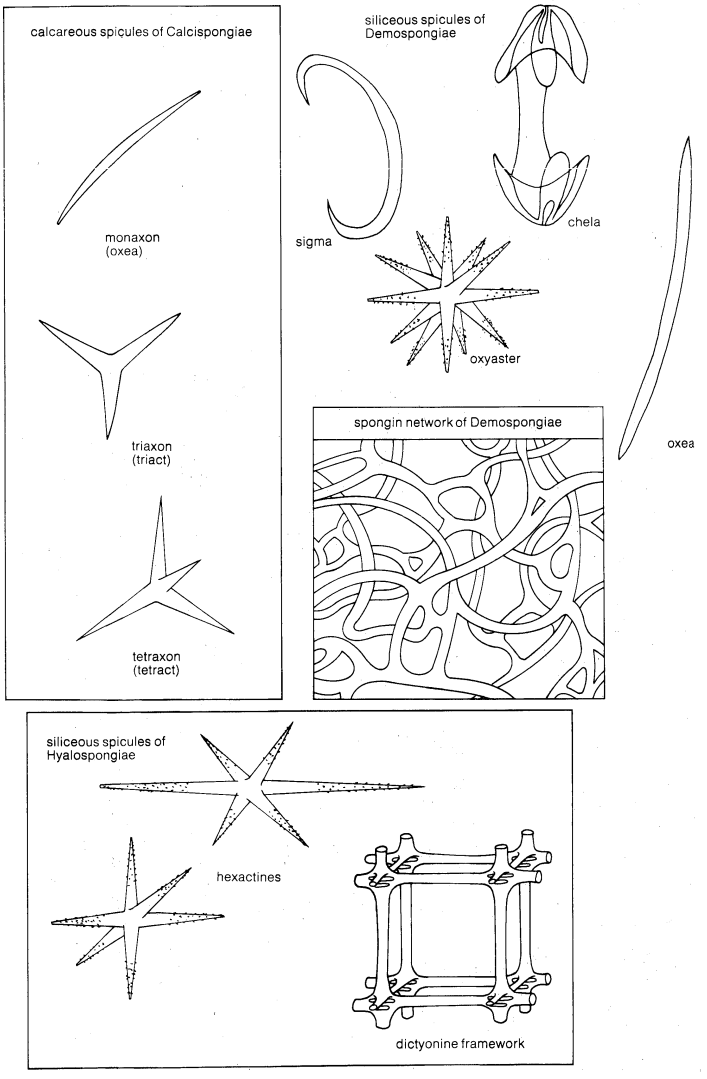

Figure 4: Types of spicules.

The siliceous spicules, consisting of both megascleres and microscleres, of the Demospongiae have an enormous variety of forms. The megascleres may be monaxons with both ends pointed (oxeas), with one end pointed and the other rounded (styles), or with both ends rounded (strongyles). If one end is swollen styles are called tylostyles and strongyles tylostrongyles; the spicules with both ends swollen are called tylotes. If the surface of the spicules is spiny instead of smooth, the spicules are called, respectively, acanthoxeas, acanthostyles, and acanthostrongyles. The megascleres also include triacts with three rays and tetracts, called calthrops, with four rays. Tetracts with one axis (rhabdome) longer than the other three (collectively the cladome) are called protriaenes, plagiotriaenes, anatriaenes, or dichotriaenes, depending on the way the rays of the cladome are directed.

All of the microscleres apparently are derived from a spherical type with many axons (polyaxon); the result is a series of star-shaped spicules, or asters, with various numbers of rays. Spicules with rays missing or reduced (called spheres, sterrasters, and discasters) often form a protective armour around the sponge. More specialized types of microscleres include sigmas, toxas, chelas, and anchoras; the last two have plates or teeth at each end and may be distinguished as isochelas and isanchoras or anisochelas and anisanchoras, depending on whether the ends are equal or unequal.

Other types. A few Demospongiae (*e.g., Oscarella, Halisarca,* and *Chondrosia*) lack skeletons. One group (Ceractinomorpha) has a type of spongin, which, in certain orders (Axinellida, Poecilosclerida, and Haplosclerida), cements the spicules in bundles or meshes, thereby increasing the elastic nature of the skeleton. In another group of Demospongiae (Keratosa), spongin fibres constitute the entire skeleton; the spongin fibres may be branched (order Dendroceratida), netlike (order Dictyoceratida), without inclusions (commercial sponges, which are therefore soft and elastic), or with inclusions (*e.g.,* grains of sand, fragments of spicules). In the genus *Ircinia,* the fibres are accompanied by thin spongin filaments that fill the mesohyl.

Spongin

Specialized types of skeletons in two groups of great paleontological importance are now represented by only a limited number of species, in the Calcispongiae and Demospongiae. Those in the Calcispongiae (Pharetronida) have skeletons formed by an amorphous mass of calcium carbonate, with which few spicules are associated. Those in the Demospongiae (Lithistida) form a heterogeneous group in which irregularly branched spicules (desmas) form a compact skeleton. Some Demospongiae, found mainly on the coral reefs, possess a compact calcareous skeleton, which incorporates both siliceous spicules and organic fibres. (M.Sa.)

Functional features. *Feeding and digestion.* The Porifera are filter feeders, utilizing food particles suspended in the water and captured by the choanocytes. Food particles consist essentially of bacteria, other microorganisms, and particles of organic debris; sponges also probably absorb dissolved organic substances. Experiments with starch grains, bacteria, and particles of carmine pigment show that the particles ingested by the choanocytes are transferred by thesocytes (specialized amoebocytes) throughout the sponge. Intracellular digestion occurs in both choanocytes and thesocytes. A large quantity of food is

absorbed by a sponge, and it can use several litres of water a day. The water-current system, therefore, is efficient, in spite of the lack of a nervous coordinating centre. The water flow into and out of the sponge is maintained by continuous movement of the flagella of the choanocytes; flagellar movement pushes water into the choanocyte chambers, creating in them a pressure that extends to the excurrent canals, as water passing into the pores is drawn along the system of incurrent canals. Water flow, which is also regulated by contraction and expansion of the pores and of the oscula, is slow at the pores, fast at the oscula; as a result, water expelled with force through the oscula cannot contaminate water entering the pores. Toxic or irritating substances cause the pores to close.

Oxygen uptake and excretion. Respiratory organs are lacking in sponges; oxygen is supplied by a direct exchange between the tissues and the surrounding water. Consequently, the consumption of oxygen is related to the velocity of the current. Excretion occurs through both the oscula and the surface of the sponge. Special amoebocytes disintegrate in the mesohyl, and their granules are expelled through the canals. The excretory products of the sponges—ammonia and other nitrogen-containing substances—account for their characteristic unpleasant odour. Many sponges (*e.g.,* the tropical sponge *Tedania ignis*) exude large quantities of mucus, and some species produce toxic substances, which may cause inflammation and skin reactions in humans.

Coordination. A sponge usually contracts if it is handled. The oscula close if the sponge is exposed to air, if oxygen is not available, if harmful chemical compounds are present, or if temperatures are extremely high or low. The lack of coordination in the oscula, pores, and choanocytes and the slow reaction of sponges to stimuli confirm the absence of a nervous system. A primitive system of coordination, probably chemical in nature, apparently exists. Contraction of myocytes occurs around the oscula and along the peripheral canals of Demospongiae. Some Calcispongiae of the ascon type reduce their volume through contraction of the superficial layer of pinacocytes.

Biochemical aspects. The sponges produce substances with antibiotic activity (*e.g.,* ectyonin), which may function during the selection of bacteria and other microorganisms on which they feed. The Porifera contain a greater variety of fatty substances (*e.g.,* sterols) than do other animals. Some of these sterols (*e.g.,* clionasterol, poriferasterol) are found only in sponges; others (*e.g.,* cholesterol) are common in other animals. Numerous carotenoid pigments occur in sponges, and melanin, chlorophyll, and phycoerythrin derived from algal symbionts and from the diet also occur. Sponges accumulate silicon, calcium, and considerable quantities of metals. The spongins are iodine or bromine-containing scleroproteins similar to the keratin found in skin, claws, hair, and feathers of other animals. The two types of spongin, known as A and B, differ in composition and structure.

EVOLUTION AND PALEONTOLOGY

Sponges have evolved in a way foreign to that of other animals. They probably arose from a flagellate Protozoa, although it is not certain which group. The choanocytes of sponges resemble the choanoflagellate protozoans. Choanoflagellate protozoan colonies, however, do not develop by way of embryological stages as do the sponges. The primitive structure of the Porifera indicates affinities with certain types of protozoan colonies; both lack integration of parts, mouths, and digestive systems, and both have a type of skeletal formation in which single elements are produced by a single cell or by a small group of cells.

The Porifera appeared in the Early Cambrian Period of the Paleozoic Era (about 550,000,000 years ago). Of the classes known in the Middle Cambrian Period (Hexactinellida or Hyalospongiae, Heteractinellida, and Demospongiae), the Heteractinellida are extinct; the Calcispongiae appear in the Carboniferous Period (about 345,000,000 to 280,000,000 years ago). Living sponges do not differ substantially from many groups in the Paleozoic Era.

Despite the mineral skeleton, the only Porifera well represented as fossils are those with a compact skeleton; *e.g.,* pharetronids (Calcispongiae), lithistids (Demospongiae), and Dictyonina (Hyalospongiae). The oldest sponge fossils, from the Lower Cambrian, are well represented in the Burgess Shale of the Middle Cambrian in western Canada by *Protospongia,* a member of the Hyalospongiae, and by *Eiffelia,* of the extinct Heteractinellida. They resembled a pouch and had very thin walls; their spicules were arranged in a single layer, and their water-current system was probably of an ascon type. Various genera of the order Lyssacina (Hyalospongiae) are known from the Paleozoic from spicules. In the Mesozoic Era (about 225,000,000 to 65,000,000 years ago), the Hyalospongiae gave rise to a group (order Dictyonina) with the compact skeleton commonly found in sediments. Beginning with the Late Cretaceous Period (about 100,000,000 years ago), the species of Hyalospongiae have affinities with recent ones.

Oldest sponge fossils

Calcispongiae appear in the Carboniferous Period (about 345,000,000 to 280,000,000 years ago). The first Pharetronida (Calcispongiae) from the Permian Period (about 280,000,000 to 225,000,000 years ago) have a compact calcareous skeleton and spicules; because calcareous spicules are easily dissolved during fossilization, Calcispongiae lack a compact skeleton and have left few traces.

Demospongiae may have followed a line of evolution originating in Tetractinellida (with four-rayed spicules) and advancing, after reduction of the tetraxon spicules into monoaxons, to Keratosa; in addition, the polyaxon microscleres (asters) evolved into specialized forms (sigmas and chelas), and spongin appeared to cement the spicules, finally developing into a skeleton formed exclusively of horny fibres. Recent opinion, however, suggests that the Demospongiae are a diphyletic class, which is separable into two large groups (Tetractinomorpha and Ceractinomorpha). The Tetractinomorpha have four-rayed megascleres, asters, and no spongin; the Ceractinomorpha have monaxon megascleres, no asters, and spongin. That these morphological differences are accompanied by important embryological differences is supported by the facts that the oldest Demospongiae, from the Cambrian, are monaxonid (with only oxeas) and that the four-rayed spicule originates later, in the Carboniferous Period. Well-represented since the Paleozoic, the Lithistida have a siliceous skeleton of netlike desmas and are considered polyphyletic; the lithistid modification of the skeleton appeared independently in different lines of the Demospongiae. Few lithistid genera are extant. Demospongiae lacking a compact skeleton are poorly represented in sediments.

The phylogenetic relationships among the classes are difficult to ascertain, although common spicular characters may be found among Calcispongiae, Hyalospongiae, and tetractinellid Demospongiae. Noteworthy is the existence of sponges with both calcareous and siliceous elements in their skeleton; these sponges show affinities with both the pharetronid Calcispongiae and the Demospongiae. The extinct Archaeocyatha, with a cup-shaped body fixed on a surface and a skeleton of porous walls, were aberrant forms that lived exclusively in the Cambrian and that are generally considered as a separate phylum, even though they do show some affinities with the Calcispongiae.

CLASSIFICATION

Distinguishing taxonomic features. The general architecture of the skeleton is used to differentiate families, the particular combinations of spicular types to define genera, and the form and dimensions of single spicule types to differentiate species. Other morphological characters include shape, colour, consistency, surface (smooth, rough, or conulose), and distribution and character of the oscula, which often shows remarkable interspecies variation. Cytological and embryological features are used as diagnostic characters in both general classification and species identification of the Demospongiae and Calcispongiae. Ecological and distributional characters are important in distinguishing species, particularly in groups (*e.g.,* haliclonids) in which skeletal and embryological characters are so uniform as to be of little taxonomic value. Although biochemical criteria—for instance, amino acid composition—have been used in some cases to evaluate general phylogenetic problems and separate orders, the results do

Ecological characters

not differ substantially from those obtained with other criteria. (M.Sa./Ed.)

Annotated classification. The classification below, which refers to the three living classes of sponges, is adapted from that of E. Topsent as modified by C. Levi on the basis of embryological data; it is accepted by most experts in the field.

PHYLUM PORIFERA (sponges)

Primitive aquatic invertebrate animals; about 5,000 species in all seas; attach to surfaces from intertidal zone to depths of 8,500 m (29,000 ft) or more; propel water containing food particles through a system of canals in body (filter feeding); composed of many cell types (archaeocytes of various kinds, pinacocytes, collencytes); structure of water-current system variable (ascon, sycon, leucon); skeleton either mineral (calcium carbonate or silicic acid), spongin, sometimes lacking, or of mixed composition; skeletal units (spicules) variable in form; both sexual and asexual reproduction (gemmulation); ability to regenerate lost parts; contain many unique chemical compounds; form symbiotic relationships with many other types of organisms.

Class Calcispongiae

Skeleton of spicules of calcium carbonate; species either vase-shaped compact structures, loose networks of thin tubes, or irregular massive colonies; mostly small in size; inhabit shallow waters of all seas, from intertidal regions to depths of 200 m (660 ft); a few species to 800 m (2,600 ft); about 300 species.

Subclass Calcinea

Larva called parenchymella (solid, compact, with outer layer of flagellated cells, inner mass of cells); flagella of choanocytes (collar cells) arise independently of nucleus; some 3-rayed spicules in most species; water-current system ascon, sycon, or leucon type; includes pharetronid sponges with rigid skeleton of fused spicules or of a calcareous network; genera include *Clathrina, Leucetta, Petrobiona* (a pharetronid).

Subclass Calcaronea

Larva called amphiblastula (oval in shape with front half of flagellated cells, rear half without flagellated cells); flagella of choanocytes arise directly from nucleus; spicules 3-rayed, with one ray characteristically longer than other two; water-current system ascon, sycon, or leucon type; *Leucosolenia, Scypha* (formerly called *Sycon*), *Grantia, Lelapia* (with a rigid skeleton composed of bundles of modified rayed spicules).

Class Hyalospongiae (Hexactinellida)

Skeleton basically of hexactinal (6-rayed) siliceous spicules and lacking in spongin; exclusively marine, in deeper waters of all seas, depths from 25 to 8,500 m (80–29,000 ft); commonly fixed firmly to a hard surface, some species anchored in soft bottom sediments; *Hexactinella, Aphrocallistes, Farrea, Dactylocalyx, Euplectella, Rhabdocalyptus;* about 500 species.

Class Demospongiae

Skeleton of either 1- or 4-rayed siliceous spicules, spongin fibres, or both; skeleton lacking in a few primitive genera; most abundant and widely distributed group of sponges (about 4,200 species); occur from intertidal regions to depths of about 5,500 m (18,000 ft) in seas; Spongillidae the freshwater sponge family; species vary greatly in form and size; range from thin encrustations several cm in diameter to huge cake-shaped species 2 m (6.6 ft) in diameter; many species with desmas (develop as a result of secondary deposits of silica around ordinary spicules); evolution independently among several orders of interlocking of adjacent desmas to form a stony skeleton (lithistid sponges).

Critical appraisal. The living orders of sponges are distributed in the Calcispongiae, Hyalospongiae, and Demospongiae. The Calcispongiae may be separated into two subclasses (Calcinea and Calcaronea), which represent two phyletic series separated mainly by cytological and embryological characters; this classification has replaced the traditional classification of the calcareous sponges into Homocoela and Heterocoela, which was based on the types of the water-current system. The traditional classification of the Hyalospongiae into the orders Lyssacina and Dictyonina is still valid. The separation of the Demospongiae into orders is not well defined, because the phylogeny of the group is not well known. Two groups of orders may be distinguished within the Demospongiae. One, in which spongin is an important skeletal element (Ceratinomorpha), includes Poecilosclerida, Haplosclerida, Dendroceratida, and Dictyocernatida, the latter two derived from another subdivision, the Keratosa. The other group (Tetractinomorpha) includes Homosclerophorida, Tetractinellida, Epipolasida, Hadromerida, and Axinellida; four-rayed spicules are important only in the Homosclerophorida and in the Tetractinellida, but the other orders are clearly related to them. Hadromerida, Axinellida, and Epipolasida are placed in a group called the Clavaxinellida. The Epipolasida, an ill-defined order, are nearest to the Tetractinellida. Many genera of Demospongiae, mainly in the Tetractinomorpha, are transitional, and their actual phylogenetic position is not clear.

Alternative subclassification systems

Other classifications of sponges may concern only differences in detail; *e.g.,* the rank of order or of suborder given to the Dictyoceratida and Dendroceratida, the inclusion of the Homosclerophorida in the Tetractinellida, or the abolition of the order Epipolasida. A classification for the Demospongiae, proposed in 1936, is similar to that stated above in its subdivision into orders but is revolutionary with regard to the placement of families and of genera. It has not been followed in general by the other systematists of the group.

Still another classification of the Porifera places them in a subkingdom of the Parazoa as two phyla (Nuda and Gelatinosa). The Nuda includes a single class and order, the Hexactinellida; the Gelatinosa is divided into two classes (Calcarea and Demospongia). The separation between Nuda and Gelatinosa is based only on the absence or presence of an intercellular matrix of fluids and fibrils around the net of cells. Although the proposal has not yet been evaluated critically, it seems justifiable to keep the Porifera in a single phylum because of the common structural basis regarding their many characters (*e.g.,* anatomy, function, and embryology). Other proposals include establishment of a new order (Pharetronida) separated from the Calcinea and Calcaronea in the Calcispongiae, and the creation of a new class (Sclerospongiae) for the silicocalcareous or coralline sponges.

An important controversy in the systematics of the sponges concerns the value given to species described using traditional criteria. The use of species in classifying sponges is justified by the great variability of diagnostic characters, especially the spicules. Attempts to merge large groups of species into single systematic units have resulted in excessive lumping of species, which has been much criticized. In classifying sponges, therefore, one diagnostic feature is not sufficient; rather, all diagnostic characters should be considered.

Major Team and Individual Sports

Many animals play, but *homo sapiens* is the only animal to have invented sports. Since sports are an invention, a part of culture rather than an aspect of nature, all definitions of sports are somewhat arbitrary. Whether sports are a human universal found in every known culture or a phenomenon unique to modern society depends upon one's definition of sports. Men and women have always run, jumped, climbed, lifted, thrown, and wrestled, but they have not always performed these physical activities competitively. Although all literate societies seem to have contests of one sort or another in which men, and sometimes women, compete in displays and tests of physical skill and prowess, sports may be strictly defined as physical contests performed for their own sake and not for some ulterior end. By this strict definition, neither Neolithic hunters nor contestants in religious ceremonies such as the ancient Olympic Games were engaged in sports. Insistence on the stipulation that sports must be performed for their own sake means the paradoxical elimination of many activities usually thought of as sports, such as exercises done for the sake of cardiovascular fitness, races run to satisfy a physical education requirement, ball games played to earn a paycheck. Strict definition also means abandonment of the traditional usage in which "sport," derived from Middle English *disporter,* refers to any lighthearted recreational activity. In the minds of some 18th-century aristocrats, a game of backgammon and the seduction of a milkmaid were both considered good sport, but this usage has become archaic.

Strict conceptualization allows the construction of an evolutionary history of sports in which extrinsic political, economic, military, and religious motivations decrease in importance as intrinsic motivations—participation for its own sake—increase. The disadvantage, however, is that the determination that a given activity is truly a sport depends on the answer to a psychological question: What is the motivation of the participants? The question of motivation cannot be answered unambiguously. It is probable that the contestants of the ancient Olympic Games were motivated by the intrinsic pleasure of the contest as well as by the religious imperatives of Greek cult. It is also probable that modern professional athletes are motivated by more than simply economic motives. Thus most scholars assume quietly that popular usage cannot be completely wrong to refer, for instance, to U.S. professional National Football League games as sports.

This article discusses the history of sports and their place in modern society and divides the major competitive sports into two main categories: team and individual. The distinction between the two is rather obvious, the one requiring teamwork among a group of players participating simultaneously, and the other requiring the effort of a single individual unaided by teammates. The particular sports that are covered here are those active ones for which adults in different parts of the world, enjoying them sufficiently in their early forms, have developed uniform codes of rules and specifications and have organized competitive play (*e.g.*, tennis, football, baseball, cricket, and basketball). Not everyone will agree on the selection of sports determined here to be "major." The selection process was based, to a large degree, on popularity, whether that element arose from attendance, participation, media exposure, or any combination thereof. Other criteria were history and tradition. Inevitably, spatial restrictions determined that some sports of obvious major proportions, such as swimming, skiing, and gymnastics, could not be covered in this article.

SPORTS IN SOCIETY

History

Origin of sports

No one can say when sports began. Since it is difficult to imagine a time when children did not spontaneously run races or wrestle, it is clear that children have always included sports in their play, but one can only speculate about the emergence of sports as autotelic (played for their own sake) physical contests for adults. Hunters are depicted in prehistoric art, but it cannot be known whether the hunters pursued their prey in a mood of grim necessity or with the joyful abandon of sportsmen. It is certain, however, from the rich literary and iconographic evidence of all ancient civilizations that the hunt soon became an end in itself—at least for royalty and nobility. Archaeological evidence also indicates that ball games were common among the ancient Chinese. If such games were contests rather than ritual performances like the Japanese football game *kemari,* then they were instances of sports in the most rigorously defined sense. That it cannot simply be assumed they were contests is clear from the evidence presented by Greek and Roman antiquity, indicating that ball games seem to have been for the most part playful pastimes like those recommended for health by the 2nd-century AD Greek physician Galen.

SPORTS IN THE ANCIENT WORLD

Egypt. Sports were certainly common in ancient Egypt, where pharaohs demonstrated their fitness to rule by prowess in the hunt and by exhibitions of strength and skill in archery. In such exhibitions, pharaohs such as Amenhotep II (ruled 1450–25 BC) never competed against another person, and there is reason to suspect that their extraordinary achievements were scribal fictions. However, Egyptians with less claim to divinity jumped, wrestled, and engaged in ball games and stick fights of the sort that can still be observed in Egypt.

Crete and Greece. Since Minoan script still baffles scholars, it is uncertain whether Cretan boys and girls who tested their acrobatic skills against bulls were engaged in sports, in religious ritual, or in both.

That the feats of the Cretans may have been both sport and ritual is suggested by evidence from Greece, where sports had a significance unequaled anywhere before the rise of modern sports. Secular and religious motives mingle in history's first extensive "sports report," found in book 23 of Homer's *Iliad* in the form of funeral games for the dead Patroclus. These games were a part of cult and were not, therefore, autotelic, but the contests in the *Odyssey* are essentially secular. Odysseus was challenged by the

Phaeacians to demonstrate his prowess as an athlete. In general, Greek culture included both cultic sports, such as the Olympic Games honouring Zeus, and secular contests.

The Olympic Games

The most famous association of sports and religion was certainly the Olympic Games, which Greek tradition dated from 776 BC but which probably began much earlier. In the course of time, the earth goddess Gaea, originally worshiped at Olympia, was supplanted in importance by the sky god Zeus, in whose honour priestly officials conducted quadrennial athletic contests. Sacred also were the games held at Delphi, in honour of Apollo, and at Corinth and Nemea. These four events were known as the *periodos,* and great athletes, such as Theagenes of Thasos, prided themselves on victories at all four sites. The extraordinary prestige accorded athletic triumphs brought with it not only literary accolades (as in the odes of Pindar) and visual commemoration (in the form of statues of the victors) but also material benefits, contrary to the amateur myth propagated by 19th-century philhellenists. Since the Greeks were devoted to secular sports as well as to sacred games, no polis, or city-state, was considered a proper community if it lacked a gymnasium where, as the word *gymnos* indicates, naked male athletes trained and competed. Except at militaristic Sparta, Greek girls rarely participated in sports of any kind. Women were excluded from the Olympic Games even as spectators (except for the priestess of Demeter). Pausanias, the 2nd-century-AD traveler, wrote of races for girls at Olympia, but these events in honour of Hera were of minor importance.

Rome. Although chariot races were among the most popular sports spectacles of the Roman and Byzantine eras, as they were in Greek times, the Romans of the republic and the early empire were quite selectively enthusiastic about Greek athletic contests. Their emphasis was on physical exercises for military preparedness, an important motive in all ancient civilizations; they preferred boxing, wrestling, and hurling the javelin to running footraces and throwing the discus. The historian Livy tells of Greek athletes appearing in Rome as early as 186 BC, but the contestants' nudity shocked Roman moralists. The emperor Augustus instituted the Actian Games in 27 BC to celebrate his victory over Antony and Cleopatra, and several emperors began similar games, but it was not until the later empire, especially during the reign of Hadrian (AD 117–138), that large numbers of the Roman elite developed an enthusiasm for Greek athletics.

Chariot races in Rome's Circus Maximus were watched by as many as 250,000 spectators, five times the number that crowded into the Colosseum to enjoy gladiatorial combats. Nevertheless, there is some evidence that the latter contests were more popular even than the former. Indeed, the *munera,* which pitted man against man, and the *venationes,* which set men against animals, became popular even in the Eastern Empire, which historians once thought immune from the lust for blood. The greater frequency of chariot races can be explained in part by the fact that they were relatively inexpensive compared to the enormous costs of gladiatorial combats. (The *editor* who staged the games usually rented the gladiators from a *lanista* and was required to reimburse him for losers executed in response to a "thumbs down" sign.) Brutal as these combats were, many of the gladiators were free men who volunteered to fight, an obvious sign of intrinsic motivation. Indeed, imperial edicts were needed to discourage the aristocracy's participation. In AD 63, during the reign of Nero, female gladiators were introduced into the arena.

Roman blood sports

The circus and the hippodrome, a stadium of Greek origin for chariot racing, continued to provide popular sports spectacles long after Christian protests (and heavy economic costs) ended the gladiatorial games, probably early in the 5th century. In many ways, the chariot races were quite modern. The charioteers were divided into bureaucratically organized factions (*e.g.,* the "Blues" and the "Greens"), which excited the loyalties of fans from Britain to Mesopotamia. Charioteers boasted of the number of their victories as modern athletes brag about their "stats," indicating, perhaps, some incipient awareness of what in modern times are called sports records. The gladiatorial games, however, like the Greek games before them, had a powerful religious dimension. The first Roman combats, in 264 BC, were derived from Etruscan funeral games in which mortal combat provided companions for the deceased. It was the idolatry of the games, even more than their brutality, that horrified Christian protestors. The lesser pagan religious association of the chariot races helped them survive late into the post-Constantine period.

SPORTS IN THE MIDDLE AGES

The sports of medieval times were less well-organized. Fairs and seasonal festivals were occasions for men to lift stones or sacks of grain and for women to run smock races (for a smock, not in one). The favourite sport of the peasantry was folk football, a wild sort of no-holds-barred unbounded game that pitted married men against bachelors or one village against another. The violence of the game, which survived in Britain and in France until the late 19th century, was such that Renaissance humanists, such as Sir Thomas Elyot, condemned it as more likely to maim than to benefit the participants.

Inter-town archery matches

The nascent bourgeoisie of the Middle Ages and the Renaissance amused itself with archery matches, some of which were arranged months in advance and staged with considerable fanfare. When town met town in a challenge of skill, the companies of crossbowmen and longbowmen marched behind the symbols of St. George, St. Sebastian, and other patrons of the sport. It was not unusual for contests in running, jumping, cudgeling, and wrestling to be offered for the lower classes who attended the match as spectators. Grand feasts were part of the program, and drunkenness commonly added to the revelry. In Germanic areas, a *Pritschenkoenig* was supposed to simultaneously keep order and entertain the crowd with clever verses.

The burghers of medieval towns were welcome to watch the aristocracy at play, but they were not allowed to participate in tournaments or even, in most parts of Europe, to compete in imitative tournaments of their own.

Sports of the medieval aristocracy

Tournaments were the jealously guarded prerogative of the medieval knight and, along with hunting and hawking, his favourite pastime. At the tilt, in which mounted knights with lances tried to unhorse one another, the knight was practicing the art of war, his raison d'être. He displayed his prowess before lords, ladies, and commoners and profited not only from valuable prizes but also from ransoms exacted from the losers. Between the 12th and the 16th centuries, the dangerously wild free-for-all of the early tournament evolved into dramatic presentations of courtly life in which elaborate pageantry and allegorical display quite overshadowed the frequently inept jousts. Some danger remained even amid the display. At one of the last great tournaments, in 1559, Henry II of France was mortally wounded by a lance blow.

Peasant women participated freely in the ball games and footraces of medieval times, and aristocratic ladies hunted and kept falcons, but middle-class women contented themselves with spectatorship. Even so, they were more active than their contemporaries in Heian Japan during the 8th to the 12th century. Encumbered by many-layered robes and sequestered in their homes, the Japanese ladies were unable to do more than peep from behind their screens at the courtiers' mounted archery contests.

SPORTS IN THE RENAISSANCE AND MODERN PERIOD

By the time of the Renaissance, sports had become entirely secular, but in the minds of the Czech educator John Amos Comenius and other humanists, a concern for physical education on what were thought to be classic models overshadowed the competitive aspects of sports. Indeed, 15th- and 16th-century elites perferred dances to sports and delighted in geometric patterns of movement. The ballet developed in France during this period. Horses were trained to graceful movement rather than bred for speed. French and Italian fencers like the famed Girard Thibault, whose *L'Accademie de l'espee* appeared in 1628, thought of their activity more as an art form than as a combat. Northern Europeans emulated them. Humanistically inclined Englishmen and Germans admired the cultivated Florentine game of *calcio* ("kick"), a form of football that stressed the good looks and elegant attire of the players.

Beginnings of organized sports

The development of sports into the forms of the present day began in late 17th-century England when the emphasis gradually shifted from measure, in the sense of balance or proportion, to measurement. During the Restoration and throughout the 18th century, traditional pastimes like stick fighting and bullbaiting, which the Puritans had condemned and driven underground, gave way to organized games, like cricket, which developed under the leadership of the Marylebone Cricket Club (founded 1787). Behind these changes lay a new conception of rationalized competition. Contests that seem odd to the modern mind, like those in which cripples were matched against children, were replaced by horse races in which fleeter steeds were handicapped, a notion of equality that led eventually to age and weight classes (but not height classes) in many modern sports. The traditional sport of boxing flourished throughout the 18th century, guided and regulated by boxer-entrepreneurs like James Figg and his pupil Jack Broughton, and, eventually, by the Marquess of Queensberry, whose 1867 rules replaced Broughton's 1743 attempt to civilize the sport.

In the 18th and 19th centuries, sports became increasingly specialized, and national organizations developed to standardize rules and regulations, to organize sporadic challenge matches into systematic league competition, to certify eligibility, and to register results. England's Football Association was formed in 1863 to propagate that sport (called soccer in the United States), which had developed out of medieval folk football (as, eventually, did rugby and American football). The Amateur Athletic Association followed in 1880. From England and then from the United States, modern sports spread throughout the globe. Sports that originally began elsewhere, such as tennis (which derives from Renaissance France), were modernized and exported as if they too were raw materials imported for British industry to transform and then ship out as finished goods. By the early 20th century, organizations like the International Olympic Committee (founded 1894), the Fédération Internationale de Football Association (1904), and the International Amateur Athletic Federation (1912) had begun to seem inevitable.

Early Asian sports

During the age of imperialism, when Europeans and Americans dominated much of Asia and most of Africa, the colonial powers suppressed traditional sports and introduced their own modern ones. Japan, one of the few non-Western nations where a traditional sport (sumo) rivals a modern one (baseball) in popularity, is also one of the few non-Western nations to contribute a sport (judo) to the modern Olympic Games.

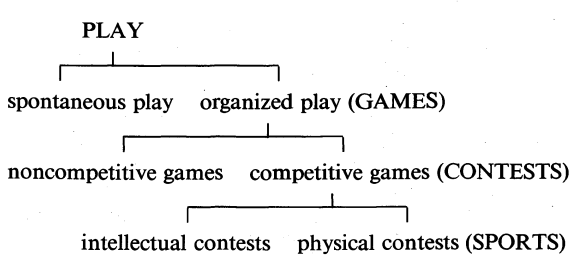
Behind the dramatic transition to modern sports lay the scientific developments that sustained the Industrial Revolution. Technicians sought to perfect equipment. Athletes trained systematically to achieve their physical maximum. New games, like basketball, volleyball, and team handball, were consciously invented to specification as if they were new products for the market. As early as the late 17th century, quantification became an important aspect of sports, and the cultural basis was created for the concept of sports record. The word "record," in the sense of an unsurpassed quantified achievement, appeared, first in English and then in other languages, only in the late 19th century.

The sociological terms used to describe the development of modern sports, such as secularization, rationalization, specialization, bureaucratization, and quantification, all suggest that the formal and structural characteristics specific to 20th-century sports are the characteristics of modern society generally. Although Marxist scholars contend that this development is the result of industrial capitalism, non-Marxists, adapting the sociological theories of the German Max Weber, the Frenchman Émile Durkheim, and the American Talcott Parsons and others, have observed that modern sports antedate industrial capitalism and flourish in societies such as the Soviet Union that have never known a "bourgeois" phase.

Economic analysis demonstrates that the boom in sports participation and in sports spectatorship has depended on the increase of leisure time for the masses. Capitalistic entrepreneurship certainly played a role in the rationalization of sports into a marketable commodity. But the transformation of traditional pastimes into modern sports took place in the schools and universities as well as in business and industry. Modern baseball was formulated by a group of New York City players, but modern soccer was invented in the elite boys' schools of Victorian England, while rowing and track-and-field athletics took their modern forms in English and American colleges and universities. The 19th-century's combination of Christian ethics and rationalized forms is best symbolized by the birth of basketball in 1891 at the YMCA Training School in Springfield, Mass., a stronghold of "muscular Christianity."

Origins of modern sports

While England may be considered the homeland of modern sports, modern physical education can be traced back to German and Scandinavian developments of the late 18th and early 19th centuries. Men like Johann Christoph Friedrich Guts Muths in Germany and Per Henrik Ling in Sweden elaborated systems of exercise that were eventually adopted by British, American, and other schools. These noncompetitive alternatives to modern sports, which also flourished in the form of central European gymnastic displays, did not develop great popularity with schoolchildren or college students. Almost universal in the late 19th century, such gymnastic systems have by and large been replaced by competitive sports—with or without the notion that sports can be a vehicle of ethical instruction. Gymnastic displays can still be witnessed in the disciplined mass formations that accompany major sports competitions, particularly in the countries of eastern Europe. Modern-day individual gymnastics is itself an outgrowth of the earlier European gymnastics form.



The controversy over professionalism

While commercial motives encouraged promoters to stage sports events open to all who had the price of admission, class solidarity and exclusiveness led to the invention of the amateur rule, originally formulated in the 1870s to prevent the participation of all those who worked with their hands. The spread of egalitarian ideals and the avarice of individual athletes has had little to do with the demise of amateurism. Rather, barriers to overt professionalization eroded with the realization that the highest levels of physical achievement (and the richest harvest of national and international championships) require expenditures of time and money incompatible with a primary commitment to work or study. Once a university's prestige or a nation's image became dependent upon stellar athletic performances, it was no longer possible to limit the pool of talent to the leisure class. Now that the modern Olympic Games are open to men and women who may earn millions of dollars by their athletic prowess, it is quite improbable that what remains of the Victorian concept of amateur sports as an avocation can endure. The line between amateurism and professionalism has changed through time and will continue to be a point of controversy in sports as long as amateurism, however defined, is a requirement in world competitions.

Sociological, psychological, and physiological aspects

SOCIOLOGICAL FACTORS

Although the Dutch historian Johan Huizinga called attention to play as an aspect of culture in *Homo Ludens* (1938), his predilection for pageantry and for play tinged with religious ritual forced sociologists to devise alternative paradigms for the relationship of play to other activities. That relationship can be expressed in the form of a diagram:

Play can be conceptualized as either spontaneous or regulated. Regulated play—*i.e.*, games—can be contests, like poker, or noncompetitive activities, like leapfrog. Contests can be purely intellectual, like chess, or a combination of physical and intellectual aspects, like rugby.

Competition

Preliterate societies. Competition is such an integral part of Western civilization that some anthropologists and sociologists assume that all games must be contests and are led, therefore, to assert that many preliterate cultures lack games. This assertion is questionable, but many cultures, including some of the most complex, have sought to diminish competition and have favoured noncompetitive games. Such cultures, like those of the Indian subcontinent, have tended to lag behind in the adoption of modern Western forms of sport. There are reasons, however, to suspect that competitiveness may be a universal trait. In Bali, for instance, where Hinduism is the dominant religion, direct social conflict is avoided wherever possible, but the mediated contest of the traditional cockfight indirectly arrays family against family and village against village as the Balinese excitedly bet large sums on the cocks with which they passionately identify.

Most preliterate peoples have sports of one sort or another. As indicated above, these sports are frequently if not invariably associated with cult. The natives of the American Southwest played a stickball game in which the role of the shaman was as important as that of the stick wielders. African youths wrestled one another as part of their rites of passage into manhood. Greek myths like that of swift-footed Atalanta, who said she would marry anyone who could outrun her, testify that footraces as a form of courtship survived into archaic times. The tendency to separate sports from the rest of culture gains strength as the division of labour in society becomes more complex, but the association of sports with the rest of culture has never been lost. An athletic image is almost as useful to the modern politician as it was to Amenhotep II.

Political influence. Politics are in fact an integral aspect of modern sports despite the efforts of some idealists to separate the two. Political decisions determine which sports will be encouraged (traditional or modern), how much public support will be available to promote recreational and elite sports, if differences in gender, race, religion, or ideology will be the basis of discrimination in sports, whether or not athletes will be free to compete in this or that international competition. All of these decisions have prompted bitter controversies, some of which have raged for decades. In nations once colonized by the British, such as Barbados, enthusiasm for cricket is associated with the continued influence of a foreign culture. In the Soviet Union, the Politburo must decide how much money to allocate for national teams of athletes who enhance the system's prestige and how much to devote to facilities to be used by the masses. Women and blacks struggled for decades to achieve integration into the white male preserve of American sports; Jews and Communists were suddenly expelled from German sports clubs in 1933 (on the initiative of the clubs, which anticipated the politics of the Nazi regime). The ostracism of racially segregated South Africa and the use of Olympic boycotts as a means of protest are prime examples of political decisions affecting participation in international sports events.

Barriers to women and minorities

Mass-media influence. That hundreds of millions of people now play sports on a regular basis and equally large numbers watch the Olympic Games and soccer's World Cup on television has enormous economic consequences. Most of the world's governments now have ministries of sport that budget large sums to construct sports facilities and otherwise promote recreational sports for the masses. Such ministries cooperate closely with national sports federations to finance research into "sport science" and to field elite representative teams for international events. Where private enterprise is encouraged, entrepreneurs market equipment, operate commercial sports facilities, and sponsor tournaments. They and other companies purchase sports-related television advertisements that in the late 20th century cost into the hundreds of thousands of dollars per minute.

The development of modern sports has been entwined with the growth of modern mass media. Each depends upon the other. Sports pages and specialized sports journals began to appear in the early 19th century when men such as Pierce Egan in England began to write in the colourfully metaphoric, argot-rich prose now recognized everywhere as typical of sportswriters. Thousands of specialized magazines are published, and sports dailies such as *L'Equipe* (France) or the *Gazzetta dello sport* (Italy) are common in many countries but not in the United States. In the early 20th century U.S. radio and German television pioneered in the development of live sports coverage. In the latter half of the century it became customary for private and public television networks to broadcast 500 or more hours of sports annually. Multiyear contracts for television rights have cost commercial networks as much as $1,000,000,000 or more. Rights to the 1988 Olympics in Seoul and Calgary, Alta., were sold for more than $600,000,000. The popularity of televised sports events guarantees that the networks will continue to budget enormous sums for the right to cover them and that commercial sponsors or governmental agencies will continue to underwrite these costs.

Impact of television

PSYCHOLOGICAL AND PHYSIOLOGICAL FACTORS

Motivational factors. The psychological aspects of sports are more difficult to assess because factors such as motivation are more difficult to measure than the size of an audience or the amount of a contract. The psychological tests that have been administered have produced such a welter of contradictory results that many specialists are ready to abandon the attempt to pinpoint motives. Some generalizations, however, seem tenable. On the whole, physical fitness and the desire for simple relaxation seem to motivate those who shun competitive sports in favour of noncompetitive physical activities such as jogging, hiking, recreational swimming, and aerobics (although the development of aerobics contests testifies to the protean nature of the competitive urge). Important to those who choose sports is the challenge of the contest, the opportunity to test one's physical and mental skills against another person, against nature, or against the abstraction of the sports record. The choice of one sport over another depends on the cultural availability of the sport (few Laotians play baseball), on social group (few truck drivers own polo ponies), on gender (women are not supposed to box), and on individual temperament (some people cannot enjoy golf). There is reason to believe that the distinction between team sports, which emphasize cooperation within the contest, and individual sports, which call for a greater sense of autonomy, is a fundamental one, although an individual may enjoy both.

The challenge of competitive sports

Mental preparation. The will to win is a powerful motive, and individual athletes as well as coaches and administrators have studied such matters as the most efficient type of leadership and the optimal level of pregame stress. Psychologists differ among themselves, but some contend that democratic leadership produces greater individual satisfaction while authoritarian leadership provides "results" (*i.e.*, a higher level of achievement and, consequently, more victories). Many psychological studies have shown that female athletes tend to attribute failure to their lack of effort or skill while male athletes point to external factors such as luck or the strength of the opposition. It has also been established that the ideal level of pregame stress falls between utter relaxation and hypertension and depends in part on the sport; successful archery, for instance, calls for less pre-match aggressiveness than rugby does. Athletes in many sports such as golf, tennis, diving, high jumping, and pole vaulting, where form and timing are crucial, often resort to a different method of pregame "psyching" called imaging or visualizing. This does not so much build aggressiveness as write a visual mental script to be followed in the contest to come.

"Psyching up"

Induced aggressiveness is, of course, a common technique, but "psyched-up" players can be a menace to themselves and others. Injuries are but one consequence. As the desire to win increases in intensity, especially when the players symbolically represent schools, cities, nations, races, religions, or ideologies, considerations of fair play

are liable to be lost in the scuffle. In such situations, aggressiveness on the field is often accompanied by violence in the stands, where crowd psychology operates (often in conjunction with alcohol) to reduce normal inhibitions on rowdy behaviour.

Fan violence

Crowd behaviour. Sports-related spectator violence is, however, often more strongly associated with social group than with the specific nature of the sport itself. Roman gladiatorial combats were, for example, history's most violent sport, but the closely supervised spectators, carefully segregated by social class and gender, rarely rioted. In modern times, association football is certainly less violent than rugby, but "soccer hooliganism" is a worldwide phenomenon, while spectator violence associated with the more upper-class but rougher sport of rugby has been minimal. Similarly, crowds at baseball games have been more unruly than the generally more affluent and better-educated fans of American football, although football is unquestionably the rougher sport. Efforts of the police to curb sports-related violence are often counterproductive because the young working-class males responsible for most of the trouble are frequently hostile to the authorities. Media coverage of disturbances can also act to exaggerate their importance and to stimulate the crowd behaviour simultaneously condemned and sensationalized, as is violence on the field. The frequent fights between U.S. National Hockey League players seem to be a consistent feature of sports highlights on television.

Drug usage. Drug abuse must be considered among the other unfortunate aspects of modern sports. The misuse of amphetamines, anabolic steroids, and other drugs has become a central problem of modern sports. One of the touted values of sports is that they better one's health. Pursued in moderation, they certainly do improve muscle tone, increase cardiovascular efficiency, and retard skeletal decalcification. When sports become an obsession, however, they tend ironically to have the opposite effect. The human body is thought of not as a part of the self but as the self's instrument, something to be used and abused. In pursuit of the absolute maximum achievement, 19th-century cyclists began to drug themselves with caffeine and strychnine; some died from the effects of the drugs. Modern chemistry has greatly enlarged the possibilities of artificial stimulation. In the late 20th century came widespread use of amphetamines and anabolic steroids. The former permit athletes to draw upon their physical reserves and continue despite the extremes of exhaustion until they collapse and, occasionally, die. Steroids are thought to increase muscle mass and muscular strength, but the side effects include damage to various organs and, in the case of women, masculinization (*e.g.*, facial hair, deeper voices). Efforts of the International Olympic Committee to limit drug abuse have often been frustrated by national Olympic committees determined upon sports victories at any cost. Efforts to control drug abuse in professional sports and in intercollegiate athletics have frequently been countered by the athletes' concerns regarding personal privacy. Nevertheless, in the United States, codes of varying strictness have been imposed in different sports, part of which includes the requirement of periodic testing for drug use. Olympic athletes now undergo testing prior to participation.

Anabolic steroids

Scientific training. Quite apart from drug abuse, publicly deplored even by some of the abusers, there is the trend to scientific training, which is practiced by most modern countries, and which the German Democratic Republic has developed to a high degree of expertise. While no one questions the instrumental efficiency of such training, there is reason to ask, as have neo-Marxist scholars, whether sports, once conceived as an alternative to work, have not become work's mirror image. The pervasive popularity of modern sports, for children as well as for adults, suggests that the answer must still be negative. Sports continue to be perceived as a domain of freedom unlike what most people experience at work. Almost everyone has experienced the joy of sports. Nevertheless, reflective observers will continue to ponder the pros and cons of the modern drive to instrumentalize the body and to rationalize sports in a quest for the ultimate possible athletic performance. (A.G.)

The quest for perfection

MAJOR TEAM SPORTS

In this article major team sports are considered first. The characteristics of team sports vary from sport to sport, but it is worth noting that some team sports involve the whole team throughout a game more than others. For example, in association football (soccer) and rugby, all players in the game handle the ball. The same is true of basketball and ice hockey. In U.S. and Canadian football, however, most linemen do not handle the ball except in unusual circumstances, such as a fumble, an interception, or a kick allowed to roll free. In baseball, on the defensive team in any given play, the ball may be handled by as few as two players and rarely by as many as four or five; among the offensive team, batters, one by one, and base runners, not exceeding three at a time, are involved.

The team sports discussed here are presented in the following order: first the bat-and-ball games (baseball and cricket), followed by the football games (association football, U.S. football, Canadian football, and rugby), and finally basketball and ice hockey. (Ed.)

Baseball

Baseball is a contest between two teams of nine or 10 players each (depending on whether or not a designated hitter is used) and is played most in the United States, where it is regarded as the national pastime, the game of summer, as cricket is in England. So entwined is baseball in the fabric of American life that many of its terms, originally applicable only to baseball, have come into common idiomatic usage among Americans. When in close combat with American troops during World War II, Japanese soldiers are said to have shouted what they believed to be the ultimate outrage: "To hell with Babe Ruth!"—a reference to the most heroic figure in baseball history.

Popularity of the game

The president of the United States often throws the ceremonial first pitch in early April to inaugurate the new major-league professional baseball season. As many as 50,000,000 spectators annually watch the best players (a number of whom earn more than $1,000,000 a year) perform with the professional American and National major league teams. The seven-month season is climaxed by the World Series, a best four-out-of-seven competition between the championship teams of the two major leagues. It is an event of enormous nationwide interest and the focus of some international attention; in the late 20th century the U.S. television audience was estimated at more than 100,000,000, with some one-third of the households equipped with television sets watching the series. A World Series income share for players on the winning team grew steadily toward the $100,000 range in response to increasing television revenues.

Baseball's appeal is universal, crossing all classes and age groups. It is a game of both individual and collective strengths, including intricate strategic maneuvers, providing a kind of intellectual attraction as well as feats of physical skill and prowess. Of all the major American team sports, it has probably undergone the fewest basic rule changes; to hit for a .300 batting average, the hallmark of outstanding offensive play, is as meaningful today as it was in the 19th century. In addition to its vast literature (the world-champion 1969 New York Mets were the inspiration for nine books), the game is supported by a perpetually growing bank of statistics and records that have been officially kept since 1900 and afford the fan with a constant source of interest.

This historical treasure and scores of traditional yarns and legends have made baseball comparable only to itself. It is, for some, not only a memorable but an almost essen-

tial event when a father takes his son to his first game. The heroes of the past have been elevated to a state bordering on mythology, their deeds passed on from generation to generation. The tradition is supported and certified by a hall of fame in Cooperstown, N.Y., a pantheon housing thousands of the game's artifacts.

Baseball is played at a leisurely pace on a field of green—often natural grass, but also lately artificial turf. This setting, unchanged through time except for larger stadiums, provides a nostalgic tie to baseball's pastoral roots. It satisfies, for some, especially older fans, the yearning for what are deemed as the lost values of a kinder age, when most small towns and villages had their "local nine." It is not unusual for fans to retain a lifelong love of the game.

It was the zealotry associated with American baseball fans that led to a long period of confusion over the game's proper roots. A.G. Spalding, a wealthy sporting goods manufacturer, around the turn of the century had felt it demeaning that what had come to be an American institution found its origins in an English game, rounders.

The Doubleday myth

Consequently, Spalding in 1904 assembled some like-minded baseball friends and established them, with the aid of a U.S. senator, as an investigative commission. In 1908 the commission issued a report attributing the inventing of the game to Abner Doubleday, a Civil War general, who, it said, devised the game with its name and modern attributes in 1839 at Cooperstown. The ancestor of baseball was said to be a U.S. children's game, old cat, called one-old cat, two-old cat, etc., depending on the number of players. This revisionist interpretation was widely accepted until 1939, when investigations revealed the essentially mythical nature of the theory. Meanwhile, in 1936 the National Baseball Hall of Fame and Museum had already been established at Cooperstown.

HISTORY

Origin. The term baseball (originally base ball) dates from 1744, when a game involving a pitcher who throws a ball to a batter who tries to hit it and then runs to a base and returns to score a run was described in *A Little Pretty Pocket-Book*. Therein an illustration shows a batter holding a bat with a curious flat, fanlike end, a catcher behind him, and a pitcher preparing to throw a small ball underhand. The two bases are marked by posts instead of the modern bags and flat home plate. The book was extremely popular in England and was reprinted in North America in 1762 (New York) and 1787 (Massachusetts).

Many other early references to bat-and-ball games involving bases are known: "playing at base" at the American Army camp at Valley Forge in 1778; the forbidding of students to "play with balls and sticks" on the common of Princeton College in 1787; a note in the memoirs of Thurlow Weed, an upstate New York newspaper editor and politician, of a baseball organized club about 1825; a newspaper report that the Rochester (N.Y.) Baseball Club had about 50 members at practice in the 1820s; and a reminiscence of the elder Oliver Wendell Holmes (Harvard, 1829) that he played a good deal of ball at college.

The Boy's Own Book (1828), a frequently reprinted book on English boys' sports, included in its second edition

Rounders

a chapter on the game of rounders. As described there, rounders had many resemblances to the modern game of baseball: it was played on a diamond-shaped infield with a base at each corner, the fourth being that at which the batter originally stood and to which he had to advance to score a run. When a batter hit a pitched ball through or over the infield, he could run. A ball hit elsewhere was foul, and he could not run. Three missed strikes at the ball and the batter was out. A batted ball caught on the fly put the batter out. One notable difference was that when a ball hit on the ground was fielded, the fielder put the runner out by hitting him with the thrown ball; the same was true with a runner caught off base. Illustrations show flat stones used as bases and a second catcher behind the first, perhaps to catch foul balls. The descent of baseball from rounders seems clear-cut. The first U.S. account of rounders was in *The Book of Sports* (1834) by Robin Carver, who credits *The Boy's Own Book* as his source but calls the game base, or goal, ball.

Early years. In 1845 Alexander J. Cartwright, an amateur New York City player, organized a group to formulate rules, many of which still remain. The significant change from rounders was that the runner was put out not by being hit with the thrown ball but by being tagged with it. This change no doubt led to the substitution of the hard ball, which made possible a larger-scale game.

Cartwright's contribution

The adoption of these rules by the Knickerbockers and other amateur club teams in the New York City area led to an increased popularity of the game. The old game with the soft ball continued to be popular in and around Boston; a Philadelphia club that had played the old game since 1833 did not adopt the hard-ball rules until 1860. Until the Civil War, the two versions of the game were called Boston baseball and New York baseball. During the Civil War (1861–65), soldiers from New York and New Jersey taught their game to others, and after the war the New York game became dominant.

In 1854 a revision of the rules specified the weight and size of the ball, dimensions not radically altered later. In 1858 there had been an attempt to organize clubs of the New York City and Philadelphia areas into leagues. In 1859, Washington, D.C., organized a club, and in the next year clubs were formed in Lowell, Mass.; Allegheny, Pa.; and Hartford, Conn. The game continued to spread after the war—to Maine, to Kentucky, and to Portland, Ore. The game was on its way to becoming the national pastime. Baseball was widely played outside the cities, but the big city clubs and their leagues were the dominant force, others being minor, a distinction later perpetuated in organized baseball. In 1865 a convention called to confirm rules and the amateur status of baseball brought together 91 amateur teams from such cities as St. Louis, Mo.; Chattanooga, Tenn.; Louisville, Ky.; Washington, D.C.; Boston; and Philadelphia.

Professional baseball. Professionalism began to appear about 1865–66 as some teams hired skilled players on a per game basis. Amateurs resented the practice and the gambling and bribery that often accompanied it. The first true professional team, the Cincinnati Red Stockings, was

The Cincinnati Red Stockings

organized in 1869; the team toured that year, playing from New York City to San Francisco and winning 56 games and tying one; the team was first defeated in 1870. The desire of many other teams to win led to their becoming professional, though many remained nominally in the amateur National Association of Base Ball Players until the amateurs withdrew in 1870. Thereafter, professional teams largely controlled the development of the sport.

The National Association of Professional Base Ball Players was formed in 1871. The teams were the Philadelphia Athletics; the Chicago White Stockings (later the Chicago Cubs, their later city rivals being named the White Sox); the Brooklyn Eckfords; the Cleveland Forest Citys; the Forest Citys of Rockford, Ill.; the Haymakers of Troy, N.Y.; the Kekiongas of Fort Wayne, Ind.; the Olympics of Washington, D.C.; and the Mutuals of New York City. The league disbanded in 1876 with the founding of the rival National League of Professional Baseball Clubs—the change from a players' association to one of clubs being particularly significant. The teams making up the new league represented Philadelphia, Hartford, Boston, Chicago, Cincinnati, Louisville, St. Louis, and New York City. When William Hulbert, president of the league in 1877–82, expelled four players for dishonesty, the reputation of baseball as an institution was established.

League formation. In 1881 the American Association was formed with teams from cities that were not members of or, like Cincinnati, had been expelled from the National League (Cincinnati's team was disciplined in 1880 for playing games on Sunday and allowing liquor on the grounds). After the National League tried to limit players' salaries (a $2,000 maximum for pitchers), the players in 1890 formed a players league, but it quickly failed. The American Association unsuccessfully challenged the National League and late in 1891 merged with it in a 12-team league that constituted a monopoly, an arrangement that prevailed through 1899. By 1900 the National League had shrunk to eight teams: Boston, Brooklyn, Chicago, Cincinnati, New York City, Philadelphia, Pittsburgh, and St.

Louis, the league remaining thus constituted until 1953. The Western League, organized in 1893, had Midwestern members. When in 1900 Charles Comiskey moved his St. Paul (Minn.) team to Chicago as the White Sox, and the Grand Rapids (Mich.) team was shifted to Cleveland, the National League agreed to the moves. When, however, permission was asked to put teams into Baltimore and Washington, D.C., the National League balked, and the "baseball war" was on. The American League, renamed from the Western League, transferred teams from Indianapolis, Ind.; Kansas City; Minneapolis, Minn.; and Buffalo to Baltimore, Washington, D.C., Philadelphia, and Boston. American League teams were also in Detroit and Milwaukee, the latter club moving to St. Louis in 1902. When the Baltimore club moved to New York City in 1903, the league took the form it was to retain until 1953.

The "baseball war"

During the "war," the American League wooed away many of the National League star players. In 1903 the leagues agreed to forbid single ownership of two clubs in the same city and the shifting of franchises from one city to another by either league without permission of the other. They also established rules for transferring players from one league to the other and for moving minor league players into the major leagues. The peace of 1903 resulted in the first World Series, which, after a hiatus in 1904, was held each year thereafter, the winner being the team to win four games out of seven (five out of nine from 1919 to 1921). In the period following the "war," two men arose who contributed greatly to the success of their respective leagues: John J. McGraw, manager of the National League New York Giants (1902–32), and Connie Mack, manager of the American League Philadelphia Athletics (1901–50). The 1903 agreement had included the creation of a three-man National Commission to govern baseball.

Survival and growth. Baseball suffered a major scandal—subsequently called the Black Sox scandal—when eight members of the Chicago White Sox were accused of accepting bribes to throw the 1919 World Series. The presiding judge for the grand jury that indicted them was Kenesaw Mountain Landis. The players, suspended for the 1921 season by the owner, were found not guilty because of insufficient evidence. Presuming a need to restore baseball's honour, however, Landis banned them from baseball for life after he was named baseball's first commissioner, supplanting the National Commission.

The Black Sox scandal

During the 1920s, generally known as a golden age of sports in the United States, the premier hero was George Herman ("Babe") Ruth, who as a New York Yankee rose to fame as a home-run hitter, the "Sultan of Swat." His performance not only assured the success of his team but came to symbolize baseball, which grew steadily in attendance. Even the Great Depression of the 1930s did little to abate the rise in popularity and financial success of the game except at the minor league and Negro league levels (see below *Blacks in baseball* and *The minor leagues*). Night baseball, tried experimentally earlier, began in the major leagues at Cincinnati in 1935. Delayed by World War II, night baseball became almost universal by the 1960s, with all teams but the Chicago Cubs scheduling about half of their home games at night. (The Cubs only acceded to night baseball at home in 1988.) The first night World Series game was played in 1971.

From the 1942 season until the end of World War II, baseball operated under the "green light" order of Commissioner Landis, approved by President Franklin D. Roosevelt. Attendance was off slightly. Many players went into the armed services, most notably Ted Williams, the last man in organized baseball to have a season batting average of more than .400 (.406, 1941; he hit .407 for an incomplete season in 1953), and the quality of play suffered somewhat.

The postwar period. The 1946 season was marked by the resumption of rising attendance with the return of prominent players from the war. It also was marked by new efforts of players to obtain better pay and conditions of employment. A portent of things to come was the formation in that year of the American Baseball Guild. Although the guild failed in strike attempts and appeals to national and state labour relations boards, its very existence led to reforms before the 1947 season: a minimum major league salary of $5,000; no salary cuts during a season for a major league player moved to the minors; weekly spring-training expense money of $25; a 25 percent limit on annual salary cuts; and establishment of a players' pension fund. Albert B. ("Happy") Chandler, Landis' successor as commissioner (1945–51), in 1950 assured the soundness of the pension fund by signing a six-year contract for broadcasting World Series and All-Star games; the television portion alone amounted to $1,000,000 a year, with a large proportion earmarked for the pension fund. Radio and television rights for season games remained with each club. Later commissioners included Ford C. Frick (1951–65), William D. Eckert (1965–69), Bowie Kuhn (1969–84), and Peter Ueberroth (1984–). A. Bartlett Giamatti was named to succeed Ueberroth in 1989.

The American Baseball Guild

Movement and expansion. Continuing financial success, buoyed especially by rising income from television and radio rights led to club movement and league expansion. The National League began the changes. In 1953 the Boston Braves transferred its franchise to Milwaukee (in 1966 it was moved to Atlanta, Ga.). In time for the 1958 season the New York Giants and the Brooklyn Dodgers transferred their franchises to San Francisco and Los Angeles, leaving the New York area temporarily a one-team city. In the American League, the St. Louis Browns' franchise was transferred to Baltimore for the 1954 season. In 1955 the Philadelphia Athletics' franchise was moved to Kansas City (and in 1968 to Oakland). In 1961 the Washington (D.C.) Senators were moved to Minneapolis–St. Paul and renamed the Twins; a new franchise was granted to Washington but lasted only until 1971, when it was transferred to Dallas–Ft. Worth, Texas, and named the Texas Rangers.

Expansion began with the granting of an American League franchise to Los Angeles (later moving to Anaheim as the California Angels) in 1961, thus bringing the American League to 10 teams. In 1962 the National League also expanded to 10 teams with new franchises in New York (the Mets) and Houston (the Astros). In 1968 new franchises to Montreal (the Expos, the first major league franchise outside the United States) and San Diego (the Padres) brought the National League to 12 teams. In the American League in 1969 new franchises to Kansas City (the Royals) and Seattle (the Pilots) brought that league to 12 teams, and both leagues were divided into eastern and western divisions. The 154-game season had been expanded to 162 in 1961. Playoffs between division winners determined the league pennant winners, who then played in the World Series, which was extended into late October. California, which had had no major league baseball prior to 1958, had five teams by 1968. Only the Seattle franchise failed outright and was moved to Milwaukee, where it became the Brewers. A new franchise was granted to Seattle (the Mariners) in 1976. A franchise to Toronto (the Blue Jays) in the same year brought the American League total to 14 teams. The expansion teams were not at first highly competitive, having been stocked from a pool of players supplied by existing teams, which protected their best players. The New York Mets was the first expansion team to win a pennant and a World Series (1969).

American League expansion

The minor leagues. The minor leagues formed a union in 1901 in order to deal with the confusion resulting from the lack of agreement on contract ownership, salaries, territoriality, and other issues. The current structure was created when the major leagues reached their agreement in 1903, and the minor leagues became a training ground for prospective major league players and a refuge for older players. In 1919 Branch Rickey, then manager of the St. Louis Cardinals, devised what came to be known as the "farm system"; as the price of established players increased, the Cardinals began "growing" their own, signing hundreds of high-school boys at no cost. Other major league clubs followed, developing their own farm clubs. In 1949 the minor leagues were at the height of their popularity: 448 teams in the United States, Canada, Cuba, and Mexico, playing in 59 leagues with an aggregate attendance of nearly 42,000,000, twice that of the 16 major league clubs. The minor leagues, at that time, were divided into

The "farm system"

six classifications, graded according to the level of playing skills: AAA (triple A), AA (double A), A (single A), B, C, and D. Attendance eroded soon thereafter when the major leagues began broadcasting and televising their games into minor league attendance areas. By the late 1980s, after the American and National leagues had annexed 10 choice minor league territories, the number of minor league teams had been greatly reduced and there remained only 17 leagues divided among four classifications; attendance had dropped, and the minor league clubs generally looked to the major league parent clubs for heavy subsidization. The purpose of the minor leagues had evolved from that of mainly providing local entertainment to that of developing major league talent.

Blacks in baseball. In 1884 two brothers, Welday and Moses Walker, played for Toledo, Ohio, in the American Association, becoming the first black players to compete at the major league level. Black acceptance in organized baseball, however, was short-lived. The first professional black team, the Cuban Giants of Long Island, New York, was organized in 1885. Other black teams were organized and played each other or barnstormed about the country playing against white teams, occasionally including major-leaguers. The Negro National League was formed in 1920 and the Negro Eastern League in 1921, playing in New York City, Chicago, St. Louis, Kansas City, Detroit, and other cities that had absorbed a large influx of blacks from the South during and after World War I. In the 1920s a Negro World Series was begun and was held annually until the leagues failed in the 1930s. A second Negro National League was founded late in that decade, and the Negro American League, formed in 1936, ultimately had eastern and western divisions that in 1952 played a Negro East–West game. Among the most famous players in the various Negro leagues were Josh Gibson, Leroy ("Satchel") Paige, Bill Yancey, John Henry Lloyd, Andrew ("Rube") Foster, and James Thomas ("Cool Papa") Bell. Gibson was credited with hitting 89 home runs in one season. After World War II, attendance at Negro leagues declined due to the loss of outstanding players to formerly all-white teams.

Breaking the colour barrier

In 1947 Jackie Robinson became the first black player in the modern major leagues. He was called to the Brooklyn Dodgers from its Montreal Royals farm club by Dodger president Branch Rickey. Robinson, who helped his team win a pennant in his first year and was named most valuable player in his league after his third year, was followed into the major leagues immediately by Larry Doby, outfielder, and Satchel Paige, pitcher, both of whom played for the American League Cleveland club. Such stars as Willie Mays; Hank Aaron, who set an all-time home-run record; Bob Gibson; Willie McCovey; Ernie Banks; Roberto Clemente; Frank Robinson, who became the first black manager in 1974; Willie Stargell; and Reggie Jackson followed. Negro League players, including Josh Gibson, John Henry Lloyd, and Cool Papa Bell, were later named to the Hall of Fame.

The business of baseball. From the beginning of organized professional baseball, the owners had controlled the game, the players, managers, and umpires. The players had begun to organize as early as 1885, when a group of players with the New York Giants formed the National Brotherhood of Base Ball Players, a benevolent and protective association. Under the leadership of John Montgomery Ward, a lawyer and former major league player, the Brotherhood grew rapidly as a secret organization. It went public in 1886 to challenge the adoption of a $2,000 salary ceiling by the National League. Rebuffed in attempts to negotiate with league owners, the Brotherhood in 1890 formed the short-lived Players' League.

During the National League–American League war of 1900–03, the Protective Association of Professional Baseball Players got National League players to switch to the other league, but with the peace treaty the association died. In 1912 came the Baseball Players' Fraternity, which included most professional players. It was organized after the suspension of Ty Cobb for punching a fan. Later, a threatened strike was settled the day before it was to begin. During World War I the War Department's "play or fight" order ended the fraternity.

Rise of the players. After a 1953 Supreme Court decision reaffirmed a 1922 decision stating that baseball was not a business that was subject to antitrust rules, baseball felt assured that its legal and economic foundation was firm. This foundation is based on the Reserve Rule, or Clause, an agreement among major league teams dating from 1879, whereby the rights of each team to the services of its players are observed by other teams; *i.e.,* a team could designate a certain number of players who were not to be offered jobs by other teams. The original number of five such players was increased to 11 in 1883 and ultimately included a whole team roster.

The Reserve Clause

The recourse the court failed to provide was in substance achieved by the Major League Baseball Players Association, founded in 1953 but largely ineffectual until 1966, when it hired as executive director Marvin Miller, a former labour union official who had also been active in government for labour–management relations. A successful negotiator, he established players' rights and benefits contractually and established grievance procedures with recourse to impartial arbitration. In 1968 the minimum salary was doubled to $10,000, and first-class travel and meal allowances were established in 1970. A threatened players' boycott of spring training was averted in 1969 by a compromise assuring a $20,000 median salary.

In 1970 a new suit was brought in federal court contesting the Reserve Clause. The suit was supported by the players' association, who hired as counsel Arthur Goldberg, a former U.S. Supreme Court justice. The plaintiff was Curt Flood, star outfielder of the St. Louis Cardinals, and the defendants were the commissioner, the two major league presidents, and the major league clubs. Flood claimed that in trading him to the Philadelphia Phillies without his knowledge or approval, the Cardinals had violated the antitrust laws. He refused to report to the Phillies and sat out the season. The court found against Flood, who appealed, and in 1972 the U.S. Supreme Court reaffirmed the 1922 and 1953 decisions exempting baseball from the antitrust laws, but it called on Congress to correct by legislation any inequities. Meanwhile Flood had signed for the 1971 season with Washington on the understanding that he would not be sold or traded without his permission. He quit in midseason, however.

First baseball strike

In 1972 baseball had its first general strike, lasting 13 days and causing the cancellation of 86 regular season games and delaying the divisional play-offs and World Series by 10 days. The players asked for and ultimately got an addition to the pension fund. Another players' strike was averted in 1973, when an agreement was reached that provided compulsory impartial arbitration of salary negotiations and a rule that allowed a player with 10 years of service in the major leagues and the last five with the same club to refuse a trade made without his consent.

These were unprecedented victories for the players, but their greatest triumph came prior to the 1976 season. Pitchers Andy Messersmith of the Los Angeles Dodgers and Dave McNally of the Montreal Expos played the entire 1975 season without signing a contract; their contracts had expired but were automatically renewed by their clubs. Marvin Miller had been waiting for such a test case. The players association filed a grievance on their behalf, contending that a player's contract could not be renewed in perpetuity, a custom first established in 1879. Arbitrator Peter Seitz found for the players. This decision substantively demolished the Reserve Rule.

Stunned, the owners appealed but without success. Negotiations followed, however, and the union agreed to a modification of the Reserve Rule: players with six or more years of major league service could become free agents when their contracts expired and would be eligible to make their own deals. The ruling allowed eligible players who refused to sign their 1976 contracts to choose free agency in 1977.

Free-agency bidding

Twenty-four players took immediate advantage of this new opportunity and went on the open market. Frantic bidding by the clubs followed. Bill Campbell, a relief pitcher with the Minnesota Twins, was the first free agent to make a new connection. He signed a four-year, $1,000,000 contract with the Boston Red Sox, which gave

him annually more than 10 times his 1976 salary. As free agency took root, salaries soared. The annual average salary rose from about $41,000 in 1974 to $175,000 in 1981; by the mid-1980s it was in excess of $300,000, with many players making more than $1,000,000 and some of the superstars climbing beyond the $2,000,000 plateau.

The free-agency procedure was the principal issue when the players struck for 50 days at the height of the 1981 season (June 12–July 31), forcing cancellation of 714 games. Once again, the players won. In the settlement it was agreed that clubs losing players to free agency would not receive direct compensation from the free agents' new teams. The union contended this would impede movement, the signing club, in effect, having to pay twice: a huge sum to the player and further compensation to the player's former employer. Under certain conditions relating to the quality of the player, however, the team that lost the free agent could draft a player from among those assigned to a compensation pool by their teams, and it could select an amateur draft choice from the signing team.

The next shutdown, lasting only two days (August 6–7), occurred in 1985, with little disruption to the schedule. It arose from a dispute that eventually centred on the issue of salary arbitration. The owners agreed to increase the minimum salary from $40,000 to $60,000, but the number of major league seasons a player had to serve before qualifying for arbitration was raised from two to three.

As the players' compensation rose, so did the value of the individual franchises. The average price was less than $10,000,000 in the 1960s. In 1984 the Minnesota Twins, operating in the Minneapolis–St. Paul metropolitan area, sold for more than $43,000,000. Fan interest also continued to rise, resulting in record major league attendance levels in the late 1980s. Also, the combined annual revenue for the major league clubs from network television grew from $15,500,000 in 1969 to $90,000,000 in 1984 and to $180,000,000 by the late 1980s.

Records. Records and statistics have long been a prominent feature of baseball, with some of them attaining hallowed status. In 1961, for example, in the first 162-game season, Roger Maris of the New York Yankees broke Babe Ruth's long-standing season home-run record of 60, but since Maris' last two home runs came in the last eight games of the season, Ruth's mark remained in the record book and Maris' was entered with an explanation. In 1974 Henry Aaron broke Ruth's career home-run record.

Babe Ruth and Roger Maris

Some records long held by Ty Cobb of the Detroit Tigers were also toppled. In 1985, Pete Rose of the Cincinnati Reds broke Cobb's lifetime mark of 4,191 hits; Rose played for one more season and then retired with 4,256 hits. Cobb's one-season modern (20th-century) stolen-base record of 96 (1915) fell to Maury Wills of the Los Angeles Dodgers in 1962, when Wills had 104 steals. This was eclipsed in 1974 by the 118 stolen bases of the St. Louis Cardinals' Lou Brock. In 1982, Rickey Henderson, then with the Oakland Athletics, amassed 130 steals. Cobb's lifetime record of 892 steals was surpassed by Brock, who had 938 steals upon retiring in 1979. Not only the lengthened season but the increasing use of fast artificial surfaces in place of grass aided record breaking, especially for hitters. Cobb's career batting average of .367, however, has remained unmatched, as has his record of 12 league batting championships. The highest modern-era single-season average of .424 was set by Rogers Hornsby of the Cardinals in 1924. In pitching, Denton ("Cy") Young set the career mark for wins with 511.

Baseball abroad. Organized baseball was played in Mexico and Cuba from the late 19th century, and in the 1980s four Mexican leagues were in the U.S. minor league system. Cuba, where baseball is the national pastime, was once a U.S. spring-training site and furnished numerous players to U.S. major leagues until the breaking off of diplomatic relations after the Castro revolution of 1958. Organized baseball is also played in Puerto Rico, Venezuela, the Dominican Republic, and frequently in Panama in the winter months. Both native and U.S. major and minor league players make up the rosters.

Baseball was introduced to Japan in the 1870s by missionaries and teachers and became a national sport. It was organized professionally in the 1930s, when U.S. professional teams toured there. Organized baseball bloomed after World War II. In the mid-1950s some U.S. players appeared on Japanese teams, and a limit on the number of U.S. players per team was imposed. Japan had its own Babe Ruth figure, Sadaharu Oh, who in his playing career (1959–80) hit 868 home runs. There are two six-team leagues, the Pacific and the Central, which play a 130-game schedule culminating in the Japan Series. Television contributes greatly to baseball revenue in Japan.

Baseball in Japan

Amateur baseball. After the divorce of amateur from professional baseball in 1870, amateur baseball continued to thrive on vacant lots in towns and cities and on pastures in the country. The first national amateur baseball program was the American Legion Junior League, founded in 1926, later called the American Legion Baseball League, with an upper age limit of 19.

The American Amateur Baseball Congress, founded in 1935, conducts baseball programs for youths from the age of eight to 19 and adults in six divisions. Little League, founded in 1939 and originally for boys eight to 12 years old, accounted for more than 2,500,000 players in the United States by the early 1980s. Two additional divisions for boys up to 18 were later added, and in 1974 girls were admitted to play. Other organized leagues for young players included the Babe Ruth League, founded in 1952, and PONY (Protect Our Nation's Youth) Baseball, Inc.

By the 1980s more than 1,600 colleges fielded baseball teams under the governance of the National Collegiate Athletic Association, which in 1963 led in the forming of the U.S. Baseball Federation, representing all amateur groups. From 1972 it conducted a collegiate world series with teams selected by its Japanese equivalent. Play by military service teams made baseball a minor sport in The Netherlands, Italy, Belgium, England, Spain, Australia, and Tunisia. Baseball was designated an official Olympic sport beginning with the 1992 Games in Spain. (Je.Ho.)

PLAY OF THE GAME

Baseball is a contest between two teams of nine or (if a designated hitter is used) 10 players each. Four bases are laid out at angles of a 90-foot (27.4-metre) square at one end of a broad field of play. Teams alternate as batters ("ins") and fielders ("outs"), exchanging places when three of the batting side are "put out"; both sides having batted constitutes an inning. As the batter, a player stands at the base designated home plate (a distance of 60 feet six inches from the pitcher's plate) and attempts to hit a ball thrown by a pitcher so that it will go out of reach of the fielding side, and then to run from base to base counterclockwise with the intent to return to home base and thus score a run. The side that scores the most runs at the end of nine innings (times at bat) wins, except that if the home team, which always bats last, is ahead after the visitors have completed their ninth turn at bat, the game ends. If the teams are tied at the end of nine innings, the game proceeds until the tie is broken, the home team again always having a last bat.

Scoring

Field of play and equipment. *Grounds.* The only restrictions for the major league playing fields are that the distance to the fence from home plate along the foul lines be 250 feet (75 metres) or more; and that for fields built after 1958 the distance along the foul lines should be at least 325 feet and the distance from home plate on a line through second base to the centre-field fence be at least 400 feet. (See Figure 1.)

The playing field was traditionally covered with grass, except for the pitcher's circle, the base paths, the adjacent infield from first to third base, and the home plate area. Since the introduction of artificial turf, the field has been mostly covered, except for the areas around the pitcher's plate, home plate, and the bases. Canvas bags filled with soft material and attached by metal stakes driven in the ground mark first, second, and third base. Home plate is a flat pentagonal white slab of rubber embedded flush in the ground. The distance to the stands or fence behind home plate should be at least 60 feet but may taper off along the foul lines in the outfield. Coaches' boxes are in foul territory behind first and third base; and next-batter

("on-deck") circles are off to one side and behind the batting boxes.

The ball and bat. The ball has a cork and rubber core, around which yarn is tightly wrapped; the cover is two snugly fitted pieces of white leather sewn together. The circumference is from nine to 9¼ inches (23 to 23.5 centimetres) and the weight between five and 5¼ ounces (142 and 149 grams). The bat is a smooth rounded stick of solid or laminated wood, not longer than 42 inches or thicker at the barrel end than 2¾ inches, tapering to the handle end. There is no weight restriction, but no metal or other reinforcement can be used in construction of the bat. (For beginning players, however, aluminum bats may be used.) The handle may have tape and adhesive material, such as pine tar, applied to it to improve the grip.

Gloves. Baseball was originally played bare-handed. First the catcher, who catches every pitch not hit, and then the first baseman, who takes many throws for putouts from the infielders, and finally all players adopted gloves. All gloves are constructed of leather with some padding. The catcher's glove, or mitt, presents a solid face except for a cleft between the thumb and index finger and is thickly padded except at the centre, where the pitched ball is caught. The glove cannot exceed 38 inches in circumference and 15½ inches from top to bottom. The first baseman's glove is thinner and more flexible, a solid expanse of leather for the four fingers with a webbing connecting the thumb and index finger. All other players' gloves are finger gloves with leather straps connecting the thumb and index finger. Batting gloves, designed to improve the batting grip, are now worn by most batters.

Protective gear. The catcher wears a padded metal mask with bars across the front, a solid, padded chest protector, and light metal, padded shin guards. The umpire behind home plate wears similar equipment. At bat, players wear a lightweight plastic batting helmet that flares down over the ears to protect the temples.

Functions of umpires

Conduct of the game. Umpires control the game. One behind home plate calls balls and strikes on the batter, determines whether a batter has been hit by a pitch or has interfered with the catcher, or vice versa, and calls runners safe or out at home plate. He and the other three umpires, stationed near first, second, and third base, may call hit balls foul or fair; the other three call runners safe or out at the first three bases. Any umpire may call an illegal pitching motion, known as a balk. An umpire may ask for help from his fellows if he was out of position to see a play, and the first or third base umpire may be appealed to when it is a question if a batter has taken a full swing or not that may account for a strike.

Principles of play. The bases are called first, second, and third base and home base or plate. All batting is done at home plate. Base running proceeds from home plate along the base lines (the boundaries of the square). A run is scored when a player, having successively touched first, second, and third, reaches home plate.

The fielding team

Seven of the nine players on the fielding team take their positions in the infield and outfield, preparing to catch (field) the ball as soon as possible after it is hit by the batter. The other two, the pitcher and the catcher, form the battery. While awaiting a pitch, the catcher crouches behind and within stepping distance of home plate but not close enough to impede the batter's activities. The pitcher stands near the centre of the infield. He puts the ball in play by throwing it to the catcher. The batter, standing on one side of home plate, gets a chance to hit the ball as it passes him on its way to the catcher.

The pitcher and the batter are the central figures in the game, which is a succession of plays. Each play begins when the pitcher delivers the ball to the batter and lasts until the pitcher holds the ball again, standing with his foot against the pitcher's plate, or rubber, ready to toss the next pitch. If the ball travels past the batter to the catcher and is then tossed directly back to the pitcher, it is a complete play. If the ball is batted, the play goes on until the ball has been fielded, all base running has come to a stop, and the ball has returned to the pitcher.

When the batter hits the ball inside fair territory (the area of the playing field between the foul lines running on a line with first and third bases and extending to the outer limit of the field), he is entitled to start running around the bases. The fielding team's defensive arrangement places its seven movable men within the fair territory. Four of them, the infielders, patrol the ground between first and second and between second and third. The other three,

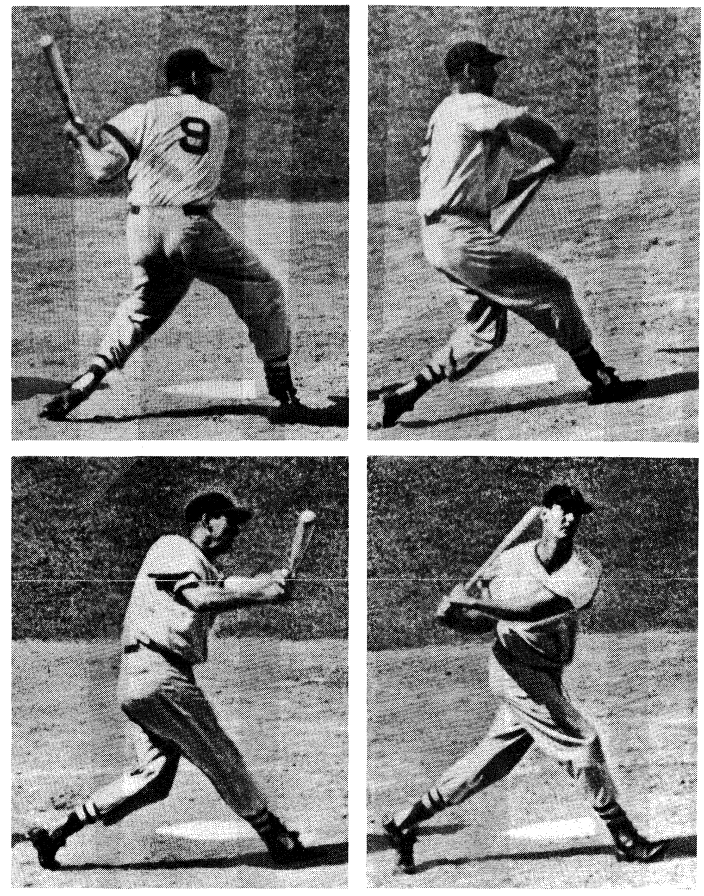
the outfielders, play the outfield, the sweep of the field from foul line to foul line beyond the two base lines.



The fielders' playing positions

The outfielders are called right fielder, centre fielder, and left fielder with relation to a man standing on home plate and facing toward second base, but there are no visible boundaries separating the three fields. With the exception of the pitcher and catcher (and in their case only at the moment of putting the ball in play), there is no restriction on the movements of the members of the fielding team. The four infielders are named first baseman, second baseman, shortstop, and third baseman, stationed in that order from first base around the rim of the infield to third.

Offense. The objective of the offense is to score runs by hitting fair balls out of the reach of the defense. Each team strives to advance its players around the bases to score as many runs as possible before the third out ends its half of the inning at bat. The first batter up for each side in the first inning is the first man in the batting order. In succeeding innings, the first batter is the next man in the order after the last batter in the previous inning to complete his turn at bat.

Hitting the ball. The ultimate successful batting feat is to drive a pitched ball inside the foul lines and beyond the confines of the playing field. This constitutes a home run, which entitles the batter to run at any speed around the bases, touching each with his foot, to score a run at home plate. Any and all runners who are on base when the home run is hit precede the home-run hitter to the plate in the order in which they reached base, and register a run each.

Failing such a hit, the batter aims to drive the ball so that it cannot be caught either before touching the ground in fair territory or soon enough after touching ground to be thrown to first or any other base before the batter or any other runner gets there. If he succeeds in getting on base before the ball gets there, he has made a hit. A one-base hit is called a single, a two-base hit, a double, and a three-base hit, a triple. If a batter makes it all the way to home plate on a hit within the confines of the field, it is called an inside-the-park home run; such a feat is quite rare. Driven balls are generally categorized as flies or fly balls (balls hit high into the air) or grounders (balls hit at a downward angle into the ground).

Advancing base runners

With the ball thus hit by the batter into fair territory, any members of his team who are already occupying bases advance as far as possible toward home plate before the ball is returned to the infield. They must avoid being tagged out. A batter may also reach base safely because of an error by the fielder; *i.e.,* failure to catch the ball or an inaccurate throw. Failure to tag a runner with the ball when the fielder has a chance to make a putout in this way also is an error.

Base on balls. A batter may reach first base without having hit the ball. Whenever the batter does not swing at a pitched ball, and the ball does not cross the plate inside the strike zone (see below *Defense: Putouts*), the umpire standing behind the catcher calls the pitch a ball. If four balls are thus called in a turn at bat—that is, before the pitcher has thrown three strikes and before the batter has hit the ball into fair territory—the batter is entitled to go to first base, the recipient of a base on balls, also known as a walk.

Hit by pitched ball. The batter reaches first base if a pitched ball at which he does not swing strikes any part of his person.

Interference. The batter also reaches first base if the catcher interferes with him by touching any part of his body or interferes with the swing of his bat as the pitched ball is on its way to home plate. The catcher in such a case is charged with an error.

When a batter is awarded first base, teammates on consecutive bases from first on advance one base; if all three bases are occupied (loaded), all advance one base; thus the man on third advances to home plate and scores a run.

Missed third strike. If, with two out or with first base unoccupied regardless of how many are out, the batter swings and misses the ball for his third strike, or the umpire calls the third strike, and the catcher does not catch the pitched ball before it touches the ground, the batter is entitled to run for first just as if he had hit the ball in fair territory. The catcher must then get the ball and throw to first ahead of the batter in order to put him out. If such a pitched ball rebounds off the catcher out into the infield, the pitcher or any infielder may make the pickup and throw to first, just as if it were an infield grounder.

The infield fly rule. The infield fly rule applies only if both first and second or first, second, and third bases are occupied, there are fewer than two out, and the batter hits a high fly that in the judgment of the umpire can readily be caught by an infielder or the pitcher or catcher inside fair territory. In such circumstances the umpire immediately declares the batter out, whether or not the ball is actually caught. This law was enacted in 1895 because clever infield players would pretend to catch the fly but at the last moment would let it strike the ground, thus setting up a force play (see below *Infielders*) at both third base and second base, which could then be made a double play with a quick throw to another base. An attempt to bunt (a light tap of the ball rather than a full swing at it; see below *The bunt*) under the conditions noted above, which results in a fair fly, is not regarded as an infield fly.

Stolen bases. The base runner need not wait on a base until a teammate hits the ball. He may advance at his own risk on the bases at any time the ball is in play, his only restraint being the threat of being tagged out; that is, of being touched with the ball in the hand of a member of the fielding team when he is not on a base. When the pitcher delivers the ball to the batter, the runner can match his speed with the strength and accuracy of the catcher's arm. If the runner makes such an attempt and succeeds in reaching the next base without being tagged out, he is said to have stolen a base. A double steal may be attempted with runners at first and third base. When a runner steals a base, the play is usually so close that he elects to slide into base to avoid the tag. Sliding is common on any close play.

The double steal

The bunt. Nearly every time a batter tries to hit a ball

he takes a full swing, aiming to drive it as fast and as far as he can. There are times, however, when he tries to bunt the ball—that is, tries to tap it lightly with the bat—to make it roll slowly along the ground in fair territory but off as much as possible to one side or the other of a straight line from catcher to pitcher. The bunt is usually intended to be a sacrifice; that is, the batter expects to be thrown out at first base, but one or more runners may be able to proceed to their next base while the ball is being fielded and thrown to first base.

The sacrifice

The batting order. Each of the nine players on a team must take his turn at bat, except as noted below. The first two positions usually are assigned to players fast afoot who make frequent contact with the ball and reach base consistently. The best leadoff hitter is also one who can judge whether the pitch will be a strike or a ball if he lets it pass him without swinging. By waiting out the pitcher, letting the bad pitches pass, he draws many a base on balls. A base on balls for the leadoff hitter is just as good as a single. Getting on base is the leadoff's main offensive function. For batter number two the manager selects a good hit-and-run player, a batter who seldom strikes out and also is skilled in driving the ball toward the right side of the field. For this reason, ideally, he should hit left-handed. A first baseman, when his base is occupied, must play close to the base to prevent the base runner from assuming a large leadoff. This leaves a vacancy between first and second base, an inviting and easy target for a good left-handed batter. The number two batter should also be a capable bunter.

Number three is usually the best all-around offensive player on the team, having running speed combined with batting power and skill. Many of the greatest hitters of all time have been, in the main, number three in their team's batting order—Ty Cobb, Babe Ruth, Rogers Hornsby, Eddie Collins, George Sisler, Joe DiMaggio, Ted Williams, Stan Musial, Willie Mays, Roberto Clemente, Al Kaline, Carl Yastrzemski, and Don Mattingly. Sometimes these hitters batted fourth, however, usually when their teams lacked another outstanding power hitter.

Numbers four and five are the long-distance hitters, not likely to hit the ball safely as often as number three, but often with greater distance. The remaining positions in the batting order scale downward to the highly skilled defensive stars, players whose value to the team is their mastery of their fielding position. Number nine is almost invariably the pitcher, except that in the American League from 1973, the pitcher did not bat. He was replaced in the batting order by a designated hitter (the DH), usually batting in one of the more likely run-producing positions. Because a pitcher is called on for duty only about once in four or five days, the hitting ability of pitchers is rarely considered in evaluating the worth of pitchers. In every other position a player's worth always represents his combined batting and fielding skills.

The designated hitter

Substitutions. Substitutions may be made at any point in the game when time has been called by the umpire. A player taken out of the lineup cannot return in the same game. Without making any substitution, the manager may at any time in the game shift his players from one fielding position to another. He may shift all nine positions in fielding, but he cannot change a player from one place to another in the batting order.

The use of a substitute as an offensive tactic most commonly involves sending in a pinch hitter; that is, taking a weaker hitter out of the lineup and substituting another player whose likelihood for driving the ball for a hit or a fly to the deep outfield is greater than that of the player next up in the batting order. Such a pinch hitter must be a player not already in the lineup nor in the batting order at any previous time in the game. Except where there is a designated hitter, the pinch hitter most often substitutes for the usually weak-hitting pitcher.

Defense. To meet the offensive force of the team at bat, the rules provide the fielding team with ways of making putouts. A putout removes the player from offensive play until his next turn at bat. The batting team's inning continues until three putouts are made; then it goes into the field and the rival team comes to bat.

Putouts. Most putouts are made by (1) striking out the batter; (2) catching a fly; (3) throwing the batter out; or (4) tagging out a base runner. The batter is struck out when the pitcher succeeds in preventing him from hitting the ball into fair territory within the limit of three strikes. Strikes are counted on the batter whenever he swings at a pitched ball and misses or when he does not swing at a pitched ball that passes him inside the strike zone. Umpires signal strikes and putouts with an emphatic movement of the right arm.

The strike zone is a prescribed area in front of the batter. Its top is in line with the midpoint between the top of the shoulders and the top of the uniform pants, and the bottom is in line with the top of the knees. Its long sides extend upward from the straight sides of home plate. The strike zone is thus an imaginary rectangular box 17 inches wide, facing toward the pitcher, the length of its vertical sides depending on the height of the batter. When the ball passes through this rectangular box at any point and the batter does not swing, it is called a strike, as if he had swung and missed. A strike also is counted when the batter fouls the ball to the ground or out of the field of play. Fouling the ball means striking it with the bat but not driving it inside fair territory. This foul strike is not counted if the batter has two strikes against him, provided he swings at the ball in fouling it. If, with two strikes, he fouls in an attempt to bunt—that is, merely blocks the ball with his bat—his foul counts as a third strike.

Foul balls and force outs

A batter is put out if a fielder catches a batted ball before it touches the ground, whether it is a fair ball or foul. A foul tip, a pitched ball that the batter merely flicks slightly with his bat, however, counts only as a strike even if it is caught and held by the catcher and does not count as a putout unless it occurs on the third strike.

A member of the offensive team is tagged out if, when running the bases and not in contact with a base, he is touched by the ball in the hand of a member of the fielding team. A member of the batting team is thrown, or forced, out if he bats a ball that touches the ground before being caught (usually by an infielder or the pitcher) and that is then thrown for the putout to the first baseman, who touches first base before the batter reaches the base.

The force play. Only one runner may have title to a base at any given moment. It is therefore possible for a runner to be thrown out at second base, third, or even at home plate without being tagged. The batter becomes a runner entitled to try to reach first base safely the instant he hits a fair ball that strikes the ground. If there is a teammate on first when the ball is hit, that base runner is no longer entitled to first base and must run to second. If runners are on first and second or on all three bases, they are all forced to run when the batter hits a fair ball that strikes the ground. Any base runner forced to run can be put out, or retired, by a fielder having the ball who can touch the base before the runner reaches it.

This method of retiring base runners is called the force play. With first base occupied and the ball driven along the ground to the pitcher or an infielder, the ball can often be first thrown to second base for a force out of the man from first base, then relayed to the first baseman to retire the batter—two outs on one play, a double play. The second-to-first double play is the most common form.

The double play

A runner can also be thrown out without being tagged if he has left his base before a fly ball is caught. With the catching of the fly, the runner must return to the base he just left before being eligible to advance. If the catcher of the fly throws the ball to that base before the runner returns and touches it, he retires the runner. The runner may attempt to reach the next base after the catch, a tag being required there for the putout.

Intentional pass. Occasionally a base on balls is given not because of the pitcher's inaccuracy (see above *Base on balls*) but for tactical reasons. If, for instance, the team at bat has a runner in scoring position (*i.e.,* on second or third base, or both) but none on first, and especially if the man at bat is more likely to make a safe hit than the man who will follow him in the batting order, it is considered sound tactics to give the batter an intentional pass, or base on balls, to first base. The catcher moves from behind the

plate to one side after the pitcher delivers the ball, and the pitcher delivers four pitches that the batter cannot reach while standing in the batter's box. The intentional pass sets up a possible force play at any base and the possibility of a double play if the next batter can be induced to hit a ground ball into the infield.

Substitutions. Defensive substitutions are also common in the late innings of a game when a team is protecting a lead. A fleet-footed outfielder, for example, will replace a slower player who is more valued for his hitting. The most frequent defensive substitution, however, is that of one pitcher for another (see below *Pitching*).

Defensive positions. An outstanding team usually has a star player at each middle position—catcher; "the keystone combination," meaning the second baseman and shortstop; and centre fielder.

Outfielders. The three outfielders are positioned in order to be able to catch batted balls driven reasonably high in the air beyond the infield. The outfielder must be able to judge the trajectory of such flies and have enough speed to run to the point where the ball will come down.

Batted or thrown balls that pass beyond the infielders along the ground must be run down and picked up by the outfielders. Strong throwing arms are essential, as is accuracy in throwing the ball to the right point in the infield. An alert outfielder can also add to his value by moving in as a backup of the infield when the ball has been batted to some point other than his own area and is being thrown about by his teammates in an effort to retire runners. The centre fielder is usually chosen for his speed and expert judgment of fly balls. The centre fielder will not only station himself at a strategic point for each batter but will often direct the playing positions of his outfield teammates on either side. Almost invariably the great defensive outfielders of baseball history, such as Tris Speaker, Max Carey, Terry Moore, Joe DiMaggio, and Willie Mays, have been centre fielders.

Role of the centre fielder

Infielders. The infielders form the inner ring of defense. They sometimes catch line drives on the fly, but mainly they pick up grounders skipping along the ground toward the outfield or shooting swiftly across the grass on one or more bounces. When a batted ball strikes the ground, the play becomes a race between the batter running to first and an infielder gaining control of the ball and throwing it.

UPI

The four infielders shift positions to guard against each batter's individual power, as do the outfielders. They have the additional responsibility of guarding the bases when occupied. When a ball is batted along the ground, only one of them is called upon to gain control of it, but at least one of the others almost always covers a base to take the throw; sometimes two bases must be covered for a possible throw, and sometimes all three. If an attempted bunt is anticipated, the first and third basemen move in from their accustomed positions toward home plate, ready, as are the pitcher and catcher, to rush toward the bunted ball and to throw it to second, third, or home for the force play or to first to retire the runner.

Each position has its special fielding requirements. Shortstop is the most difficult and demanding of the defensive positions, requiring outstanding agility, range, and a strong throwing arm. The throw from the shortstop to first base is the longest and most difficult. The batted ball may be hit to his right or left or straight at him. He may have to come in quickly on a slow "hopper," or catch a line drive or towering pop-up (a usually easily caught fly). Many of the game's greatest fielding players have been shortstops, among them John ("Honus") Wagner, Dave Bancroft, Luke Appling, Lou Boudreau, Harold ("Pee Wee") Reese, Marty Marion, Luis Aparicio, and Ozzie Smith.

The shortstop

The second baseman's function is very much the same as the shortstop's, but on the right side of the infield. His shorter distance from first gives him an extra instant to throw. On a force play at second, whether or not a part of a double play, either the second baseman or the shortstop must cover second to catch the throw, with his foot touching the base, just as the first baseman does on an out at first. The force play is always a potential double play. The second baseman, coming to the base to take the throw, must turn to his left for the throw to first base to complete the double play. Thus, acrobatic skill in pivoting and avoiding the oncoming runner is vital in a second baseman. Among the great second basemen are Nap Lajoie, Charlie Gehringer, Eddie Collins, Billy Herman, Joe Gordon, and Bill Mazeroski.

The third baseman, playing nearer the batter than the shortstop or second baseman, is not called on to cover as much ground, but his reflexes must be exceptional. The grounder aimed his way reaches him or is past him into the outfield sooner than at second or short. On his most difficult play, the fielding of a bunt or a roller between home plate and his position, the third baseman has a throw to first that is shorter than those the second baseman and shortstop ordinarily make, and he often has more time in which to make it. Harold ("Pie") Traynor, Eddie Mathews, Brooks Robinson, and Mike Schmidt have been considered outstanding third basemen.

The first baseman's fielding of grounders is made easier because of his position near the base that the batter is running toward. Often the first baseman is able to touch base with his foot with ample time to spare after picking up the grounder. When there is no time for that, his throw may be a mere underhand toss to the player (usually the pitcher) who moves over to cover first. When the first baseman plays in for a bunt, the second baseman covers first base. First basemen are often left-handers, an advantage in throwing from their position, and are generally among the most powerful hitters in the lineup; they have included stars such as Lou Gehrig, Jimmie Foxx, Willie McCovey, and Hank Greenberg.

The battery. The pitcher and catcher together are known as the battery or as batterymen. As a fielder, the pitcher may function as an emergency first baseman, and he fields bunts or other infield grounders hit his way.

The catcher, as a fielder, is mainly a catcher of high flies, usually fouls. On such flies, ability to perceive the angle at which the ball leaves the bat is necessary to get a quick start in the right direction from home plate.

The "good hands" essential to every player are especially important for the catcher. Throughout the game he must catch the pitched balls not hit by the batter and sometimes pitches that strike the ground near the plate. When the

Skills of the catcher

bat flicks the ball slightly in passing, the catcher's good hands are needed most. If the batter has two strikes, the ability of the catcher to catch such a tipped ball and hold it results in a strikeout. If the ball eludes the catcher's grasp, it becomes a mere foul ball.

The catcher sometimes fields a bunt or a half-hit ball just in front of the plate. Agility in pouncing upon the ball and accuracy in throwing to the proper base are then required. The catcher's throwing arm is a valuable element in his team's defense. Base runners will be cautious of straying too far from their bases when the catcher has a quick and strong arm. When a runner attempts to steal a base, the attempt usually becomes a match between the catcher's throwing arm and the runner's speed. A strong throwing arm has been the hallmark of baseball's greatest catchers, including Mickey Cochrane, Leo ("Gabby") Hartnett, Bill Dickey, Yogi Berra, and Johnny Bench.

Important as is his fielding, the catcher functions even more importantly as the counselor of the pitcher, as well as the rest of the team. As the only player in the defensive lineup who has the whole game in front of him at all times, the catcher is best placed for advising teammates when necessary. In general, the catcher directs the pitching strategy. For most pitchers, and particularly for those with less experience, the catcher, squatting behind the plate with his hands together between his knees, signals with the fingers of his bare hand what the next pitch should be. His knowledge of the pitcher's and the batter's abilities and peculiarities guides him. The catcher keeps his partner under constant study, alert to signs of weakening, even in a veteran pitcher. Occasionally, the catcher consults with the manager to replace one pitcher with another.

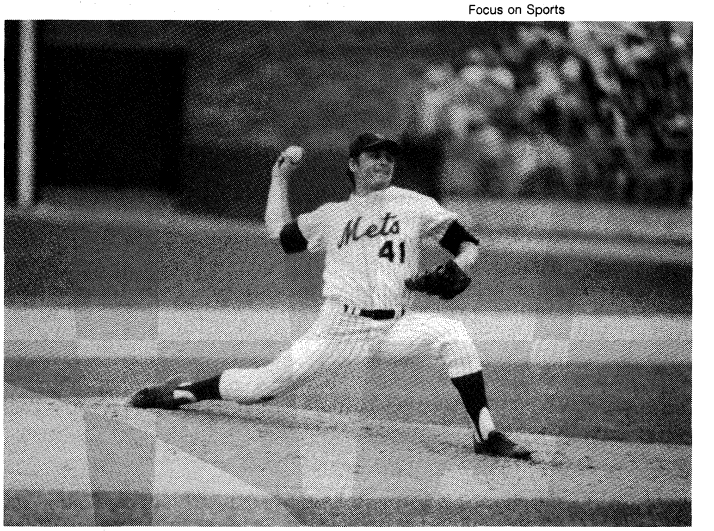
Pitching. Until a batter hits the ball, the game is a duel between the pitcher (and catcher) and the batter, which is repeated as each batter comes to bat. Each batter that a pitcher strikes out or forces to hit a pop-up (an easily caught fly) or easily fielded grounder is a gain for the defense, preventing runs and bringing the team closer to its turn at bat and a chance to score.

Until about 1870, the pitcher was merely a player assigned to put the ball in play by pitching it to the batter to hit. One man generally did nearly all the pitching for a club all season, with a change pitcher to relieve him of some of the load. This change pitcher was usually an outfielder, and the two would often merely exchange fielding positions without leaving the game. With the start of league baseball in the 1870s, the pitcher became more important in defensive play. His use of speed and control became a deciding element in championship contests.

Pitching rotation

Of the 24 players on a major league club's normal active roster, usually 10 are pitchers. In a staff of 10 pitchers, the manager usually names his best four or five at any given time as starting pitchers, or the rotation starters. They take their turn every four or five days, resting in between. The remainder of the staff constitutes the bullpen squad or the relief pitchers. When the manager or pitching coach detects signs of weakening on the part of the pitcher in the game, these bullpen pitchers begin warming up by throwing practice pitches. An effective relief pitcher is one who has good control of his pitches. He often enters the game when the offensive team poses a scoring threat with one or more base runners and a dangerous hitter at bat. Since the early 1950s relief pitching has grown in importance, and it has become extremely difficult for a team to win a championship without a strong bullpen.

Control. Pitching demands more exact coordination of mental and muscular faculties and more continuous physical exertion than any other position in the game. On each pitch the pitcher is aiming at the strike zone, or a small part of it, 60 feet six inches from the plate on which his foot pivots in the act of pitching the ball. His ability to throw the ball where he aims it is known as his control. Lapses of control become apparent to the catcher with a slowing up of fast pitches and a dulling in the break of the curve. To the spectators, they are seen as increasing bases on balls and safe hits. Less often, as a pitcher begins to tire, his loss of control may result in hit batters and wild pitches. Each base on balls puts a potential run on first base, as does each batter hit with a pitched ball.



The balk. A balk is an infraction the pitcher can commit with a runner or runners on base. It may occur when: (1) in pitching the ball to the batter, the pitcher does not have his pivoting foot in contact with the pitching plate; (2) the pitcher does not hold the ball in both hands in front of him at chest level before starting his delivery, or, once started, does not continue his motion; or (3) the pitcher starts to make a throw to first base when a runner is occupying that base but does not go through with the throw. When a balk is called by the umpire, all runners on base advance one base each.

The pitching repertoire. A pitcher's speed is usually the index of his general ability. Although the curve was developed in the late 1860s and other variations from the straight line of fastball pitching developed in succeeding epochs, the fastball remains the basis of pitching skill. Some pitchers have been capable of throwing the ball 100 miles per hour. Noted fastball pitchers include Walter Johnson, Robert ("Lefty") Grove, Bob Feller, and Nolan Ryan.

The curveball

The fundamental, or regulation, curve is a swerving pitch that breaks away from the straight line, to the left (the catcher's right) if thrown by a right-handed pitcher, to the right if by a left-hander.

Focus on Sports

Some pitchers also employ a curving ball that breaks in the opposite way from the regulation curve, a pitch known variously as the fadeaway (Christy Mathewson), the screwball (Carl Hubbell), or some other name applied by the pitcher himself. The effect is to endow the pitcher with a reverse curve. In both curves and reverse curves, the ball reaches the batter at a slower rate of speed than the fast ball, and the deception is almost as much a result of the slower ball's falling away from the bat as of its swerving from a straight trajectory.

A comparatively new pitch, called the slider, was introduced in the 1920s by George Blaeholder, who otherwise had an undistinguished major league career. The slider is a cross between the fast ball and the curve and includes the best features of both. It is thrown with the speed and the pitching motion of the fast ball, but, instead of the wide sweep of the conventional curve, it has a short and mostly lateral break; in effect, it slides away from the hitter.

Relatively few pitchers use the knuckleball, the power of which lies in its lack of axial rotation, making it subject to air currents. No one, including the pitcher, knows exactly how any knuckleball pitch will behave. The ball is wobbly as it approaches the batter and so is harder to hit solidly than a spinning ball. The knuckleball, however, is difficult to catch, and rather often it is missed by the catcher (a passed ball). The knuckler is thrown with an easy, almost lobbing, motion, and, because of the minimal arm strain, knuckleball pitchers may have remarkable longevity.

In the 1970s the premier relief pitcher, Bruce Sutter, introduced the split-finger fast ball, which broke downward

Illegal pitches

at the plate in a motion often compared, with some exaggeration, to a ball rolling off a table. In the early days of organized baseball, artificial aids were allowed the pitcher in throwing what was called the spit ball. Simple saliva, saliva produced by chewing tobacco or sucking on slippery elm, or sweat was applied to the ball. The ball thus treated dropped sharply at the plate. The pitch was outlawed in 1920, though pitchers then using it were allowed the pitch until they retired. Since then, pitchers have from time to time been suspected of using it.

Similar effects have been sought by those who illegally scar the surface of the ball with a sharp object like a belt buckle or tack or with an abrasive tool, such as a file or emery board. Some batters, for their part, have looked for illegal advantage by drilling a hole down the barrel of a bat and filling it with cork or rubber balls, which decreases weight and increases bat speed and "liveliness."

Cricket

Cricket, England's national summer sport, is a game of skill played with bat and ball between two teams of 11 players each on a large field. It is played throughout the world, particularly in the British Isles and the Commonwealth, and matches range from informal, weekend afternoon encounters on village greens to top-level international contests spread over five days and played between leading professional players in grand stadiums.

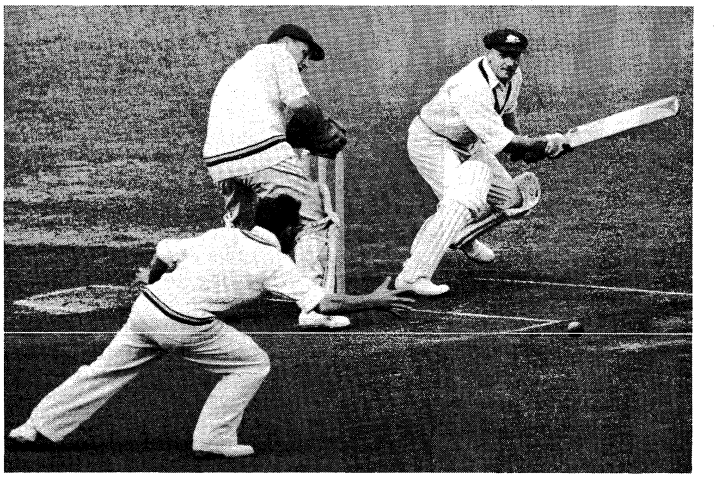
The teams take turns at batting (an innings) and bowling, changing places at the conclusion of an innings. Teams have one or two innings each depending on the prearranged duration of the match, and the object of the game is for one side to score more runs than the other. The batting side defends its wickets (two sets of three sticks set in the ground 22 yards [20.12 metres] apart at the centre of the field) and attempts to score runs by hitting the ball and running to the far wicket or by hitting the ball to or beyond the marked boundaries of the field. The bowlers, delivering the ball with a straight arm, try to break (hit, so that the bails [see below *Play of the game*] fall) the wicket with the ball, which is one of several ways that the batsman is dismissed, or put out.

HISTORY

Origin. Cricket is believed to have begun as a game in which country boys bowled at a tree stump or at the hurdle gate into a sheep pen. This gate consisted of two uprights and a crossbar resting on the slotted tops; the crossbar was called a bail and the whole gate a wicket. The fact that the bail could be dislodged when the wicket was struck made this preferable to the stump, which name was later applied to the hurdle uprights. Early manuscripts differ about the size of the wicket, which acquired a third stump about 1780, but by 1706 the pitch, the area between the wickets, was 22 yards long.

The ball, once presumably a stone, has remained much the same since the 17th century, weighing between five and six ounces (140 and 170 grams). Its modern weight was laid down in 1774 and its circumference standardized in 1838. The primitive bat was no doubt a shaped branch of a tree, resembling a modern hockey stick but considerably longer and heavier. The change to a straight bat was made to meet the cult of length bowling (see below *Bowling*), which had been evolved by the Hambledon cricketers. The bat was shortened in the handle and straightened and broadened in the blade, which led to forward play, driving, and cutting (see below *Batting*). As few bowlers were able to combine length with break, swerve, and flight, batting dominated bowling through the 18th century.

The early bat



The early years. The earliest reference to an 11-a-side match, played in Sussex for a stake of 50 guineas, dates from 1697. In 1709 Kent met Surrey in the first recorded intercounty match at Dartford, and it is probable that around this time a code of laws (rules) existed for the conduct of the game, although the earliest known version of importance is dated 1744. Sources suggest that cricket was limited to the southern counties of England during the early 18th century, but it was soon discovered by society and transferred to London, notably at the Artillery Ground, Finsbury, which saw a famous match between Kent and All-England in 1744. Heavy betting and disorderly crowds were common at matches.

The Hambledon Club, playing in Hampshire on Broadhalfpenny Down, was the predominant cricket force in the second half of the 18th century before the rise of the Marylebone Cricket Club (MCC) in London. Founded in 1787, the MCC had its home from the outset at Lord's Cricket Ground, which was named after its founder, Thomas Lord, and has become the headquarters of world cricket. In the following year the MCC published a revised code of laws, of which it remains the controlling body for world cricket, although it has ceded authority in England (see below *Reorganization*).

Lord's Cricket Ground and the MCC

In 1836 the first North counties versus South counties match was played, clear evidence of the spread of cricket. In 1846 the All England XI, founded by William Clarke, of Nottingham, began touring the country, and from 1852, when some of the leading professionals seceded to form the United All England XI, these two teams monopolized the best cricket talent until the rise of county cricket (see below *County cricket*). They supplied the players for the first English touring team overseas to Canada and the United States, in 1859.

Technical development. Until early in the 19th century all bowling was underhanded, and most bowlers favoured the high tossed lob. The next bowling development was "the round arm revolution," in which many bowlers began raising the point at which they released the ball. Controversy raged furiously, and in 1835 the MCC rephrased the law to allow the hand to be raised as high as the shoulder. The new style led to a great increase in pace, or bowling speed. Gradually bowlers raised the hand higher and higher in defiance of the law. Matters were brought to a head in 1862 when an England team playing against Surrey left the field at London's Kennington Oval in protest against one of their number's being no-balled (penalized for throwing an unfair pitch) for raising his bowling arm above the shoulder. As a result of the incident, in 1864 the bowler was officially accorded full liberty to bowl overhand. From time to time umpires have had trouble with bowlers who, rather than bowling the ball, illegally "threw" it (*i.e.*, cocked and then, in the release, straightened the arm).

Bowling methods

The batsmen now learned to protect themselves better with pads and tubular rubber batting gloves, and a cane handle increased the resilience of the bat. Only the best batsmen, however, could cope with fast bowling because most pitches were bad. As the grounds improved, the batsmen went over to the offensive.

In the early 20th century so many runs were being scored that a reform of the leg-before-wicket law (introduced in the 1774 laws against a batsman deliberately preventing

the ball from hitting his wicket) was debated, and the MCC denounced the overpreparation of pitches. But the heavy scores were due primarily to the performances of several outstanding batsmen. This was cricket's golden age.

The googly and new bowling styles

There now appeared in cricketing vocabulary the googly, a word coined in Australia when B.J.T. Bosanquet, on the 1903–04 MCC tour, first exploited his ability to bowl an offbreak with a leg-break action. Other new bowling styles were also discovered, causing batsmen to adjust their technique.

The reaction of authority to the evolution of cricket in the 20th century was visible in a series of attempts to help the bowler and to quicken the tempo of the game. As early as 1902 the bowling crease had been extended in length; in 1907 the use of a new ball after every 200 runs had been legalized; in 1918–19 the eight-ball over was first used in Australia (it became standard for many years there and in South Africa, New Zealand, and the West Indies); in 1927 a smaller ball was authorized; in 1937 the leg-before-wicket law was extended to cover balls pitching outside the off stump; in 1947 the size of the wicket, increased in 1931, was established at its present size; and in the 1980s daily minimum numbers of overs to be bowled were established in Test and county cricket.

County cricket. Although the press acclaimed a "champion county" as early as 1827, qualification rules for county cricket were not laid down until 1873, and it was only in 1890 that the format of the county championship was formalized by the counties themselves. Gloucestershire dominated the 1870s, thanks to the legendary W(illiam) G(ilbert) Grace and his brothers E.M. and G.F. Grace. From the 1880s to World War I, Nottinghamshire, Surrey, Yorkshire, Lancashire, Kent, and Middlesex constituted the Big Six that dominated county cricket. After World War I the northern counties, led by Yorkshire and Lancashire, largely professional teams, were the leaders. Surrey, with seven successive championships, dominated in the 1950s and Yorkshire in the 1960s, followed by Kent and Middlesex in the 1970s.

The legendary W.G. Grace

After a postwar boom slow play and lower numbers of runs characterized the 1950s, and this defensive nature of county cricket led to progressively decreased attendance. In the 1960s the MCC and the counties introduced a one-day knockout competition (the Gillette Cup—since 1981 the NatWest Bank Trophy) and a separate Sunday afternoon league, which revived public interest, although most counties remained dependent financially on proceeds from football pools and money received from Test (international) matches and broadcasting fees. The immediate registration of overseas players was permitted, and each county was allowed one such player, who, however, could still play for his national team. While the change worked well for the counties, it also strengthened the national teams for whom those players appeared. In county cricket, bonus points were created to encourage batsmen and bowlers to be more attacking, and in 1988, to help the development of young batsmen and spin bowlers, a limited number of four-day games partially replaced the hitherto traditional three-day format for the county championship.

Other first-class cricket. From 1806 (annually from 1819) to 1962, the Gentlemen versus Players match pitted the best amateurs against the best professionals. The series was ended in 1962 when the MCC and the counties abandoned the distinction between amateurs and professionals. The Oxford versus Cambridge match has been played mainly at Lord's since 1827. University cricket was a kind of nursery for county cricket, and the match became a high point of the summer season in London.

Reorganization: the Cricket Council. A reorganization of the administration of English cricket took place in 1969, resulting in the end of the MCC's long reign as the controlling body of the game, though it still retained responsibility for the laws. With the setting up of the Sports Council (a government agency charged with control of sports in Great Britain) and with the possibility of obtaining government grant aid for cricket, the MCC was asked to create a governing body of the game on the lines generally accepted by other sports in Great Britain. Thus was inaugurated the Cricket Council, comprising the Test and County Cricket Board (TCCB), the National Cricket Association (NCA), and the MCC. The TCCB, which amalgamated the Advisory County Cricket Committee and the Board of Control of Test matches at Home, is responsible for all first-class and minor counties cricket in England and for overseas tours. The NCA consists of representatives from clubs, schools, and armed services cricket, umpires, and the Women's Cricket Association.

End of MCC control

International cricket. The English introduced cricket wherever a ground was available and two teams could be collected. The firmest roots are in those countries that were members of the Imperial Cricket Conference. The conference was founded in 1909 by England, Australia, and South Africa (which ceased to be a member on leaving the Commonwealth in 1961), and they were joined as full members by India, New Zealand, and the West Indies in 1926 and Pakistan in 1952. In 1965 the conference was renamed the International Cricket Conference and brought in as associate members the United States, Sri Lanka, and Fiji, followed by Bermuda, The Netherlands, Denmark, East Africa, Malaysia, Canada, Gibraltar, Hong Kong, Papua New Guinea, Argentina, Israel, Singapore, West Africa, Bangladesh, Kenya, and Zimbabwe. In 1981 Sri Lanka was elevated to full-member status, and from 1984 Italy, Switzerland, The Bahamas, France, and Nepal entered in a subsidiary class of affiliate membership.

Australia. Cricket began in Australia in 1803, introduced by a British ship's crew, and play among cricket clubs began in the mid-1820s. The first interstate match took place in 1856, and the first English touring team was received in 1861–62. In 1892–93 New South Wales, Victoria, and South Australia contested the Sheffield Shield, presented by Lord Sheffield, who had taken an English team to Australia in 1891–92. Queensland joined the competition in 1926–27, Western Australia in 1947–48, and Tasmania in 1977–78. A one-day knockout competition began in 1969–70. Each state has an association of affiliated clubs that controls players and grounds. Clubs are graded and competitions are arranged for each grade. First-grade teams, in which novices play with great cricketers, are the recruiting ground for the state team.

National cups and trophies

New Zealand. Cricket was first played in New Zealand in the 1840s, and the first interprovincial match was played between Auckland and Wellington in 1860. In South Island, the discovery of gold in Otago brought many Australians, who helped to spread the game. An English team first visited the country in 1864.

The New Zealand Cricket Council was formed in 1894. Each province has its own association, made up of delegates from affiliated clubs. The Plunket Shield, donated by a former governor general, has been played for annually since 1906–07 by Auckland, Wellington, Canterbury,

Otago, Northern Districts, and Central Districts. It was replaced in 1975–76 by the Shell Series.

West Indies. Cricket began in the West Indies in the early 19th century, but the first intercolonial match took place in 1865 between Barbados and Demerara (now Guyana). In 1891 a triangular tournament was contested between Demerara, Barbados, and Trinidad, and in 1894–95 the first English team visited. In 1927 a board representing all the islands was set up to control competitions and to organize overseas tours. Jamaica joined the other three in a knockout tournament in 1956. In 1965–66 the Windward Islands and the Leeward Islands joined the others in an annual competition for the Shell Shield, succeeded in 1987–88 by the Red Stripe Cup.

India. English settlers introduced cricket in India during the 18th century, and the army helped to popularize it. The first all-Indian club was the Orient Cricket Club, formed in 1848 by the Parsis, a religious sect. In 1877 the Parsis defeated the Europeans in Bombay, and this encouraged the Parsis to send teams to England in 1886 and 1888. The first English side visited India in 1889–90.

The Bombay Pentangular series

In 1892–93 the Parsis met the Europeans in the Presidency Matches, which developed into the Bombay Pentangular series with the additional participation of the Hindus, Muslims, and a team not ethnically connected to the above groups called "The Rest." In 1926–27 the MCC sent a strong side to India, and the princes began to pick their own sides and to employ professional English coaches. A national championship was instituted in 1934–35 for the Ranji Trophy, and the zonal Duleep Trophy was introduced in 1961–62.

Pakistan. After partition in 1947, Pakistan staged its initial first-class match in February 1948. A national championship for the Qā'id-e A'zam (Great Leader) trophy, named for Mohammed Ali Jinnah, one of the creators of Pakistan, was begun in 1953–54 and was later joined by the Patron's Trophy tournament and the Pakistan Automobile Corporation (PACO) tournament.

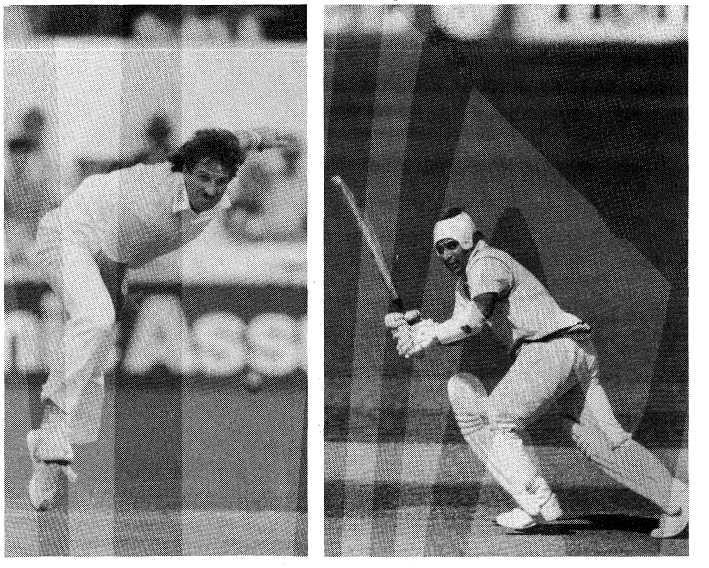
South Africa. Cricket was taken to South Africa in the early 19th century by British troops, and by the time the first English side visited in 1888–89 the game was established in several centres. The Currie Cup, the main domestic championship, began the following year.

Since the late 1960s race and politics have dominated cricket in South Africa. It was cut off from most of its traditional international competition in 1970 because of its apartheid (racial separation) policies. In 1977, with the fusion of the three existing national bodies into the South African Cricket Union, the game became officially nonracial, but controversy continued, as did the international ban.

Sri Lanka. The first Ceylonese cricket club was formed in Colombo in 1832, and from 1887 until the 1930s the main match of the season was Europeans (locals) against Ceylonese. The first visiting English side came in 1882, and it was England who provided the opposition in Sri Lanka's inaugural Test match 100 years later.

Test matches. The first Test (international) match, played by two national teams of the best players, was between Australia and England in Melbourne in 1877, Australia winning. When Australia again won at the Oval at Kennington, London, in 1882, the *Sporting Times* printed an obituary notice announcing that English cricket would be cremated and the ashes taken to Australia, thus creating the "play for the Ashes." The Ashes, kept in an urn at Lord's irrespective of which country is victorious, are those of a stump or bail burned on the England tour of Australia in 1882–83. For the rest of the 19th century, the two countries met almost yearly. With W.G. Grace, the greatest cricketer of Victorian England, on its side, England was generally too strong, though Australia had the greatest bowler of his era in F.R. Spofforth and the first of the great wicketkeepers in J.McC. Blackham.

The "Ashes"



In 1907 South Africa first played Test matches in England and also took on Australia, whose dominance between the two world wars was symbolized by the prodigious run scoring of D.G. (later Sir Donald) Bradman. This period saw a notable growth in the number of Test-match countries, with the arrival of the West Indies in 1928, New Zealand in 1930, and India in 1932. The visit of the English side to Australia, in 1932–33 severely strained relations between the countries because of the "bodyline" (leg theory) bowling tactics, in which the ball is bowled close to or at the batsman; this scheme was devised by the English captain, D.R. Jardine, to curb Bradman's scoring.

After World War II there were Test matches in England every summer, Australia being the most frequent visitor, and the Test ranks were increased by the addition of Pakistan in 1952. With interest stimulated by radio and television broadcasts and extensive newspaper coverage, there was a steady escalation of tours between the Test-playing countries, to the extent that while the first 500 Test matches were spread over 84 years, the next 500 occupied only 23. Sri Lanka's entry as the eighth Test-playing nation in 1982 came during an era dominated by the West Indies, whose attack was devastatingly founded, for the first time in cricket history, on four fast bowlers.

Test crises of the late 1960s

Test cricket has faced a number of crises since the late 1960s. One of these occurred in 1969–70, causing a South African tour of England to be canceled because of opposition to the South African racial separation policy. Violence, damage, and disruption of play had been

threatened. A further threat to Test cricket was posed by an Australian television network executive, Kerry Packer, who signed many of the world's leading players for a series of private contests between 1977 and 1979. Reprisals were brought against the players but were overruled after court action in England. The players returned to the fold, but commercialism had taken hold of the game. In 1982 the agreement of 12 first-class English players to take part, in breach of official guidelines, in a commercially-sponsored South African tour with fees of up to £50,000 per player led to the players' being banned from Test cricket for three years. Cricketers from Sri Lanka and the West Indies also toured to South Africa and received more stringent sanctions, and the engagement of English professionals as players and coaches in South Africa threatened a serious division between the Test-playing countries.

One-day internationals—answering the complaint that Test matches went on too long—began in 1972. In 1975 England, Australia, the West Indies, New Zealand, India, Pakistan, Sri Lanka, and East Africa contested the first World Cup in England in a series of one-day matches of 60 overs a side. The event was a great success and continued at four-year intervals. It was held outside England, in India and Pakistan, for the first time in 1987. By this stage the one-day international was supplanting the five-day Test match in public appeal.

Women's cricket. Women first played cricket in England in the 18th century. In 1887 the first club, White Heather, was formed, and it survived to 1957. In 1890 two professional teams known collectively as the Original English Lady Cricketers were in action.

The International Women's Cricket Council

In 1926 the Women's Cricket Association was founded and in 1934–35 sent a team to Australia and New Zealand. Australia paid a return visit in 1937, and since World War II tours have increased. The International Women's Cricket Council was formed in 1958 by Australia, England, The Netherlands, New Zealand, and South Africa and later included India, Denmark, and several West Indian islands. A World Cup was instituted in 1973, two years ahead of men's cricket, and England and Australia played in the first women's matches at Lord's in 1976.

PLAY OF THE GAME

Field of play and equipment. *The ground.* Cricket grounds vary in size from great arenas such as Lord's in London (5½ acres [two hectares]) and Melbourne Cricket Ground that is even larger (9¼ acres) to village greens and small meadows. Level turf of fine texture is the ideal surface, but where this is unavailable, any artificial covered surface, such as coir matting or artificial turf on a firm base, may be used. The limits of the playing area are usually marked by a boundary line or fence (see Figure 3).

Wicket and creases. A wicket consists of three stumps or stakes, each 28 inches (71.1 centimetres) high and of equal thickness (about 1¼ inches in diameter), stuck into the ground and so spaced that the ball cannot pass between them. Two pieces of wood called bails, each 4⅜ inches (11.1 centimetres) long, lie in grooves on the tops of the stumps. The bails do not extend beyond the stumps and do not project more than half an inch above them. The whole wicket is nine inches (22.86 centimetres) in width. There are two of these wickets, which a batsman defends and a bowler attacks, and they are approximately in the centre of the ground, facing one another at each end of the pitch (also sometimes called the wicket), which is an area 22 yards (20.12 metres) long and 10 feet (3.04 metres) wide between the wickets.

Bowling, return, and popping creases

Lines of whitewash demarcate the creases at each wicket: the bowling crease is a line drawn through the base of the stumps and extending four feet four inches (1.32 metres) on either side of the centre stump; the return crease is a line at each end of and at right angles to the bowling crease, extending behind the wicket; and the popping crease is a line parallel with the bowling crease and four feet in front of it. The bowling and return creases mark the area within which the bowler's rear foot must be grounded in delivering the ball; the popping crease, which is 62 feet (18.90 metres) from the opposing bowling crease, demarks the batsman's ground.

Bat and ball. The blade of the paddle-shaped bat is made of willow and must not be broader than 4¼ inches (10.8 centimetres). The length of the bat, including the handle, must not exceed 38 inches (96.5 centimetres). The ball, which has a core of cork built up with string, is encased in polished red leather, the halves of which are sewn together with a raised seam. Slightly smaller, harder, and heavier than a baseball, it must weigh between 5½ and 5¾ ounces (156 and 163 grams) and be between 8 13/16 and nine inches (22.4 and 22.9 centimetres) in circumference.

Dress. Players usually wear white trousers and shirt, white boots (shoes), a white sweater, often trimmed with club colours, and club caps of kaleidoscopic variety. The batsman wears white pads (leg guards), an abdominal protector, and batting gloves reinforced to protect the fingers; at the top levels of the game batsmen also wear helmets, sometimes with a face guard, and other body protection. The wicketkeeper also wears pads and reinforced gauntlets (the other fielders do not wear gloves).

Rules of the game. One player on each team acts as captain. There are two umpires, one standing behind the bowler's wicket, the other at square leg about 15 yards from the batsman's popping crease (see Figure 3), to control the game according to the laws; two scorers record its progress. The object of the game is for one side to score more runs than the other.

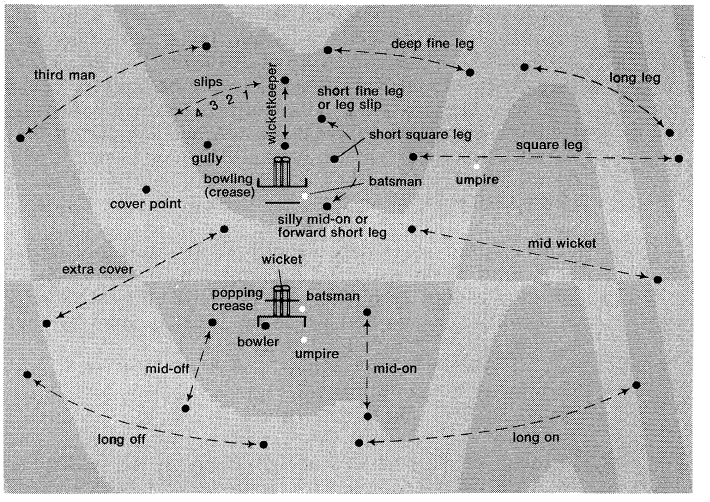

Figure 3: Location of wickets and principal playing positions on cricket field.

At the start of a match, the captain who wins the toss of a coin decides whether his own or the other side shall take first innings (always plural); *i.e.,* proceed successively as batsmen—the first two as a pair together—to the wicket and try to make as many runs as possible against the bowling and fielding of their opponents. An innings is completed when 10 batsmen have been dismissed (the remaining batsman, having no partner, is declared "not out"), when the captain of the batting side declares his innings closed before all 10 men are out, or, in a match of one innings a side, when the allotted number of overs expires. Results are recorded by the margin of runs, or, if the side batting last passes the other side's total before all their batsmen have been dismissed, by the number of their wickets (*i.e.,* batsmen still to be dismissed) outstanding.

Scoring innings and matches

Matches are decided either by the number of runs scored in one innings each (usually one-day matches), or on the aggregate of runs made by each side in two innings. International (Test) matches last five or six days (30 playing hours), other first-class matches from three to four days, and the bulk of club, school, and village matches one day.

The nonbatting side takes up positions in the field. One man is the bowler, another is the wicketkeeper, and the remaining nine are positioned as the captain or the bowler directs (see Figure 3). The first batsman (the striker) guards his wicket by standing with at least one foot behind the popping crease. His partner (the nonstriker) waits behind the popping crease at the bowler's end. The bowler tries to

hit the batsman's wicket or to dismiss him in other ways (see below *Methods of dismissal*).

Runs. The batsman tries to keep the bowler from hitting the wicket, while also trying to hit the ball sufficiently hard to score a run; *i.e.,* enable him to run to the other end of the pitch before any fieldsman can pick up the ball and throw it to either wicket to knock off the bails. If the wicket is broken, either by a thrown ball or by the wicketkeeper or bowler with ball in hand, before either batsman is in his ground, the batsman is dismissed. The striker does not have to run after he has hit the ball, nor does it count in any way if he misses the ball or if his body is struck by it. But if he gets a good hit and thinks he can score a run, he races for the opposite wicket and his partner runs toward him. When each has made good his ground by touching his bat beyond the popping crease at the opposite end, one run is recorded to the striker; if there is time, they will run back for a second or more runs, crossing again. If an even number of runs is scored, the striker will receive the next ball; if an odd number, then the nonstriker will be at the wicket opposite the bowler and will face the next ball. Any runs thus made count to the batsman, otherwise they are extras. When a ball from a hit or any of the extras mentioned below goes as far as the boundary, the runners stop and four runs are scored. If the batsman hits the ball full pitch over the boundary (on the fly) he scores six runs.

Extras. Only runs scored from the bat count to the batsman, but to the side's score may be added the following extras: (1) byes (when a ball from the bowler passes the wicket without being touched by the bat and the batsmen are able to make good a run); (2) leg byes (when in similar circumstances the ball has touched any part of the batsman's body except his hand); (3) wides (when a ball passes out of reach of the striker); (4) no balls (improperly bowled balls; for a fair delivery the ball must be bowled, not thrown, the arm neither bent nor jerked, and in the delivery stride some part of the bowler's front foot must be behind or covering the popping crease), off which a batsman cannot be out (except as noted under *Methods of dismissal* below) and which, apprised in time by the umpire's cry of "no ball," he may try to hit.

Byes, leg byes, wides, and no balls

Overs. When a bowler has bowled six balls (eight are permitted), not counting wides and no balls, he has completed an over and a new over is begun by a different bowler at the opposite wicket, with a corresponding adjustment of the positions of the players in the field. If a bowler delivers a complete over without a run being scored from the bat (even though the opponents may have scored extras by means of byes or leg byes), he has achieved a maiden over.

Methods of dismissal. There are 10 ways in which a batsman or striker can be dismissed (put out), the most usual being:

Bowled. The batsman is out bowled if the bowler breaks the wicket; *i.e.,* dislodges a bail with the ball.

Caught. He is out caught if a ball hit by the batsman is caught before it touches the ground.

Stumped. He is out stumped if, in playing a stroke, he is outside the popping crease (out of his ground) and the wicket is broken by the wicketkeeper with ball in hand.

Leg before wicket. Essentially, leg before wicket (lbw) is illegal interference, whether accidental or intentional, with a ball that otherwise, in the opinion of the umpire, would hit the wicket. The batsman is out lbw if he intercepts with any part of his person, except his hand, that is in line between wicket and wicket, a ball that has not first touched his bat or his hand and that has or would have pitched (hit the ground) in a straight line between the wickets or on the off side provided the ball would have hit the wicket. The batsman may also be out lbw if he intercepts the ball outside the off stump having made no genuine attempt to play the ball with his bat.

Run out. Either batsman is out run out if, while the ball is in play, his wicket is broken while he is out of his ground. If the batsmen have passed each other, the one running for the wicket that is broken is out; if they have not crossed, the one running from that wicket is out.

Hit wicket. The batsman is out hit wicket if he breaks his own wicket with his bat or any part of his person while playing the ball or setting off for a run.

Less usual ways of dismissal are:

Handled the ball. Either batsman is out if, with the hand not holding the bat, he willfully touches the ball while it is in play, unless with the consent of the opposing side.

Hitting the ball twice. Batsman is out if he hits the ball, except in defense of his wicket, after it has been struck or stopped by any part of his person.

Obstructing the field. Either batsman is out if he willfully obstructs the opposite side by word or action.

Timed out. An incoming batsman is out if he willfully takes more than two minutes to come in.

Strategy and technique. The disposition of the field will vary widely according to the technique of the bowler or of the batsman, the condition of the pitch, the state of the game, and the tactics determined by the captain. He may place his fieldsmen as he thinks best, and he may alter their positions, if he wishes, after each ball. There are no foul lines in cricket so a hit in any direction is a fair ball. The objectives of the captain of the fielding side are: (1) to place his men in positions where the batsman may give a catch; *i.e.,* hit a drive or a fly ball to a fielder and (2) to save runs; *i.e.,* to block the path of the ball from the batsman's scoring strokes (intercept or trap grounders). The tactical possibilities for a captain in directing his bowlers and fieldsmen and the batsmen are manifold and constitute one of the attractions of the game.

Fielding positions

As there are only 11 players on a team and two of them must be the bowler and wicketkeeper, only nine other positions can be occupied at any one time. The field is spoken of as being divided lengthwise into off and on, or leg, sides in relation to the batsmen's stance, depending upon whether he bats right- or left-handed; the off side is the side facing the batsman, and the on, or leg, side is the side behind him as he stands to receive the ball.

To sum up, the objective of the bowler is primarily to get the batsman out and only secondarily to prevent him from getting runs, though these objectives have tended to become reversed in one-day, limited-overs cricket. The objective of the batsman is to protect his wicket first and then to make runs, for only runs can win a match. The objective of each fielder is, first, to dismiss the batsmen, and, second, to prevent the striker making runs.

Bowling. Bowling can be right- or left-arm. For a fair delivery, the ball must be propelled, usually overhand, without bending the elbow. The bowler may run any desired number of paces as a part of his delivery (with the restriction, of course, that he not cross the popping crease). The ball generally hits the ground (the pitch) before reaching the batsman, although it need not.

Length and spin in bowling

The first requisite of a good bowler is command of length; *i.e.,* the ability to pitch (bounce) the ball on a desired spot, usually at or slightly in front of the batsman's feet, and varying with the pace of the bowler, the state of the pitch, and the reach and technique of the batsman. The second requisite is command of direction. On this foundation a bowler may elaborate with variations—finger spin, swerve, alteration of pace and flight, the path of the ball, and the manner in which it is propelled—that lend deceptiveness and uncertainty as to exactly where and how it will pitch. A good-length ball is one that causes the batsman to be uncertain whether to move forward to play his stroke or to move back. A half volley is a ball pitched so far up to the batsman that he can drive it fractionally after it has hit the ground without having to move forward. A yorker is a ball pitched on or inside the popping crease. A full pitch is a ball that the batsmen can reach before it hits the ground. A long hop is a ball short of good length.

The primary purpose of the spin is to bring the ball up from the pitch at an angle that is difficult for the batsman to anticipate. The two swerves are the inswinger, which moves in the air from off to leg, and the away swinger, or outswinger, which swerves from leg to off.

Batting. A batsman may hit right-handed or left-handed. Good batting is based on a straight (*i.e.,* vertical) bat with its full face presented to the ball, although a cross (*i.e.,* horizontal) bat can be used effectively to deal

Batting strokes

with short bowling. The chief strokes are: forward stroke, in which the batsman advances his front leg to the pitch (direction) of the ball and plays it in front of the wicket (if played with aggressive intent, this stroke becomes the drive); back stroke, in which the batsman moves his rear leg back before playing the ball; leg glance (or glide), in which the ball is deflected behind the wicket on the leg side; cut, in which the batsman hits a ball on the uprise (after it has hit the ground on the off side), square with or behind the wicket; and pull or hook, in which the batsman hits a ball on the uprise through the leg side.

Fielding. The ideal fieldsman is a fast runner, with quick reactions and the ability to throw quickly and accurately. He should be able to anticipate the batsman's strokes, to move quickly to cut off the ball in its path, and to judge the flight of the ball in the air to make a safe catch.

Wicketkeeping. The wicketkeeper is a key member of the fielding side. He takes position behind the striker's wicket, 10 to 20 yards back for the fast bowlers or directly behind for those of slower pace. He must concentrate on every ball, being ready to stop a ball that passes the wicket, to stump a batsman if he leaves his ground, or to receive a ball returned to him by a fielder. (M.K.W./R.Al.)

Association football (soccer)

Association football, called soccer in the United States, is usually played outdoors, between two teams of 11 players each with the object of putting a ball by kicking or butting into the opposing team's goal. It is the most widely played ball game in the world and the most popular as a spectator sport. The simplicity of the rules and the ability to play it practically everywhere has contributed to this popularity. It is played on all continents and in well over 150 countries. At the last census by the world governing body, there were 40,000,000 registered players at all levels. In addition, there are many thousands of others in numerous countries involved in pickup games in streets, on parking lots, on school playgrounds, in parks, and even, as in Brazil, on beaches. At the 1984 summer Olympic Games the football matches registered almost 1,500,000 spectators, the highest number for any Olympic sport. The world's largest football stadium, in Rio de Janeiro, holds crowds of up to 200,000 for football matches.

HISTORY

Origins. From antiquity, games existed in which two teams, or sides, attempted to kick, push, or otherwise propel a ball in opposite directions toward the opponents' goal. The ball varied in shape from round to oval as it does today. A football game was played in China as early as 206 BC, and by AD 500 round footballs stuffed with hair were in use. In ancient Greece a game with elements of football, *episkuros,* or *harpaston,* was played, and it had migrated to Rome as *harpastum* by the 2nd century BC. In this game play began with a ball being thrown in the air between two teams, each of which tried to push it beyond the opponents' goal line. Roman legions may have introduced the game throughout Europe and in England during the Roman occupation (AD 43/44–410). One report has the Irish kicking a stuffed ball even earlier.

In 7th-century Japan there was a football game. In the 14th century *calcio* ("kick") was played in Florence; it persists as a festival game. Also in medieval Europe there were mob games, called *mêlées,* or mellays, in which a ball, usually an inflated animal bladder, was advanced by kicking, punching, and carrying. As many as 100 players from two towns or parishes started at a midpoint and used their localities' limits as goals. King Richard II of England banned the game in 1389 because it interfered with archery practice, and later monarchs issued similar proscriptions into the 15th century, to little effect.

The medieval *mêlée*

Shrove Tuesday was a traditional football day in both England and Scotland from the 12th century. At Chester the game was said to be in commemoration of the day in 217 when a mighty flying wedge drove the Romans out. A similar explanation was given for a game celebrating the driving out of the Danes from Kingston-on-Thames in the 8th century. The field in later games came to be from 80 to 100 yards (about 73 to 91 metres) long with a goal at each end formed by driving two sticks in the ground two or three feet (0.6–0.9 metre) apart. The ball was an inflated bladder encased in leather. When one team drove the ball through the opponent's goal, the game ended.

Football in a less violent form was played in England from the 17th century by youths from wealthy and aristocratic families at public (*i.e.,* private) schools, although the authorities frowned on it as too rowdy for young gentlemen. Rules varied from school to school, but all forbade running with the round ball or passing it forward.

The early years. When association football arose in England, it was first played as a winter game between residence houses at public schools such as Winchester, Charterhouse, and Eton but not often between schools, for each school had its own rules, some allowing limited handling of the ball and others not. Public schoolboys who went up to the universities could not play football there except with old schoolmates. An attempt to codify rules and remove differences was made at Cambridge University in 1843, and in 1846 most of the public schools adopted what were called the Cambridge rules, which were also used at that university and later by graduates who formed football clubs. Then in 1862 and 1863 a series of meetings of school and nonschool clubs in the London area and surrounding counties agreed to print the rules and by so doing left the rugby game outside of the newly formed Football Association (FA).

The Cambridge rules

The new rules were not at once universally accepted; many clubs continued to play their own, especially in and around Sheffield, the first provincial club to join the FA. In 1867 the Sheffield Football Association was founded, the forerunner of county associations formed later. Sheffield and London played two matches in 1866, and in 1867 a match pitting Middlesex against Kent and Surrey was played under the revised rules. In 1871 all 15 FA clubs were invited to subscribe for purchase of a trophy cup to be played for by all clubs. By 1877, 43 clubs were competing, and the original dominance of the London area began to diminish. By the end of the 1870s only the Scottish Association rules varied from the FA's. Attendance grew until in 1893 the final Cup game drew 45,000 spectators, in 1897 more than 65,000, and in 1901 more than 100,000.

Professionalism. Professionalism became an issue in 1884, and two clubs were excluded from the FA for using professional players, but professionalism was eventually permitted by the FA, though not all clubs allowed it. The issue of professionalism first arose with "broken time," recompense for time lost at football from players' regular jobs. Ultimately professionalism came to mean full-time employment of players. The teams using professionals were mainly in the midlands and the north. Professionalism led 12 clubs to form the Football League, intended to be national in scope, in 1888. A second division was introduced in 1892, and the total number of teams increased to 28. The Irish formed a league in 1890 and the Scottish in 1891. The Southern League began in 1894.

The Football League

Later national leagues outside Great Britain followed the British model. A league was formed in The Netherlands in 1889, but professionalism was not adopted there until 1954. Germany completed its first national championship season in 1903, but the Bundesliga, a comprehensive national league, did not evolve until 60 years later. In France, where the game was introduced in the 1870s, a professional league did not begin until 1932, shortly after professionalism had been adopted in the South American countries of Argentina and Brazil. The FA, while legalizing professionalism from 1885, was determined to preserve amateurism, as were some of Britain's southern clubs, but ultimately professionalism prevailed, the London FA yielding to it in 1906.

The Football League became more national in 1920, when the Southern League was absorbed as a third division, the midlands and northern clubs maintaining their superiority. Thereafter, though the FA Cup was prestigious, the weekly Football League matches formed the backbone of British football. Seasonal attendance at Football League

matches in the years between the two world wars rose to around 28,000,000 by 1938. After World II it peaked at 41,000,000 in 1949. By 1986, however, attendance had slumped to a low of 16,000,000 before reorganization of the four divisions, the introduction of play-offs, and associated cup competitions produced a modest revival.

International competition. British engineers and businessmen first carried the game abroad: to Prague and Graz, Austria, in the 1880s, and to Vienna, where two clubs were formed in the 1890s. In 1887 a textile mill representative introduced the game in Russia. The first football match in Turkey was played in 1895 between British residents and Greek students, who had learned the game from British sailors. Danes formed the Boldspil (ball game) Union in 1889, the same year that The Netherlands federation was formed. In Malmö, Swed., English residents played both rugby and association football and occasionally combinations of the two. Belgian and Swiss associations were formed in the 1890s, and British sailors had introduced the game to Brazil in the late 1870s.

Oddly enough, in comparison with other British sports in the 19th century, association football did not travel first or even very effectively to what later became the Commonwealth countries and to the United States. The game played from the 1870s in Canada and from the 1880s in Australia and New Zealand was rugby, often in the same confusion with soccer that had attended the late and slow establishment of the rules in Great Britain.

Soccer in the United States

After U.S. football emerged early in the 20th century as the most popular football sport in the United States, soccer survived as an intercollegiate sport, first under the aegis of the National Collegiate Athletic Association (NCAA) from 1905, and from 1924 under that of the Intercollegiate Soccer Association of America, which in turn later affiliated with the NCAA. The soccer schools were originally all in the East: Pennsylvania, Cornell, Harvard, Haverford, Princeton, and Yale in the 1920s. Originally a spring game, soccer became a spring and autumn game, and finally an autumn game. Later, where climate allowed, as in California, it was played year round.

Outside the schools, the game was most popular in cities where immigrant groups played it: St. Louis, Mo.; Philadelphia; Chicago; Cincinnati, Ohio; and Cleveland, to which later Hispanic migration added New York City and Los Angeles. The U.S. Soccer Federation was formed in 1913, affiliated with the Fédération Internationale de Football Association (FIFA), and sponsored competitions. The American Football League, a group of Eastern professional teams, began in 1923. Most of the players were imported, the Bethlehem Steel Company team specializing, for example, in Scottish players. Foreign teams toured the United States, at first usually winning all their games, and U.S. teams began to play abroad. U.S. teams have participated in the World Cup from 1930, but traditionally they have not gone far in the competition.

The U.S. professional game became national in 1968 when the new North American Soccer League (NASL) began play. The league did not survive long, however. The game was slow to attract American sports fans, and the mortality rate of teams ran high along with the frequent switching of franchises from one city to another. Competition from such favourite U.S. sports as baseball and football was difficult to overcome. If one player was responsible for popularizing the game as a spectator sport in the United States, it was the Brazilian World Cup player Pelé, signed by the New York Cosmos in 1975. But interest waned after the early 1980s, and the NASL finally collapsed prior to the 1985 season. The demise of the NASL, however, did not result in a total collapse of professional soccer. After experimentation, soccer officially

Indoor soccer

moved indoors in 1978 with the institution of the six-a-side Major Indoor Soccer League, a concept designed to create a faster, higher-scoring game for American tastes. It developed attendance problems nonetheless. At the same time, at grass-roots level, progress was such that in 1987 more than 2,000,000 youngsters were regularly playing in youth leagues throughout the country and filtering talent into high schools and colleges. More universities were fielding soccer teams than squads for U.S. football.

International organization. In 1904, when the game had spread across the continent of Europe to the point at which international organization was needed, Belgium, Denmark, France, The Netherlands, Spain, Sweden, and Switzerland founded the FIFA. The English FA had been consulted earlier, but "in a monumental example of British insularity," as the official FA history later put it, had failed to take the lead expected of it, though England voiced agreement with the concept in 1905 and joined the association the following year. The FA had, however, in 1882 set up the International Football Association Board as an international rule-making body, with English, Scottish, Welsh, and Irish representation, and it continued as such. In 1913 the FIFA was given representation on the board, but they were voted out after Britain withdrew from the world governing body in 1920 over the reinstatement of Germany and its World War I allies. The FIFA representation, however, was resumed four years later.

The FA did consult with the FIFA, especially on the question of amateurism, a problem that came to a head with the unofficial inclusion of soccer in the Olympic Games of 1900 and 1904 and its official inclusion thereafter, except in the 1932 Games. The commitment of the International Olympic Committee (IOC) was to pure amateurism; the FIFA allowed its national associations to handle the question independently. Uruguay won in the 1924 and 1928 Games with virtually professional teams. Some nations refused to compete. The IOC wavered; the popularity of the sport worldwide may have discouraged ironhanded enforcement. After winning in 1908 and 1912, Britain withdrew in protest of the professionalism of other national teams in 1920 and did not permanently rejoin the FIFA until 1946, having temporarily returned in the interim. After World War II Communist-bloc countries were almost completely dominant.

The World Cup

World championships. The FIFA organized the World Cup championship series, the first being played at Montevideo in 1930 and won by Uruguay. The World Cup competition was scheduled every four years between the Olympic Games. The European Cup of Champion Clubs play for national league champions began in 1955 among the 33 countries of the Union des Associations Européene de Football (formed in 1954), which also began the European Cup-Winners' Cup series in 1960. Other cup competitions followed, including the South American Copa Libertadores de América in 1960, which led to an unofficial championship played between the winners of the South American and the European Champions' cups. It was later given FIFA approval. (For winners of these cups, see SPORTING RECORD in the *Micropædia*.) The International Inter-City Industrial Fairs Cup began tentatively in 1955 but by 1971 was firmly established, renamed the UEFA Cup, and with an annual entry of 64 teams had become Europe's largest tournament. For national teams there are established competitions as well: South American Championship (1916), African Nations Cup (1957), and European Football Championship (1960), formerly known as the European Nations Cup.

Spectator problems. The excitement of regional, national, and international rivalries in soccer has provided the game with intensely loyal fans whose enthusiasm at times has turned them to violence. Before the late 1950s, crowd disturbances before, during, and after British matches were rare and confined to a few spontaneous, isolated incidents. In contrast, Latin-American countries had years before fenced off and even dug moats around the fields of play to keep unruly fans at bay. But the 1960s brought frightening increases in violent, sometimes premeditated, activity, which contributed to the decrease in attendance. Soccer became the unwilling catalyst for antisocial behaviour. The problem worsened in the next decade when segregation of rival fans became essential. The trend culminated in the 1985 Heysel Stadium tragedy in Brussels. Thirty-nine spectators, mostly Italian, died and 400 were injured at the European Champions' Cup final when a wall collapsed under pressure from rioting Liverpool supporters charging fans of the Italian Juventus of Turin team. English clubs were then banned from European competition, but the so-called British disease

of hooliganism had already been exported to most other European countries.

PLAY OF THE GAME

Equipment and field of play. The object of the game is to propel the ball into the goal, using any part of the body except the hands and arms; the side scoring more goals wins. The ball is a round, leather-covered, inflated rubber bladder 27–28 inches (about 68–71 centimetres) in circumference and 14–16 ounces (397–454 grams) in weight. The players move the ball by hitting it with head or foot from one teammate to another or by dribbling—a series of very short kicks, usually with the instep or side of the foot. Only the goalkeeper of the 11 players is allowed to handle the ball, and he is restricted to the penalty area, a rectangular area in front of the goal, 44 yards (40.2 metres) wide and extending 18 yards (16.5 metres) into the field. The goal is eight yards (7.3 metres) wide and eight feet (2.4 metres) high. The game is of 90 minutes' duration and is divided into halves. The teams change ends after a five-minute half-time interval. FIFA rules prescribe a playing field (pitch) 100 to 130 yards (90 to 120 metres) long and between 50 and 100 yards (45 and 90 metres) wide; however, for international matches, it must be 110–120 yards (100–110 metres) long and 70–80 yards (64–75 metres) wide (see Figure 4). Women and schoolchildren usually play a shorter game on a smaller field. The game is controlled by a referee, who is also the timekeeper, and two linesmen who patrol the touchlines, or sidelines, signaling when the ball goes out of play.

The ball

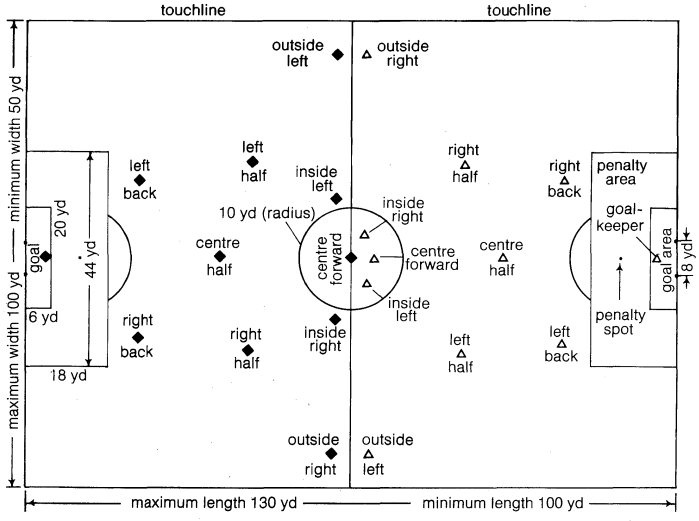

Figure 4: Soccer field and the positions of players at the kickoff.

The biggest changes have been in uniforms and equipment. Clothing has become attenuated, and heavy boots have given way to shoes. Many players have discarded shin guards. Conformity of dress is not essential, provided that the sides can be identified and the goalkeeper is distinguishable. Players may participate barefoot.

Fouls. Free kicks are awarded for fouls or violations of rules; all players of the offending side must be 10 yards (nine metres) from the ball. Free kicks may be either direct, from which a goal may be scored, for more serious fouls such as kicking an opponent, tripping, or handling the ball; or indirect, from which goals cannot be scored until after the ball has touched another player, awarded for lesser violations such as obstruction (interfering with an opponent while not playing the ball). A penalty kick, a direct free kick awarded to the attacking side in the penalty area, is taken from a spot 12 yards (11 metres) from the centre of the goal, with all players other than the defending goalkeeper and the kicker outside the penalty area. Variance in rule interpretations was notable from the 1960s. In South America, for example, shoulder charges, harassment of the goalkeeper, and tackling from behind were not viewed as seriously as they were elsewhere; but interfering with a player not playing the ball was strictly penalized. From 1970 a player guilty of a serious foul was given a warning yellow card, and a second such foul brought a red card and ejection from the game.

The penalty kick

Rules. Considering the tremendous advances in play in the 20th century, it is remarkable that there have been only two major alterations of the rules in the period—those related to "offside" and to player substitution. A man is offside if he receives a forward pass from a colleague in the opponent's half with fewer than two opponents—three before the rule was changed—between himself and the goal line. The interpretation often causes controversy, even though the linesmen generally guide the referee by positioning themselves alongside the foremost attacker on each team. The flagrant use of substitutes in many countries forced the International Board to alter the rule limiting teams to 11 players. At first it was hoped to restrict changes to injured players, but it is now permissible to replace any two at any time in competitive matches. Substitutes were used for the first time in the World Cup in 1970—two from five on the reserve bench—and it proved an invaluable innovation because of the heat and altitude of Mexico City, site of the contest. Substitutions can be made at any time during a match but only after the referee stops play. The exchange must take place at the halfway line. A substitute can only enter the field of play after the player he is replacing is taken off, either as a result of an injury or for tactical reasons. A substituted player may not return to the game.

Use of substitutes

Maneuvers. While solo runs and dribbles are spectacular, association football is essentially a team game, based on accurate passing of the ball among members of the same side. Passing produces the fluid movements and varied patterns that contribute to the game's attractiveness. A distinctive feature is the development of heading (introduced in the 1860s), and many thrilling goals are scored by a forward jumping to hit the ball with his forehead.

Too much can be made of numbers and systems. Basically, the aim is to put a man with time and room to spare in a shooting position near the opponent's goal, and it does not matter whether the man is nominally a forward or a defender. Attitude is an important factor to go along with technical excellence in achieving the aim.

Tactics. Although professionalism and the league system brought benefits, they are partly responsible for the growing blight of defensive football. Herbert Chapman, shrewd manager of England's Arsenal team in the 1930s, pulled back the centre halfback to be a third back and operated with four forwards instead of five. Italy, possibly the most commercialized soccer country, introduced the Catenaccio system (see Figure 5), with an extra man, named the sweeper or libero (free man), behind another four defenders, plugging holes where they developed.

Defensive strategies

Ideally, with both tactics the solid defenses were the springboard for quick counterattacks and, in Scotland's Alex James, Arsenal had the man to organize them. But with most imitators it was solely a case of stopping the other side from scoring. A defensive outlook was also encouraged by the European club tournaments, which were played on a home and away basis, the winning side being that with the greater aggregate of goals. As a result, visiting teams did not go for a win but concentrated on keeping down the opponent's score in the hope of obtaining more goals in the return match.

One of the few attacking ideas to come forward after World War II was the withdrawn centre forward (see Figure 6) of Hungary's Nandor Hidegkuti in the 1950s. He played behind the attack, luring the centre halfback with him, and the inside forwards were the spearhead. The line had an M shape instead of the fashionable W formation.

Teams used to have specialists who stuck to their roles—

Modern formations

wingers out on the touchlines, backs deep in defense, and centre forwards lying upfield. They gradually gave way to all-around players who realized their responsibilities in all departments of the game. Work rate became as important as skill, and method football took over. Brazil grouped its outfield players in a 4–2–4 formation when winning the 1958 World Cup and still gave outlet to its brilliant individualists. England won the World Cup in 1966 playing 4–3–3—without a winger—and four years later often operated 4–4–2, fielding only two strikers up front.

UPI

World-famed soccer star Pelé (Brazil) has characteristically darted past the defender to intercept the ball and take a shot at the goal during the 1970 World Cup final against Italy at Mexico City. Brazil won 4–1 to become world champions for the third time.

In the early 1970s, however, The Netherlands' innovation of "total football," in which positions were largely ignored, enjoyed some success. Every outfield player attacked as well as defended. The quality of the individuals carried the system along, but The Netherlands failed to win the 1974 World Cup. Then in the late 1980s, experiments were made with a variation of 4–4–2 using a packed midfield in a 4–5–1 formation, which was able to saturate the opposition, leaving a solitary striker in attack. Emphasis on defense to avoid defeat continued in the pressurized atmosphere of a highly competitive professional business.

U.S. football

United States-style football is a body-contact, 11-man team sport of running, kicking, and passing the ball. The gridiron sport, as it is called because of the field's design, is indigenous to the United States and has not been taken up in the rest of the world to the degree that other U.S. sports, such as basketball and baseball, have; it has spread to some other countries, however, and has achieved some international popularity through television viewing.

U.S. football evolved as the product of the imagination of early players and coaches who continuously adapted the game to the equipment, players' skills, and the playing rules in effect during their time. It was coaches such as Walter Camp, Amos Alonzo Stagg, Glenn ("Pop") Warner, Bob Zuppke, Knute Rockne, Robert Neyland, Don Faurot, and Herbert ("Fritz") Crisler who developed the fundamentals of play and generated public interest in football.

The game began as a college sport that was played in the fall and was usually over by Thanksgiving. Today, colleges have a limited practice of about three weeks in the spring, begin their fall schedule in late August, and continue through the New Year holiday with National Collegiate Athletic Association (NCAA) divisional championships and bowl games. The professional teams play exhibition games in July and continue their season through the Super Bowl in the last week of January. High school teams play shorter schedules that often lead to city and state championship tournaments.

HISTORY

Amateur football. Football in its crudest form was known in America virtually from the time British colonists established their first settlements. There is evidence that as early as 1609 teams or groups of men were kicking around an air-filled bladder, as they had in their mother country. More than two centuries were to pass, however, before the game took root in the colleges.

Students at Princeton University in 1820 played a game known as Ballown, in which a ball was batted with the fist. By 1840 an organization had been formed to schedule games and choose sides. Many other colleges developed forms of the game, some of them becoming notoriously violent. There were no established rules at any of the colleges, and sides might be of any number agreed upon. Following the introduction of a round rubber ball in the 1850s, considerable skill was developed in kicking the ball a long distance, dribbling it with the foot, and passing it (by foot) to a teammate; these were the skills of modern association football (soccer).

The first formal football organization in the United States was established in 1862 by Gerritt Smith Miller, a 17-year-old student. He organized the Oneida Football Club of Boston, which from 1862 to 1865 was never beaten or scored upon.

Roots in soccer and rugby. In 1867 so-called Princeton Rules were drawn up for the soccer style of football. They called for 25 players to a side. Rutgers College, New Brunswick, N.J., not far north of Princeton, also drew up rules in 1867, and in November 1869 the two met in the first intercollegiate game of football in the United States at New Brunswick. Exception has been taken to so labeling the game because it was the soccer style of football that was played. The distinction of being the first intercollegiate game has also been bestowed on the first Harvard–Yale game in 1875, which was part rugby and part soccer, or on a second game between them (1876), which was rugby.

Soccer—Princeton versus Rutgers, 1869

The rules drawn up for the first game between Princeton and Rutgers were a modification of those of the London Football Association. There was a maximum of 25 players to a side. The team first scoring six goals was the winner. The round ball that was used could be kicked or batted with the hand or fist, although running with it or throwing it was not allowed. Rutgers won the game, 6 goals to 4. The second game, at Princeton, was won by Princeton, 8 goals to 0. A third scheduled game was barred by the two colleges.

Columbia, Cornell University of Ithaca, N.Y., and Yale were among the schools that took up football in the early 1870s, all adopting the kicking game. Harvard, where football had been banned, revived the game in 1871 and played what was known as the Boston Game, essentially a kicking game with elements of rugby. Representatives from Princeton, Yale, Columbia, and Rutgers met in New York City in 1873 and formulated the first intercollegiate rules in the United States with the code of the London Football Association as their model. In that year Yale lost to Princeton, 3 goals to 0, in the inaugural meeting of what is today intercollegiate football's oldest continuous rivalry. Yale then met a team from England known as the Eton Players in the first international match in the United States and won, 2 goals to 1. The game played was probably soccer. Yale was won over by the Eton Players to 11-man football and thereafter fought for the principle until it was adopted generally in 1880.

First intercollegiate rules

Harvard, because it played a different game, had declined to participate in the 1873 rules convention and looked elsewhere for competition. It found a rival in the football club of McGill University in Montreal. The teams met twice in the spring of 1874 at Cambridge, Mass. McGill

played football under the code of the Rugby Football Union of England. Harvard's football was largely soccer. The first of the two games was played under Harvard's rules. The next day the teams met under McGill's rules, using an egg-shaped, rugby-style ball.

Harvard was won over completely to rugby as a result of its matches with McGill. Then came an event that contributed greatly to the shape of the game as it developed in the United States. Harvard challenged Yale to a game under "Concessionary Rules" and thus inaugurated one of the most celebrated of all U.S. football rivalries. The game was played in November 1875 at New Haven, Conn., and was part rugby and part soccer. They played with 15 players on a side instead of 11 as Yale would have preferred, and Harvard won by 4 goals and 4 tries, or touchdowns, to none. Despite its decisive defeat, Yale was so taken with rugby that it became a convert and adopted the rules. Observers from Princeton who saw the game also were won over to rugby, and in 1876 representatives of Princeton, Harvard, Yale, and Columbia organized the Intercollegiate Football Association. They adopted the code of the Rugby Football Union with a change in the scoring rule—instead of a match being decided by a majority of goals alone, it was decided by a majority of touchdowns. The egg-shaped leather ball replaced the round rubber ball of soccer. Rugby thus became the American college football game just as other schools were entering the intercollegiate lists.

Rugby—Harvard versus Yale, 1875

The first game in the Middle West was played in 1879 between the University of Michigan, Ann Arbor, and Racine College of Wisconsin. Though Michigan had organized a team as early as 1873, it had been unable to find an opponent until the Racine game. In 1881 Michigan inaugurated intersectional competition by sending its team east to play Yale, Harvard, and Princeton, losing to all three in the space of five days. In 1887 the University of Notre Dame in South Bend, Ind., made its debut against Michigan and lost 8–0 at South Bend. On the Pacific coast, football was being played between classes at the University of California, Berkeley, as early as 1881, but not until the 1890s did football take hold seriously. The Southwest was a late starter, but in no part of the country did the game become more of a craze. The University of Texas, Austin, was the first to organize, in 1893.

Evolution of American football. In its early years, American game was purely a test of brawn, with dull pileups and entanglements of bodies in marked contrast with rugby's speed and wide-open action over the breadth and length of the field. The man who conceived and designed most of the basic changes and departures from rugby and brought about their acceptance was Walter Camp, now rightly known as the "Father of American Football."

Walter Camp

In 1880 Camp initiated the first of the major changes in the evolution of the American game. This was the substitution of scrimmage for the scrummage, or scrum, of rugby. In scrummage the ball was put between two opposing interlocked packs of rushers, or forwards, who endeavoured to heel the ball backward to their own backs. In the new scrimmage, the ball was given into the orderly possession of one team, one of whose members, the snapback (now the centre), then put it in play without interference by "snapping" it with the foot to another player designated the "quarterback." Thus Camp also initiated the role of the quarterback, which was to become, for many, the most glamorous position in football. In the same year, he finally succeeded in his efforts to have the number of players reduced from the 15 of rugby to the 11 of modern U.S. football. Camp, too, was the one who came up with the standard alignment for 11 men—seven forwards in the line, a quarterback, two halfbacks, and a fullback.

In 1882 Camp introduced a system of downs and yardage to be gained. This followed as a result of the tactics used at the time to keep indefinite possession of the ball. No means had been devised for forcing surrender of the ball, and a team that was unable to score but chose not to let its opponent have the chance to score was able to maintain possession indefinitely. Camp's rule called for a team to surrender the ball if it failed to gain five yards (raised to 10 in 1906) in three downs (raised to four in 1912). The new rule gave rise to the practice of marking the field with horizontal lines five yards apart, giving it the appearance of a gridiron. The rule was the heart of American football. It encouraged the planned running attack, replacing kicking as the predominant element of play.

The following year Camp introduced a scoring system to end disputes over the outcome of games. Point values were given to the various scoring methods—safety (tackling a ball carrier behind his own goal line), 1 point (against team in possession of the ball); touchdown, 2 points; goal after touchdown, 4; and field goal, 5. Over the years the point values changed several times, reflecting especially the diminishing importance of kicking. In 1912 the scoring had evolved as follows: the safety was 2 points, the field goal 3, the touchdown 6, and the conversion after touchdown was 1 point. In 1958 teams were given the option of running or passing for a 2-point conversion.

In 1888 came another change that was to transform the pattern of the game. Tackling up to this time had been permitted only from the waist up—the rule of rugby. An 1888 rule permitted tackling as low as the knees, and along with this came a prohibition against linemen blocking with extended arms, requiring them to keep their arms at their sides. The forward line of players, which had been extended across the field, was therefore forced to contract. The players in the backfield, who also had spread wide for the lateral passing of the ball, as in rugby, also moved close together behind their forwards for protection. In these positions the backs formed the close-order alignment of the T—which became the original, standard formation of American football (see Figure 8).

The T formation

Mass formations. In 1890 the first of many mass formations that were to make the game so hazardous was unveiled. The man who originated it was Amos Alonzo Stagg, famous as a player at Yale from 1885 to 1889 and far more renowned for his 63 years of coaching college teams, 41 of them at the University of Chicago. Stagg devised the "ends back" formation in his first year of coaching at the International YMCA Training School in Springfield, Mass. He moved the ends from their regular positions at each end of the line to positions behind the line, where, along with the back, they became interferers, pushers, and pullers, helping the ball carrier to advance. The resulting impact on the defense was much more forceful than anything previously known. In 1891 Stagg presented a second mass formation known as the "turtleback," a massing of the team into a solid oval directed against the opposing tackle. Harvard used this formation in 1893 and was credited by some with being its originator.

In 1892 the most devastating of the mass plays was introduced—the "flying wedge," a kickoff tactic invented at Harvard. The flying wedge was an extension of the so-called V trick, credited to both Princeton and Lehigh University, Bethlehem, Pa., in which the kicker, instead of kicking off to start a half, nudged the ball with his toe and then picked it up and ran with it as his teammates formed a V-shaped mass around him. In 1892 Harvard added momentum to the mass by starting the wedge in motion before the ball was put in play. The sensational device was adopted immediately, and in 1893 it was in general use. It added to the roughness of the game and, by the end of the season, football was under attack for its violence. The army and navy departments canceled the game between the service academies in 1894, and the Intercollegiate Football Association began to break up.

Flying wedge

In 1894 the University Athletic Club of New York invited Yale, Princeton, Harvard, and Pennsylvania to send representatives to a meeting to form a new rules committee. This group banned the V trick and the flying wedge by a requirement that the kickoff travel at least 10 yards to be in play unless touched by a member of the receiving side. It was also against the rules for more than three men to group more than five yards in back of the line of scrimmage to project a mass play.

The violence of mass plays continued, however. In 1894 Stagg, then at the University of Chicago, introduced a "tackles back" formation and at Pennsylvania, the coach, George Woodruff, originated a "guard back" arrangement that was widely imitated. Harvard declined to give up its

flying wedge. Yale and Harvard broke relations after a rough 1894 game. In 1895 Yale and Princeton adopted a separate code. To curb mass play they ruled that the team on offense must have seven players on the line of scrimmage and that only one back might be in forward motion before the snap of the ball.

Also in 1895, colleges in the Middle West, dissatisfied with the divided leadership of the East, asserted their independence. The presidents of Chicago, Illinois, Michigan, Minnesota, Northwestern, Purdue, and Wisconsin universities met and took steps toward organizing what was to become the Western Conference (Big Ten). At a second meeting in 1896 they barred freshmen from varsity teams and set a limit of three years on varsity eligibility. Later they established faculty control of athletics.

In the summer of 1896 the two groups in the East met in an effort to resolve their differences. They set up a permanent rules committee and put a curb on momentum in mass plays by ruling that "no player on the side in possession of the ball shall take more than one step toward his opponent's goal before the ball is in play without coming to a full stop." In 1910 the rules committee required seven men on the line to put an end to mass plays.

Emergence of the modern game. The season of 1905 was one of the ugliest, if not the most critical, U.S. football has ever gone through. According to tabulations of the *Chicago Tribune,* there were 18 deaths and 159 other injuries of consequence resulting from college games. There was a mounting uproar of protest as the season progressed. President Theodore Roosevelt summoned representatives of Harvard, Yale, and Princeton to the White House and requested them to take steps to save the game.

National opposition to violence

At a meeting in New York City late in 1905, representatives of about 60 colleges and universities appointed a football rules committee of seven members and organized the Intercollegiate Athletic Association of the United States with Captain Palmer E. Pierce of West Point as its first president. The American Football Rules Committee (the old committee), under Walter Camp, met with the association's Football Rules Committee in 1906 in New York City. In 1910 the Intercollegiate Athletic Association of the United States became the National Collegiate Athletic Association (NCAA), the governing body of intercollegiate athletics in the United States.

The forward pass

One of the committee's changes was the legalization of the forward pass. One of the men most instrumental in the introduction of the forward pass was John Heisman, for whom college football's most prized individual trophy was later named. In 1895, while a coach at Auburn, he had seen a forward pass thrown in a game between North Carolina and Georgia, 11 years before it was legal to throw the ball forward. The North Carolina player who caught it ran 70 yards for a touchdown. The Georgia coach, Pop Warner, protested the pass as illegal, but the referee stated that he had not seen it and allowed the touchdown.

In 1903 it occurred to Heisman that the forward pass he had seen thrown eight years before could be the salvation of the game by loosening up the strangling mass play. He wrote to Camp suggesting that the forward pass be incorporated into the game, and in 1904 he did so again. Others joined in, and the forward pass was approved in 1906.

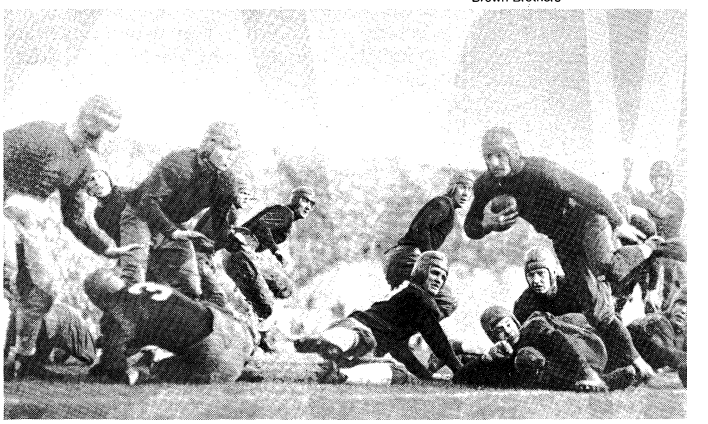
In addition to legalizing the forward pass, the 1906 rules changes were: (1) reduction of the length of the game from 70 to 60 minutes, divided into 30-minute halves, (2) establishment of a neutral zone, separating the forward line of teams by the length of the ball, (3) increasing the distance required to be gained in three downs from five to 10 yards, (4) banning of hurdling (jumping over opposing players), (5) prohibiting offensive centres, guards, and tackles from dropping behind the line of scrimmage unless they fell back five yards to replace a back, (6) stipulation that punts striking the ground put all members of the kicking team on side (behind the ball) except the kicker, (7) marking of the field with lengthwise stripes five yards apart, changing it from a gridiron to a checkerboard, (8) addition of a second umpire, and (9) requirement that substitutes report to the referee. A central board of officials, which Camp had advocated in 1905, was established.

In 1910 the rules committee took the final step to end mass plays. Seven men of the offensive team were required on the forward line, while interlocked interference and aiding the runner by pushing or pulling were outlawed. The effect of these changes was so pronounced that the balance of power switched from the offense to the defense. There was a falling off in scoring, and numerous games ended in scoreless ties. To correct the imbalance, the rules committee in 1912 increased the number of downs from three to four. The length of the playing field was reduced from 110 to 100 yards (90 metres) and end zones 10 yards deep were established behind the goal lines, within which forward passes could be completed for touchdowns. The kickoff, formerly made from the centre of the field, was moved back to the kicking side's 40-yard line. Gradually, early restrictions on the forward pass were removed.

Emergence of Notre Dame

The awakening to the immense possibilities of the forward pass came primarily as a result of a sensational exhibition by Notre Dame in defeating Army in the inaugural game of their rivalry in 1913 at West Point. Notre Dame's name in football meant nothing to the East at the time, and Army was heavily favoured. With quarterback Gus Dorais throwing to end Knute Rockne (later the most famous coach in football history) and to back Joe Pliska, Notre Dame caught Army completely unprepared and scored an astonishing 35–13 victory over the cadets and their battering-ram running game. Later that same season Army used the forward pass against Navy and won 22–9.

Actually, Notre Dame was not the only trailblazer of the forward pass. Numerous teams had used the pass since its inception in 1906. Probably the most successful of all in that year was a St. Louis University (Missouri) team, coached by Eddie Cochems, that won every game in its season and used the pass from the very first.



Spread of the game. The early dominance of Harvard, Princeton, and Yale gave way in the 1890s as other teams and regions achieved renown for football prowess. Legendary teams included Pennsylvania in 1894–98, Fielding Yost's "point-a-minute" teams at the University of Michigan in 1901–05, and Stagg's 1905–09 teams at Chicago. The rise of the Carlisle Indian School to fame began in the 1907 season. In 1907, 1911, and 1912 Carlisle was one of the strongest teams in the country and gave the football world the player who is often ranked as the greatest of all time—Jim Thorpe. During the 1912 season Thorpe scored the remarkable total of 25 touchdowns and 198 points.

The Carlisle Indians and Jim Thorpe

Coaching. With the opening up of the game, the coach became more important, as a deviser of systems, plays, pass patterns, and defensive arrangements. Famous coaches of the day, in addition to Camp, Stagg, Heisman, and Yost, included Percy Haughton of Harvard, Gilmour Dobie of the University of Washington, Seattle, and especially Knute Rockne of Notre Dame and Pop Warner.

Rockne achieved a celebrity status that surpassed that of any other coach in history, with the possible exception of Stagg. Rockne created little, but he was the most magnetic of all coaches, one of the smartest and wittiest. Becoming head coach at Notre Dame in 1918, he saw his team (which included George Gipp, who Rockne later said was

the greatest back Notre Dame ever had) win every game in 1919 and again in 1920. His fame became nationwide when his 1924 team, with its "Four Horsemen" backfield, won the national championship.

Knute Rockne's Notre Dame shift

Rockne credited Stagg as the originator of the shift installed at Notre Dame in 1914, in which the backs moved just before the snap of the ball from their T formation into a box alignment behind the left or right side of the line. A year later the ends also shifted out from the line. The Notre Dame shift lost its effectiveness with successive decrees of the rules committee to eliminate its momentum. In 1924 it was ruled that the team must come to an absolute stop and remain stationary "momentarily." In 1927 a pause of one second was imposed. In 1931 the pause had to be "at least one second," and after Rockne's death that year the shift vogue waned.

Tactical innovations. Contributing to the decline of the Notre Dame system was the rise in popularity of the wingback formations originated by Warner. One of the most creative minds in football and one of the most successful of all coaches in 44 years at Georgia, Cornell, Carlisle, Pittsburgh, Stanford, and Temple University (Philadelphia), Warner devised first a single wingback formation and then a double wingback (see Figure 8).

Football became increasingly complex as coaches devised new formations, plays, and defenses. The modern T formation—employing principles worked out by Stagg, including the stand-up position of the quarterback behind centre, quarterback fakes in which the quarterback pretends to hand the ball to one back and then gives it to another or keeps it himself, and the man in motion—was the creation in the 1930s of George Halas and his Chicago Bears coaching staff of the professional National Football League and Clark Shaughnessy, who had succeeded Stagg at the University of Chicago. The Bears' 73–0 defeat of the Washington Redskins in the NFL championship game of 1940 and the overwhelming success that same year of Stanford University, then coached by Shaughnessy, started the trend toward reviving the formation. The T has not been displaced since then, although many variations have been introduced. In 1941 Don Faurot at the University of Missouri introduced the split T, with wider line spacing (splits) and a sliding, ball-carrying quarterback rather than a spinning ball feeder, with options of keeping, pitching out, and passing. Another variation was a so-called wing T, a combination of the T and the single wing.

The split T

During the late 1950s and 1960s, the University of Delaware wing T, which had been developed by Dave Nelson and popularized by Forest Evashevski at the University of Iowa, was the dominant offensive formation. The Delaware wing T followed other wing T formations of the post-World War II era. Ray Eliot at Illinois, Lou Little at Columbia, Aldo ("Buff") Donelli at Boston University, Clarence ("Biggie") Munn at Michigan State, and Charles ("Rip") Engle at Pennsylvania State had variations of the wing T formation. The wishbone T, I formation, wing T, veer, "shotgun," and various flanker formations came into vogue thereafter (see below *Strategy and tactics*).

Teams, players, and scandals. Football had become a national mania and large-scale business enterprise in the United States by the 1920s. Highly publicized football heroes such as the Four Horsemen of Notre Dame and Harold ("Red") Grange of Illinois won new football followers the country over. Attendance mounted, and huge crowds became commonplace as new and larger stadiums went up across the land. As money poured in and more and more colleges assumed heavy obligations in expanding their athletic plants, winning teams were needed to draw income to meet mounting budgets. The scramble to obtain the best high-school and preparatory-school talent led to unscrupulous recruiting practices by some schools. Financial inducements were offered in violation of amateur regulations, and educational requirements were let down to get good players into college.

Recruiting practices

The college football world was rocked in 1929 when a *Carnegie Foundation Bulletin* exposed the extent of unethical practices and named some of the most prestigious universities. Respectable colleges took corrective measures, and for a while it seemed football might be limited to intramural competition. But the intercollegiate game had too strong a hold in society to be downgraded more than temporarily. Despite crackdowns by individual colleges and the NCAA, such practices continued. (D.M.Ne./A.D.)

The money game

The problem grew more critical when college football moved into the multimillion-dollar category during the 1960s and '70s. Attendance for college games increased to more than 35,000,000 in 1980. Huge stadiums were built and big ones were enlarged; Michigan Stadium, for example, seats well over 103,000. But it was television, more than anything else, that turned the big-time sport into a gigantic, million-dollar enterprise. Major colleges budgeted more than $1,000,000 a year for football and took in millions of dollars in television revenue and gate receipts. By the late 1980s television networks were paying more than $46,000,000 a year for rights to college games. The regulation of television rights to college games led to court battles between the NCAA and individual colleges and the NCAA lost control of television rights for its members. Increasing numbers of colleges were punished by the NCAA for recruiting violations, and academic scandals arose as some colleges changed athletes' transcripts to meet eligibility requirements.

All-America teams. In 1889 an all-star college football team was picked, and it has been an annual custom since. Walter Camp's All-America teams appeared annually in *Collier's Weekly* for many years, but it has been established that it was Caspar Whitney who picked the first teams, probably in consultation with Camp. The first All-America team that Camp picked was in 1897. Camp died in 1925, and from that year through 1947 Grantland Rice picked the teams. In 1925 the Associated Press started selecting a team, and the other two major news-gathering agencies, the United Press and the International News Service (which merged in 1958), came out with teams. Other magazines and newspapers have printed their own selections over the years. None has been looked upon as official to the degree that Camp's and Rice's were.

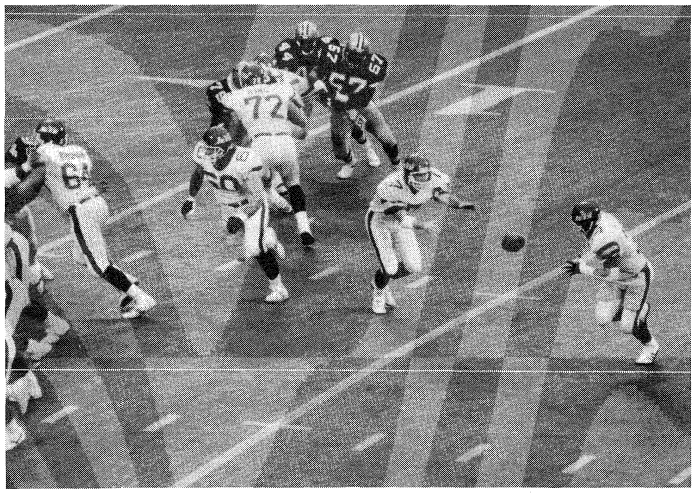
Postseason games. The idea of the postseason, or "bowl," game was launched at Pasadena, Calif., on Jan. 1, 1902, when the Tournament of Roses Committee of that city arranged the first Rose Bowl game between Michigan and Stanford. Michigan's "point-a-minute" team, coached by Fielding Yost, won 49–0. The next Rose Bowl was not played until 1916, but since then it has been held every New Year's Day. In the mid-1930s Miami, New Orleans, Dallas, and El Paso, Texas, started the Orange, Sugar, Cotton, and Sun bowls, respectively. The number of bowl games has continued to grow since that time.

The Rose Bowl

The bowls began contracting with college conferences to have the league champions play against an invited opposing team each year. The Rose Bowl has pitted the Big Ten Conference champion against the Pacific Eight (later the Pacific Ten) Conference champion since 1947. The Sugar Bowl has the Southeastern Conference champion as one of its teams; the Orange Bowl has the Big Eight Conference winner; and the Cotton Bowl is hosted by the Southwest Conference champion.

Professional football. *Early history.* The first professional football game to be officially recognized as such was played in the township of Latrobe, Pa., on Aug. 31, 1895, when a team from Latrobe beat one from Jeannette, 10 miles away, by the score of 12–0. During the next few years other professional teams appeared. In Pittsburgh the Allegheny Athletic Club was created, and its rosters bore the names of the most famous college players of the day. Upper New York state followed Pennsylvania into professional football soon after the start at Latrobe. There were teams in Buffalo, Syracuse, Watertown, Auburn, Corinth, Clayton, Oswego, Alexandria Bay, and Ogdensburg.

In 1902 Connie Mack of baseball fame organized a football team that he named the Philadelphia Athletics. In the lineup was George ("Rube") Waddell, the pitcher of Mack's baseball team. Mack claimed the "championship of the world" after his club vanquished a squad representing Pittsburgh, which had Christy Mathewson, another baseball pitcher, as its fullback.



Zuppke's idea

The combination of World War I, a chance remark by Robert Zuppke, veteran coach of the University of Illi-

nois, and the enthusiasm of George Halas in Chicago for football combined in 1918 to spark the beginning of the modern major league game. Zuppke, at the postseason banquet of his 1917 Illinois team (on which Halas had been an outstanding end), said that it was unfortunate that football players at the time when they were just beginning to learn something about the game were graduated from college and played it no more. A few weeks later, reporting for training at Great Lakes Naval Training Station in Illinois, Halas found several former college stars eager to continue playing.

League organization. Eleven league franchises were sold at $100 each when the American Professional Football Association was officially formed on Sept. 17, 1920. Jim Thorpe was elected president, and George Halas purchased a franchise for the Staley Starch Company of Decatur, Ill., which had recently made him athletic director. The first 11 teams in the league were the Canton (Ohio) Bulldogs (Thorpe's team); Cleveland Indians; Dayton (Ohio) Tigers; Chicago Cardinals; Decatur Staleys, who became the Chicago Bears in 1922; and teams in Akron, Ohio; Massillon, Ohio; Rochester, N.Y.; Rock Island, Ill.; Muncie, Ind.; and Hammond, Ind.

The league had a perilous beginning that fall. Few games were played, and there seemed little chance that the league would survive. In April 1921, however, the league elected Joe Carr, an experienced promoter, as its new president. Carr created an immediate realignment of teams. Massillon, Muncie, and Hammond dropped out; Green Bay, Wis.; Buffalo; Detroit; Columbus, Ohio; and Cincinnati, Ohio, came in; and a full schedule was completed, with the Chicago Bears winning more games than any other team. The name was changed to the National Football League in 1922, with Carr continuing as president until his death in 1939. In 1933 the NFL played in two divisions, with an annual championship game.

Red Grange joins the Chicago Bears

The first trend toward prosperity began in 1925, when Red Grange left the University of Illinois to play with the Chicago Bears. Grange was the biggest name in the sports world at that time, and he was the spark that professional football needed. Grange and the Bears then went on a coast-to-coast tour that sowed the seeds of interest in the sport. Grange established himself as one of the all-time stars of the NFL before he retired in 1935.

The modern era. With considerable opposition from NFL owners, a rival league, the All America Football Conference began play in 1946 with eight teams representing Brooklyn (N.Y.), Buffalo, Chicago, Cleveland, Los Angeles, Miami (replaced by Baltimore the following year), New York City, and San Francisco. Under an agreement between the leagues, Baltimore, San Francisco, and Cleveland moved their teams into the NFL in 1950, and the balance of the AAFC players were pooled and drafted by the 13 clubs in the NFL. After one season the NFL was reorganized into 12 clubs: the New York Yanks, Chicago Bears, Chicago Cardinals, Cleveland Browns, Detroit Lions, Green Bay Packers, Los Angeles Rams, New York Giants, Philadelphia Eagles, Pittsburgh Steelers, San Francisco 49ers, and Washington Redskins. In 1952 the Yanks franchise moved to Dallas for one year, after which it was allowed to transfer to Baltimore.

Interest in the game was spurred by the introduction of unlimited substitution of players (1950), which led to specialization in player and coaching roles and a more polished game. There also developed a greater emphasis on passing. The 1958 championship between Baltimore and New York, a nationally televised game and the first to be decided in overtime, is often referred to as the turning point in the popularity of the professional game.

Bert Bell, veteran player, coach, and owner, was commissioner of the league from 1946 until his death in 1959. Pete Rozelle, general manager of the Los Angeles Rams, was named as Bell's successor in 1960. In that year the Cardinals moved to St. Louis, and a new team, the Dallas Cowboys, was added to the league. The Minnesota Vikings (Minneapolis–St. Paul) were added to the league in 1961, the Atlanta Falcons in 1966, and the New Orleans Saints in 1967.

Rozelle succeeds Bell

In 1959 another rival, the American Football League (AFL), was organized, with Lamar Hunt the first president and Joe Foss serving as its first commissioner. Initially, in 1960, the teams were the Boston (later New England) Patriots, Buffalo Bills, Denver Broncos, Houston Oilers, New York Titans (from 1963, Jets), Oakland Raiders, Dallas, and Los Angeles; the Los Angeles franchise was transferred to the San Diego Chargers in 1961, and the Dallas franchise to the Kansas City Chiefs in 1963. The Miami Dolphins were added to the league in 1966.

A merger of the two leagues was announced in 1966, effective in 1970. By the start of the 1967 season, the two leagues had begun preseason interleague play, and a total of 26 cities from coast to coast were represented. In January 1970 the new National Football League began and consisted of two conferences—the National Conference and the American Conference, each with three divisions. Rozelle remained as commissioner. The league was increased to 28 teams in 1976 with the addition of the Seattle Seahawks and the Tampa Bay Buccaneers. In 1982 the Oakland franchise moved to Los Angeles, in 1984 the Baltimore Colts moved to Indianapolis, Ind., and in 1988 the St. Louis Cardinals moved to Phoenix, Ariz.

NFL expansion

The teams were aligned as follows:

National Conference, Eastern Division: Dallas, New York Giants, Philadelphia, Phoenix, Washington, D.C. *Central Division:* Chicago, Detroit, Green Bay, Minnesota, Tampa Bay. *Western Division:* Atlanta, Los Angeles, New Orleans, San Francisco.

American Conference, Eastern Division: Buffalo, Indianapolis, Miami, New England, New York Jets. *Central Division:* Cincinnati, Cleveland, Houston, Pittsburgh. *Western Division:* Denver, Kansas City, Los Angeles, San Diego, Seattle.

The boom period. Interest in the merged leagues was immediate and universal. The Green Bay Packers, under coach Vince Lombardi, were the NFL champions, and they defeated the Kansas City Chiefs, the AFL champions, 35–10 in the first Super Bowl in January 1967 before 63,035 fans in the Los Angeles Coliseum. From then on, the Super Bowl became the biggest annual one-day sports event in the United States. Starting in 1970, when the merger was completed and the two leagues became one, a play-off system was developed in which eight teams played down to the final two for the Super Bowl game and the NFL championship. This was increased to 10 teams in 1978. (For NFL, AFL, and Super Bowl champions, see SPORTING RECORD in the *Micropædia.*)

Rozelle led the league through the days of merger and into the era of great wealth. When he took over as NFL commissioner in 1960, each of the fairly solid 13 franchises in the league was worth an average of $2,000,000. By the early 1980s, largely because of television contracts amounting to billions of dollars, each of the 28 franchises was estimated to be worth $40,000,000 and more.

Rozelle negotiated a contract for television rights in 1961 that was worth $4,650,000, and each of the 13 teams shared equally. In 1982 the NFL signed a five-year television contract for a total value of $2,000,000,000. Each of the 28 teams in the league would then earn an average of $14,000,000 a year before selling a single ticket.

As owners began reaping great profits, players began demanding a greater share of the income. Numerous strike threats came and went, and in the summer of 1970 there was a boycott of training camps by veteran players. This, too, was settled, with added money in the players' pension fund and insurance and other fringe benefits. But when the owners signed the television contract of 1982, the players demanded 55 percent of gross income as their share. The league owners refused, and a strike was called midway in the season of 1982. After eight weeks a settlement was reached. According to the terms of the settlement, each player's salary was increased significantly. The owners, however, won the battle against giving the players a fixed percentage of team income.

The mid-season players' strike

Despite these vicissitudes, fans turned out to fill stadiums across the nation and watched games on television by the millions. Magnificent new arenas were built, including ones with roofs—such as the Superdome in New Orleans, the Astrodome in Houston, the Kingdome in Seattle, and the Silverdome in Pontiac, Mich.—to house NFL teams.

The 1960s saw a greater emphasis on the refinement of defensive tactics against the pass. In the belief that the defenses had become too dominant, rules were amended in the 1970s to increase offensive production. The effect was immediate, and defensive coaches responded in the 1980s by utilizing a 3–4 formation; other formations and specialized players against the pass have continued to develop (see below *Other rule variations*).

Yet another rival of the NFL came into existence in 1982 with the formation of the 12-team United States Football League (USFL). The teams in the USFL were New Jersey, Philadelphia, Boston, and Washington, D.C., in the Atlantic Division; Chicago, Michigan, Tampa Bay, and Birmingham (Ala.) in the Central Division; and Arizona, Oakland, Los Angeles, and Denver in the Pacific Division. The league, in its first season in 1983, played its games in the spring and early summer, contrary to the traditional fall football season, and the owners signed a two-year, $20,000,000 television contract before the league staged its first game. The USFL went out of business after three seasons and sued the NFL for antitrust violations; it won the case but received only one dollar in damages.

PLAY OF THE GAME

Rules for college, professional, and high school football are fundamentally the same; the most notable differences are pointed out in the following discussion.

Field of play and equipment. U.S. football is played on a field measuring 100 yards (91 metres) in length from goal line to goal line, with an end zone 10 yards in depth behind each goal line, and 160 feet in width (Figure 7). Goalposts 23 feet 4 inches apart—18 feet 6 inches apart in the NFL—are erected on each end line, the limit of the end zone. A connecting crossbar is 10 feet above the ground. Parallel lines the width of the field are marked five yards apart between goal lines. An inbounds line the length of the field is marked 53 feet 4 inches inside each side line—70 feet 9 inches in the NFL.

The ball has the shape of a prolate spheroid. A leather case covers a rubber bladder inflated to the pressure of 12½ to 13½ pounds (0.78–0.94 kilograms per square centimetre). Its long axis measures 10⅞ to 11 7/16 inches (27.62 to 29.05 centimetres); its short circumference measures 20¾ to 21¼ inches; and its weight is from 14 to 15 ounces (400 to 425 grams). A rubber-covered ball may be used by NCAA and High School Federation teams.

The mandatory equipment for college and high school players includes head protectors, shoulder pads, hip pads, thigh guards, mouthguards, jerseys with numbers, and soft knee pads covered by pants. Other equipment, including shoes, knee braces, gloves, and injury pads, is worn but not required. The NFL has less stringent requirements for much mandatory equipment.

Principles of play. The number of players on a team (11) was established by rule in 1880, and until 1941 players were required to play offense and defense and participate in the kicking game. In 1945 the University of Michigan took advantage of the 1941 rule change, permitting unlimited substitution, for the first time and instituted platoon football, one of the game's most important innovations. Free substitution was banned in 1953, but subsequent rule changes allowed its return by 1965. Presently, the offensive, defensive, and kicking teams may each have 11 players, most of whom specialize in a particular position.

The free-substitution rule

Before the start of the game, the referee tosses a coin in the presence of the opposing captains after asking one of them to call heads or tails. The winner of the toss has the choice of goals, or kicking or receiving the first kickoff. The loser of the toss gets the choice at the start of the second half. In college football the winner of the toss may delay his choice until the second half.

Each team's objective is to score more points than its opponent, and the team with the most points at the end of the game is the winner. Points are usually scored by running the ball or receiving it from a pass above, on, or across the opponent's goal line for a touchdown (six points) or by kicking the ball from scrimmage by place kick or drop kick (a virtually obsolete technique) above the crossbar and between the uprights for a field goal (three points). A touchdown may also be scored when a loose ball is recovered in the opponent's end zone. If a play ends with the ball behind the defenders' goal line, and

the impetus that caused the ball to cross the goal line was generated by the defenders, it is a safety, and two points are awarded to the defenders; the team scored against then must make a free kick from their 20-yard line.

Each touchdown carries the privilege of trying for extra point(s), which is called the conversion, or try. The ball is put in play on the three-yard line in college and high school games and on the two-yard line for the professionals. If the ball is carried into the end zone by run or pass in college or high school football, two points are scored. A conversion by kick scores one point. In NCAA rules, a score by the defense is two points on the conversion play. A forfeited game is scored 1–0.

Timing

The ball is in play 60 minutes during a game divided into 15-minute quarters (12 minutes in high school). After the second quarter there is an intermission of 20 minutes in college and 15 minutes in professional and most high-school games. High schools have an additional three-minute warm-up period. After the first and third quarters, there is a one-minute interval while the teams change goals and the ball is relocated. Timeouts are taken during the game for a variety of reasons, causing games to last well beyond the hour's playing time. Televised games with commercial timeouts average around three hours.

Each half starts with a kickoff by place kick or drop kick from the kicking team's 35-yard line (40-yard line in high school play), with the receiving team behind a line 10 yards distant. A member of the receiving team attempts to catch the kicked ball or recover it and run it back as far as possible toward the kicking team's goal. The kicking team may recover the ball once it has gone at least 10 yards, and they may fall on a loose ball in the end zone for a touchdown. For a recovery by the kicking team, college and high school rules require the ball to touch a member of the receiving team before it reaches the end zone.

Following the kickoff, players line up in various offensive and defensive formations. When a scrimmage begins (with the snap of the ball), all players must be onside (*i.e.*, on the proper side of the ball), and the team in possession of the ball (the offense) must have at least seven players on the line of scrimmage. One player of the offensive side may be in motion, laterally or backward. Movement of defensive players is not restricted if they remain onside.

The team in possession of the ball gets a series of four scrimmage downs during which it must either advance the ball a minimum of 10 yards or forfeit possession to the defenders. Each down starts with the ball resting on the ground and the teams separated by a neutral zone the width of the ball's length. The centre snaps or passes the ball between his legs to a back who may run with or kick the ball or hand or pass it to a teammate who runs or passes. Opponents try to stop any advance toward their goal line by tackling the runner, batting down or intercepting passes in flight, or legally kicking the ball. Tackling is grasping the runner's body with the arms and putting him to the ground, pushing him out of bounds, knocking him down with a body block, or stopping his forward progress by any legal means. Each down ends when the ball becomes dead—as when the ball carrier is stopped or tackled, when a forward pass is incomplete, when the ball is carried or fumbled out of bounds, or when the opponents gain possession. If the attacking team has advanced the ball 10 yards from where the series started at the end of any down, it gets a new series of four downs with a new scrimmage line from which it must again gain 10 yards or relinquish the ball. If the attacking team has not advanced the ball at least 10 yards at the end of the fourth down, the ball is given to the defenders and they become the attacking team. Scrimmage downs, in successive series for one team or the other, continue until a series ends in a score, the opponents gain possession, or time expires. Another kickoff (free kick) follows a score, and the same pattern (free kick–run back–scrimmage–score–change of possession) is repeated until playing time for the half expires. After a touchdown (and try for extra points), or after a field goal, the former defenders receive the ensuing kickoff.

First down renewal

During any scrimmage down, but usually the fourth and last, the attacking team may surrender the ball to the defenders by kicking it. When this is done, the kicking team may not interfere with a defender's opportunity to catch the ball. A defender may gain added protection by signaling (arm aloft) for a fair catch. If he does so, he must stand fast after a catch, and the kicking team is prohibited from tackling him. A free kick after a fair catch is permitted in the NFL and high school rules.

Three methods of kicking the ball are permitted: the now-rarely-used drop kick, made by dropping the ball from the hands and kicking it as it touches the ground; a place kick, made by kicking the ball while it is resting on the ground or a tee (the ball may be steadied by another member of the team); and a punt, made by dropping the ball from the hands and kicking it before it strikes the ground.

Strategy and tactics. *Offense.* After the change from a scrum to a scrimmage and the establishment of a scrimmage line (1880) and the snapping of the ball with the hand, the T formation with a balanced line became the dominant offensive formation in the game. (See Figure 8 for offensive formations.) In the T formation, three of the backs (left halfback, fullback, and right halfback) line up from four to five yards from the ball and parallel to the line of scrimmage. The fourth back, the quarterback, is positioned directly behind the centre and parallel with the line of scrimmage. In the modern T, the quarterback handles all the snaps. Handing the ball from the snapper to the quarterback went out of style for several decades beginning in 1910 when the quarterback was no longer required by rule to handle the ball before it could be touched by another back, except on a kick. The direct pass from centre entered the game during this period, and the single wing, double wing, and Notre Dame box were in command until the post-World War II era. Rockne's Notre

The backs

Dame system, employing a balanced line and a backfield shift from the T to the box formation, was widely used in the 1920s and 1930s but was seldom employed after World War II. General Robert Neyland of Tennessee and Henry Russell ("Red") Sanders of UCLA were two of the most successful single-wing coaches in the early 1950s.

In the Notre Dame box the two forward backs (quarterback and wing back) lined up slightly more than one yard behind the line, with the two rear backs (tailback and fullback) about 4½ yards behind it. The ball was always passed to them by a direct pass from the centre.

The direct snap

Warner's single and double wing with a direct pass from centre, developed largely at Pittsburgh and Stanford, operated from an unbalanced line with two linemen on one side of the centre and four on the other and a widely deployed backfield. In the single-wing formation, the forward halfback (wingback) stands one yard behind the line and up to one yard outside the end. The quarterback (blocking back) is placed about a half yard to the rear of the wingback and about two yards inside the wingback position. The fullback (plunging back) is 1½ yards to the rear and one yard inside the quarterback. Single-wing teams shift to the left as well as the right. In the double-wing formation each of the halfbacks (wingbacks) stands one yard behind the line and one yard outside his end. The quarterback (blocking back) stands about two yards behind the strong side guard. The fullback (plunging back) is positioned from 3½ to 4½ yards behind the centre; he handles the ball first on most plays and is a key man in starting the delicately measured reverses. Warner's unbalanced single- and double-wing formations and variations of them remained popular beyond World War II.

The I formation and the wishbone are variations of the T formation. The I began as the invention of Coach C.M. Hollister of Northwestern University around 1900 with all four backs lined up in tandem behind the centre. The quarterback would hand to one of them, diving directly into the line or slightly off tackle. Coaches in recent years took one of the backs out of the tandem lineup behind the centre and placed him as a wide receiver or a wingback or slot-back blocker. This formation change developed the power-sweep toss and off-tackle plays complemented by play-action and drop-back passing attacks.

The wishbone and veer attacks, both triple-option systems featuring running attacks, became highly popular in the 1970s and have continued to have wide usage. The wishbone sets the backs in an inverted Y behind the centre. The quarterback may hand off or pretend to hand off to the fullback, keep the ball and pass or himself run (usually wide around the defensive line), or pitch to a halfback. The veer accomplishes a similar option technique with a split backfield.

The "shotgun"

The "shotgun," a variation of an earlier short-punt formation, has become extremely popular as a passing formation especially on third-down, long-yardage situations. Positioned five to seven yards behind the centre, the passer is able to observe the defensive formation and the type of pass defense. The formation also helps the blockers to protect the passer.

Defense. Defensive objectives vary with the down, distance to gain, score, time, and position of the ball on the field. The main objectives in order of importance by most standards are: (1) prevent a score; (2) acquire the ball by forcing a fumble, intercepting a pass, or stealing the ball; (3) prevent a first down; (4) consume time by giving up yardage but not scores; (5) score by interception, blocked punt, or stolen ball; (6) intimidate by hard tackling; (7) discourage the offense by confusing them; (8) limit the offense to as few plays as possible. Changing defenses from down to down requires a change of personnel. The Nickel Defense, using five defensive backs in obvious passing situations, is the most visible of defensive changes. All defenses are subject to the chess principle of meeting offensive strength with defensive strength, which requires defensive players to oppose an equal number of offensive players. (See Figure 8 for defensive formations.)

Unlike the offense, the defense may have as many or as few players on the line of scrimmage or in the secondary (the defensive backfield) as required to meet the defensive objective. Defensive linemen are players in three- or four-point stances (a low crouch with one or both hands touching the ground) on the line of scrimmage and positioned opposite offensive linemen or in seams between them. Linebackers, in a variety of spacings, stand from one to three yards behind the defensive linemen and outside the offensive formation, their number determined by the number of linemen and players in the secondary. The secondary players are generally positioned behind the linebackers but sometimes are on the line of scrimmage and may rush the passer. Players in the secondary are called safeties and cornerbacks. Each defensive scheme has a number of different pass coverages that are zone (covering a specific defensive area), man-to-man, and combination zone and man-to-man. There are variations of the zone defenses and man-to-man coverages.

Defensive formations

To accomplish their defensive objectives, coaches use a variety of defenses, and there have been 12 basic defenses in football history. Defenses change as rules are altered and the style of play swings through cycles. Before the development of the forward pass in 1906, the 7–3–1 was the common defense, and this was followed by the 7–1–2–1 (7 and a diamond) and 7–2–2 (7 and a box), which were effective until around 1930. The 6–2–2–1 appeared in the 1930s and still had adherents in the 1980s. Since World War II, defenses, called by various names, with seven-man lines, four-deep backs, and a variety of linebackers and pass coverages dominated all levels of football. Both six- and seven-man line defenses have been altered over the years to four- and five-man line defenses to meet particular offensive threats. The 3–4 defense is a popular defense against the pass.

Playing rules. U.S. football celebrated its playing-rules centennial in 1976 by commemorating the first meeting in Springfield, Mass., where eight college students assembled the original 61 rules. Although students started U.S. football, they have no voice on the NCAA rules committees today. Football has always been a sport with a relatively high risk of injury. As the sport developed, safety and injury prevention became the dominant playing-rules priority. All U.S. football was governed by the NCAA playing rules until a rash of serious injuries and fatalities prompted the National Federation of State High School Associations (NFSHSA) to write its own rules in 1932. The NFL followed suit in 1933 and 1934 and, like the high schools, used the NCAA rules as their basis. The NFSHSA and the small-college National Association of Intercollegiate Athletics (NAIA) joined forces in 1958 to form the National Rules Alliance. The alliance dissolved in 1977 and the small colleges adopted NCAA rules. Today there are three separate rules committees and codes: the NCAA, the NFL, and the NFSHSA.

Officials. The game is supervised by seven officials in the NFL, four to seven in the colleges, and as few as three in high school. All officiating crews have a referee with general oversight and control of the game, who is assisted by umpires, linesmen, field judges, back judges, line judges, and side judges. The referee is the sole authority for the score, and his decisions on rules and other matters pertaining to the game are final. The referee declares the ball ready for play and keeps track of the time between plays when it is not assigned to another official. He administers all penalties and, at the snap, is positioned behind and to the side of the offensive backfield. The umpire has jurisdiction over players' equipment and line play on both sides of the neutral zone, including noting any linemen illegally downfield. He is also responsible for the legality of the snap, counting offensive players, and determining the legality of passes and kicks relative to the neutral zone. He is positioned five to seven yards behind the defensive line. The linesman is responsible for the operation of the chain and down indicator outside the sideline and has jurisdiction over the neutral zone and scrimmage formation infractions. He keeps count of the downs and indicates forward progress of the ball on his side of the field. The line judge is responsible for actions in the neutral zone and scrimmage formation infractions. He indicates forward progress on his side of the field and instructs the auxiliary down-indicator operator. The

The referee

back judge counts the number of players on the defensive team, rules on long kicks and passes, and observes eligible receivers leaving the neutral zone. The field judge is responsible for timing the 25-second count and observing kicks, passes, and eligible receivers on his side of the field. He rules on the status of the ball in his area. The side judge observes eligible receivers, kicks, and passes on his side of the field and assists in counting defensive players.

In addition to their primary duties, all officials have a joint responsibility for calling fouls (*i.e.,* infractions of the rules). Each one carries a marker, which he drops when he calls a foul, and a whistle to signal that the ball is dead. At the end of the play, he reports the infraction to the referee, who enforces the prescribed penalty and uses one or more of the 47 hand signals. The officiating crew has assistants on the field and in the press box.

Fouls and penalties. Penalties may be the loss of five, 10, or 15 yards or half the distance to the goal line; loss of down (for a foul committed by the offensive team); automatic first down (against the defense); the award of the ball to the offended team at the spot of the foul; and disqualifications. Distance penalties may be combined with loss of down, automatic first down, and disqualification. The enforcement spot of the penalty depends on whether the foul occurred during a pass, kick, or run. In NCAA rules, violations are fouls without a distance penalty and the offending teams are charged a time out. Violations are charged for improper equipment, crowd noise, and coaches' conference violations.

The most frequent penalties

In the NCAA, NFL, and NFSHSA, offensive illegal procedure, false starts, offensive holding, offside and encroachment, clipping, delay of game, and illegal-motion fouls are the most frequently called penalties. Procedure fouls have been the most-penalized infractions since the inception of the game and constitute about 65 percent of all fouls. Personal fouls—roughing the passer, kicker, or holder, late hits, striking a blow to the head, spearing, ramming, butting, and other contact acts—are automatic first downs when inflicted by the defense. Loss of down, the severest of offensive penalties, also includes a yardage penalty for pass interference, illegally kicking, batting, handing the ball, or illegally throwing or touching a forward pass. Illegally throwing a backward pass out of bounds is also a loss of down and a five-yard penalty. Penalties may not exceed half the distance from the enforcement spot to the offending team's goal line. The most controversial fouls, because of the difficulty of the judgments called for, are defensive pass interference and offensive holding.

Other rule variations. Some of the main differences between the NCAA, NFL, and NFSHSA rules not mentioned above are as follows:

NFL divisional play-offs or championships cannot end in a tie. If the score is tied after the regulation 60 minutes, additional periods of 15 minutes each are played. The first team to score is declared the winner, and the game ends immediately. Only one period of overtime is allowed after regular season games, which may thus eventually end in a tie.

Overtime periods

High schools and NCAA teams may use kicking tees for field-goal attempts.

NCAA defensive players may not advance a recovered fumble or backward pass; an NFL defense may advance a recovered fumble; and high schools allow any player to advance a fumble or backward pass.

The NCAA and NFL permit one forward pass during a down; the high schools, two.

The NCAA and high schools allow a team 25 seconds to put the ball in play after it is declared ready for play; the NFL permits 30 seconds.

The NFL has an official time out two minutes before each half ends.

The NFL has a spot penalty (the ball is advanced to the spot where the foul occurred) for defensive pass interference; the NCAA has a spot penalty if the foul occurs less than 15 yards downfield and a 15-yard penalty from the previous spot if the infraction occurs more than 15 yards downfield. High schools always have the 15-yard penalty, and both NCAA and high schools award an automatic first down.

The NFL and high schools permit a free kick for a field goal after a fair catch.

The NCAA and high schools declare the ball carrier down when any part of the body, other than the hand or foot, touches the ground. In the NFL a ball carrier who falls can get up and run again unless he was first in contact with an opponent.

The NFL declares the ball dead when the quarterback is in the grasp of a tackler (he need not be put to the ground).

The NFL allows a restricted defensive checking of pass receivers.

The NFL requires that a pass receiver touch both feet to the ground inbounds for a pass to be complete; the NCAA and high schools require one foot.

The NFL uses instant videotape replays to determine some questionable calls, and an official's decision on the field may be changed by an official in the press box.

The NFL has fewer restrictions on blocking below the waist than the NCAA, and high schools prohibit it.

Canadian football

HISTORY

The early years. Football in the form of rugby was taken to Canada by British immigrants not long after William Webb Ellis' historic run with a soccer ball in 1823 on the playing fields of Rugby School. The first account of rugby football in Canada dates to 1862 when British regiments in Montreal were playing the game on an informal basis, and the formation of the Montreal Football Club in 1868 gave the sport an official Canadian birth date.

In the United States at that time, the schools were still playing according to the Princeton Rules, a game that more closely resembled soccer. Soccer might even have become the great U.S. game if Harvard had not broken away and started playing a rugbylike game under Boston Rules, which isolated them from their Ivy League brethren at Yale, Columbia, Princeton, and Rutgers. Harvard's search for opponents brought them into competition with Montreal's McGill University.

The schools first met in Cambridge, Mass., on May 14 and 15, 1874, for two games that had a profound effect on the development of football on both sides of the border. Because McGill only brought 11 of their usual 15 players, Harvard players decided that they preferred this innovation, and 11 eventually became the standard number of a U.S. football team. The Canadians, however, returned home and reverted to the English-style game with 15 players on a side. Today, a Canadian team has 12 men on a side, a move suggested as early as 1900 but not widely used until 1912.

The McGill–Harvard matches

The colleges did not set the early pace in Canadian football as they did in the United States. Instead it was the clubs, such as the Toronto Argonaut Rowing Club, the Hamilton Amateur Athletic Association, and other groups in Guelph, Stratford, London, and Port Hope, that banded together to form the first league.

In 1882 the Ontario Rugby Football Union was formed, immediately followed by the Quebec Rugby Football Union. These groups and others combined in a loose confederation under the name of the Canadian Rugby Football Union, later shortened to Canadian Rugby Union. The colleges formed the Intercollegiate Rugby Football Union in 1898. In its formative years Canadian football was a player's game with no stadiums, admission charges, or other forms of commercialization. By 1900 railroads were opening the west and the game was played over most of Canada's 3,000-mile expanse. Still, when Governor General Lord Earl Grey offered a cup for the amateur football championship of Canada in 1910, Ontario and Quebec were playing the best football by far, with teams in other regions more or less overlooked. Despite its amateur beginning, competition for the Grey Cup, as Lord Grey's trophy came to be known, has, since 1954, been challenged exclusively by teams that now make up the professional Canadian Football League.

Grey Cup competition

Development of the modern game. As with many Canadian institutions, the game of football felt a strong U.S.

influence. One of the earliest and most prominent came in the person of Frank ("Shag") Shaughnessy, a former Notre Dame player and coach who in 1912 took over as football coach at McGill. He brought motion into the backfield, created the idea of a secondary on defense, and generally kept one step ahead of those who copied his moves. Within 10 years he had completely transformed the Canadian game.

In the 1930s several U.S. college stars went north in search of jobs in cities like Winnipeg, Regina, Calgary, and Edmonton. Among them was Fritz Hanson, a running back from North Dakota State University, who in 1935 teamed with seven other Americans to lead Winnipeg through an undefeated season in the west. Winnipeg fans contributed a then unheard-of $7,500 to send the club east, where they beat a powerful Hamilton team 18–12 and brought the west its first Grey Cup. The eastern teams responded with a rule that only Americans living in town on January 1 could play during that year. When the Regina (now Saskatchewan) Roughriders won the western championship in 1936 without adhering to the rule, they were ruled ineligible for Grey Cup play. Sarnia beat Ottawa 26–20 for the cup that year amid howls of western protest.

After the 1936 controversy, the colleges withdrew from Grey Cup competition altogether. Professionalism had been increasing in the game to that point, and professional–amateur interplay became common. By the 1950s, however, it was obvious that the days of amateur–professional play were numbered, as the professional teams of the Eastern Big Four (Toronto, Hamilton, Ottawa, Montreal) and the Western Interprovincial Football Union (Winnipeg, Saskatchewan, Calgary, Edmonton, Vancouver) dominated competition. (In 1987 Montreal dropped out and Winnipeg moved into the Eastern Division.) In 1956 the two groups joined the Canadian Football Council (later the Canadian Football League) and the amateurs were ruled out of Grey Cup play.

A major impetus in the turn of professionalism was the 1948 Calgary team, a powerhouse built around coach Les Lear, quarterback Keith Spaith, receiver Woody Strode, and Chuck Anderson, all from U.S. professional teams. After the team won in the west, a large proportion of the population of the city boarded special trains for Toronto, where the fans staged a wild two-day celebration and the team won the Grey Cup, beating Ottawa 12–7. After this, every city in the country felt it had to put on a better show than Calgary and hire U.S. players to compete on the football field. The league limit on imports per team was gradually increased from six to 16, with the remaining 20 nonimports. Players in the CFL have, since 1965, been classified as imports or nonimports based on football training rather than place of birth or citizenship.

Use of U.S. players

Canadian teams found themselves competing with U.S. professional teams for top U.S. college players. At one point, in 1951 and 1953, Winnipeg raided the NFL and signed defensive tackle Dick Huffman of Los Angeles and end Harry ("Bud") Grant of Philadelphia, respectively, while in 1954 Calgary signed quarterback Eddie LeBaron of Washington, end Gene Brito of Washington, and defensive end Ed Henke of San Francisco. In 1955 Harry Sonshine did the same type of raiding for Toronto. Dozens of U.S. players joined the Canadian league, which at the time offered higher salaries than the NFL. With the new players came a mercurial rise in status for the Grey Cup competition, which became a week-long festival and the premier sporting event in the country.

The 1960s were sobering years, as the rivalry between the NFL and the AFL priced the Canadians out of the top talent market. Merger of the two U.S. leagues in 1970 restored a degree of normalcy.

PLAY OF THE GAME

Although Canadian football stems from English rugby, modern rules changes have brought it closer and closer to U.S. football. The playing field is larger, being 110 yards (100 metres) long and 65 yards (59.4 metres) wide. The end zones are 20 yards (18.6 metres) deep. The wide field encourages lateral passing, and the deep end zones, forward passing for touchdowns. There are 12 men on a team. The extra man is invariably used in the backfield or as a wide receiver on offense and as a back on defense. The other positions are the same as those in U.S. football and have the same names.

A team has only three downs in which to make a first down in the Canadian game. Teams must try for the big gain, which makes the play more open than in U.S. football. To offset the lack of a down, defensive linemen must be one yard away from the ball when they take their stance. Also, all offensive backs may be in motion before the ball is snapped. Blocking is unlimited on rushing plays and is permitted downfield after a pass has been completed. Blocking above the waist is allowed only on punt returns, and a kicked ball still in bounds must be played; tacklers, however, cannot come within five yards of the safety back fielding the punt until he has touched the ball. One point is scored if the team in possession kicks the ball over the defending team's goal line and the defending team fails to return the ball out of the goal area, 20 yards beyond the goal line, or if the defending team's safety back is tackled or run out of bounds in his own end zone or he chooses to concede the point after receiving a kick.

After scoring a touchdown, the scoring team may choose to kick for a one-point convert (conversion in U.S. football) or, scrimmaging from the five-yard line, to attempt a two-point convert by either running or passing the ball over the goal line. The defending team on all convert plays can score two points if, by blocking a one-point convert attempt and recovering the ball, or intercepting a pass, or recovering a fumbled ball on all convert attempts, it returns the ball over the other team's goal line.

Other scoring is exactly the same as that of the U.S. professional game. Offensive and defensive formations are also similar to those in U.S. football. (D.Gi./J.F.I.)

Rugby

Rugby, also known as rugger, is a football game played with an oval ball by two teams of 15 or 13 players each, its distinctive features being: (1) players may use their hands and catch, throw, or run with the ball in addition to maneuvering it with their feet as in association football (soccer); and (2) the scrum, or scrummage, a method of putting the ball in play from a set formation in which eight men on each team—six in a 13-per-side game—form a closely packed group including two front rows of three men each, the ball being thrown onto the ground between them and each team trying to get possession. Although the ball may be kicked or carried or passed from player to player by hand or foot, it may not be passed forward. Players running with the ball inevitably caused tackling to become a part of the game. A tackle occurs when, depending on the form of rugby being played, a player carrying the ball is held by one or more opponents so that he is brought to the ground or the ball touches the ground, or he is unable to free himself without delay and is unable to continue play. Scoring in the game is achieved by touching the ball down in the opponents' goal area behind their goal line (a try) and by kicking the ball over the crossbar between the opponents' goalposts (a goal).

Running and tackling

There are two principal types of rugby football: Rugby Union, which is the 15-a-side amateur game; and Rugby League, a 13-a-side partly professional game. The chief differences between the two are described under *Rugby League* below.

HISTORY

Rugby Union. *Origins.* According to tradition, rugby began in 1823, when, during a game of football at Rugby School, William Webb Ellis picked up the ball and ran with it. The run was a clear violation of the rules of the game that later came to be called association football, or soccer; but the illegality proved popular and led to the game of rugby, the primarily ball-handling game, as distinct from soccer, the primarily kicking game. More exact historians date the origin of rugby to about 1838–39 and identify the dauntless runner as one Mackie. In the early 1840s it became accepted that a player could "run-in," that is, catch a ball on the rebound and, if none

of his teammates was ahead of him, carry the ball across the goal line and touch it down. In 1846 rules of rugby were published at the school. From 1840 to 1860 many varieties of football were played with rules varying from school to school and from club to club, in some cases mixing soccer and rugby. In 1863 the Football Association (FA) was formed in London, and after a futile attempt to reconcile the rules to accommodate the two games, rugby was left outside the FA.

In 1871 the Rugby Football Union (RFU) was formed as the English governing body, and the first match between England and Scotland was played. The Scottish Football Union was founded in 1873 (from 1924 it was called the Scottish Rugby Union). The game in both England and Scotland had developed mainly at the public (private) schools. In Ireland a club had been organized at Trinity College in 1865 and others followed. The Irish Football Union and a rival North of Ireland Football Union were formed in 1874. The two merged as the Irish Rugby Football Union in 1879. The Welsh Rugby Union was formed in 1881, and the organization of what came to be called the home unions was complete.

Rugby abroad. Soldiers, businessmen, engineers, diplomats, and students carried rugby to the countries of the British Empire. The Southern Rugby Football Union (later called the Australian Rugby Football Union) was founded in 1875. In that year rugby was first played in southern Africa at Cape Town. British regiments helped found a club at King William's Town in 1878. The Kimberley diamond discovery spread the game into that region (1883–86), and rugby was being played in the Johannesburg and Pretoria areas by 1888. The Western Province formed a union in 1883; the South African Rugby Football Board was established in 1889. The first match in New Zealand was played at Nelson in 1870, and by 1890 there were about 700 clubs organized in various provincial unions. The New Zealand Football Union was founded in 1892. Australia, South Africa, and New Zealand, particularly the last two, remained strongholds of the game.

Australian rugby

In 1882 unions were formed in Ontario and Quebec that soon affiliated with the Canadian Rugby Union. The original game was played through World War II in the two provinces, but a modified form of it arose and came to be called Canadian football. In the Maritime Provinces and British Columbia the rugby game persisted. Intercollegiate competition began in 1898, although in 1874 McGill University, playing an essentially rugby game, had two matches with Harvard University in the United States, playing an essentially soccer game. This event was important in the development of U.S. football.

Influence in Canada

British businessmen, students, and foreign-service personnel introduced the game to Europe from the 1870s, particularly in the French cities of Le Havre, Nantes, Bordeaux, and Paris. In France the game was governed by the Union des Sociétés Françaises de Sports Athlétiques, a multisports group, from 1887, and from 1920 by the Fédération Française de Rugby, with which 173 clubs were affiliated (increased to 400 in the 1980s). Romanian students at the University of Paris took the game home with them and formed clubs that at first were affiliated with a multisports organization as in France. The Federatia Romana de Rugby was founded in 1931. Just as Australia, South Africa, and New Zealand became rugby strongholds, so did France and, to a lesser extent, Romania.

English engineers introduced the game to Argentina in the 1880s, and the Argentine Rugby Union was founded in 1899. Soldiers took the game to Fiji in the mid-1880s; the Fiji Rugby Union was formed in 1913. A Japanese student who had learned the game at Cambridge University took it home with him in 1899, and by the late 1980s Japan had more than 80,000 players representing schools, universities, and factories.

In the United States and Canada, rugby competed with association football in a situation like that earlier in Great Britain, where clubs played by their own rules and occasionally combined elements of both games. Although U.S. football had largely supplanted both soccer and rugby by late in the 19th century, rugby enjoyed a revival from 1905 on the Pacific coast after U.S. football was banned there in the aftermath of a public furor over violence and player deaths and injuries. Rugby remained popular there after U.S. football had been restored to its preeminent position. West coast players largely made up the teams that won at the 1920 and 1924 Olympic Games, after which rugby was dropped as an Olympic sport. In the late 1920s rugby began to be played in the New York area, and it soon spread to such eastern universities as Yale, Princeton, and Harvard, which formed the Eastern Rugby Union. English teams, notably Cambridge University, visited during the 1930s. During World War II rugby largely disappeared, but it was revived in New York in the early 1950s, as was the collegiate game.

On the centenary of the RFU in 1971, 50 countries sent representatives to the Centenary Congress at Cambridge. At that time, England had 1,600 clubs, with more than 100,000 regular players. Japan had 60,000 players; Fiji, 12,000; and Romania, 6,500. The United States of America Rugby Association was formed in 1975, including the Eastern, Midwestern, Pacific Coast, and Western unions and involving 1,000 clubs and 50,000 players. In Canada, Rugby Union was particularly strong in British Columbia. Across Canada during the 1970s, rugby clubs increased from 100 to nearly 200 and players from 5,000 to 10,000, and they continued to grow thereafter.

Growth in North America

Two significant schisms occurred in the history of rugby. First, in 1895, 22 northern England clubs resigned from the RFU and formed the Rugby League. The dissident clubs had asked for "broken time," compensation for players who lost time from work while playing rugby. Second, allegations of professionalism in French rugby led to a breaking off of competition between the United Kingdom and France (1931–39); play was resumed in 1947.

Development of Rugby League. The Northern Football Union, comprising the teams that had seceded from the RFU in 1895, was called the Rugby Football League from the 1920s, and the breakaway game was thereafter referred to as Rugby League. Rugby League professionals are different from other sports professionals in that they do not devote full time to the game but hold other jobs. They are paid a fee for matches. (Differences in rules and play between Rugby Union and League are discussed below under *Play of the game.*)

Development of game. Although it has been played in other parts of the British Isles, such as southern Wales and the London area, the professional Rugby League game has established a firm foothold in Britain only in the three northern counties of Yorkshire, Lancashire, and Cumbria. An amateur branch of the game has, however, spread throughout Britain since its organization was taken over by the British Amateur Rugby League Association in 1973. At that date there were 150 amateur league clubs; by 1987 there were more than 800 clubs with some 20,000 players. It is played in nearly 40 universities.

The League game has also taken firm root in France, Australia, New Zealand, and Papua New Guinea. Like Rugby Union, the League game in France is largely confined to the southern part of the country, and it has flourished on a strictly competitive basis. In Australia the main centres of the game are Sydney and Brisbane, though it is widely played in cities and towns throughout the country and has a larger following than has Rugby Union. In New Zealand the game is less firmly established than Rugby Union, but it is played in most cities and big towns and is notably strong in Auckland and Wellington.

Rugby League strongholds

As a partly professional game, requiring a steady intake of money from gate receipts, Rugby League has been ahead of Rugby Union in developing along crowd-pleasing lines. The reduction of a team from 15 to 13 players, for instance, left the field less cluttered and so more suitable for attractive open play. Rugby League was also ahead of Rugby Union in introducing laws to curb the stagnation of repeated kicks over the touchline.

Organization and tournaments. *Rugby Union.* That rugby was predominantly a British and Commonwealth game is shown by the fact that the International Rugby Football Board, the rule-making body established in 1886, had only English (six) and Scottish, Irish, and Welsh (two each) members at its founding in 1886. The number of

English members was reduced to four in 1911 and to two in 1948, when New Zealand, South Africa, and Australia were admitted with one member each. In 1958 all were given two members. Although France played its first international matches (against New Zealand and England) in 1906, it was not admitted to the board until the late 1970s. It was not until the mid-1980s that the scope of the board was widened by the creation of associate member countries, which, however, were not accorded voting rights.

Meanwhile in 1934 the Fédération Internationale de Rugby Amateur (FIRA) was founded with Germany, France, The Netherlands, Italy, Portugal, Romania, Sweden, Czechoslovakia, and Catalonia as members. The federation later expanded to include other European and Mediterranean countries. All FIRA matches were to be played under International Board rules. Thus, unlike other sports, Rugby Union has two international bodies.

Play variation among countries

The kinds of competition vary among different rugby countries. From the beginning in England, Scotland, Ireland, and Wales, club competition consisted mainly of friendly matches. County cup competition from the late 1880s involved an elimination (knockout) tournament, not league play. The same was true of university competition. National club competition came only in the 1970s.

Elsewhere club rugby was almost universally based on the league system, often with cup competitions added. Such was the case in New Zealand from the early days, so that interclub leagues came to span a range of 15 grades of players from those for small boys up to the senior clubs. Interprovincial competition began in 1902 with play for the Ranfurly Shield, given by the Earl of Ranfurly, who was then governor general. Play for the shield is by challenge. South Africa, too, has leagues for clubs and a national competition among provincial teams for the Currie Cup, given in 1891 by Sir Donald Currie to the British team about to tour South Africa, for presentation to the best South African team. Ultimately the cup went to the South African Board as a trophy.

The highest level of international competition for Rugby Union teams is the World Cup, played for the William Webb Ellis Trophy. The World Cup was inaugurated in 1987 and hosted jointly by New Zealand and Australia, with the final in Auckland. Sixteen countries took part, by invitation. The eight International Board countries—minus South Africa because of its government's apartheid (racial segregation) policy—were joined by Argentina, Romania, Fiji, Tonga, Japan, the United States, Canada, Italy, and Zimbabwe.

The highest level of international rugby before the staging of the first World Cup was the Test series—two or more games between national teams. Such competition began between New Zealand and Australia in 1894 and continued under firm Test conditions from 1903. South African and British Test matches began in 1891. In 1888 a British team toured New Zealand and Australia, and its successors continued to do so regularly. New Zealand first played in Great Britain in 1888–89 and 1905–06, and South Africa did so in 1906–07 and 1912–13. Such tours continued except in the war years. In the 1920s New Zealand, South Africa, and Australia toured regularly in each other's countries, and by mid-century New Zealand and South African matches were recognized as unofficial world matches. In 1967, however, the South African policy of apartheid led to postponement of a tour by South Africa because the New Zealand team included Maoris. New Zealand, with Maori players, did tour South Africa in 1970. A South African tour in Great Britain in 1969–70 aroused protests against apartheid, but the matches were played. National rugby unions did not ostracize South Africa because of the apartheid policy as did other national sports organizations. In 1973 the New Zealand Rugby Union protested its government's refusal to let South Africa tour there. South Africa did tour New Zealand in 1981.

Political involvement

International competition in France began when New Zealand toured there in the 1905–06 season, and England first met France later in the same season. France played in the home unions competition in 1909–10 but was not truly competitive until after World War II. The French made their first overseas tour in 1958, to South Africa, where they became the first visiting national team to win since a British team did so in 1896. France played Romania regularly from 1924; in their first match after World War II, in 1957 at Bucharest, the crowd numbered 110,000, the largest attendance at any rugby game up to that time.

In the last quarter of the 20th century, touring continued to be popular. South America (usually mostly Argentines) became a new force, even beating South Africa. The troubles of the latter on tour continued, not from national unions or clubs but from segments of the public, with matches in the United States canceled or played clandestinely after a New Zealand tour had been violently protested during play. Romania rose in stature as a touring team. (For records of Rugby Union international competition, see SPORTING RECORD in the *Micropædia.*)

Rugby League. Although Rugby League is played at strength in no more than four countries, the national teams of these four, Great Britain, France, Australia, and New Zealand, played a World Cup tournament from 1954 to 1972 under the governancy of the Rugby International Board (founded 1946). There were regular tours somewhat after the manner of Rugby Union tours, by Australia, for example, in Great Britain and France and by Great Britain in Australia and New Zealand. The French toured Australia and New Zealand, and the New Zealanders toured in Great Britain and France.

In less far-ranging international encounters, Great Britain settled into a pattern of playing France at home and away each season, and Australia had more or less regular matches against New Zealand. Matches between Australia and New Zealand were for the Trans-Tasman Cup, which was retained by the one country until beaten in a Test series by the other. A national team, though less regularly, represented Wales. (For records of Rugby League World Cup competition and Test matches, see SPORTING RECORD in the *Micropædia.*)

In 1975 international Test-match championships involving England, France, Australia, and New Zealand replaced the World Cup competition.

PLAY OF THE GAME

Field of play and equipment. Based on International Board rules, rugby is played on a rectangular field not more than 75.5 yards (69 metres) wide; the maximum distance between the goal lines is 110 yards (100 metres) and beyond each goal line the end zone, called "in goal," extends not more than 24.07 yards (22 metres). At the centre of the goal lines are two goalposts 18 feet six inches (5.6 metres) apart with a crossbar 10 feet (three metres) above the ground. (See Figure 9.)

Ball dimensions

The inflated ball is oval, less pointed than the U.S. and Canadian football. It is 11 to 11.8 inches (280 to 300 millimetres) long, 22.9 to 24.4 inches (580 to 620 millimetres) in circumference, and weighs 14.5 to 15.5 ounces (400 to 440 grams). The outside casing of the ball is usually of leather or plastic.

The players wear jerseys, shorts, stockings, and studded (cleated) boots. Rigid protective equipment is not allowed.

Principles of play. *Rugby Union.* The game is controlled by a referee assisted by two touch judges, and there are normally two periods of 40 minutes each.

From the general free-for-all with hacking (kicking in the shins) and tripping that existed in the early days, the game was gradually refined until it reached its present state. When the first match between England and Scotland was played in 1871, there were 20 men on each team, and it was not agreed to reduce the number to 15 until 1877. Scotland won the 1871 game, scoring the only goal of the match. Scotland and England each achieved a try, but it was not possible to win a match in any other way than by scoring goals. A try, touching the ball down in the goal area behind the opponents' goal line, scored no points but allowed the player's team an unimpeded place kick at goal from a point on the field not farther from the touchline than the try had been scored. In 1875–76 it was agreed that if the number of goals (field goals) kicked by each side

Tries and goals

was the same or if no goal was kicked, the result would be decided by the number of tries achieved. Thus was the try (in U.S. and Canadian football, a touchdown), the scoring of which was to become the chief aim of the game, for the first time brought into the reckoning. A further refinement was introduced during the 1886–87 season with the adoption of the Cheltenham College rating, which had been in force at that college for some 20 years, making three tries equal to one goal. A number of changes to the scoring system were made over the next several years, but from 1905 the modern scoring values were essentially established, a try being worth three points, its subsequent conversion into a goal providing an additional two points. Dropped goals, at that stage worth four points, in 1948 were devalued to three, and in 1971 a try was revalued at four points. A dropped goal is scored by a drop kick from the field—*i.e.,* when a player, in play, lets the ball fall from his hands and kicks it at the first rebound as it rises so that it goes between the goal posts and above the crossbar. Three points may also be scored by a successful penalty kick at goal awarded for an infringement of the laws by the opposition.

Scrums and line-outs

The two basic set pieces, or formations, of the game are the scrum and the line-out. A scrum is formed by the eight forwards of each side bending forward, binding one another with their arms, and pushing against the opposing eight forwards similarly bound in three ranks or rows. The ball is put into the tunnel between the two front rows, whose members use their feet to try to procure the ball for their team. A line-out is the method of bringing the ball back into play after it has gone out over the touchline (out-of-bounds). To form a line-out, at least two forwards of each team line up in single files in a line perpendicular to the spot where the ball crossed the touchline. A gap or space is left between the two lines of players, and the ball is thrown in above this gap so that the forwards of both teams may try to grab it or otherwise obtain possession of it for their team.

While the forwards are forming a scrum or a line-out, the other players, normally divided into two halfbacks, four three-quarters (the left- and right-centre backs and left- and right-wing backs), and a fullback, take up position several yards apart in various formations between their forwards and their own goal line. For a line-out the three-quarters stay at least 10 yards back, the idea being that by passing or running or kicking the ball in the open field they may find a way either of scoring a try or of dropping a goal.

Besides the scrum and the line-out there is also the loose maul or ruck. This occurs when, in the open field, the progress of the ball is temporarily checked—by a player dropping it, falling over while carrying it, or being held by an opponent while in possession of it, for instance—and two or more players gather round and struggle to procure the ball for their team. The maul or ruck is an especially profitable source of possession because the opposing defense is unlikely to be as strictly aligned as it is for a scrum or a line-out. Blocking, an integral part of U.S. and Canadian football, is not allowed.

The game settled into the pattern of big forwards struggling for the ball so that their faster and more agile backs could pass it and run with it in the hope of scoring goals. But as players increased in pace through improved fitness, without a corresponding increase in the size of the field, the open spaces became fewer, defenses became more effective, and attacking moves were all too easily stifled. Play began to stagnate and to become dull, both for the player and for the spectator. In order to reverse this trend and to encourage the return of flowing movement to the game, the International Board made several important changes in the laws in 1964. It was ruled that while a line-out (putting the ball back in play after it had gone out-of-bounds) was taking place, each set of three-quarters must remain at least 10 yards nearer their own goal line than the point of the line-out, thus leaving a clear no-man's-land in which attacks could be developed; that backs must not advance beyond the hindmost foot of scrums until the ball was out; that forwards must not advance from a scrum until the ball was out; and that the team throwing in the ball at a line-out had the right to determine the shortness of the line-out, thus preventing opponents from straggling across the field in a defensive screen. Another change, in 1970, made it illegal for a player to kick the ball directly over the touchline or sideline except from within 25 yards of his own goal line.

Rule changes of 1964

One of the charms of the Rugby Union game is the infinite variety of its tactics. In a basic orthodox situation, like a scrum on the right-hand side of the field, the ball may simply be passed rapidly by hand through the halfbacks and the centre three-quarters to the left-wing three-quarter, each man running a few yards before parting with the ball. The wing may then be able to run past his immediate opponent by swerving or sidestepping or simply by using strength and speed; a try will probably be scored. But the attacking team may already have tried an orthodox move of this kind and may have discovered that the opposition is especially strong defensively and also possesses exceptional speed. In this case, the attacking team must depart from the orthodox and try to discover a chink in their opponents' armour elsewhere.

Rugby League. The League variant is played on similar

Scoring variations

fields, and the aim, as in Union football, is to score tries and goals. As in Rugby Union, a try in Rugby League is worth four points and a conversion two points, but a penalty kick is two points instead of three and a dropped goal one point rather than the three in Rugby Union.

There are only 13 men on a Rugby League team instead of 15. The two who have been dispensed with are the two wing forwards, so that a League scrum has three men in the front row, two in the second, and one in the back. There are no line-outs in Rugby League; if the ball goes out of play over the touchline, a scrum is ordered. Nor is the Union game's ruck or maul to be found in Rugby League. When a player is brought down in possession of the ball, he has to be allowed to stand up face-to-face with an opponent and attempt to tap the ball back to his own teammates with his foot. Basketball

The only major sport strictly of U.S. origin, basketball was invented by James Naismith (1861–1939) on or about Dec. 1, 1891, at the International Young Men's Christian Association (YMCA) Training School (now Springfield College), Springfield, Mass., where Naismith was an instructor in physical education. Naismith prepared a set of 13 simple rules embodying five principles that still govern today's game:

> 1. There must be a ball—large, light, and handled with the hands. 2. There shall be no running with the ball. 3. No member of either team shall be restricted from getting the ball at any time it is in play. 4. Both teams are to occupy the same area, yet there is to be no personal contact. 5. The goal shall be horizontal and elevated.

Principles of the game

Naismith used as goals two half-bushel peach baskets, which gave the sport its name. The students were enthusiastic. After much running and shooting, William R. Chase chanced to connect on a mid-court shot and that historic contest ended in a 1–0 score. The Springfield students went home on Christmas vacation and told their friends and the local YMCA people about the newly invented game. Numerous associations wrote Naismith for a copy of the rules, which were published in the Jan. 15, 1892, issue of the *Triangle,* the campus paper.

HISTORY

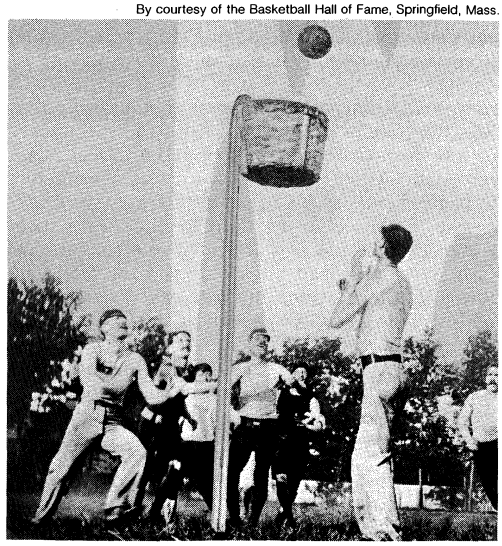
The early years. In the early years, the number of players on a team varied according to the number in the class and the size of the playing surface. In 1894 teams began to play with five on a side when the playing surface was less than 1,800 square feet (167.2 square metres); the number rose to seven when the gymnasium measured from 1,800 to 3,600 square feet and up to nine when the playing areas exceeded that. In 1895 the number was occasionally set at five by mutual consent and, two years later, the rules stipulated five, and this number has remained.

Since five of Naismith's original players were Canadians, not surprisingly Canada was the first country outside the United States to play the game. Basketball was introduced in France in 1893, in London in 1894, in Australia, China, and India soon thereafter, and in Japan in 1900.

While basketball helped swell the membership of YMCAs because of the availability of their gyms, within five years the game was outlawed by various associations because where the gyms formerly were occupied by classes of 50 or 60 members, the areas were now monopolized by only 10 to 18 players. The banishment of the game induced many members to terminate their YMCA membership and to hire halls to play the game, thus paving the way to the professionalization of the sport.

Early uniforms and equipment

Originally, players wore one of three styles of uniforms: knee-length football trousers; jersey tights, as commonly worn by wrestlers; and short padded pants, forerunners of today's uniforms, plus knee guards. The courts often were of irregular shapes with occasional obstructions such as pillars, stairways, or offices that interfered with play. In 1903 it was ruled that all boundary lines must be straight. In 1893 the Narragansett Machinery Co., of Providence, R.I., marketed a hoop of iron with a hammock style of basket. Originally, a ladder, then a pole, and finally, a chain fastened to the bottom of the net was used to retrieve a ball after a goal had been scored. Nets open at the bottom were adopted in 1912–13. In 1895–96 the points for making a basket (field goal) were reduced from three to two, and for making a free throw (shot uncontested from a line in front of the basket after a foul had been committed) from three to one.



At first, spectators behind the basket leaned over the railings and deflected the ball to favour one side or hinder the other, and in 1895 teams were urged to provide a four-by-six-foot screen for the purpose of eliminating interference. Soon after, wooden backboards proved more suitable. Glass backboards were legalized by the professionals in 1908–09 and by colleges in 1909–10. Fan-shaped backboards were made legal in 1940–41, and transparent backboards, although commonly used in public auditoriums since the mid-1930s, were finally authorized in 1946–47. In 1920–21 the backboards were moved two feet, and in 1939–40 four feet, in from the end lines to reduce frequent stepping out-of-bounds.

A soccer ball was used for the first two years. In 1894 the first basketball was marketed. It was laced, close to 32 inches (81 centimetres) or about four inches larger than the soccer ball in circumference, and weighed less than 20 ounces. By 1948–49 when the laceless molded ball was made official, the size had been set at 30 inches.

Introduction to colleges

The distinction of becoming the first college to play the game belongs to either Geneva College (Beaver Falls, Pa.) or the University of Iowa. C.O. Bemis heard about the new sport at Springfield and tried it out with his stu-

dents at Geneva in 1892. At Iowa, H.F. Kallenberg, who attended Springfield in 1890, wrote Naismith for a copy of the rules and also presented the game to his students. At Springfield, Kallenberg met Amos Alonzo Stagg, who became athletic director at the new University of Chicago in 1892. The first college basketball game with five on a side was played at Iowa City, Iowa, on Jan. 18, 1896. The University of Chicago won, 15–12, with neither team using a substitute. Kallenberg refereed that game, a common practice in that era—and some of the spectators took exception to some of his decisions. (R.G.Lo./W.G.M.)

The colleges formed their own rules committee in 1905, and by 1913 there were at least five sets of rules: the collegiate, YMCA-Amateur Athletic Union, and state militia groups, and two varieties of professional rules. Teams often agreed to play under a different set for each half of a game. To establish some measure of uniformity, the colleges, AAU, and YMCA formed the Joint Rules Committee in 1915. This group was renamed the National Basketball Committee (NBC) of the United States and Canada in 1936 and until 1979 served as the game's sole amateur rule-making body. In that year, however, the colleges broke away to form their own rules committee, and during the same year the National Federation of State High School Associations likewise assumed the task of establishing separate playing rules for the high schools. The NCAA Rules Committee for men is a 12-member board composed of representatives from six Division I schools and three each from Divisions II and III. It has jurisdiction over colleges, junior colleges, the National Association of Intercollegiate Athletics (NAIA), and Armed Forces basketball. There is a similar body for women's play.

Growth of the game. Basketball grew steadily but slowly in popularity and importance in the United States and internationally in the first three decades after World War II. Interest in the game deepened as a result of television exposure, but with the advent of cable television, especially during the 1980s, the game's popularity exploded at all levels. Given a timely mix of spectacular players, such as Earvin ("Magic") Johnson, Julius Erving ("Dr. J"), Larry Bird, and Michael Jordan, and the greatly increased exposure, basketball moved quickly to the forefront of the American sporting scene, alongside such traditional leaders as baseball and football. Four areas of the game developed during this period: U.S. school and college basketball, women's basketball, international basketball, and professional basketball. (For results of the U.S. college tournaments, international men's and women's champions, and U.S. professional champions see SPORTING RECORD in the *Micropædia*.)

U.S. school and college basketball. Basketball at the school and college level developed from a structured, rigid game in the early days to one that is often fast-paced and high-scoring. Individual skills improved markedly, and although basketball continued to be regarded as the ultimate team game, individualistic, one-on-one performers came to be not only accepted but used as an effective means of winning games.

In the early years games were frequently won with point totals of less than 30, and the game, from the spectator's viewpoint, was slow. Once a team acquired a modest lead the popular tactic was to stall the game by passing the ball without trying to score, in an attempt to run out the clock. The NBC, seeing the need to discourage such slow-down tactics, instituted a number of rule changes. In 1932–33 a line was drawn at mid-court and the offensive team was required to advance the ball past it within 10 seconds or lose possession. Five years later, in 1937–38, the centre jump following each field goal or free throw was eliminated. Instead, the defending team was permitted to inbound the ball from the out-of-bounds line underneath the basket. Nearly four decades passed before an alteration of like magnitude was made in the college game. After experimentation the NCAA Rules Committee installed a 45-second shot clock in 1985, restricting the time a team could control the ball before shooting, and one year later implemented a three-point shot rule for baskets made beyond a distance of 19 feet nine inches.

Rule changes to speed up the game

More noticeable alteration in the game came both at the playing and coaching levels. Stanford University's Hank Luisetti was the first to use and popularize the one-hand shot in the late 1930s. Until then the only outside attempts were two-handed push shots. In the 1950s and 1960s a shooting style evolved from Luisetti's push-off one hander to a jump shot, which is released at the top of the jump. West Virginia University guard Jerry West and Purdue University's Rick Mount were two players who demonstrated the devastating effectiveness of this shot.

Coaching strategy changed appreciably over the years. Frank W. Keaney, coach at Rhode Island University from 1921 to 1948, is credited with introducing the concept of "fast breaking" basketball, in which the offensive team rushes the ball upcourt hoping to get a good shot before the defense can get set. Another man who contributed to a quicker pace of play, particularly through the use of the pressure defense, was Adolph Rupp, who became the University of Kentucky's coach in 1931 and turned their program into one of the most storied in basketball history.

Defensive coaching philosophy, similarly, has undergone change. Whereas pioneer coaches such as Oklahoma A&M University's Henry Iba or Long Island University's Clair Bee taught strictly a man-to-man defense, the zone defense, developed by Cam Henderson of Marshall University in West Virginia, later became an integral part of the game (see below *Play of the game*).

Over the years one of the rules makers' concerns was to neutralize the advantage of taller players. At six feet five inches Joe Lapchick was considered very tall when he played for the Original Celtics in the 1920s, but as even taller players appeared, rules were changed in response. To prevent tall players from stationing themselves near the basket, a rule was instituted in 1932–33 prohibiting the player with the ball from standing inside the foul lane with his back to the basket for more than three seconds; the three-second rule later applied to any attacking player in the foul lane. In 1937–38 a new rule forbade any player from touching the ball when it was in the basket or on its rim (basket interference), and in 1944–45 it became illegal for any defending player to touch the ball on its downward flight toward the basket (goaltending).

Restricting taller players

Nevertheless, with each passing decade, the teams with the tallest players tended to dominate. Bob Kurland (seven feet) led Oklahoma A&M to two NCAA championships in the 1940s and led the nation in scoring in 1945–46. In the same era George Mikan (six feet 10 inches) scored more than 550 points in each of his final two seasons at DePaul University before going on to play nine professional seasons in which he scored more than 11,000 points. Mikan was an outstanding player, not only because of his size but his ability to shoot sweeping hook shots with both hands.

Era of George Mikan

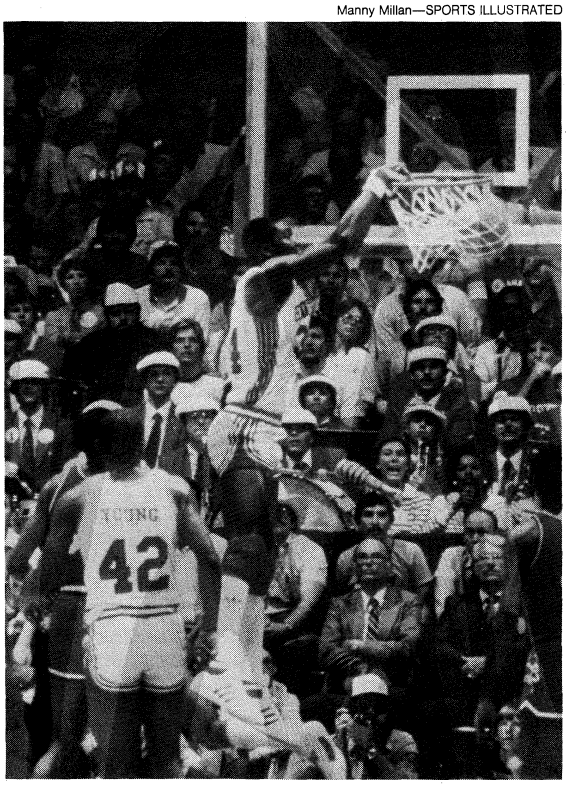
In the 1950s Bill Russell (six feet nine inches) led the University of San Francisco to two NCAA championships before going on to become one of the greatest centres in professional basketball history. Wilt Chamberlain (seven feet, $1^{1}/_{16}$ inches) played at the University of Kansas before turning professional in the late 1950s and is regarded as the greatest all-around big man ever to play. It remained, however, for seven-foot $1^{3}/_{8}$-inch Lew Alcindor (later Kareem Abdul-Jabbar) to most influence the rules. After his sophomore (1966–67) year at the University of California at Los Angeles (UCLA), the dunk shot was banned from collegiate basketball, ostensibly because the rules committee felt, again, that the big men had too great an advantage. The rule was rescinded for the 1976–77 season and the dunk shot became an important part of the game, electrifying both fans and players.

Much as the big men were important in the game's development, so too did the small- and medium-sized performers play a vital role. Bob Cousy, playing at Holy Cross College and later for the Boston Celtics, was regarded as one of the game's first great playmakers. He was among the first to use the behind-the-back pass and between-the-legs dribble as effective offensive maneuvers. Later, such smaller players as Providence College's Ernie DiGregorio, the University of North Carolina's Phil Ford, and Indiana's Isiah Thomas, proved the importance of their role. Between those two extremes are players like Louisiana State University's Pete Maravich, who set an

all-time collegiate scoring record of 44.5 points per game in the 1969–70 season; Earvin Johnson, the point guard who led Michigan State University to a championship in 1979; Oscar Robertson, a dominating performer for the University of Cincinnati in the late 1950s; and Larry Bird of Indiana State University, who demonstrated versatility.

Effect of television

Nothing influenced the college game's growth, however, more than television. The NCAA championship games were televised nationally from 1963, and by the 1980s all three major television networks were telecasting intersectional college games during the November-to-March season. Rights fees for these games soared from a few million to well over $50,000,000 by the late 1980s. During the regular season more than 200 Division I basketball games were being telecast nationwide by cable networks, generating both revenue and tremendous exposure.



In the evolution of college basketball the darkest hours have been related to gambling scandals, the most serious of which arose in 1951. But in the 1960s, '70s, and '80s the game was again touched by the problem. Also, as the game began to draw more attention and generate more income, the pressure to win intensified, resulting in an outbreak of incidents of rule violations, especially with regard to recruitment of star players.

Postseason tournaments

The most identifiable phase of college basketball in America is the postseason tournament held in March. Interest in the NCAA tournament paralleled the growth of the game. The first basketball tournament was staged by the AAU in 1897 and was won by New York City's 23rd Street YMCA, later to become a traveling professional team known as the New York Wanderers. Although the YMCA was prominently identified with the game in its early years, it did not hold its first national tournament until 1923, and that event took place until 1962. The first national tournament for colleges was held in 1937 and was conducted by an organization in Kansas City, Mo., that later became the National Association of Intercollegiate Athletics.

New York City basketball writers organized the first National Invitation Tournament (NIT) in 1938, but a year later the New York City colleges took control of the event. Until the early 1950s, the NIT was considered the most prestigious U.S. tournament, but with the growth of the college-run NCAA championship, the NIT became a consolation event for teams that failed to make the NCAA selections. Originally all teams in the NIT were invited to New York City and the games were played in Madison Square Garden. From the early 1980s, however, the first three rounds were played at regional or campus sites before the final four teams were brought to New York City.

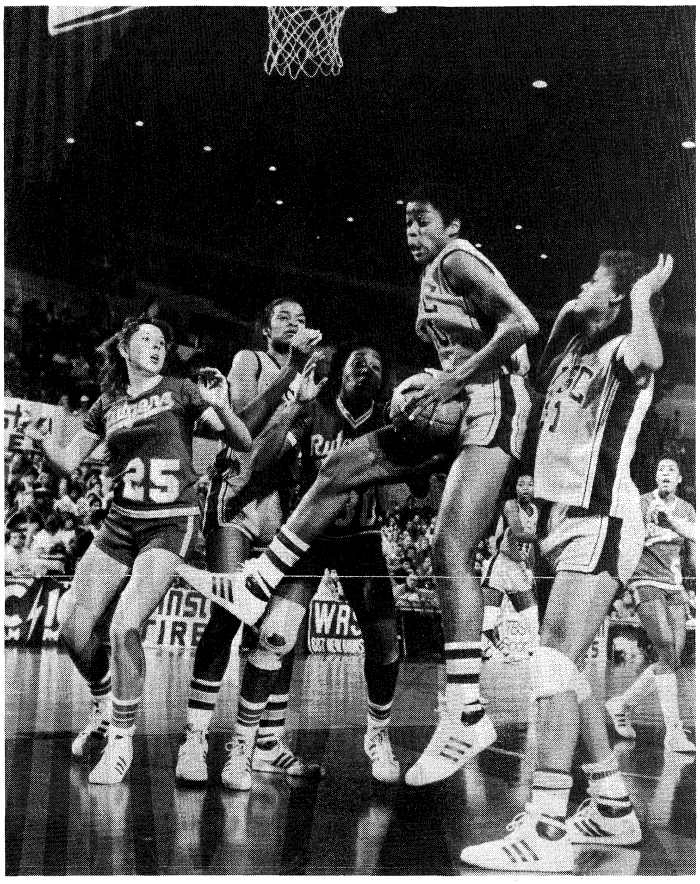
The first NCAA tournament was played in 1939, and its growth took place in three stages. The first era ran through 1964, when it was essentially a tournament for champions of various conferences. There were just eight teams in the 1939 field, and by 1963 it had been expanded to 25 teams, all champions of their respective conferences, plus several successful independent teams. The most outstanding teams of the 1940s and 1950s participated in both tournaments, but, after the gambling scandals that followed the 1950 NIT championship, a rule was passed prohibiting a team from playing in both. Afterward the NCAA tournament progressively outgrew the NIT.

In 1964 the second era dawned as the UCLA Bruins, coached by John Wooden, began a period of domination over the NCAA field. From that season until 1975 Wooden led his teams to 10 NCAA championships. Only championships by Texas Western in 1966 and North Carolina State in 1974 interrupted UCLA's reign. In the eyes of many, the UCLA dynastic period probably had a regressive effect on the game's growth; a sport with such high predictability lost some of its attractiveness.

The third growth stage came with the end of UCLA's dominance. Champions began to emerge from all sections of the country. From the field of 25 in 1974, the NCAA tournament expanded to 64 participants, including not only conference championship teams but other outstanding teams from the same conferences as well. Three weeks of play culminate with the Final Four weekend, an event now comparable in general public interest and media attention with the Super Bowl and World Series.

Championships at the Division II, Division III, and NAIA levels also continued to grow in interest, reaping some of the fallout from the Division I popularity. The National Junior College Athletic Association tournament, first held in 1945, has been held in Hutchinson, Kan., since 1949. (L.W.D.)

High school basketball



About 17,000 high schools in the United States have basketball teams. Forty-eight of the 50 states annually conduct statewide tournaments in one or as many as five divisions. The other two states, New York and California, which formerly conducted state tournaments, now have district or area championships. Several states, including Arkansas, Georgia, Louisiana, Iowa, Oklahoma, Pennsylvania, Rhode Island, South Carolina, Tennessee, and Texas, conduct annual tournaments for girls. Between 1917 and 1930 the University of Chicago, under Stagg, sponsored a national schoolboy tournament, but the National Federation of State High School Athletic Associations, founded in 1920, opposed its continuance.

The most famous high school team of all time was the Passaic (N.J.) "Wonder Team" between 1919 and 1925, which won 159 consecutive games, until defeated by Hackensack. Another colourful team was Carr Creek, Ky., of 1927–28, consisting of eight players, all related, who owned no uniforms, lost the state tourney finals in four overtime periods, to Ashland High (13–11), then won three contests in the national tournament in Chicago before losing to Vienna, Ga., the national champions.

Basketball for children

While basketball is competitively a winter sport, it is played on a 12-month basis—on summer playgrounds, in church, municipal, and industrial halls, in schoolyards and family driveways, and in summer camps—often on an informal basis between two or more contestants. Many grammar schools, youth groups, municipal recreation programs, churches, and other organizations conduct basketball programs for youngsters of less than high school age. Jay Archer, of Scranton, Pa., introduced "biddy" basketball in 1950 for boys and girls under 12 years of age, the court and equipment being adjusted for size.

U.S. women's basketball. Clara Baer, who introduced basketball at the H. Sophie Newcomb College for Women in New Orleans, influenced the women's style of play with

her set of women's rules, published in 1895. On receiving a diagram of the court from Naismith, Baer mistook dotted lines, indicating the areas in which players might best execute team play, to be restraining lines, with the result that the forwards, centres, and guards were confined to specified areas. This seemed appropriate because many felt that the men's game was too strenuous for women.

Women's rules

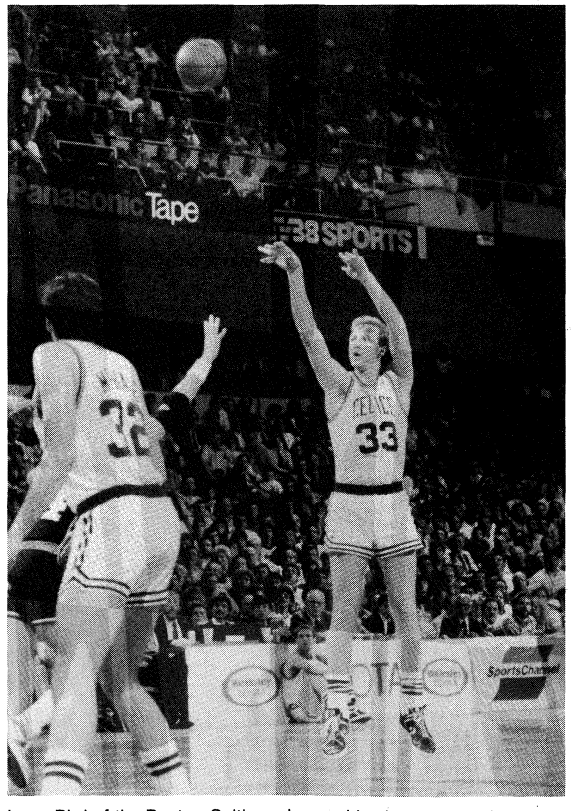
Women's rules over the years frequently have been modified. Until 1971 there were six players on a team, and the court was so divided that the three forwards played in the forecourt and did all the scoring, while the three guards covered the backcourt. Senda Berenson staged the first women's college basketball game in 1893 when her freshman and sophomore Smith College girls played against one another. In April 1895 the girls of the University of California (Berkeley) played Stanford University. Despite a multitude of hindrances (such as being "unladylike"), women's basketball gradually secured a foothold. In 1971, when women's rules were changed to reduce the number on a team from six players to five and women were freed from the limits imposed by the halfcourt game, it quickly raised the level of individual skills and competition.

NCAA jurisdiction

In the early 1980s control of the women's game was shifted from the Association for Intercollegiate Athletics for Women (AIAW) to the NCAA, a move that not only streamlined the operation and made it more efficient but also added to its visibility. The women's NCAA championship tournament runs concurrently with the men's, and its final game is nationally televised. Under NCAA rules the size of the basketball used by women was reduced slightly, creating a higher-scoring game. The Olympics added women's basketball in 1976. The U.S. team lost 112–77 to the Soviet team in the finals that year. Individual women stars have been heavily recruited by colleges, but the Women's Professional Basketball League (WPBL), begun in 1978, lasted only three years. This, however, did not slow the development of stars in the college ranks.

International competition. The success of international basketball was greatly advanced by Forrest C. ("Phog") Allen, a Naismith disciple and a former coach at the University of Kansas, who led the movement for inclusion of basketball in the Olympic Games in 1936 and thereafter. (For Olympic champions, see OLYMPIC GAMES: *Team sports.*) Basketball has also been played in the Pan-American Games since their inauguration in 1951. The international game is governed by the Fédération Internationale de Basketball Amateur (FIBA). World championships began in 1951 for men and in 1953 for women. Under international rules the court differs in that there is no front or back court, and the free-throw lanes form a modified wedge shape (see Figure 11). There are some differences in rules, including those governing substitutions, technical and personal fouls, free throws, intermissions, and time-outs. A team must try for a goal within 30 seconds. Outside the United States there are few places that strictly separate amateur from professional athletes.

International rules



Basketball has caught on particularly well in Italy. There are three levels of amateur competition in Italy, roughly comparable to the NCAA's Divisions I, II, and III. The Superior Division has 12 teams in major cities, including two in Rome. The national team, which represents Italy in world tournaments, is selected from among the best performers on all teams.

Throughout Europe, where much basketball activity is sponsored by corporations, spring tournaments match teams in a two-year cycle. In Soviet-bloc countries most teams are sponsored by the military or by trade unions. Every four years, two years before the Olympics, the world tournament is held, bringing zone qualifiers together in brackets designed to pair teams of near-equal ability.

Professional basketball. The professional game first prospered largely in the Middle Atlantic and New England states. Trenton (N.J.) and the New York Wanderers were the first great professional clubs, followed by the Buffalo Germans, who started out in 1895 as 14-year-old members of the Buffalo (N.Y.) YMCA and, with occasional new members, continued for 44 years, winning 792 out of 878 games.

in their heyday consisted of Edward and Lew Wachter, Jimmy Williamson, Jack Inglis (a behind-the-back dribbler), and Bill Hardman. They introduced the bounce pass and long pass as offensive weapons and championed the rule (adopted in 1923–24) that made each player, when fouled, shoot his own free throw.

The Original Celtics, Rens, and others

Before World War II, the most widely heralded professional team was the Original Celtics, which started out in 1915 as a group of youngsters from New York City, kept adding better players in the early 1920s, and became so invincible that the team disbanded in 1928, only to regroup in the early 1930s as the New York Celtics. They finally retired in 1936. The Celtics played every night of the week, twice on Sundays, and largely on the road. During the 1922–23 season they won 204 of 215 games.

Another formidable aggregation was the New York Renaissance (the Rens), organized by Robert Douglas in 1923 and regarded as the strongest all-black team of all time. During the 1925–26 campaign they split a six-game series with the Original Celtics. During the 1932–33 season the Rens won 88 consecutive games. In 1939 they trimmed the Harlem Globetrotters and the Oshkosh All Stars for the world championship pro tournament in Chicago. Among the great professional clubs were the New York Nationals; Fond du Lac, Wis.; East Liverpool, Ohio; the Paterson, N.J., Crescents; and the South Philadelphia Hebrew All Stars—better known as the Sphas.

The pro leagues

The first professional league was the National Basketball League (NBL) formed in 1898 to protect the players against unscrupulous promoters and to save the sport from extinction because of rough play. Their game differed from the college rules in that a netting usually separated the players from the spectators and the players bounced off the ropes like prizefighters in a ring; the ball could not go out of bounds; and the players were permitted to resume dribbling after halting. Because of the inequality of the teams or inability of the weaker clubs to meet expenses, leagues did not survive for more than a few seasons, and new circuits invariably arose. As a rule, the same players performed in these leagues, some playing for several cities or clubs within the same seasons.

The Depression of the 1930s hurt professional basketball, and a new NBL was organized in 1938 in and around the upper Middle West. Professional basketball assumed major league status with the organization of the new Basketball Association of America in 1946 under the guidance of Walter A. Brown, president of the Boston Garden. Brown contended that professional basketball would succeed only if there were sufficient financial support to nurse the league over the early lean years, if the game were conducted upon a high standard, and if all players were restricted to contracts with a reserve rule protecting each team from raiding by another club. Following a costly two-year war, the BAA and the NBL merged in 1949 to form the National Basketball Association (NBA).

Formation of the NBA

To help equalize the strength of the teams, the NBA established an annual college draft permitting each club to select a college senior in inverse order to the final standings in the previous year's competition, thus enabling the lower standing clubs to select the more talented collegians. In addition, the game was altered through three radical rules changes in the 1954–55 season: (1) a team must shoot for a basket within 24 seconds after acquiring possession of the ball; (2) a bonus free throw is awarded a player anytime the opposing team commits more than six (later five, now four) personal fouls in a quarter or more than two personal fouls in an overtime period; and (3) two free throws are granted for any backcourt foul.

After a struggle to survive, including some large financial losses and several short-lived franchises, the NBA took its place as the major professional basketball league in the United States. A rival 11-team American Basketball Association (ABA), with George Mikan as commissioner, was launched in the 1967–68 season, and a bitter feud developed with the NBA for the top collegiate talent each season. In 1976 the ABA disbanded, and four of its teams were taken into the NBA.

Like college basketball, the NBA grew increasingly popular through the 1980s. Attendance records were broken in that decade by most of the franchises, a growth pattern stimulated at least in part by the increased coverage by cable television. The NBA grew to a membership of 27 teams in the late 1980s, including expansion teams in Charlotte, N.C.; Miami; Minneapolis, Minn., and Orlando, Fla. The play-offs followed the traditional 81-game schedule, involving 16 teams and beginning in late April. Played as best-of-seven series, the final pairings stretched into late June. Although basketball is traditionally a winter game, the NBA still fills its arenas and attracts a national television audience in late spring. The NBA grew to a point at which the average annual player salary reached around the $500,000 level by the late 1980s. Many superstars earned more than $1,000,000 yearly.

PLAY OF THE GAME

Court and equipment. The standard basketball court is in the shape of a rectangle 50 feet (15.24 metres) by 94 feet; high school courts may be slightly smaller. There are various markings on the court, including a centre circle, free-throw lanes, and a three-point line, that help regulate play. The international court varies somewhat in its markings. (See Figure 11.) A goal, or basket, 18 inches (45.7 centimetres) in diameter is suspended from a backboard at each end of the court. The metal rim of the basket is 10 feet above the floor. The backboard in professional and college play is a six-foot-wide by 3½- or (in college) four-foot-high rectangle made of a transparent material, usually glass. A fan-shaped board is used in high school games. The spherical inflated ball measures 29 to 30 inches in circumference and weighs 20 to 22 ounces (567 to 624 grams). Its covering is leather or composition.

Rules. The rules governing play of the game are based on Naismith's five principles requiring a large, light ball, handled with the hands; no running with the ball; no player restricted from getting the ball when it is in play; no personal contact; and a horizontal, elevated goal. The rules are spelled out in specific detail by the governing bodies of the several branches of the sport and cover the playing court and equipment, officials, players, scoring and timing, fouls, violations, and other matters. The officials include a referee and two umpires in college play (one umpire in NBA play), two timers, and two scorekeepers. One player on each team acts as a captain and speaks for his team on all matters involving the officials, such as interpretation of rules. Professional and high school games are divided into four periods, college into two.

The officials

Since the 1895–96 season, a field goal has scored two points and a free throw one point. When the ABA was founded in 1967, it allowed three points for shots from outside a boundary line set at a maximum of 25 feet from the basket. With varying distances, the change was

adopted officially by the NBA and, in 1985, by colleges.

Basketball is a noncontact game. A player may pass or bounce (dribble) the ball to a position whereby he or a teammate may make a try for a basket. A foul is committed whenever a player makes such contact with an opponent so as to put him at a disadvantage. It provides the offended player with a free throw, an unhindered throw for a goal from behind the free-throw (foul) line, which is 15 feet from the backboard. If a player is fouled while shooting and the shot is good, the basket counts and he is awarded one free throw; if the shot misses, he gets two free throws. Infractions such as unsportsmanlike conduct or grasping the rim are technical fouls, which award a free throw to the opposition.

Fouls and violations

In other rules changes designed to speed up college games, a team loses possession if it fails to advance the ball within five seconds while being "closely guarded." Other common infractions occur when a player (with the ball) takes an excessive number of steps or slides; causes the ball to go out-of-bounds; steps over the foul line while tossing for a free throw; steps over the end line or sideline while tossing the ball in to a teammate, or fails to pass the ball in within five seconds; runs with, kicks, or strikes the ball with his fist; dribbles a second time after having once concluded his dribble (double dribble); remains more than three seconds in his free-throw lane while he or his team has the ball; causes the ball to go into the backcourt; retains the ball in the backcourt more than 10 seconds (30 seconds for women); or fails to shoot within 45 seconds of the time the ball is put into play (24 seconds in the professional game). Penalty is loss of the ball—opponents throw in the ball from the side.

Common terms used in basketball include the following:

Blocking. Any illegal personal contact that impedes the progress of an opponent who does not have the ball.

Dribble. Ball movement by bouncing the ball. A dribble ends when a player touches the ball with both hands simultaneously or does not continue his dribble.

Held ball. Called when two opponents have one or two hands so firmly upon the ball that neither can gain possession without undue roughness. It also is called when a player in the front court is so closely guarded that he cannot pass or try for a goal or is obviously withholding the ball from play.

Jump ball. A method of putting the ball into play. The referee tosses it up between two opponents who try to tap it to a teammate.

Pass. Throwing, batting, or rolling the ball to another player. The main types are: (1) the chest pass—ball is released from a position in front of the chest; (2) the bounce pass—the ball is bounced on the floor to get it past a defensive opponent; (3) the roll pass on the floor; (4) the hook pass (side or overhead); and (5) the baseball pass—the ball is thrown a longer distance with one hand in a manner similar to a baseball throw.

The bounce pass

Pivot. A movement in which a player with the ball steps once or more in any direction with the same foot while the other foot (pivot foot) is kept at its point of contact with the floor.

Pivot player. Another term for centre; also called a post player. He may begin the offensive set from a position just above the free-throw line.

Rebounding. Both teams attempting to gain possession of the ball after any try for a basket is unsuccessful but the ball does not go out-of-bounds and remains in play.

Screen, or pick. Legal action of a player who, without causing contact, delays or prevents an opponent from reaching his desired position.

Shots from the field. One of the main field shots is the layup, in which the shooter, close to the basket, jumps and lays the ball against the backboard so it will rebound into the basket or just lays it over the rim. Away from the basket, players use a one-hand push shot from a stride, jump, or standing position, and a hook shot, which is overhead. Some players can dunk or slam dunk the ball, jamming the ball down into the basket.

Traveling (running with the ball). Progressing in any direction in excess of the prescribed limits while holding the ball.

Turnover. Loss of possession of the ball by a team before any member has been able to try for a basket.

Other special terms are discussed below.

Principles of play. Each team of five players consists of two forwards, two guards, and a centre, usually the tallest man on the team. At the beginning of the first period of a game the ball is put into play by a jump ball at centre court; *i.e.,* the referee tosses the ball up between the opposing centres, higher than either can jump, and when it descends each tries to tap it to one of his teammates, who must remain outside the centre circle until the ball is tapped. Subsequent periods of professional and college games begin with a throw in from out-of-bounds. Jump balls are also signaled by the officials when opposing players share possession of the ball (held ball), or simultaneously cause it to go out-of-bounds. In U.S. college games the alternate-possession rule is invoked in jump-ball situations, with teams taking turns getting possession. After each successful basket (goal or field goal) the ball is put back in play by the team that is scored on by one player passing the ball in from behind the end line where the score was made. The ball is put in play in the same manner after a successful free throw; if two have been awarded, after the second if it is successful. After non-shooting violations the ball is awarded to the opposing team to be passed inbounds from a point designated by an official.

The jump ball

A player who takes possession of the ball must pass or shoot before taking two steps or must start dribbling before taking his second step. When the dribble stops, the player must stop his movement and pass or shoot the ball. The ball may be tapped or batted with the hands, passed, bounced, or rolled in any direction.

As basketball has progressed, various coaches and players have devised intricate plays and offensive maneuvers. Some systems emphasize speed, deft ball handling, and high scoring; others stress ball control, slower patterned movement, and lower scoring. A strategy based on speed is called the fast break. When fast-break players recover possession of the ball in their backcourt, as by getting the rebound from an opponent's missed shot, they race to beat the defense to its backcourt by a combination of speed and passing and try to make a field goal before the opponents have time to set up a defense.

Systems of offense

Some teams, either following an overall game plan or as an alternative when they do not have the opportunity for a fast break, employ a more deliberate style of offense. The guards carefully bring the ball down the court toward the basket and maintain possession of the ball in the front court by passing and dribbling and by screening opponents in an effort to set up a play that will free a player for an open shot. Set patterns of offense generally use one or two pivot, or post, players who play near the free-throw area at the low post positions (between the free-throw line and the end line) or at high post positions (between the free-throw line and the basket). The pivot players are usually the taller players on the team and are in position to receive passes, pass to teammates, shoot, screen for teammates, and tip in or rebound (recover) missed shots. All of the players on the team are constantly on the move, executing the patterns designed to give one player a favourable shot—and at the same time place one or more teammates in a good position to tip-in or rebound if that player misses.

Systems of defense also have developed over the years. One of the major strategies is known as man-to-man or man-for-man. In this system each player guards a specific opponent, except when "switching" with a teammate when he is screened or in order to guard another player in a more threatening scoring position. Another major strategy is the zone, or five-man, defense. In this system each player has a specific area to guard irrespective of which opponent plays in that area. The zone is designed to keep the offense from driving in to the basket and to force the offense into taking long shots. The zone defense is not permitted in the professional game.

Systems of defense

A great many variations and combinations have been devised to employ the several aspects of both man-to-man and zone defensive strategies. The press, which can be either man-to-man or zone, is used by a team to guard its

opponent so thoroughly that the opposition is forced to hurry its movements and especially to commit errors that force turnovers. A full-court press applies this pressure defense from the moment the opposition takes possession of the ball at one end of the court. Well-coached teams are able to modify both their offensive and defensive strategies according to the shifting circumstances of the game and in response to their opponents' particular strengths and weaknesses and styles of play.

Ice hockey

Ice hockey requires two teams, each with usually six players who wear ice skates. The object is to propel a vulcanized rubber disk, the puck, past a goal line and into a net guarded by a goalkeeper. With its speed and its frequent physical contact, ice hockey has become one of the most popular of international sports. The game is an Olympic sport, and in the Soviet Union there are more than a million registered players performing regularly in leagues. It is perhaps Canada's most popular game. For good reason ice hockey is called the world's fastest team game. In no other contact sport do the competitors reach speeds of 30 miles (almost 50 kilometres) per hour, and the puck has been clocked at speeds of over 100 miles per hour. (For records, see SPORTING RECORD in the *Micropædia* and the article OLYMPIC GAMES.)

HISTORY

Canadian origin

Origins. Until the mid-1980s it was generally accepted that ice hockey derived from English field hockey and Indian lacrosse and was spread throughout Canada by British soldiers in the mid-1800s. Research then turned up mention of a hockeylike game, played in the early 1800s in Nova Scotia by the Micmac Indians, which appeared to have been heavily influenced by the Irish game of hurling; it included the use of a "hurley" (stick) and a square wooden block instead of a ball. It was probably fundamentally this game that spread throughout Canada via Scottish and Irish immigrants and the British army. The players adopted elements of field hockey, such as the "bully" (later the face-off) and "shinning" (hitting one's opponent on the shins with the stick or playing with the stick on one "shin" or side); this evolved into an informal ice game later known as shinny or shinty. The name hockey—as the organized game came to be known—has been attributed to the French word *hoquet* (shepherd's stick). The term rink, referring to the designated area of play, was originally used in the game of curling in 18th-century Scotland. Early hockey games allowed as many as 30 players a side on the ice, and the goals were two stones, each frozen into one end of the ice. The first use of a puck instead of a ball was recorded at Kingston Harbour, Ont., in 1860.

Early organization. The first recorded public indoor ice hockey game, with rules largely borrowed from field hockey, took place in Montreal's Victoria Skating Rink in 1875, between two teams of McGill University students. Unfortunately, the reputation for violence that the game would later develop was presaged in this early encounter, where, as *The Daily British Whig* of Kingston, Ont., reported, "Shins and heads were battered, benches smashed and the lady spectators fled in confusion." The first organized team, the McGill University Hockey Club, formed in 1877, codified their game's rules and limited the number of players on a side to nine.

By the late 1800s ice hockey competed with lacrosse as Canada's most popular sport. The first national hockey organization, the Amateur Hockey Association (AHA) of Canada (which limited players to seven a side), was formed in Montreal in 1885, and the first league was formed in Kingston during the same year, with four teams: the Kingston Hockey Club, Queen's University, the Kingston Athletics, and the Royal Military College. Queen's University scored a 3–1 victory over the Athletics in the first championship game.

By the opening of the 20th century sticks were being manufactured, shin pads were worn, the goaltender began to wear a chest protector (borrowed from baseball), and arenas (still with natural ice and no heat for spectators) were being constructed throughout eastern Canada. In 1892 national attention was focused on the game when the Canadian governor general, Frederick Arthur, Lord Stanley of Preston, donated a cup to be given annually to the top Canadian team. The three-foot-high silver cup became known as the Stanley Cup and was first played for in 1893–94. The first winner was the Montreal Amateur Athletic Association team; since 1917 it has gone to the winner of the National Hockey League play-offs.

In 1899 the Canadian Amateur Hockey League was formed. All hockey in Canada at the time was "amateur," it being "ungentlemanly" to admit to being paid for athletic services. Thus the first acknowledged professional hockey team in the world was formed in the United States, in 1903, in Houghton, Mich. The team, the Portage Lakes, was owned by a dentist named J.L. Gibson, who imported Canadian players. In 1904 Gibson formed the first acknowledged professional league, the International Pro Hockey League. Canada accepted professional hockey in 1908 when the Ontario Professional Hockey League was formed. By that time Canada had become the centre of world hockey.

Emergence of professional hockey

League rivalries. The National Hockey Association (NHA), the forerunner of the National Hockey League, was organized in 1910 and became the strongest association in North America. Rising interest in the game created problems, however, for there were few artificial-ice rinks. In 1911 the Pacific Coast Hockey Association (PCHA) was formed by Joseph Patrick and his sons, who built two enclosed artificial-ice arenas, beginning a boom in the construction of artificial-ice rinks.

The PCHA became involved in a money and player war with the NHA. Although the NHA ultimately emerged as the stronger league, it was the PCHA that introduced many of the changes that improved the game. The only radical rule change adopted by the NHA was to reduce the number of players on a side to six, and that move was made to save money. The western league retained seven-man hockey, but it allowed the goalie to leap or dive to stop the puck. Under the previous rules, a goalie had had to remain stationary when making a save. The western league also changed the offside rule. Under the old rules a player had been deemed offside if he was ahead of the puck carrier when he received a pass. The PCHA divided the ice into three zones by painting two blue lines across the surface and allowed forward passing in the centre zone between the blue lines. This opened up the game and made it more exciting. Another innovation in the western league was the idea of the assist. Previously, only the goal scorer had been credited with a point. In the PCHA the player or players who set up his goal were credited with an assist. The first numbered uniforms also appeared in their league.

Formation of the NHL

The National Hockey League. Like some of its predecessors the NHA had its dissenters. In a move to eject one of the league members, the NHA decided to disband and form a new league. The result was the creation in 1917 of the National Hockey League (NHL), which became the world's foremost professional hockey league. In 1924 the first U.S. team, the Boston Bruins, joined the NHL. In 1925 the New York Americans and Pittsburgh Pirates were admitted, followed in 1926 by the New York Rangers, the Chicago Black Hawks, and the Detroit Cougars (later called the Red Wings). To stock the new teams, the NHL bought out the Patricks' league in 1926 for $250,000. Among the players who shifted to Boston was Eddie Shore, known as a "rushing" defenseman, whose style helped change the game. He was one of the sport's most ferocious and, many experts say, its most skilled player, a forerunner of such future NHL players as Gordie Howe, who played mostly for the Detroit Red Wings. Pittsburgh and the New York Americans eventually dropped out of the league, and until the expansion of 1967, the NHL was composed of six teams—the Rangers, the Bruins, the Black Hawks, the Red Wings, the Toronto Maple Leafs, and the Montreal Canadiens.

In 1967 the NHL undertook one of the greatest expan-

sions in professional sports history when it doubled in size to 12 teams. A new 12-team league, the World Hockey Association (WHA), was formed in 1972, and the ensuing rivalry caused an escalation in players' salaries. In 1979 the NHL, which had grown to 17 teams, merged with the WHA to become a 21-team league.

International ice hockey

On the international level, amateur hockey remained supreme. League competition among amateurs in England began in 1903. The International Ice Hockey Federation (IIHF) was formed in Europe in 1908. Its five original members were Great Britain, Bohemia, Switzerland, France, and Belgium. The first European championship was held at Avants, Switz., in 1910, with Great Britain the winner. From that time the federation broadened its membership, taking applicants from the world over. Canada captured the first Olympic Games title in 1920 and, concurrently, the first IIHF world championship. Canada also won at the first Winter Olympic Games in 1924, retaining both Olympic and world ice hockey championships until 1936, when Great Britain triumphed. In 1963 the Soviet Union began a long series of victories. Except for the increasing number of teams, there was little change in the organization of European ice hockey.

Play-offs and championships. In the NHL, the ultimate prize is the Stanley Cup. The winner is determined after a series of play-offs. Before 1967 the teams that finished first and third and second and fourth played best-of-seven series to determine which would play for the Stanley Cup. The winners then met in another best-of-seven series for the cup. When the league formed two divisions, each division held a similar play-off series. The finalists from each then met. Beginning in 1980, an expanded play-off system involved 16 of the league's 21 teams.

NHL individual awards are the Vezina Trophy to the goalie voted best at his position by NHL managers; the William M. Jennings Trophy for the goalie or goalies with the team permitting the fewest goals; the Calder Trophy, for the rookie of the year; the Hart Trophy, for the most valuable player; the Norris Trophy, for the outstanding defenseman; the Art Ross Trophy, for the top point scorer; the Lady Byng Trophy, for the player best combining clean play with a high degree of skill; the Conn Smythe Trophy, for the play-offs' outstanding performer; the Frank J. Selke Trophy, for the best defensive forward; the Jack Adams Award, for the coach of the year; the Bill Masterton Memorial Trophy, for the player who best exemplifies perseverance, sportsmanship, and dedication to hockey; and the Lester Patrick Trophy, for outstanding service to hockey in the United States. NHL players receive cash awards if they are voted onto the first or second teams of the all-stars chosen by the Professional Hockey Writers' Association after the completion of each season.

Until the late 1970s only a few non-Canadians had played in the NHL. The growth of collegiate hockey in the United States, however, led to a greater proportion of NHL players born in the United States. The level of hockey in Europe—especially in the Soviet Union, Czechoslovakia, Finland, and Sweden—increased greatly in the years following World War II, and the NHL had many European players by the 1980s. The Soviet Union's national team became one of the strongest in international competition and in 1972 almost beat Team Canada, made up of selected Canadian-born NHL stars.

Amateur hockey

The Amateur Hockey Association of the United States (AHAUS), in conjunction with the U.S. Olympic Committee, chooses players for the Olympics; the AHAUS also chooses the national team for world championships, held annually. Most of its players are collegians. The major college championship in the United States is the National Collegiate Athletic Association (NCAA) tournament. The decline of the Canadian Amateur Hockey Association in international competition has been blamed on the fact that many of its men were turning professional while teenagers. Canadian senior amateur hockey—which has no age limit—has as its top prize the Allan Cup, determined after eliminations. Canadian junior players—up to 20 years of age—meet in a similar series for the Memorial Cup.

To determine which teams meet for the world amateur championship, the IIHF has set up three classes. Six countries are in Class A, eight in Class B, and the rest in Class C. The six teams in Class A automatically are eligible for the world championship and the Olympics. The team that does the worst in that division moves down the next year to Class B. The team with the best record in Class B automatically moves up to Class A. The same procedure is followed in Group C.

PLAY OF THE GAME

Rink and equipment. NHL hockey is played for the most part on a standard-sized rink shaped like a round-cornered rectangle that is 200 feet (61 metres) long and 85 feet wide (see Figure 12). International rinks are usually 184–200 feet by 85–98 feet, and U.S. college rinks, 200 feet by 100 feet. The goal cage is four feet high and six feet wide. Any shot that completely clears the goal line, a two-inch- (five-centimetre-) wide stripe on the ice across the front of the cage, is a goal. In front of the goal is the crease, an area four feet deep and eight feet wide, demarcated by a red line; no attacking player may enter the crease unless the puck is there. The IIHF crease is semicircular. The blue lines that divide the ice into three zones are 60 feet out from the goal line and are painted across the width of the ice. The area between the blue lines is called the neutral zone. This zone is bisected by the red centre line.

The crease

Virtually all equipment—for children, amateurs, or professionals—is the same. Goalies wear face masks. Forwards and defensemen wear the same type of skates, but the goaltender's blades are flatter because they need more balance and are stationary for longer periods. The shoes of goaltenders' skates are fitted with rubber protection for the toes. Under their uniforms goaltenders wear a chest protector, shoulder pads, quilting from wrist to shoulder, and pads to protect the kidneys, thighs, and knees. Except for the chest protector, forwards and defensemen wear the

same protective gear under their uniforms. Since 1979–80 all players entering the NHL must wear helmets; helmets and face masks are mandatory in NCAA and IIHF play.

Over his uniform a goalie wears extra equipment. Pads up to 10 inches wide protect him from the tips of his skates to above his knees. They not only afford protection but also aid in blocking shots. On his free hand the goalie wears a glove similar to a first-baseman's baseball mitt, with a wide webbing that enables him to catch the puck. The stick hand is encased in a glove with a wide backing that protects his arm. The goalie's stick has a wider shaft and blade than those of the other players. Fully dressed, goaltenders carry 30 pounds (over 13 kilograms) of equipment, five pounds more than the others.

NHL influence

Rules and principles of play. The modern game on every level—amateur, collegiate, international, and professional—has been influenced largely by the National Hockey League.

Checking—body contact to take an opponent out of the play—is permitted anywhere on the ice. Players may not make or take a pass that has traveled over a red line and a blue line; if this occurs, the play is ruled offside. A face-off, in which an official drops the puck between opposing players, follows the infraction. In hockey competition that has no red line an offside infraction involves a pass that has traveled across the two blue lines. Face-offs are held at the point of the infraction. Players who precede the puck into the attacking zone also are ruled offside, and a face-off is held at a "face-off spot" near the attacking blue line. A face-off also begins each period and is used as well after a goal and after any stoppage of play.

Players

The goalkeeper rarely leaves his goal area. The usual alignments of the other five players are three forwards—the centre, a left wing, and a right wing—and two defensemen—a left defenseman and a right defenseman.

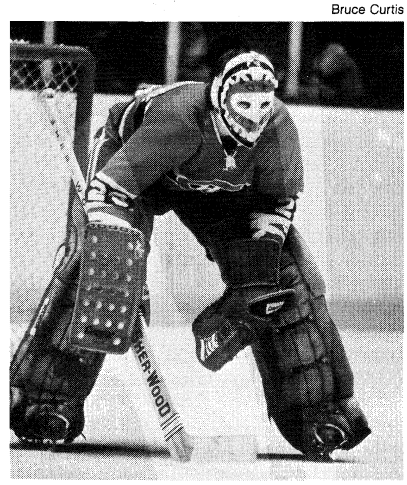
Ideally, the attacking team moves as a unit, led by the forwards. The centre generally is the most adroit stickhandler of the attackers and must be able to get by onrushing defenders. When he cannot, he passes off to one of his wings or drops the puck behind him for one of his defensemen. If he is able to get over the other team's blue line, he attempts to set up his men. He tries to do this by drawing the opposition toward him and then passing to one of his wings or defensemen.

A player may handle the puck as often or as long as he likes, so long as he does not close his glove on the puck. A player may not pass the puck with his open hand. The goalie, however, is generally not subject to either restriction.

The game is divided into three periods of 20 minutes playing time each. Hockey games may end in a tie unless the rules stipulate an overtime period to serve as a tiebreaker. In the case of a tie in college hockey one 10-minute sudden-death overtime period is played in regular season play. NHL teams play a five-minute sudden-death overtime period. During the play-offs college hockey has 10-minute overtime periods until there is a winner, while the NHL has the same system with 20-minute periods. There is no overtime period in international hockey.

In organized ice hockey a victory is worth two points in the standings; a tie is worth one. A goal counts as a point for the team, but individual points may be awarded to as many as three players for one goal. One point goes to the player who scored the goal, and a point each is awarded for an assist to the last two of the scorer's teammates who touched the puck, providing that the opposition did not handle the puck in the interim.

Of the major sports ice hockey is the only one in which substitutions are permitted while the game is in play. The game is so fast and so demanding that forwards generally skate only 90 seconds at a time. This means that there are at least 10 "line changes" a period, and if play were stopped each time a line change is made the tempo would be markedly decreased. Defensemen usually stay on the ice for a slightly longer period of time.



Infractions and penalties

Because of the speed and contact there are many infractions, not all of them having to do with "hitting" penalties. Play is stopped for an offside and for the infraction called icing, which occurs when a team shoots the puck out of its zone past the other team's goal line. Icing is not called against a team when it is shorthanded; if the teams are even-handed, the puck is returned to the defensive zone of the team that iced it for the face-off. No player, however, may delay the game by intentionally shooting the puck out of the rink or by shifting the goalposts.

Minor penalties are most commonly assessed for excessive use of the body or equipment to impede the opposition. For a minor infraction the offending player must remain in the penalty box at the side of the rink for two minutes while his team plays shorthanded. If the opponents score at any time during that penalty period, the penalized player may return to the ice. Penalties incurred by the goalie are served by a teammate. A major penalty for violent play or a misconduct penalty for abusing an official results in the loss of a player for five or 10 minutes or for the remainder of the game. Unless there is deliberate injury, the offender's team makes a substitution and is not shorthanded when play resumes. Violent play in modern professional hockey has drawn much criticism.

There are three common types of shots in hockey. One of these, the slap shot, has been timed at more than 100 miles an hour. Bobby Hull, who played mostly for the Chicago Black Hawks and was the first NHL player to score more than 50 goals in a season, had one of the game's hardest slap shots. The slap shot differs from the wrist shot in that the player brings his stick back so far that it is nearly perpendicular with the ice and then brings

the stick down in an arc, swatting the puck as he follows through. It is not as accurate as the wrist shot, in which the player puts his stick on the ice near the puck and without a windup snaps his wrist to fire off a shot.

The other most common shot is the backhander, taken when the puck goes to the other side of the stick from which the player normally shoots. If he is a right-handed shooter, for example, he takes the backhander from his left side. It is taken when there is not enough time to shift the puck to his normal shooting position. The backhander generally is not as hard or as accurate as the wrist shot, but it has the advantage of being taken quickly. Many experts agree the hardest backhander in the professional game belonged to Maurice ("The Rocket") Richard of the Montreal Canadiens. A natural left-handed shooter, he played right wing. He was the first in the NHL to score 50 goals in a season.

Strategies. Speed is an essential requirement of the game. In the sport's early days a team could get away with having a few slow defensemen. But contests at all levels became so quick that offensive and defensive roles often are reversed, and defensemen may find themselves at the forefront of the action. Slower players must have other attributes to make a team; they must, for example, be able to check well, to prevent the other players from getting past them. But, since everyone on the team handles the puck at some point during a game, a premium is placed on puck-carrying ability. The man with the puck is in control, and the play can go only so fast as he directs it. Centre Wayne Gretzky, while playing for the Edmonton Oilers, was the dominant scorer in the NHL for most of the 1980s due to his outstanding puck handling and his accurate shooting and passing.

Offensive and defensive play and strategy

If a forward has the puck, the defensemen trail the play. If a defenseman is leading an offensive thrust, called a "rush," one of the forwards backs him up. The opposition, meanwhile, attempts to gain control of the puck or to dislodge it. The most common way is for the defending player to poke his stick at the puck. A defender may also block, check, or hit the player with his body, as long as it falls within the rules defining allowable contact. Ideally, the defending team's defensemen lay back, straddling their blue line, away from the boards. They then can move to the centre to halt a breakthrough or can drive a man into the boards if he attempts to go along the sides. If the attacking players find that they have difficulty in stickhandling past the opposition, they may try a long shot "on goal." They may also shoot the puck into the other team's zone and chase it, two attacking players going after the puck—one to handle the opponent, who is sure to go after it, and the other to try to wrest the puck away. The third forward, meanwhile, takes up a position about 20 feet in front of the goal, in the centre of the ice, in a spot known as the "slot." In the slot he is in position to shoot if he gets the puck. The defensemen on the attacking team take up positions on the blue line to prevent the defending team from getting a breakaway. Often the puck is passed to the defensemen, who shoot from the blue line, 60 feet out, from their position known as the "point." Long shots rarely go in, so defensemen try to keep long shots low, which gives the attackers a chance at a rebound.

Many fans do not see goals scored in hockey because so many go in on rebounds or deflections. While a shot is taken, no attacking player may be in the goalie's crease, a rectangle eight feet across and four feet out from the goal line; but there is much physical contact in front of the net, and the puck may ricochet off a skate, a stick, or any part of the body. Any kind of shot that puts in a goal is allowable, unless the shooter has raised his stick above his elbow; but the puck may not be deliberately kicked in, and it cannot be thrown in with the hand.

One of the most unusual spectacles in hockey occurs when a team that is trailing by one goal takes its goaltender out of the net in the final seconds of the game. The goalie is replaced by a forward in the hope that the extra man on offense will give the team a chance for a tie. Another rare and exciting play is the penalty shot, which is called when a stick is thrown to deflect a shot or when a player with an open path to the goal is pulled down from behind. The team against which the infraction was committed selects a player to skate unopposed to the opponent's goal and take one shot to beat the goalie; this generally results in a score for the shooting team.

Officiating. All NHL and international games and many collegiate games are under the control of one referee, two linesmen, and various off-ice officials. Referees are responsible for calling penalties and are the final arbiters of whether a goal has been scored. Linesmen call offsides and icing infractions; they may also stop play in order to inform a referee that a team has too many players on the ice. In some NCAA games two referees and no linesmen or two referees and one linesman are used, one of the referees being the final arbiter of disagreements. The IIHF sanctions the two-referee system for games under the jurisdiction of national federations. The goal judges are stationed behind each cage in a raised booth behind the boards. The goal judges' function is to signal a goal when the puck has crossed the goal line. They are not concerned with whether the goal is legal, merely whether it was scored. To indicate a goal, they flip a switch that stops the clock and triggers a red light. The other officials are the penalty timekeeper, who must not let a player out of the penalty box until his penalty time is served or a goal is scored; the game timekeeper, who is in charge of running the official clock and who stops the clock during play stoppages; and the official scorer, who decides who gets credit for the goals and assists and also keeps track of the goalie's saves, or stops. MAJOR INDIVIDUAL SPORTS

The individual sports are those that require the skill of a single athlete in competition with one or more other athletes. Sometimes the athletes are in a one-on-one competition, as in singles tennis, and sometimes they compete against a field of players, the best score winning, as in golf. Participants in individual sports are sometimes called a "team" when they form a group from a single school or institution that plays other like groups or teams, such as golf teams, tennis teams, or bowling teams. The difference here is that the athlete on an individual sport "team" still performs largely without the aid of teammates, as opposed to such sports as football and basketball, which are heavily dependent on teamwork. All of the major team sports discussed in the first part of this article involve the use of a ball, or as in the case of ice hockey, a puck; some of the individual sports, on the other hand, such as boxing and athletics, do not involve a ball. The individual sports discussed here are the ones that have generally achieved the widest international participation and interest, including tennis, golf, athletics, boxing, and bowling. (Ed.)

Tennis

Reduced to its simplest terms, tennis is a game in which two opposing players (singles) or pairs of players (doubles) use tautly-strung rackets to hit a ball of specified size, weight, and bounce over a net on a rectangular court. Points are awarded to a player or team whenever the opponent fails to correctly return the ball within the prescribed dimensions of the court. Organized tennis is played according to rules sanctioned by the International Tennis Federation (ITF), the world governing body of the sport. Tennis originally was known as lawn tennis, and formally still is in Britain, because it was played on grass courts by Victorian gentlemen and ladies. It is now played throughout the world on a variety of surfaces.

The origins of the game can be traced to a 12th–13th-century French handball game called *jeu de paume* ("game of the palm"), from which was derived a complex indoor racket-and-ball game: real (royal) tennis. This ancient game is still played to a limited degree and is usually

called real tennis in Britain, court tennis in the United States, and royal tennis in Australia. The modern game of tennis is played by millions in clubs and on public courts. Its period of most rapid growth as both a participant and a spectator sport began in the late 1960s, when the major championships were opened to professionals as well as amateurs, and continued in the 1970s, when television broadcasts of the expanding professional tournament circuits broadened the appeal of the game.

Modern innovations

A number of major innovations in fashion and equipment fueled and fed the boom. The addition of colour and style to tennis wear created an entirely new subdivision of leisure clothing. Tennis balls, which historically had been white, now came in several hues, with yellow the colour of choice. Racket frames, which had been of a standard size and shape and constructed primarily of laminated wood, were suddenly manufactured in a wide choice of sizes, shapes, and materials, the most significant milestones being the introduction of metal frames beginning in 1967 and the oversized head in 1976.

While tennis can be enjoyed by players of practically any level of skill, top competition is a demanding test of both shot making and stamina, rich in stylistic and strategic variety. From its origins as a garden-party game for ladies in whalebone corsets and starched petticoats and men in long white flannels, it has evolved into a physical chess match in which players attack and defend, exploiting angles and technical weaknesses with strokes of widely diverse pace and spin. Tournaments offer tens of millions of dollars in prize money annually. (For winners of the major men's and women's championships and of the Davis Cup competition, see SPORTING RECORD in the *Micropædia*.)

HISTORY

Origin and early years. There has been much dispute over the invention of modern tennis, but the officially recognized centennial of the game in 1973 commemorated its introduction by Major Walter Clopton Wingfield, of Nantclwyd in north Wales, in 1873. He published the first book of rules that year and took out a patent on his game in 1874, although historians have concluded that similar games were played earlier and that the first tennis club was established by the Englishman Harry Gem and several associates in Leamington in 1872. Wingfield's court was of the hourglass shape that had been adopted by badminton. The publication of his version of "Sphairistiké, or Lawn Tennis," led to a spate of other claims to the invention of the game, most of which involved a rectangular court. At the time, the Marylebone Cricket Club (MCC) was the governing body of real tennis, whose rules it had recently revised. After a distinguished real tennis player, J.M. Heathcote, developed a better tennis ball of rubber covered with white flannel, the MCC in 1875 established a new, standardized set of rules for tennis.

Meanwhile, the game had spread to the United States in the 1870s. Mary Outerbridge of New York has been credited with bringing a set of rackets and balls to her brother, a director of the Staten Island Cricket and Baseball Club. But research has shown that William Appleton of Nahant, Mass., may have owned the first lawn tennis set and that his friends James Dwight and Fred R. Sears popularized the game.

The All-England Croquet and Lawn Tennis Club

An important milestone in the history of tennis was the decision of the All-England Croquet Club to set aside one of its lawns at Wimbledon for tennis, which soon proved so popular that the club changed its name to the All-England Croquet and Lawn Tennis Club. In 1877 the club decided to hold a tennis championship, and a championship subcommittee of three was appointed. It decided on a rectangular court 78 feet (23.77 metres) long by 27 feet (8.23 metres) wide. They adapted the real tennis method of scoring—15, 30, 40, game—and allowed the server one fault (*i.e.*, two chances to deliver a proper service on each point). These major decisions remain part of the modern rules. Twenty-two entries were received, and the first winner of the Wimbledon Championship was Spencer Gore. In 1878 the Scottish Championships were held, followed in 1879 by the Irish Championships.

Spread of the game. There were several alterations in some of the other rules (*e.g.*, governing the height of the net) until 1880, when the All-England Club and the MCC published revised rules that approximate very closely those still in use. The All-England Club was the dominant authority then, the British Lawn Tennis Association (LTA) not being formed until 1888. In 1880 the first U.S. championship was held at the Staten Island Cricket and Baseball Club. The victor was an Englishman, O.E. Woodhouse. The popularity of the game in the United States and frequent doubts about the rules led to the foundation in 1881 of the U.S. National Lawn Tennis Association, later renamed the U.S. Lawn Tennis Association and, in 1975, the U.S. Tennis Association (USTA). Under its auspices, the first official U.S. national championship, played under English rules, was held in 1881 at the Newport Casino, Newport, R.I. The winner, Richard Sears, was U.S. champion for seven consecutive years.

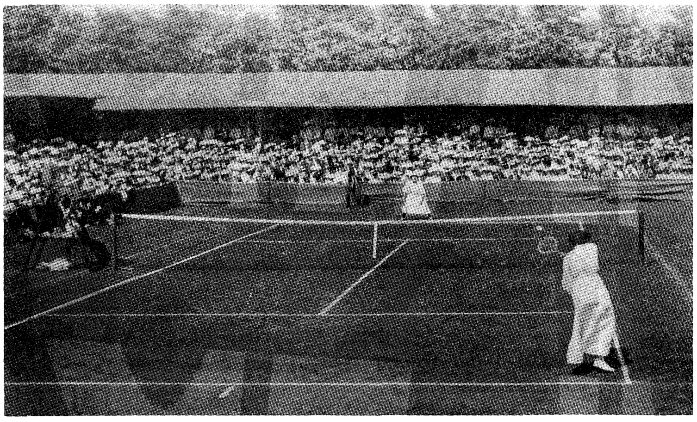
The first official U.S. championship

Tennis had taken firm root in Australia by 1880, and the first Australian championships were played in 1905. The first New Zealand National Championship was held in 1886. In 1904 the Lawn Tennis Association of Australasia (later of Australia) was founded.

The first French National Championships were held at the Stade Français in 1891, but it was an interclub tournament that did not become truly international until 1925; the French Federation of Lawn Tennis was established in 1920. Other national championships were inaugurated in Canada (1890), South Africa (1891), Spain (1910), Denmark (1921), Egypt (1925), Italy (1930), and Sweden (1936). In 1884 a women's championship was introduced at Wimbledon, and women's national championships were held in the United States starting in 1887.

Outstanding players. Tennis in the 1880s was dominated by the remarkable twin brothers William and Ernest Renshaw. William won the Wimbledon singles championship seven times, on three occasions defeating his brother in the final. Ernest was victorious once, and in partnership they won the doubles championship, first played at Oxford in 1879, seven times.

In the 1890s public interest began to wane. The Wimbledon Championships showed a financial loss in 1894 and 1895; the All-England Club committee turned back to croquet to revive its flagging fortunes. The popularity of Wimbledon and tennis were reestablished by two more brothers: Reginald and Laurie Doherty. Reginald won the Wimbledon singles from 1897 to 1900. Laurie won from 1902 to 1906, took the U.S. championship in 1903, and won a gold medal in the Olympic Games in 1900.



Revival by the Doherty brothers

The early 20th century. The first international team competition was the Davis Cup, officially called the International Lawn Tennis Challenge Trophy, which was donated by U.S. doubles champion Dwight Davis in 1900. Only Great Britain challenged the first year and was defeated by the United States, Davis himself playing on the victorious team. There was no challenge in 1901, but in 1902 a strong British team that included the Doherty brothers went to America. The United States retained the trophy, but the following year the Doherty brothers helped Britain win the cup, which it retained the next three years.

The Doherty reign ended in 1906, but tennis was by then firmly established. The new star was Norman Brookes, the first in a long line of Australian champions and the first left-hander to reach the top. He won at Wimbledon in 1907 and again on his next visit, in 1914. He and his doubles partner, Tony Wilding of New Zealand, wrested the Davis Cup from Great Britain in 1907 and held it until 1911, arousing enduring public interest in Australia and New Zealand.

Of the women champions of the early 1900s, Dorothea Douglass (later Mrs. Lambert Chambers) won the Wimbledon Championship seven times, beginning in 1903. In 1905, however, Douglass met her match in the first U.S. women's champion to win at Wimbledon, May Sutton, who again defeated her at Wimbledon in 1907. The outbreak of World War I in 1914 interrupted tennis activities in Britain and Europe, but with the exception of 1917, when a Patriotic Tournament was held, U.S. championships continued to be played.

W.T. ("Big Bill") Tilden of the United States and Suzanne Lenglen of France. Tilden, the U.S. champion from 1920 through 1925 and again in 1929, won the Wimbledon title in 1920, 1921, and 1930. In the same period Tilden won 15 Davis Cup singles.

Suzanne Lenglen

Lenglen reigned supreme over the ladies' game from 1919 to 1925, and were it not for the war might have started her international career earlier. She won the Wimbledon championship at her first attempt in 1919, from 1920 to 1923, and in 1925, not having competed in 1924 because of illness. She had developed a powerful as well as accurate game by practicing with men, and she needed far more freedom of movement than restrictive ladies' fashion of that time had allowed. Her first appearance at Wimbledon in a calf-length white dress with short sleeves and without petticoat or suspender (garter) belt caused a sensation.

France also made its mark on men's tennis with the fabulous "Four Musketeers"—Jean Borotra, Henri Cochet, René Lacoste, and Jacques Brugnon. Among them, they monopolized the Wimbledon singles title from 1924 through 1929, won 10 French and three U.S. singles championships, and won five Wimbledon and 10 French doubles championships. They captured the Davis Cup from the United States in 1927 and held it until 1933.

Helen Wills Moody

A new U.S. woman star, Helen Wills (later Mrs. Moody and then Mrs. Roark), won the first of her seven U.S. singles titles in 1923; she went on to win at Wimbledon eight times between 1927 and 1938 and won the French singles four times between 1928 and 1932. Only once, early in her career, did she play against Lenglen, at Cannes on the French Riviera, where she lost in two straight sets. That historic meeting between the poker-faced Wills, in her trademark white eyeshade, and the flamboyant Lenglen, in her daring dress and silk bandeau, was chronicled in sports and society pages on both sides of the Atlantic. Wills's great rival, however, was another American, Helen Jacobs, Wimbledon champion in Wills's absence in 1936 and U.S. champion from 1932 to 1935.

The Englishman Fred Perry won the Wimbledon singles for three consecutive years (1934–36), the U.S. championship in 1933, 1934, and 1936, the Australian in 1934, and the French in 1935. From the United States came champions that included Sidney Wood, Ellsworth Vines, and Don Budge, who in 1938 became the first man to win all four major titles—the Australian, French, Wimbledon, and U.S.—in one season, a feat that came to be known as the grand slam. Alice Marble, the most aggressive net-rusher the women's game had seen to that time, won the U.S. singles in 1936 and from 1938 to 1940, and in 1939 won the singles, doubles, and mixed doubles at Wimbledon, a "triple" previously accomplished only by Lenglen and Budge.

Alice Marble's triple

The postwar period. The development of the game was interrupted by World War II, but international tennis resumed in 1946 with U.S. players again dominant, led by Jack Kramer, the U.S. champion of 1946–47 and Wimbledon champion of 1947 before he turned professional. He was succeeded by Pancho Gonzales, Bob Falkenburg, Frederick (Ted) Schroeder, J. Edward ("Budge") Patty, and Dick Savitt. American women won every Wimbledon and U.S. singles title from 1946 through 1958, the string of champions including Pauline Betz, Louise Brough, Margaret Osborne DuPont, Doris Hart, Maureen Connolly, Shirley Fry, and Althea Gibson, the first black champion. Connolly, nicknamed "Little Mo," won the three Wimbledon and three U.S. championships that she played between 1951 and 1954 and in 1953 became the first woman to achieve the grand slam.

Australian domination in the 1950s and '60s

Australia ruled men's tennis in the 1950s and '60s, winning the Davis Cup in 15 of 18 years. Among the Wimbledon and U.S. singles champions who played for Harry Hopman, the outstanding nonplaying Australian captain, were Frank Sedgman, Lew Hoad, Ken Rosewall, Mal Anderson, Ashley Cooper, Neale Fraser, Rod Laver, Fred Stolle, Roy Emerson, and John Newcombe.

The broadening international horizons of the game were reflected in the Wimbledon triumphs of players such as Jaroslav Drobny, an expatriate Czech, in 1954 and Alex Olmedo, from Peru, in 1959; and in the victories of Mexican Rafael Osuna in the U.S. championship in 1963; Manuel Santana of Spain in the U.S. championship in 1965 and Wimbledon in 1966; and Brazilian Maria Bueno, the U.S. champion four times and Wimbledon champion three times between 1959 and 1966.

Australian Margaret Smith Court was the second woman to win the grand slam, in 1970, and she set the all-time record for singles, doubles, and mixed-doubles titles in the four major championships; 65 between 1960 and 1975, including three Wimbledon, six U.S., five French, and 11 Australian singles. Billie Jean Moffitt King set a record for career Wimbledon titles, winning six singles, 10 doubles, and four mixed between 1961 and 1979.

Professional and open tennis. As tennis began to establish its popularity, there was need for professionals to coach and to organize, but unlike real tennis, there were no competitions in which professionals could play. This changed in 1926 when Charles C. ("Cash and Carry") Pyle, a successful sports promoter in the United States, offered Suzanne Lenglen $50,000 to go on a professional tour of America playing Mary K. Browne, who had been U.S. singles champion from 1912 to 1914. He also signed four male players. The tour, played in major arenas, drew large crowds and was a financial success. For the next 40 years, pro tennis consisted primarily of barnstorming tours that featured the reigning champion playing a recently signed amateur champion.

Pro barnstorming

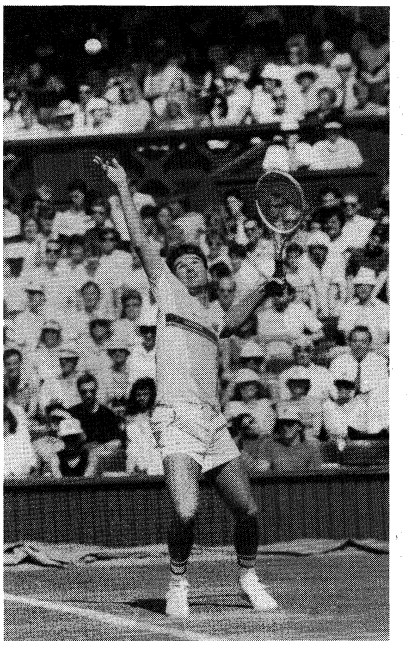
Starting in the 1930s, many of the amateur champions became barnstorming professionals. After World War II, Jack Kramer became the pro champion and in the early

1950s took over promotion of the pro tour. He kept raiding the amateur ranks, signing such stars as Frank Sedgman, Tony Trabert, Lew Hoad, and Ken Rosewall. They made money with the one-night stands, but their matches were virtually unreported. Although the traditional tournament circuit was avowedly amateur, leading players were paid substantial guarantees "under the table" in addition to expenses. For more than four decades there was discussion of having "open" competition between amateurs and pros to end the hypocrisy of "shamateurism," but proposals were always defeated by conservative elements within the ILTF. In 1967, however, two new professional groups were formed: the National Tennis League, organized by former U.S. Davis Cup captain George MacCall, and World Championship Tennis (WCT), founded by New Orleans promoter Dave Dixon and funded by Dallas oil and football tycoon Lamar Hunt. Between them, they signed a significant number of the world's top players, professional and amateur.

In 1967 a British proposal for a limited schedule of open tournaments was voted down by the international federation, but the British LTA refused to accept the verdict. In December 1967, despite threat of expulsion from the International Lawn Tennis Federation (ILTF—later the ITF), the LTA voted to abolish the distinction between amateurs and pros in their tournaments. This revolutionary step forced an emergency meeting of the ILTF in March 1968 in which 12 open tournaments were approved. The era of open professionalism in tennis dawned in 1968.

Acceptance of open tournaments

The first open tournament was the British Hard Courts at Bournemouth in April 1968, where the champions were Ken Rosewall and Virginia Wade. The first open Wimbledon was a joyous occasion, as many past champions who had been stripped of membership in the All-England Club when they turned professional were welcomed back. The total prize money was £26,150 ($62,760), of which £2,000 went to men's singles champion Rod Laver and £750 went to women's singles winner Billie Jean King. The singles titles at the first U.S. Open, with a total purse of $100,000, were won by Arthur Ashe, the sport's first black male champion, and Wade. Within two decades the major championships had multimillion-dollar purses, and top players could expect to earn in excess of $1,000,000 a year on the court alone. Laver became the first player to sweep the major titles a second time and the first to do so as a professional.



The transition years from quasi-amateurism to full-fledged professional tennis were rife with political disputes and lawsuits for control of what had become a big-money sport. Both male and female players formed guilds: the men's Association of Tennis Professionals (ATP) and the Women's Tennis Association (WTA), which in 1986 became the Women's International Tennis Association (WITA). Previous player unions had been ineffective, but the ATP showed itself a potent political force when the majority of its members boycotted Wimbledon in 1973 in a dispute over the eligibility of the Yugoslav pro Nikki Pilic. The women's union proved similarly unified. The women had a separate pro tour, apart from the men, except at the major championships, since 1971.

Players' guilds

The first few seasons of open tennis were ruled by players who were products of the old system and reflected its behavioral standards and norms. These included the compact, classical Rosewall, the Australian John Newcombe, and the Americans Arthur Ashe and Stan Smith.

As television, in America and later worldwide, became an increasingly significant force in tennis, a new breed of flamboyant and often flippant, cocky, and quick-tempered player developed. Among them was Ilie Nastase—a dark, handsome, mercurial Romanian noted for his rapid mood swings. While winning the 1972 U.S. Open, the 1973 French Open, and four Masters titles, he created chaos and controversy on the court with colourful, and occasionally off-colour, tantrums and tirades. He was perhaps an influence on Jimmy Connors, a brash American whose aggressive, blood-and-guts, all-court style and feisty temperament captivated audiences whether they loved or loathed him. In 1974 Connors won Wimbledon and the Australian and U.S. opens. In an intensely competitive era that produced short careers, Connors enjoyed extraordinary longevity at the top. He won Wimbledon again in 1982, the U.S. Open four more times, and the WCT Championship in 1977 and 1980.

Following the fiery Connors as the dominant player was the relatively cool Bjorn Borg, who led Sweden to its first triumph in the Davis Cup in 1975. Practically unbeatable on slow clay, he won the French Open six times between 1974 and 1981 and remarkably adapted his game to fast grass, adding a sledgehammer serve and underspin approach shot, to win Wimbledon five years running, 1976–80. No player had done that since the champion had to play through the draw, starting in 1922. The American John McEnroe ended Borg's Wimbledon reign in 1981 and beat him in the 1980–81 U.S. Open finals. Between 1979 and 1984 McEnroe, a torrid-tempered left-hander of exquisite athleticism and racket control, won Wimbledon three times, the U.S. Open four times, the Masters three times, and the WCT Championship four times.

The balance of power in men's tennis shifted back to Europe in the 1980s. Borg inspired a new wave of players in Sweden. A sophisticated junior-development system created a group of Swedish players—led by 1982, 1985, and 1988 French Open champion Mats Wilander. Another European country with a long tennis tradition that reached new heights in the 1980s was Czechoslovakia. One of the foremost players and coaches in Europe in the 1920s and '30s was the Czech Karel Kozeluh. Czechoslovakia produced men's Wimbledon champions Jaroslav Drobny in 1954 and Jan Kodeš in 1973. Among the players to come out of Czechoslovakia's player-development system and become dominant in the 1970s and 1980s were Martina Navratilova, who became a U.S. citizen; Hana Mandlikova, who became an Australian citizen in 1987; and Ivan Lendl, who took up residence in the United States. The European tennis boom of the 1980s also swept West Germany, which produced Boris Becker, who won the Wimbledon singles in 1985 at age 17 (the youngest man and first unseeded player to do so), and Steffi Graf, who in 1987 ended Navratilova's five-year reign as the top-ranked woman in tennis and in 1988 won the grand slam, becoming the first woman to do so since Margaret Court in 1970.

The Czech tradition

Emergence of Steffi Graf

Graf's emergence also ended an extraordinary streak by the American Chris Evert, who had won at least one of the grand slam singles titles for 13 consecutive years, 1974–86, an unprecedented feat. A paragon of back-court consistency and controlled temperament, Evert was the

perfect contrast in both style and personality to several net-rushing rivals: the Australian Evonne Goolagong, who won her first Wimbledon in 1971, at age 19, Billie Jean King, and Navratilova, whom Evert played in 13 grand slam finals in one of the game's greatest rivalries. Evert, probably more than anyone, popularized the two-handed backhand, and she made a steady baseline game the prevalent style of a whole generation of women players.

Organization and tournaments. The ITF and the national associations that comprise it govern tennis worldwide; they oversee international competitions such as the Davis Cup and Federation Cup and tennis in the Olympic Games, which was restored to medal-sport status for the 1988 Games—the first time since 1924. The professional circuits were governed from the late 1970s by the Men's and Women's International Professional Tennis councils. These groups, made up of representatives of the ITF, players, and tournaments, oversee the international calendar, the implementation of rules and codes of conduct, and the training and supervision of tour officials. The councils work closely with the ATP and WITA, which supply a number of services and benefits to players and tournaments and maintain rankings that provide the basis for entry into tournaments and seedings.

The major championships. Until 1974, when South Africa won by default over India, only four nations had won the Davis Cup: Australia, Great Britain, France, and the United States. The championships of those four countries are the traditional "major" tournaments that make up the grand slam. Wimbledon in Britain is the oldest, having been played on the lawns of the All-England Club since 1877. The French championships, played at Stade Roland-Garros in Auteuil, on the outskirts of Paris, are recognized as the world's premier clay-court tournaments. The U.S. championships were played on grass from their inception in 1881 through 1974; the next three years they were played on a synthetic clay surface at the West Side Tennis Club in Forest Hills, N.Y., and in 1978, the tournament moved to the rubberized asphalt courts of the USTA National Tennis Center in nearby Flushing Meadow Park. The Australian Championships were played on grass in several cities until 1968, when they moved to Melbourne; in 1988 they moved within that city to the synthetic courts of the new Australian National Tennis Centre.

The championship team events

The principal team events are the Davis Cup, Federation Cup, and Wightman Cup (U.S. versus British women). The Davis Cup series consists of five matches played over three days: two singles, one doubles, then two "reverse" singles. From 1923 through 1965 the Davis Cup draw was played in two zones, and from 1966 through 1980 in four zones. Starting in 1981, the top 16 teams competed in a World Group and all other participating nations in four zones. The Federation Cup, inaugurated in 1963, is contested at one site over a one-week period, each series consisting of three matches: two singles and a doubles. The Wightman Cup alternates between U.S. and British sites and comprises best-of-seven matches: five singles and two doubles.

PLAY OF THE GAME

Court and equipment. The dimensions of the tennis court are 78 by 27 feet (23.77 by 8.23 metres) for singles and 78 by 36 feet (23.77 by 10.97 metres) for doubles. The height of the net at the centre is three feet, and it is supported at each side of the court by posts 3½ feet high at three feet outside the court (see Figure 13). Tennis was originally called "lawn tennis," and grass courts are still in use, but the most common court materials today are clay (called "hard courts" in most places, although in the United States that term refers to any hard surface), cement, and a number of cushioned asphalt derivatives and synthetic surfaces. The latter may be hard surface or artificial grass, materials that have become popular for indoor courts along with the traditional wood. A tennis ball consists of a pressurized rubber core covered with high-quality cloth, usually wool mixed with up to 35 percent nylon. Balls gradually go soft with use, and in tournament play they are changed at regular intervals agreed upon by officials and depending upon such factors as the court surface. Balls must have a uniform outer surface, and, if there are any seams, they must be stitchless. The ITF specifies that the ball must be between 2½ inches (6.35 centimetres) and 2⅝ inches in diameter, and between two ounces (56.7 grams) and 2 1/16 ounces in weight. The ball must have a bound between 53 inches and 58 inches when dropped 100 inches upon a concrete base.

Court surfaces

Nothing in the rules defined the racket until 1981. After an ITF committee had made studies of the so-called "double-strung" or "spaghetti" racket, introduced in 1977, which had two layers of strings that imparted topspin on the ball, it was banned by the following rule: "A racket shall consist of a frame, which may be of any material, weight, size or shape and stringing. The stringing must be uniform and smooth and may be of any material. The strings must be alternately interlaced or bonded where they cross. The distance between the main and/or cross strings shall not be less than one quarter of an inch nor more than one-half inch. If there are attachments they must be used only to prevent wear and tear and must not alter the flight of the ball."

The ITF racket rule

Principles of play. Opponents spin a racket or toss a coin to decide on side and service. The winner may decide to serve or receive serve first, in which case his opponent chooses the side, or may decide on a choice of side, in which case the opponent may choose to serve or receive service first. The players serve alternate games and change sides after every odd number of games.

Beginning each game from behind his right-hand court, the server has both feet behind the baseline and strikes the ball diagonally across the net and into the opponent's right-hand service court. Should the ball on service strike the top of the net before falling in the correct service court, it is a "let" and is replayed. The server is allowed one miss, or "fault," either into the net or outside the opponent's service court. Failure to deliver a correct service on two attempts constitutes loss of the point.

To return service, the receiver strikes the ball back before it hits the ground a second time, over the net and within the boundaries of the opponent's court. After the service has been correctly returned, either player may volley the ball (*i.e.*, hit it before it bounces) or hit it after its first bounce, and the point continues until one player fails to make a correct return. This may occur if he fails to hit the ball over the net, if he hits it outside the opponent's boundaries, or if he fails to hit it before it strikes the ground a second time on his side of the net.

Return service and volley

To win a game, a player must win four points and have a margin of two. The scoring goes 15, 30, 40, game; this system, derived from real tennis, is medieval in origin. It never has been satisfactorily explained why three points equal 40 rather than 45. Zero is generally referred to as "love," which is thought to be derived from *l'oeuf,* the French word for "egg." The server's score is called first; thus, 30–15 means that the server has two points to one, whereas 15–30 means that the receiver has two points to one. If both players reach 40, the score is said to be "deuce," and the game continues until a player achieves first "advantage" and then the two-point margin for "game." There is no limit to the number of times a game can go to deuce before it is decided, but in some competitions, a so-called "no-ad" system is used, which means that no two-point margin is required and the first player to win four points wins the game. As points make

up a game, games make up a set, and sets make up a match. The first player to win six games traditionally wins the set, although again a two-game margin is required; thus, a five-games-all set cannot be won before 7–5.

Since the early 1970s virtually all competitions have come to employ tiebreakers to eliminate marathon sets. Usually played at six games all, the tiebreaker can consist of an odd number of points with no two-point margin required ("sudden death") or an even number of points with a two-point margin required. For example, in a 12-point tiebreaker the first player to reach 7 points with a margin of 2 wins the tiebreaker game and the set, 7–6. Virtually all tournaments now play tiebreakers at six games all. In major tournaments and the Davis Cup and Olympic Games, men generally play best-of-five-set matches and women best-of-three. In most other tournaments, men now also play best-of-three sets; women occasionally play best-of-five for finals.

Doubles play and scoring

The same basic principles of play and scoring apply to doubles. Service alternates between the two opposing teams, but each team must decide at the start of each set which partner shall serve first. Equally, the receiving team must decide at the start of each set which of them shall receive service first, and they then receive service on alternate points for that game and set. Thus, the server will alternate sides of the court on successive points in each game, but the receiver will always receive on the same side of the court during that game (and the set).

Strategy and technique. Although successful strokes and strategy can vary widely on different court surfaces, on all but the slowest courts there has always been a premium on a punishing serve and effective play at the net. The server usually has a considerable advantage for two reasons. With a combination of power and clever angle and spin, he can win points outright with the serve, called an "ace" if the opponent cannot get his racket on the ball and a "service winner" if the opponent reaches it but cannot play it, or the server can force such a weak return that his second shot is an easy "kill." Especially on faster surfaces, the server may also follow his delivery to the net and establish his position. At the net, a player is always vulnerable to a passing shot—one angled cross-court or played down-the-line, beyond reach—but if the serve or approach shot puts the opponent under enough pressure, the server, now at the net, has the upper hand, since a volley is generally easier to put away (play for a point) than a ground stroke (one played on a bounce). An effective first serve is a considerable asset on any surface. The best servers not only deliver the ball hard, but they vary their patterns so that a receiver cannot anticipate where the serve is coming. Equally important is the ability to deliver an effective second service (one made after an initial fault), usually with less power but more spin or "kick."

Volleying technique

For good volleyers, the key to winning is to get to the net, behind either the serve or approach shot. For players whose strength is their ground stroke, the priority is to maneuver the opponent into a vulnerable position for a winning passing shot, placement, or drive that forces an error. All shots after the serve—volley or ground stroke—can be played either on the forehand (where, if the racket were viewed as an extension of the hand, the palm would be striking the ball) or the backhand (where the back of the hand would be striking the ball).

Styles of play at the top level have varied widely with changing court surfaces. When most major tournaments were played on grass, for instance, there was a distinct advantage to a powerful serve-and-volley game and short, controlled, underspin ground strokes that kept the ball low. When slow clay became the predominant surface of the professional game in the mid-1970s, there was more emphasis on solid ground strokes and topspin, which allowed players to loop the ball well over the net and have it bounce high, pinning opponents to the backcourt. Hard-surface courts of medium speed and true bounce favour an all-court game and enable both net rushers and baseliners to play their preferred styles.

Other strokes, besides the serve, volley, and drive, include the lob, overhead smash, half volley, and drop shot. The lob, a soft high-arched loop, can be played either defensively, to try to recover from an awkward, vulnerable position where an attacking stroke is impossible, or offensively, to get the ball over the reach of an opponent at the net and put him on the defensive. The player who makes an offensive lob often follows it to the net, but if a lob is not high enough to get over the opponent, it can be returned with an overhead smash, the most forceful of strokes. The player making the smash often leaps to hit the ball with a stroke similar to the serve from a position approximating the service toss. The half volley is a shot played on a very short bounce, usually a defensive stroke effected when one cannot quite reach an opponent's shot in the air and volley it. The drop shot, which is often hit from the same motion as a drive, attempts to get the ball just over the net with underspin so that it barely bounces, either catching an opponent flat-footed in the backcourt where he cannot reach the ball or forcing him to run in and lunge at the ball, leaving him off balance.

Golf

Golf is a cross-country game played by striking a small ball with various clubs from a series of teeing grounds into a like series of holes on a course. The player who holes his ball in the fewest strokes wins. The game originated in Scotland and has spread from obscure antiquity to world-wide popularity. Played in the beginning on seaside links with their crisp turf and natural hazards and afterward on downs, moorland, and parkland courses of various lengths and characteristics, it combines with its open air and exercise an intrinsic fascination. Its players participate at every level, from recreational golf to popular televised professional tournaments. Despite its attractiveness golf is not a game for everyone; it requires a high degree of skill that is honed only with great patience and dedication, and it requires an investment in equipment and fees that persons of average means may not feel worthwhile. The novice is often discouraged by these factors.

HISTORY

Origin and early years. The game's origin has long been a subject of controversy. Broadly, the issue has been whether it originated in Scotland or Holland. Its antiquity in Scotland is beyond question because of documentary proof of its long lineage. The first written reference to the sport was made in 1457, when the Parliament of King James II decreed that both "Fute-ball and Golfe be utterly cryed downe" because they interfered with the practice of archery, which was necessary for the defense of the realm. Similar decrees were also enacted in 1471 and 1491; the latter decree, which was issued during the reign of James IV, indicted them as "unproffitable sportis." One obvious implication of these laws is that golf had become a popular obsession in Scotland even before the mid-15th century.

Controversy over origin of the game

Continental games. Comparisons between ancient continental games and Scottish golf make an interesting study, with the balance of evidence in favour of Scotland. During the Roman domination in Europe, a popular game was *paganica* (from *paganus,* "country-man," or "rustic"), a cross-country pastime played with a bent stick and with, it seems, a leather ball stuffed with feathers, like the early golf balls in Scotland; but it can be disregarded merely as a link between legend and history. Early games in the Netherlands have a more striking similarity to golf, notably the Dutch game of *kolven* or *kolf* because of the name *kolf* for a club and the fact that the clubs seen in early Dutch pictures suggest something like golf. Of the continental games the game of *chole* (*choulla* or *choulle*) had some resemblance to golf. More Belgian (Flemish) than Dutch, it was a cross-country pastime in which each side, whether one player or several, used one ball and played to a prearranged target—a church door, for example—at a considerable distance from the starting point.

The games of *kolven* and *chole*

Scotland. Scotland's King James IV, who had embargoed the game in 1491, later became the first player of whom there is authentic record. The Lord High Treasurer's accounts early in the 16th century include payments for the King's equipment—"golf clubbis and ballis." The

Stuarts gave the game its first woman golfer, too—Mary, Queen of Scots, who was charged with playing in the fields beside Seton only a few days after the murder of her husband, Darnley. James VI was noted for promoting the game. When he succeeded to the English throne as James I, he took his courtiers and his clubs with him.

Development of golfers' associations. *Early British societies.* There is a tradition that James I introduced golf to Blackheath in 1608, which has been given, erroneously according to some authorities, as the foundation year of the historic Royal Blackheath Golf Club. Although King James and his courtiers played their golf somewhere in the vicinity, it is doubtful whether any organized societies then existed, and research has set its date nearly two centuries later. W.E. Hughes, editor of the *Chronicles of Blackheath Golfers,* ascribes the club's foundation to 1787.

The oldest club with documentary proof of its origin is the Company of Gentlemen Golfers, now the Honourable Company of Edinburgh Golfers, whose modern home is at Muirfield in East Lothian. Its genesis was a move by a group of players to hold a competition or tournament. In 1744 "several Gentlemen of Honour skillful in the ancient and healthfull exercise of Golf" petitioned the Edinburgh city council to provide a silver club for annual competition on the links of Leith.

The Society of St. Andrews, now the Royal and Ancient Golf Club of St. Andrews, Scotland, was formed in 1754 by a group of 22 golfers who played there. The rules that the society adopted were almost identical with the Edinburgh Gentlemen Golfers' rules. These two clubs played major roles in the development of the game in Scotland. Eventually, the Royal and Ancient Golf Club (R. and A.) became, by common consent, the oracle on rules. In 1919 it accepted the management of the British Open and Amateur championships. The R. and A. thus became the governing body for golf in the British Isles and throughout most of the Commonwealth.

Early clubs in England

With the birth of the Royal North Devon Club in 1864, the game took a firm foothold in England. It was the first course on seaside links outside Scotland. The Royal Liverpool Club was established in 1869 on a rabbit warren at Hoylake. In its infancy players simply cut holes with their penknives and stuck feathers in them for the guidance of those who were coming behind. The rabbits were the greenkeepers. By 1870 the club was fairly founded, and members played matches against Blackheath, Royal North Devon Club at Westward Ho!, and others. Their influence widened interest in the game. The Royal Liverpool Club hosted Great Britain's first Amateur Championship in 1885 and the first English Amateur Championship in 1925. The first Scotland–England amateur match was organized in 1902, and it was at Hoylake in 1921 that an unofficial contest between British and U.S. players, a curtain raiser to the Amateur Championship, was played and served as the genesis of the Walker Cup series.

The United States and Canada. The following advertisement, which appeared in James Rivington's *Gazette* in New York on April 21, 1779, clearly refers to golf: "To the GOLF PLAYERS: The Season for this pleasant and healthy Exercise now advancing, Gentlemen may be furnished with excellent CLUBS and the veritable Caledonian BALLS, by enquiring at the Printer's." The *South Carolina and Georgia Almanac* of 1793 published, under the heading "Societies Established in Charleston," the following item: "Golf Club Formed 1786." The *Charleston City Gazette and Daily Advertiser* of Sept. 18, 1788, reported: "There is lately erected that pleasing and genteel amusement, the KOLF BAAN." Later notices dated 1791 and 1794 referred to the South Carolina Golf Club, which celebrated an anniversary with a dinner on Harleston's Green in the latter year. Although these fragments constitute the earliest clear evidence of golf clubs in the United States, the clubs appear to have been primarily social organizations that did not survive the War of 1812.

Early records of golf in America

The first permanent golf club in the Western Hemisphere was the Royal Montreal Golf Club, established in 1873. The members played on Fletcher's Fields in the city's central area until urban growth compelled a move of some miles to Dixie, a name derived from a group of Southern refugees who arrived there after the U.S. Civil War. The Royal Quebec Golf Club was founded in 1874; the Toronto and Niagara, Ont., clubs in 1876; and the Brantford, Ont., club in 1879. In the meantime, golf was played experimentally at many places in the United States without taking permanent root until, in 1885, it was played in Foxburg, Pa. The Oakhurst Golf Club in West Virginia, which later became the Greenbrier Club, is said to have been formed in 1884; and the Dorset Field Club in Dorset, Vt., claims to have been organized and to have laid out its course in 1886, although in both instances written records are lacking. The Foxburg Golf Club has provided strong support for the claim that it was organized in 1887 and is the oldest golf club in the United States with a permanent existence. Foxburg also claims the oldest U.S. golf course.

Golf as an organized game in the United States, however, usually is dated from the founding of the St. Andrew's Golf Club at Yonkers, N.Y., in 1888. Its progenitor was John Reid, a Scot from Dunfermline who became known as "the father of American golf." Reid, on learning that fellow Scot Robert Lockhart was returning to the old country on business, asked him to bring back some golf clubs and balls. This done, Reid and his friend John B. Upham tried them out on Feb. 22, 1888, over an improvised three-hole layout. That fall, five men formed the club and in the spring moved to a course in an apple orchard. There, it is said, they hung their coats and a jug of good Scotch whiskey in a convenient apple tree, and they subsequently became known as the "Apple Tree Gang." The club made its final move in 1897 to Mt. Hope in Westchester County, N.Y.

Other early courses included Newport, R.I. (1890); Shinnecock Hills on Long Island (1891); and the Chicago Golf Club (1892) at Wheaton. The Tuxedo Golf Club, New York, founded in 1889, met the Shinnecock men in 1894 in what has been assumed to be the first interclub match in the United States. The Newport club staged an invitation tournament for amateurs in September 1894, and in October the St. Andrew's Club promoted a similar competition. These were announced as championships, but that was questioned because the events were each promoted by a single club and on an invitational basis. It was from the controversy roused by these promotions that the United States Golf Association (USGA) was instituted in 1894. Its aims were to organize the U.S. Amateur and Open championships and to formulate a set of rules for the game. The founding fathers, two from each club, were from St. Andrew's, Shinnecock Hills, Chicago, the Country Club at Brookline, and Newport. The U.S. national championships—the Amateur, the Women's Amateur, and the Open—were inaugurated in 1895.

First championships and the founding of the USGA

Other countries. Before organized clubs had been established in North America, colonies of British settlers, merchants, and civil servants carried golf with them.

India has the oldest club outside of Great Britain; the Royal Calcutta Golf Club was founded in 1829, and the Royal Bombay Golf Club came about 12 years later. The Royal Calcutta initiated an amateur championship for India, and the two clubs paved the way for many in the Far East. The Royal Bangkok Golf Club (1890) was first housed in an ancient temple. Golf came to China when the Shanghai Golf Club was formed in 1896, until which time the game was apparently unknown outside of Hong Kong. The Japanese a few years later constructed a course at Kōbe. The Tokyo Golf Club was founded in 1914. With the boom in the popularity of the game in Japan after World War II, players came to be numbered in the thousands, despite the fact that the shortage of open land made the game enormously expensive to play.

The first club in Australia, the Royal Adelaide Golf Club, was formed in 1870, and it is believed that the game was played in Melbourne in 1847 but went into abeyance for nearly half a century, the gold rush having taken priority over golf for the settlers.

New Zealand origins have been dated from the formation of the Christchurch Golf Club in 1873. South Africa's first course was at the Maritzburg Golf Club, the first in Natal, in 1884, though the Royal Cape Golf Club (1885) has been rated as the country's senior club.

Development of equipment. How the ball is hit and directed is the essence of the game. The result can be fun or frustration, delight or despair. The changing story of the ball's manufacture falls broadly into well-defined phases, beginning with the "feathery," which was used for centuries until it was superseded by gutta-percha.

The feather-ball era. For many years balls were made from wood, but in the early 17th century feather balls were introduced and were hailed as an advance. These balls consisted of boiled feathers that were compressed through a hole left in pieces of stitched leather that composed the cover. For stuffing in the feathers a wooden tool was first used, after which the stuffing iron had to complete the job. When the leather case was crammed beyond increase, the hole was stitched up, the ball hammered and made as round as possible, and then painted white. The whole process was so slow that the maker did well to finish four in a day, so that they cost as much as five shillings each. Although the "feathery" could be hit a long way, it became sodden and disabled in wet weather and was destroyed by hacks from iron clubs, so that the balls were short-lived as well as expensive.

Manufacture of the feather ball

The gutta-percha era. Gutta-percha, the evaporated milky juice or latex of various South American and South Pacific islands trees, is soft and impressible at the temperature of boiling water, but becomes hard and nonbrittle and retains its shape when cooled. It is not affected by water except at boiling temperature. The emergence of the gutta-percha ball about 1848 brought a revolutionary change in the game. The professionals had divided views, however. St. Andrews' Allan Robertson, a leading manufacturer of "featheries," would have nothing to do with it at first; but "Old Tom" Morris, who was then his assistant, wisely foresaw the possibilities of the "gutty," and on this issue the two actually parted company in 1852, Morris going into business on his own. The ball was heartily welcomed by the golf community, not least for its economy—cost, one shilling each—and its coming immediately swelled the golfing ranks. The first examples were smooth and ducked suddenly, a problem corrected when the ball makers learned to mold balls with raised or indented surface patterns so they would fly properly.

The rubber ball. The beginning of the 20th century introduced a new ball and a new era. The U.S. patent of the rubber ball, the invention of Coburn Haskell, a golfer of Cleveland, and Bertram G. Work of the B.F. Goodrich Company, involved a tension-wound rubber thread around a solid rubber core. Its resilience was a great improvement over the "gutty," which was a hard, irresponsive ball that required skill and strength to get into the air after the tee shots. The rubber ball was easier to hit and gave the striker great pleasure and a sense of power. Its impetus created a tidal wave in the game's popularity. Elderly men found it easier to play, and hosts of women and children were drawn into the game. A number of varieties of ball then appeared from manufacturers catering to the golfer's desire to hit the ball farther. Length was the lure, and the trade race upset the design of courses. Championship and other tees had to be sited farther back. Shortly after World War I the Royal and Ancient Club enacted what is called "the 1-62 formula"—that the ball should have a maximum weight of 1.62 ounces (45.93 grams) and a minimum diameter of 1.62 inches (4.11 centimetres). The USGA tried for two years a ball 1.55 ounces (43.94 grams) in weight and 1.68 inches (4.27 centimetres) in diameter, but in 1932 it reverted to a weight of 1.62 ounces while retaining a diameter of 1.68 inches. This larger-sized "American" ball was ruled mandatory by the British Professional Golf Association in 1968 and had replaced the small ball throughout the world by 1980.

Invention of the rubber ball

Early clubs. No golf club from the early 17th century exists; the oldest clubs known were discovered in a house in Hull along with a newspaper carrying a date of 1741. All of these clubs were made of wood, and antiquarian theory is that they were used in the time of the Stuart kings.

In the Royal and Ancient Club's museum there are specimens of ancient clubs including two woods and an especially notable putting cleek—*i.e.*, a putter having an iron head on a wooden shaft—made in the second half of the 18th century by Simon Cossar of Leith, club maker to the Company of Gentlemen Golfers. When Robertson saw that golfing would not be ruined by the gutta-percha ball, he realized the value of iron clubs for approaching and made a cleek for steadier putting. Other developments included "Young Tom" (son of "Old Tom") Morris' idea for the cup-faced niblick for playing the shorter approaches.

Introduction of iron heads

The club makers of outstanding repute in the early 19th century were Hugh Philp at St. Andrews and the McEwan brothers of Musselburgh, notably Douglas, whose clubs were described as models of symmetry and shape. They were artists at a time when clubs were passing from "rude and clumsy bludgeons" to a new and handsome look.

New manufacturing methods. The hickory shafts of the woods—the play club (modern driver), the spoons, and the brassie—had been spliced to heads of apple or beech faced with horn. The harder rubber ball, however, brought about the use of persimmon and, later, laminated club heads. Hard insets appeared in the faces. Increased demand led to the adaptation of shoe-last machine tools for the fashioning of wooden club heads. Sockets were bored in the club heads, and shafts were inserted rather than spliced. Drop-forging completely replaced hand forging in the fashioning of iron clubs, and faces were deepened to accommodate the livelier ball and were machine lined to increase the spin on the ball in flight. Composition materials were developed as an alternative to leather in grips, and the grip foundations were molded in so many ways that they were regulated in 1947. Inventive minds created novel clubs, not only centre-shafted and aluminum putters and the sand wedge but also types that were such radical departures from the traditional form and make that they could not be approved by the USGA or the R. and A. In its revised code of 1908 the R. and A. ruled that it would not sanction any substantial departure from the traditional form and make of golf clubs. This principle has been invoked many times.

Steel shafts

Experiments with steel shafts went through several phases. In 1924 the Union Hardware Company of Torrington, Conn., drew a seamless shaft of high-carbon steel that could be heat-treated and tempered. It was approved by the R. and A. in 1929 and substantially replaced hickory in the early 1930s. Later, shafts of fibreglass, aluminum, graphite, and titanium were introduced. By the 1970s the technique of investment casting, a method of casting rather than forging to enhance the perimeter weighting of iron clubs, was commonplace, and a decade later "woods" made of metal were in widespread use, even by many tournament professionals. These and dozens of minor innovations were incorporated into production techniques that were quality controlled by computers and other electronic means. Balls also underwent a major change with the introduction principally of Surlyn, a synthetic material that was difficult to cut and thus could withstand the hacking blows of the game's millions of weekend practitioners.

Improvement of the shaft was accompanied by the general introduction of numbered, rather than named, clubs and by the merchandising of matched sets rather than individual clubs. Clubs had become more numerous and more finely graduated than the names that traditionally had been applied to them, and shafts could be manufactured to specifications for flexibility and point of flex. Whereas formerly a golfer seeking new clubs went through a rack of mashies until he found one that "felt right" and then tried to find other clubs of similar feel, he later bought a whole set manufactured to impart the same feel. The merchandising opportunities inherent in the numbered and matched sets were carried to an extreme, and in 1938 the USGA limited the number of clubs a player might use in a round to 14. The R. and A. concurred in a similar edict the next year.

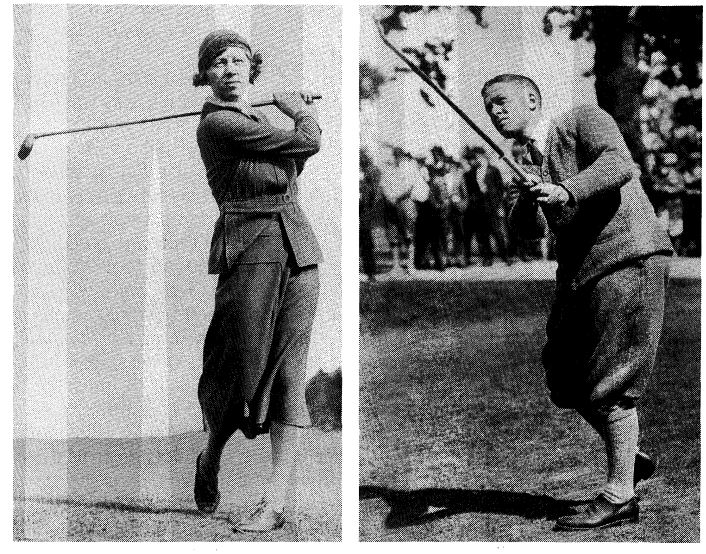
The British tradition

Players and tournaments. There is no doubt that the development of golf as an organized sport was distinctly British, and Britain produced the first great players of the game. As the early golfing associations, or clubs, became established in Scotland and then England, there emerged a group of professionals who made golf balls, fashioned and repaired clubs, laid out and maintained courses, and gave lessons. Many of them were outstanding golfers and

would take on all comers in the popular stakes (money) matches of their day. St. Andrews' Robertson, for example, regarded as the greatest golfer of his time, according to legend, was never beaten in a stakes match played on even terms (that is, without giving his opponent a handicap). The British professionals and their amateur counterparts represented the best golf in the world from the second half of the 19th century, when the sport began to gain some world prominence, up to about the 1920s, when U.S. players began to excel. With the tremendous increases in financial rewards to be gained in golf after about 1950, especially on the U.S. professional tour, and with the great mobility provided by jet transportation, golfers from other countries (*e.g.*, Australia, New Zealand, South Africa, Japan, and Argentina) began to appear in the top tournaments.

The premier championships. The most prestigious championships are the Open and Amateur championships of the British Isles and the U.S. Open, Amateur, Professional Golfers Association (PGA), and Masters. The Walker Cup for amateurs and the Ryder Cup for professionals are important team golfing tournaments that have pitted U.S. golfers against those of Great Britain and Ireland. From 1979 a European team (including Britons) replaced Great Britain in Ryder Cup play. (For winners of these championships, see SPORTING RECORD in the *Micropædia.*)

British tournaments and players. The Open Championship of the British Isles, which the British like to call The Open to emphasize the tradition and priority of the event begun in 1860, was the concept of the Prestwick Club in Scotland, whose minutes recorded a proposal that all clubs should contribute to raise a fund for a trophy for professional competition. Their hope, however, was badly disappointed, and the offer of support was so meagre that Prestwick decided to go it alone and spent 30 guineas on the ornamental challenge belt to be awarded to the champion. The early championships were dominated by Willie Park, "Old Tom" Morris, and his son, "Young Tom," who retired the belt by winning it three times in succession, 1868–70. In the absence of a prize, there was no championship in 1871; but the next year a cup, which has been in competition ever since, was put up.



The Open Championship

At the end of the 19th century, England was producing great players. John Henry Taylor and Harry Vardon, together with James Braid, a Scotsman, among them won the Open Championship 16 times between 1894 and 1914. These three supreme golfers were known as "the great triumvirate" and were primarily responsible for the formation of the Professional Golfers Association in 1901. This body is responsible for professional tournaments in Great Britain and for the biennial Ryder Cup match (for professionals) when it is played there.

The British Amateur Championship was started in 1885 after the Royal Liverpool Golf Club at Hoylake had proposed a tournament "open to all amateur golfers." The tournament attracted nearly all the best amateurs of the time, but it was not immediately recognized as the championship. The following year the Royal Liverpool suggested to the R. and A. that the tournament be established as the amateur championship, and 24 clubs joined together to purchase a trophy and manage the event. Among British players who won the amateur championship at least two times before the series was interrupted by World War I were H.G. Hutchinson, John Ball (who won it eight times), J.E. Laidlay, and H.H. Hilton. The interwar years were marked by many outstanding players, including Cyril Tolley, Amateur champion in 1920 and 1929; Roger Wethered, Amateur champion in 1923; and Scots Hector Thomson, Jack McLean, and A.T. Kyle.

The British Amateur Championship

The Ladies' Golf Union in Britain was formed in 1893. The first British Ladies Amateur Championship was held that year on the old St. Anne's course in England. One of the first outstanding woman golfers was Dorothy Campbell, who won the Ladies Amateur Championship in 1909 and 1911 and was runner-up in 1908. She won the U.S. Women's Amateur Championship in 1909, 1910, and 1924 and the Canadian championship in 1910, 1911, and 1912. Among the many notable women who played championship golf between the wars were Joyce Wethered and Cecil Leitch, each of whom won the British Ladies Amateur title four times. (For winners of the U.S. Women's Open, the British and U.S. Amateur Championships, and the Curtis Cup, see SPORTING RECORD in the *Micropædia.*)

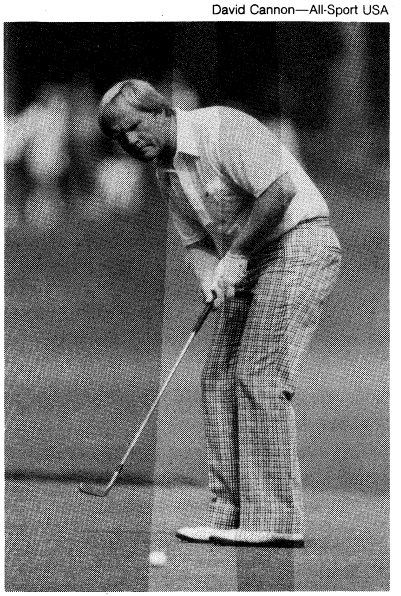
U.S. tournaments and players. The first official U.S. Open, Amateur, and Women's Amateur championships were held in 1895. Walter J. Travis was the first great U.S. golfer. He proved his ability as a golfer by winning the U.S. Amateur (1900–03) and the British Amateur title the only year he entered this event—1904. Jerome D. Travers, the next great American champion, was a player with indomitable courage and nerve that rarely failed him. He won the U.S. Amateur Championship (1907–08, 1912–13) and the U.S. Open title in 1915.

The U.S. championships

After World War I the influence of the many Scottish golfers who had emigrated to the United States became evident. U.S. golfers virtually monopolized the British Open Championship until Henry Cotton won in 1934, a feat he repeated in 1937 and 1948. From the 1920s into the 1980s U.S. teams dominated the Walker Cup and Ryder Cup matches, as U.S. women golfers did the Curtis Cup tournament from its inception in the 1930s.



U.S. golfers had begun to show their prowess in 1913, when Francis Ouimet became a national hero by defeating Vardon and Edward Ray, two of the best British professionals, for the U.S. Open. Also notable was Charles ("Chick") Evans, who was the first golfer to win the U.S. Open and Amateur in the same year (1916). But Bobby Jones has been regarded as the greatest amateur golfer of modern times. His career was brilliant from his debut in national competition in the U.S. Amateur of 1916 until his unparalleled performance in 1930 of winning all four of the world's most difficult titles—the British Amateur, the British Open, the U.S. Amateur, and the U.S. Open.

Early amateur golf champions

The popular appeal of the U.S. Amateur Championship has been seriously weakened by departures to the professional ranks, however, and it has become exceptional for an amateur champion to resist the lure of tournament money. In the late 1930s the professional circuit, underwritten by civic and club organizations throughout the country, began putting up major prize money for the experts. In 1936 aggregate prize money totaled $100,000, but by the late 20th century the PGA circuit was offering several million dollars in prizes annually. The first outstanding golfers were Walter Hagen and Gene Sarazen. After 1940 Byron Nelson, Ben Hogan, and Sam Snead shared the major portion of prize money and were followed by such top competitors as Arnold Palmer, Billy Casper, Lee Trevino, Jack Nicklaus, and Tom Watson. By the 1980s Nicklaus was not only the game's all-time money winner,

he had won a remarkable 20 major championships, more than anyone else in golfing history. It was not until 1970 that a British professional made the first serious dent into U.S. supremacy. Tony Jacklin, after playing successfully on the American circuit, became U.S. Open champion by a seven-shot margin. This was the first time a Briton had won America's most important championship since Ted Ray had done so half a century before. U.S. dominance of the men's British Open from 1970 to 1983 was broken only by Gary Player of South Africa in 1974 and Severiano Ballesteros of Spain in 1979.

U.S. women golfers

Among the great U.S. women golfers was Glenna Collett Vare, who dominated the game in the 1920s. After World War II, the Ladies' Professional Golf Association (LPGA) was established, thanks in large part to the skill and appeal of Mildred ("Babe") Didrikson Zaharias and Patty Berg. Then came Louise Suggs and Betsy Rawls, who were followed by Mickey Wright, Kathy Whitworth, and JoAnne Carner. The LPGA tour made a leap in popularity in 1978 when Nancy Lopez won nine tournaments in her rookie season, including five in succession.

International competition. *Matches and tournaments.* The first organized series of regular international matches were between Great Britain and the United States. The amateur team match between the two countries for the Walker Cup was inaugurated in 1922 and the professional team match (Ryder Cup) in 1927. The women's amateur team match (Curtis Cup) began in 1932. Although the competition in all of these contests has often been close, the U.S. teams managed to win the cups with great consistency. In an attempt to bring parity to the Ryder Cup the format was changed in 1979 to broaden the British team to include continental European players as well.

Circuits. The coming of jet transport stimulated competition. Ocean hopping became routine, enabling outstanding players from South America, Australia, New Zealand, and South Africa to compete in the premier championships in Great Britain and the United States and on the rich U.S. PGA tour. Among the successful players from the Southern Hemisphere were Bobby Locke (South Africa), a magnificent putter, Peter Thomson and Kel Nagle (Australia), left-hander Bob Charles (New Zealand), and Roberto de Vicenzo (Argentina). Also prominent was South Africa's Gary Player, who was one of only four men (with Sarazen, Hogan, and Nicklaus) to win each of the game's four major professional championships, constituting the grand slam of modern golf.

With more overseas players entering, and sometimes winning, tournaments in the United States and Great Britain, more U.S. and British players began to take part in various circuit itineraries in other parts of the world—in Australia, New Zealand, South Africa, and the Far East. In Japan the game has become an endemic fever.

Finance. Professionals with expertise and crowd-pulling attributes have become a new affluent society thanks to the cosponsorship, by the PGA, local promoters, and private companies, of lucrative weekly tournaments with television rights to negotiate. The modern professional also has many sources of peripheral income. The great Harry Vardon received £50 with his medal for winning his record sixth British Open in 1914. By 1971 the winner's prize was £5,500; and in 1972 for the first time all professionals in the championship proper received prize money. Prize money in the United States, however, far exceeded that of any other country. By the mid-1980s the total purse for the U.S. professional tour was $25,000,000. A PGA senior tour was launched at the beginning of the 1980s, and within seven years its total purse was $10,000,000. (Senior golf tournaments, for players age 55 and over, had been organized from the early part of the 20th century.)

The emoluments of professional golf

PLAY OF THE GAME

Courses. The game consists in playing the ball from a teeing ground into a hole by successive strokes in accordance with the rules. The stipulated round consists of 18 holes, and most golf courses have 18. Standard 18-hole courses measure from 6,500 to 7,000 yards (5,900 to 6,400 metres); individual holes are from 100 to 600 yards (90 to 550 metres). Some courses, however, have only nine holes, and these are played twice in a stipulated round. The clubs are designed for the various positions in which the ball may come to rest and for the various distances to the hole. The objective is to hole the ball in the fewest strokes.

In the early 19th century there was no agreement on the number of holes on a golf course; localities differed widely in the matter. When the popularity of Leith, with its five holes, waned and St. Andrews became the hub, the round of 18 holes was established. Originally the St. Andrews holes filed straight out alongside the shore and were played in reverse for the return journey—11 holes each way. In 1764 the round was modified to 18 holes. The variety of courses gives golf an intrinsic charm.

Equipment. *Golf balls.* Regulation balls have a maximum weight of 1.62 ounces (45.93 grams) and a minimum diameter of 1.68 inches (4.27 centimetres). In U.S. competition the velocity of the ball may not exceed 250 feet (75 metres) per second when measured under prescribed conditions on an apparatus maintained by the USGA, but there is no velocity specification for British play.

Golf clubs. In the average good player's set there are usually either three or four wood clubs and nine or 10 irons (no more than 14 clubs may be carried during a round). No two clubs in a set are the same. There are differences in length and suppleness of shaft, weight, size and shape of head, the angle at which the shaft ends and the head begins (the lie), and the angle of the face of the club from the vertical (the loft).

Club purposes by number

The various clubs are known both by number and by name. The number of a club largely designates its length and the pitch of its head, which translates into the distance and height a club will drive a ball. Generally, the lower the number, the greater the distance potential; distance decreases and pitch (thus height) increases progressively as club numbers go up. The woods are mostly used for driving the longer distances. Sources differ on the name equivalency of the numbered clubs, but the most widely used clubs may be identified as follows: Woods—number 1 (driver), number 2 (brassie), number 3 (spoon), number 4 (baffy), and number 5 (replaces number 3 or 4 iron). Irons—number 1 (driving iron), number 2 (midiron), number 3 (mid-mashie), number 4 (mashie iron), number 5 (mashie), number 6 (spade mashie), number 7 (mashie-niblick), number 8 (pitching niblick), number 9 (niblick), number 10 (wedge), and putter (carries no number).

Rules. The rule-making bodies for golf are the R. and A. and the USGA. They attempt to perpetuate the uniformity in rules by exchanging views on interpretations and on recommendations for revision. The present code makes

an amazing contrast with the first rules, 13 in number, that were framed by the Honourable Company. The first of them ordained that the ball had to be teed within a club length of the previous hole and the tee had to be on the ground. Tee and green were one. The ball struck from the tee was not to be changed, and the player could (Rule 5) take his ball out of water or "watery filth" to play it and allow his opponent a stroke. The St. Andrews golfers, in founding the Royal and Ancient Club, adopted almost exactly the Leith rules. There were periodical reforms before the rules committee of the R. and A. was formed in 1897 to become the final authority.

The rules committee has co-opted representatives from the Commonwealth, the European Golf Federation, the United States, and the British Unions Advisory Committee. Britain and America have had separate codes at various times, but a uniform code went into effect in 1967.

The rules of golf define an amateur golfer as "one who plays the game solely as a nonremunerative and nonprofit-making sport." But the elasticity of this definition perturbs the game's legislators for what it does not define. The whole question of status in its various aspects engages the attention jointly of the R. and A. and the USGA. In general, an amateur remains so until and unless he takes specific action toward becoming a professional, even though he might have indicated his intention of becoming a professional in the future.

Driving, playing the fairway, and hazards

Procedure. The starting place for each hole to be played is the teeing ground. The front is indicated by two markers, and the teeing ground is the rectangular space two club lengths in depth directly behind the line indicated by the markers. The player tees his ball anywhere within this space, usually setting it up on a small wooden or plastic peg (called a tee), and strikes it toward the hole. The stroke from the teeing ground is called the drive. For this, the player usually employs a number 1 wood club, or driver, although to avoid a hazard or to attempt to place his ball in a favourable position for his second shot (for example, on a long hole with a sharp bend, or dogleg) he may prefer one of the other woods or an iron. On short, par-three holes most players use an iron.

The preferred line to the hole is generally a clear, mowed route called the fairway. The fairway was historically bordered by unmowed vegetation—heather, grasses, weeds, bushes—called rough. Most modern courses in the United States, however, are not characterized by deep and tangled rough and when inland make effective use of trees. At strategic places along the preferred line to the hole and guarding the putting green are obstacles called bunkers, depressions filled with sand (sand traps). Some holes require the player to cross streams or ponds. Both bunkers and bodies of water are termed "hazards."

Approaching and putting

Middle irons are used until the player has come within close range of the green. Two methods of play are then open for the approach shot: the golfer may pitch the ball all the way and depend on backspin to stop it near the pin, or he may play a chip shot, in which the ball flies part way through the air, as to the edge of the close-clipped surface of the green, and then rolls the remaining distance.

The hole itself measures 4¼ inches in diameter and at least four inches deep, and it is set in an area of turf especially prepared and maintained and closely mowed for putting. When the player putts he uses a straight-faced club and rolls the ball across the putting green toward and eventually into the hole.

Forms of play. *Match and medal play.* There are two distinct forms of play: match play and stroke (medal) play. In match play the player and his opponent are playing together and competing only against each other, while in stroke play each competitor is competing against every other player in the tournament. In match play the game is played by holes, and each hole is won by the player who holes his ball in the fewer strokes. If both players score

Scoring

the same number of strokes, the hole is halved. When a player has won one more hole than his opponents, he is said to be 1 up. The match is won by the player who is leading by a number of holes greater than the number of holes remaining to be played, as, for example, 3 up and 2 to play. In stroke play the competitor who holes the stipulated round or rounds in the fewest total strokes is the winner. Amateur championships once were all at match play and open championships and most professional events at stroke play, covering four 18-hole rounds. Some amateur events have adopted stroke play (the match play U.S. Amateur event was at stroke play from 1965 to 1973), as has the U.S. PGA Championship.

Stroke play requires a greater degree of consistency in a player, for one hole where he lapses into a high figure can ruin his total and cost him victory. The same high score on a hole in match play means only the loss of that hole. In both match and stroke play, players can compete as individuals or as partners. When two players compete as partners, each playing his own ball, the better ball on each hole is their score for that hole; this is a four-ball or best ball match. Two players may compete as partners with two others, each pair playing alternate strokes on a single ball; this is a match foursome. The advent of televised championships wrote the death notice for match play in professional golf. By scheduling the leaders together on the final round, exciting finishes are made most probable.

Handicaps. Players of varying abilities compete against each other by using handicaps. A handicap is the number of strokes a player receives to adjust his score to a common level. The better the player, the smaller his handicap, and the best players have handicaps of zero (scratch players). A scratch player whose average score is 70 can have an even match with a player whose average score is 80 by giving him a handicap of 10 strokes. Handicap golf is limited to amateur competitions, and championship tournaments are played without handicaps.

Par golf. Every course has a par, which is defined as the score an expert (*i.e.*, a scratch player) would be expected to make, and many courses also have a bogey, which is defined as the score that a moderately good golfer would be expected to make. Both par and bogey are defined as errorless play without flukes and under ordinary weather conditions, allowing two strokes on the putting green. Par is essentially a U.S. term that came into use in the early 1900s as a base for computing handicaps. Bogey is essentially a British term that came into use in England in 1891 and was derived from a mythical Colonel Bogey, who was described as uniformly steady but never overbrilliant. Colloquially in the United States, "bogey" is used to indicate a score one stroke above par.

The bogey

Variants. *Par-three golf.* Par-three golf courses, on which each hole measures 100 yards more or less and plays at par three, were developed as a result of the shortage of available open land in congested urban areas. Whereas a regulation 18-hole course may stretch to more than 7,000 yards, about four miles, an 18-hole par-three, or short-hole, course can be laid out in about 1,800 yards.

Driving ranges. Driving ranges were developed as commercial establishments at which golfers and aspiring golfers could, for a small fee, practice their swings. They, too, have appealed to golfers in areas in which courses are overcrowded and are especially popular in Japan, where such conditions prevail. (F.Mo./J.R.Go.)

Athletics

Athletics, or track-and-field sports, consist of competitions in running, walking, jumping, and throwing events. Although these contests are called track and field (or simply track) in the United States, they are generally designated as athletics elsewhere. This section covers the history, the organization, and the administration of the sport, the conduct of competitions, and the rules and techniques of the individual events, and some of the sport's most prominent athletes. (For records, see SPORTING RECORD and OLYMPIC GAMES in the *Micropædia.*)

Track-and-field athletics are the oldest forms of organized sport, having developed out of man's most basic activities—running, walking, jumping, and throwing. Athletics has become the most truly international of sports, with nearly every country in the world engaging in some form of competition. Most nations send teams of men and women to the quadrennial Olympic Games and to the official World Championships of track and field. There

also are several continental and intercontinental championship meets held, including the European, Commonwealth, African, Pan-American, and Asian.

Within the broad title of athletics come as many as two dozen distinct events. These events, generally held outdoors, make up a meet. The outdoor running events are held on a 400-metre or 440-yard oval track, and field events (jumping and throwing) either inside the track's perimeter or in adjacent areas.

In many parts of the world, notably the United States, Canada, and Europe, the sport moves indoors during the winter; because of limited space, some events are modified and several are eliminated altogether.

Also within the general scope of track-and-field athletics come separate but related competitions that are not contested on the track. Cross-country running competition is carried out on various types of countryside and parkland. Marathons and races of other long distances are run on roads, and the long-distance race walks are contested on measured road courses. The rules followed by all organized competitions are established and enforced by the International Amateur Athletic Federation (IAAF) and its member body from each nation. The IAAF also ratifies all world records.

HISTORY

Origin and early development. There is little in the way of definitive records of athletics' early days as an organized sport. Egyptian and Asian civilizations are known to have encouraged athletics many centuries before the Christian Era. Perhaps as early as 1829 BC, Ireland was the scene of the Lugnasad or Tailteann Games involving various forms of track-and-field activity. The Olympic Games of Greece, traditionally dated from 776 BC, continued through 11 centuries before ending in about AD 393. These ancient Olympics were strictly male affairs. Greek women were reputed to have formed their own Heraea Games, which, like the Olympics, were held every four years.

The Olympic Games

Athletics as practiced today was born and grew to maturity in England. The first mention of the sport in England was recorded in 1154, when practice fields were first established in London. Sport was banned by King Edward III in the 1300s, but revived a century later by Henry VIII, reputed to be an accomplished hammer thrower.

Modern development. The development of the modern sport, however, has come only since the early 19th century. Organized amateur footraces were held in England as early as 1825, but it was from 1860 that athletics enjoyed its biggest surge to that date. In 1861 the West London Rowing Club organized the first meet open to all amateurs, and in 1866 the Amateur Athletic Club (AAC) was founded and conducted the first English championships. The emphasis in all these meets was on competition for "gentlemen amateurs" who received no financial compensation. In 1880 the AAC yielded governing power to the Amateur Athletic Association (AAA).

The first meet in North America was held near Toronto in 1839, but it was the New York Athletic Club, formed in the 1860s, that placed the sport on a solid footing in the United States. The club held the world's first indoor meet and helped promote the formation in 1879 of the National Association of Amateur Athletes of America (NAAAA), to conduct national championships. Nine years later the Amateur Athletic Union (AAU) took over as national governing body, amid reports that the NAAAA was lax in enforcing amateurism.

Athletics was well established in many countries by the late 1800s, but not until the revival of the Olympic Games in 1896 did the sport become truly international. Although begun modestly, the Olympics provided the inspiration and standardizing influence that was to spread interest in athletics worldwide. In 1912 the International Amateur Athletic Federation (IAAF) was founded, and by the time that organization celebrated its 75th anniversary in 1987 it had more than 170 national members. Its rules applied only to men's competition until 1936, when the IAAF also became the governing body of women's athletics.

The Olympic Games revival

Major international competitions before World War II included the Olympics, the British Empire Games, and the European Championships, but after the war athletics experienced its greatest period of growth, taking root especially in the developing countries. By the 1950s African, Asian, and Latin-American nations had begun to produce world-class athletes.

Organization and tournaments. Top-level competition in athletics is still restricted to the amateur athlete, although the definition of "amateur" continues to evolve. The IAAF over time has reduced its definition of an amateur athlete to the simplest possible terms: "An amateur is one who abides by the eligibility rules of the IAAF" is the complete rule, allowing for change whenever the federation alters any of its other rules.

Until the 1980s the IAAF attempted to keep its athletes from benefiting financially from the sport. This was always a struggle, however, as star athletes and eager meet promoters managed to circumvent the rules. So did entire nations: eastern European countries provided government aid to athletes, other countries encouraged military personnel to concentrate on track and field training, and U.S. athletes received college scholarships in return for their skills.

Funding athletes

Financial aid was made acceptable in the 1980s through the use of trust funds. Athletes were permitted to accept payment for appearing in competition, for performing well, for appearing in television commercials, or for other sport-related activities. The money was placed in trust; training expenses could be charged to the fund, with the remaining funds, if any, going to the athlete on retirement from competition. Some athletes were reported to have made several hundred thousand dollars a year under the new system.

The primary functions of the international federation are to maintain a set of rules that are uniform throughout the world, to approve world records for outdoor and indoor competition, and to promote international athletics. While continuing to administer athletics competition in the Olympic Games, the IAAF began its own quadrennial World Championships in 1983, established World Cup competitions, and established walking, cross-country, marathon and other road-races, indoor track-and-field, and junior competitions.

Each IAAF member nation has its own set of rules and maintains its own set of records in line with international guidelines. The amateur athletic federations of individual countries conduct their own national championships.

In the United States, for example, The Athletic Congress (TAC) alone has the power to select international teams (except for the Olympic team, which is under the jurisdiction of the United States Olympic Committee), to establish rules, and to accept or reject records. It also conducts the national championships and other competitions. Meets in which participation is restricted to college or university athletes usually are governed by the rules of the National Collegiate Athletic Association (NCAA), National Association of Intercollegiate Athletics (NAIA), or one of two junior (two-year) college groups. Most U.S. secondary schools come under the aegis of the National Federation of State High School Athletic Associations.

U.S. governing bodies

The details of the conduct of athletics competitions vary with the location and the level and type of meet. To a great degree the basic sport has been standardized by the rules of the IAAF. Outdoor track events take place on the 400-metre (about 440-yard) oval running track. Track compositions differ greatly. Once almost all tracks were of natural materials (dirt, clay, cinders, and crushed brick being the most common), but all major competition tracks now are made of synthetic materials. The synthetic track provides more consistent and faster footing in all weather conditions. Field-event performers also benefit from improved footing; jumpers and javelin throwers perform on the same materials used for synthetic tracks, while the throwers of the shot, discus, and hammer work in circles made of concrete.

Indoor track meets adapt themselves to widely varying and often limiting conditions. Tracks range in size generally from 150 to 200 metres or 160 to 220 yards and have synthetic surfaces over wood. Some tracks have banked curves, other are unbanked. Cross-country running utilizes

any terrain that is available—parks, golf courses, farmland. The prescribed IAAF distance in international races for men is approximately 12,000 metres (7.5 miles) and for women 4,000 metres. Road events include walking, marathon, and other road runs of widely varying distances.

MEETS

Equipment. Every event has items of equipment that are essential to the conduct of the event. All athletes, for example, require shoes that give traction and protection with minimum weight. Other items of equipment include the starting blocks used by sprinters and hurdlers, hurdles, vaulting poles, and the implements employed in the various throwing events.

Timing and measurements. Exacting timing and measurement of performances are a vital part of athletics, not only to determine winners at the meet in question but also to provide marks that can be compared for record purposes. Fully automatic timing, using photography, is required for world records and all major competitions. Timing, once done in fifths of a second and then in 10ths, now is done in 100ths of a second. By rule, an aiding wind of more than two metres per second (4.473 miles per hour) nullifies a record time in distances up to 200 metres. Metric measurements are required for both track and field events. even in the United States. The only English-measure distance that remains popular is the one-mile run. With the 1987 inauguration of the World Indoor Championships the IAAF began accepting indoor records. There are, however, no official records for any track event not run or walked entirely on the track, such as the marathon or road races.

Metric measurements

Presentation. Athletics meets differ greatly in presentation. The typical school, university, or club meet is of one-day duration. Conference meets generally last two days, while national championships require three to four days to accommodate large numbers of athletes. The Olympic Games and World Championships are scheduled for eight days of athletics competition.

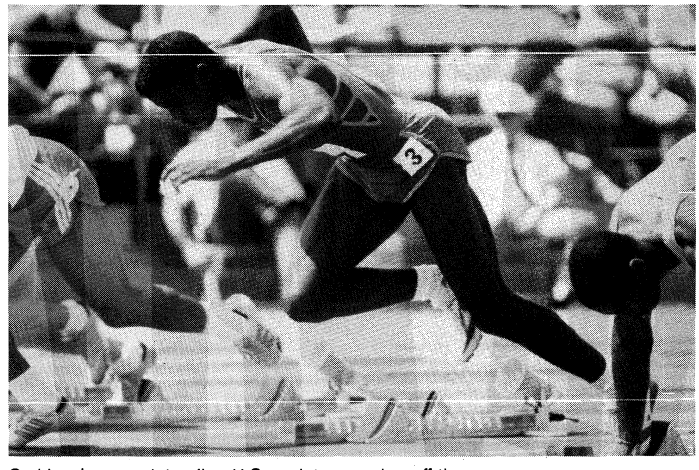
All track events begin with the firing of a gun. In races of one lap or less the runners remain in their marked lanes for the entire distance. In longer events the runners may ignore the lane markers and run as close to the inside edge of the track as is prudent. The runner whose torso reaches the winning line first is the winner.

Field events

Field events have two types of qualifying competitions. In the smaller meets all participants are allowed three attempts, with the top six to nine athletes getting three more. In the larger meets there is a qualifying round from which about 12 athletes advance to the finals, at which stage the remaining competition proceeds in the same manner as in the smaller meets. The exceptions in field-event competition are the vertical jumps—the high jump and pole vault. Jumpers are given three tries at each height; three consecutive misses cause elimination.

Although athletics is basically an individual sport, team scoring is sometimes important. Dual meets are always scored, but there are no official scores for multi-team international meets, such as the Olympic Games. Conference and national meets among universities also are scored officially. The points allotted to individual events and places vary from meet to meet. A national competition may award 10 points for first place, eight for second, and so on. Similarly, an international dual meet awards five points for first place, three for second, two for third, and one for fourth. The team with the highest point total wins the meet. Cross-country meets always are scored, with the winner getting one point, second place two points, etc., the low score winning.

Runners have a chance to compete the year round. The indoor season lasts from January through March; the outdoor competition lasts until June for schools and colleges, with the higher-level individual competitors participating in track through September. In the United States autumn is given over to cross-country running. International cross country is held in winter.



Conflicts and controversies. Athletics, occupying centre stage at all international games, generates its share of conflicts. Until the IAAF's trust-fund system there was continual concern about athletes earning money by violating rules. From about 1970 the question of drug usage has been a major issue. Athletes are forbidden to use a number of drugs that are said to improve performance. Testing for such use is required at the major meets, and, while the great majority of athletes tested are found to be free of banned drugs, each year a small number of athletes are found guilty of violating the drug rule and are suspended from competition, usually for 18 months. Most frequently the violators have used anabolic steroids in an attempt to increase muscle size and strength.

EVENTS

As many as 25 events may make up a men's meet; women compete in a few less. The men's track events at championship meets generally include the 100-, 200-, 400-, 800-, 1,500-, 5,000-, and 10,000-metre runs; the 3,000-metre steeplechase; the 110- and 400-metre hurdles; and the 400- and 1,500-metre relays. The field events usually include the high jump, pole vault, long jump, and triple jump; and the shot put and the discus, hammer, and javelin throws. The decathlon, combining 10 track and field events, is also included. Women run much the same schedule, with 100-metre instead of 110-metre hurdles. but do not compete in the steeplechase, pole vault, or hammer throw. They compete in the heptathlon rather than the decathlon, and both men and women run the marathon. Women walk up to 10,000 metres and men up to 50,000 metres.

Running. *The sprints.* The relatively short sprint distances, ranging up to 400 metres, require a sustained top speed. Originally all sprinters started from a standing position, but in the 1880s the crouch start was invented, and it became a rule that sprinters must start with both feet and both hands on the track. The introduction of the adjustable starting block aided the quick start, critical in the sprints.

"The fastest human"

The current record holder at 100 metres generally is considered to be "the fastest human." Holding that title have been such champions as Eddie Tolan, Jesse Owens, Bobby Morrow, Bob Hayes, and Carl Lewis (all of the United States), Valeriy Borzov (U.S.S.R.), and Ben Johnson (Canada). Johnson set a record-breaking time of 9.83 seconds as he won the 1987 World Championships. Outstanding women sprint champions have included Fanny Blankers-Koen (The Netherlands), who won four gold medals in the 1948 Olympics, Wilma Rudolph (U.S.), who won three in 1960, Marita Koch (East Germany), who was a winner at all three sprint distances, and Florence Griffith Joyner (U.S.), who set world records at 100 and 200 metres in 1988.

The 400 metres is run in lanes all the way; distance is equalized by a staggered start, the sprinters being spaced progressively farther up the track based on the distance their lane is from the inside edge. Outstanding in this event were Lee Evans (U.S.), whose 43.86 mark remained the

modern pits are of value because jumpers often land on the back of the shoulders and neck.

Jumping styles have evolved in the 20th century with techniques called the scissors, eastern cut-off, western roll, and straddle (or belly roll) preceding the universally accepted Fosbury flop. Named for its inventor, Dick Fosbury (U.S.), the 1968 Olympic champion, the flop involves an approach from almost straight ahead, then twisting on takeoff and going over head first with the back to the bar. Charles Dumas (U.S.), a notable example of the straddle jumpers, in 1956 became the first man to clear 7 feet (2.13 metres). Valeriy Brumel (U.S.S.R.) held the high-jump record for 10 years using the straddle jump. A woman jumper, Iolanda Balas (Romania), achieved remarkable feats in the event, establishing 13 world records and a winning streak of 140 meets.

The pole vault. Pole vaulting is conducted along the lines of the high jump; *i.e.,* vaulters attempt to vault over a crossbar placed on uprights, they have three tries at each height, and they land in an inflated or composition pit.

The vaulter runs down a runway for about 45 metres (150 feet) carrying a pole. After planting the end of the pole in a box that is sunk below ground level, the vaulter leaves the ground and pulls himself upward until he is almost doing a handstand on the pole. He twists as he nears the crossbar and arches over it feet first and face down.

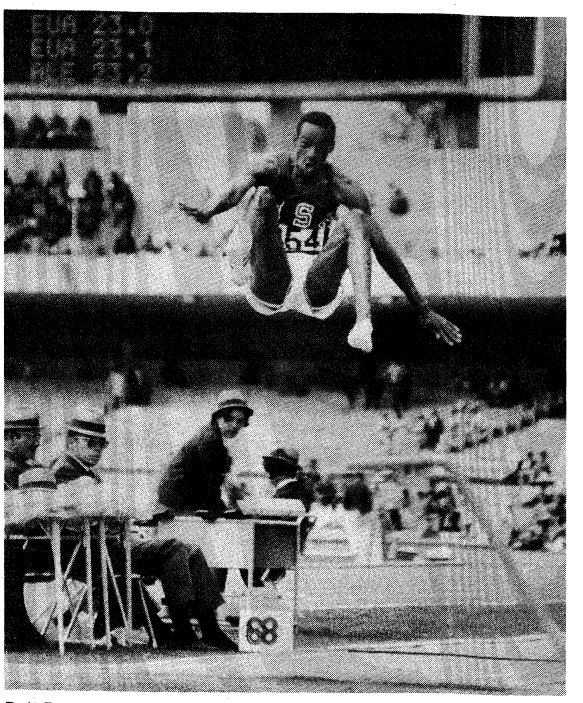
Evolution of the pole

The first poles, of solid ash, cedar, or hickory, were heavy and cumbersome. Once the bamboo pole was introduced in 1904 it was quickly adopted. Records set with bamboo lasted until 1957, when records were set with an aluminum pole and a steel pole; these were followed by the fibreglass pole in the 1960s.

The dominant vaulter of all time was Cornelius Warmerdam (U.S.), who scored six world records; he was the first vaulter to go over 15 feet and he set a record of 15 feet 7¾ inches (4.77 metres) that lasted for 15 years. No one came close to him in the bamboo era, but the constant improvement of fibreglass poles helped vaulters such as Sergey Bubka (U.S.S.R.) push the record well over 5.79 metres (19 feet) in the 1980s.

The long jump. Long jumping, formerly called broad jumping, is the least complicated of the field events. Speed is the most essential ingredient for a successful jump. Jumpers make their approach down the runway at nearly top speed, plant a foot on the takeoff board, and leap into the air. A legal jump requires that no part of the forward foot extend beyond the board. The most popular long-jumping style is called the "hitch-kick," in which the runner seemingly walks in air.

Two distinct landmarks stand out in the history of long jumping. The first of these was the achievement of Jesse Owens (U.S.), who on May 25, 1935, jumped 26 feet 8¼ inches (8.13 metres), a record that was to endure for 25 years. The second, believed by many to be the greatest single track-and-field feat ever, was Bob Beamon's (U.S.) leap of 8.90 metres (29 feet 2½ inches), a jump that exceeded the old world record by 55 centimetres (21½ inches). In 33 years the record had gone up less than nine inches and in one day Beamon pushed it up almost two feet.



Notable among the women jumpers are Heike Drechsler (East Germany) and Jackie Joyner-Kersee (U.S.), both of whom leaped over 7 metres (23 feet).

The triple jump. Once known as the hop, step, and jump, the triple jump includes three distinct segments of action. The jumper comes down the runway and bounds off a takeoff board, similar in style to but a little slower than long jumpers. The first segment involves the jumper executing a hop by landing on the same foot from which he took off. Then he takes a step, landing on the other foot, and concludes with a jump into the sand pit.

Outstanding triple jumpers

Among the outstanding competitors, Adhemar da Silva (Brazil) won two Olympics and set five world records; Jozef Schmidt (Poland), also a two-time Olympic Champion, set a record in 1960 of 17.03 metres (55 feet 10½ inches) and was the first to go over the 17-metre barrier; and Viktor Saneyev (U.S.S.R.) had three world records and three Olympic wins and one second place. Women began competing in the triple jump in the mid-1980s.

Throwing. The four standard throwing events—shot put, discus, hammer, and javelin—all involve the use of implements of various weights and shapes that are hurled for distance.

The shot put. The putting action is best described as shoving the shot since the rules require that the arm may not extend behind the shoulders during the putting action. The spherical shot is made of metal. The men's implement weights 16 pounds (7.256 kilograms) and is about five inches (12.7 centimetres) in diameter. Women put a four-kilogram (eight-pound 13-ounce) shot about 10 centimetres in diameter. The IAAF allows a slight range in specifications.

The putter must launch the shot from within a ring 2.134 metres (seven feet) in diameter and so must gather momentum for the put by a rapid twisting movement. Shot putters are among the largest athletes in track and field, the biggest ranging from 250 to 300 pounds (113 to 136 kilograms). Beginning in the 1950s weight training became a major part of a shot putter's training program. In that same period the O'Brien style of putting was popularized with outstanding results. Developed by Parry O'Brien (U.S.), the style involved a 180-degree turn (rather than the usual 90-degree turn) across the ring, getting more speed and momentum into the action. O'Brien was the best exponent of the style, winning three Olympic medals (two gold) and raising the record from 58 feet 10¾ inches (17.95 metres) to 63 feet four inches (19.30 metres).

Some athletes have turned to a style in which the putter spins one and a half turns before releasing the shot, a technique developed by Brian Oldfield (U.S.).

The discus throw. Discus throwing is considered by many the classic event of athletics, the Greek poet Homer having made references to discus throwing in the 8th century BC. Modern male athletes throw a two kilogram (four-pound 6½-ounce) platter-like implement from a 2½-metre (eight-foot 2½-inch) circle. The discus is launched after the thrower, starting at the back of the circle, has completed one and a half turns. The women's discus weighs one kilogram.

Feats of Al Oerter

Among discus throwers the feats of Al Oerter (U.S.), the first to throw over 200 feet, are legendary. As a 20-year-old he won at the 1956 Olympic Games, and he won at the following three games as well. He also set four world records. A standout among women throwers was Faina Melnik (U.S.S.R.), who set 11 world records.

world record 20 years after he set it in 1968, and Alberto Juantorena (Cuba), whose 44.26-second time in the 1976 Olympics was the fastest without the aid of high altitude. He also won the 800 metres, becoming the first man to win both events in the Olympics. Jarmila Kratochvilova (Czechoslovakia) also won such an unprecedented double victory in the 1983 World Championships for women.

Middle-distance running. The longer the race, the more endurance is needed. The middle-distance events, in this discussion, range from 800 to 2,000 metres. Some authorities regard the 3,000-metre race as a middle-distance.

Middle-distance runners usually are able to perform well at either the shorter or the longer distances. Racing tactics, including pacing, are more important at these than at any other distances. Even though it is no longer a championship event the mile is still a glamour event. The race to be the first to run a mile in less than four minutes captured world attention. It finally was achieved in 1954 by Roger Bannister of England. A "sub-four" is still a notable time, even though it is now accomplished regularly and some runners, such as John Walker (New Zealand) and Steve Scott (U.S.), have run under four minutes more than 100 times. Other great middle-distance runners include Paavo Nurmi (Finland), who won both the 1,500 (the metric "mile") and 5,000 metres on the same day in the 1924 Olympics, and Sebastian Coe (U.K.), who won two Olympic gold medals at 1,500 metres and two silver at 800 metres. Two Soviet women created memorable middle-distance records. Tatyana Kazankina won five world records, while Lyudmila Bragina established eight. Mary Decker Slaney (U.S.) also won consistently at the middle distances.

The four-minute mile

Long-distance running. There is some difference of opinion over the dividing line between middle-distance and long-distance runs. The long-distance events considered here are those ranging from 3,000 metres upward and including the marathon, steeplechase, cross-country, and road runs. The 30,000-metre run is the longest for which the IAAF keeps records. Speed becomes an even less important factor in the longer runs and pace and endurance correspondingly more so. The longer the run the less likely there is to be a "finishing kick," a burst of speed at the end of the race.

Runners may also overlap the long- and middle-distance events. Nurmi, Gunder Hägg (Sweden), and Said Aouita (Morocco) all set world records at both 1,500 and 5,000 metres. Nurmi won at all distances above 1,000 metres except the marathon. Distance runners provide the most prolific record setters, including Nurmi, Ron Clarke (Australia), and Emil Zátopek (Czechoslovakia), the last of whom performed the remarkable feat of winning the marathon and the 5,000- and 10,000-metre races at the 1952 Olympic Games. The longer races for women have been slow to develop, but a number of runners have been able to compete at various distances, including Ingrid Kristiansen (Norway).

The steeplechase combines long-distance running with hurdling, each runner being required to clear seven water jumps and 28 hurdles in a 3,000-metre course. Although hurdling is an important aspect of the event, by far the greatest need is the ability to run the distance. Steeplechase competitors are often specialists, but there are examples of fine distance runners who have successfully overcome more experienced hurdlers. Henry Rono (Kenya), one of the most successful at the steeplechase, also held world records at 3,000, 5,000, and 10,000 metres.

The marathon

The marathon was a key event at the first modern Olympic Games in 1896, and it has become a major attraction of the Olympics and other international contests. The race originally commemorated the feat of a Greek soldier who in 490 BC supposedly ran from Marathon to Athens to bring news of the Greek victory over the Persians. At 26 miles, 385 yards (42,186 metres) the marathon is the longest race of the track meet. Hannes Kolehmainen (Finland) and Zátopek are two of the more memorable marathoners. Records for the marathon are not officially recognized.

Hurdling. The hurdling events combine sprinting with negotiating a series of obstacles called hurdles. Men run the

110-metre high hurdles over 10 barriers 42 inches (106.7 centimetres) high and 10 yards (9.14 metres) apart. The 400-metre intermediate hurdles also covers 10 hurdles, 36 inches (91.4 centimetres) in height and 35 metres (38.29 yards) apart. Women now run both the 100-metre high and 400-metre hurdles. A hurdler may knock down any number of hurdles but is disqualified if he runs out of his lane or uses his hands to knock over hurdles. The object is to make the hurdling action smooth and rhythmic so as not to disrupt forward progress.

High hurdlers need excellent speed, most champions also being good sprinters. An excellent example is Harrison Dillard (U.S.), who won the 100-metre flat race in the 1948 Olympics and the high hurdles in the 1952 Games. Intermediate hurdlers also combine speed with hurdling ability. Glenn Davis (U.S.), who won both the 1956 and 1960 Olympics, was a world-record breaker on the flat as well as over the hurdles. Edwin Moses (U.S.) virtually revolutionized the event with his unusual 13-stride (between hurdles) technique. He also won two Olympics and achieved a winning streak lasting nearly 10 years.

Relays. The relays involve four runners per team, each member carrying a baton for 25 percent of the total distance before passing it to the next team runner. Two events, the 4×100- and 4×400-metre relays, are standard. They are included both in low-level dual meets and in the Olympic Games and the IAAF World Championships. Speed is essential in both events, and the ability to pass the baton well is especially crucial in the shorter event, where each runner covers 100 metres. Exchanging the baton while running about 25 miles per hour brings to the event a quality of suspense. Many races have been won or lost by the quality of baton passing. Other relay events—the 4×200-, 4×800-, and $4 \times 1{,}500$-metres—are run much less frequently.

Baton passing

Walking. This event, also called race walking, is relatively minor. Aside from the Olympic and other multination competitions, it is seldom a part of track meets. Olympic competition is over 20,000 and 50,000 metres, while other distances are used in individual competitions. Records are approved only when made on the track.

Jumping. Men compete in four jumping events: the high jump, long jump, triple jump, and pole vault. Women compete in all except the pole vault.

The high jump. There is one basic rule for high jumping: the jumper must leave the ground from one foot, not two. The object is to clear a thin bar perched atop two standards, and as long as the jumper does not have three consecutive misses, he remains in the competition. Jumpers may enter the competition at any height above the minimum height and are allowed to pass any height as the bar is raised to new levels. Inflated or foam-rubber landing pits have replaced dirt and sawdust pits. The

The hammer throw. The implement used in the hammer throw is not a conventional hammer but a metal ball about 127 millimetres (five inches) in diameter attached to a wire, the whole implement being about 1,200 millimetres in length and weighing a minimum of 7.26 kilograms (16 pounds). The handle at the opposite end of the wire from the ball is gripped by the thrower and released after three or four body turns have developed maximum centrifugal force. The launching area is slightly smaller than that of the discus. Women do not compete in the event.

American athletes of Irish birth or descent totally dominated the event from the 1890s to the 1930s and included John Flanagan, who unofficially set 17 world records and won three Olympic Games (1900, 1904, and 1908). Since the passing of the Irish dynasty the power shifted to the eastern Europeans. Among them was Yury Sedykh (U.S.S.R.), who won the 1976 and 1980 Olympics and raised the record from 80.32 metres to 86.74 metres.

The javelin throw. Javelin throwing involves a spearlike implement that is hurled with an over-the-shoulder motion at the end of an approach run. It is a direct descendant of spear-throwing contests, introduced in the Olympics of 708 BC. The men's javelin weighs about 800 grams (one pound 12 ounces) and must be at least 260 centimetres (8½ feet) long. The women throw a javelin that must weigh at least 600 grams and be at least 220 centimetres long. It is the only throwing event not using a circle. The javelin is not required to stick but must land point first for a valid throw.

Throwers from Finland have historically been a force in the event. Matti Järvinen, a Finn, established 10 world records and improved the record by 6.22 metres, finally reaching 77.23 metres (253 feet 4½ inches) in 1936. As records continued to be broken there was less and less space within the stadium to throw the javelin safely. Terje Pedersen (Norway) broke the 300-foot (91.44-metre) barrier in 1964, and by 1984 Uwe Hohn (East Germany) had thrown a prodigious 104.80 metres, a throw so great that it influenced a change in the design of the javelin to keep it within the safe confines of the field. Beginning in 1985, throwers used a javelin that, at the same weight, was designed to reduce the length of the throw by 9 to 12 metres (30 to 40 feet). The design of the women's javelin was not changed, and successive world records pushed close to 80 metres by the late 1980s.

Modification of the javelin

Decathlon and heptathlon. Both men and women participate in multi-event competitions, the men in the 10-event decathlon and the women in the seven-event heptathlon, which superseded the earlier pentathlon. The events, which require a two-day schedule, are held basically in worldwide competitions and national championships. In the United States they also are scheduled in many college-conference championships.

Each athlete is given points for his performance in each event, with more points awarded for better marks. The athlete with the most total points wins.

Men compete in five events each day, doing consecutively the 100 metres, long jump, shot put, high jump, and 400 metres on the first day and the 110-metre hurdles, discus throw, pole vault, javelin throw, and 1,500-metre run in that order on the second day. Women do, in order, the 100-metre hurdles, high jump, shot put, and 200-metres on the first day, followed by the long jump, javelin, and 800-metres on the second day.

Jim Thorpe, the great all-around American athlete, won the first decathlon, taking the 1912 Olympic Games contest, and for many years it was mostly an American event. Bob Mathias (U.S.) won his first decathlon at age 17 in 1948 and repeated it four years later. Another two-time winner was Daley Thompson of England, victorious in 1980 and 1984. Notable in the heptathlon was Jackie Joyner-Kersee, a record setter and winner of the 1987 World Championships and 1988 Olympics. (B.Ne.)

Boxing

Boxing is the art of attack and defense with the fists in which the two contestants wear padded gloves, box bouts of from three to 15 rounds (each round normally lasting three minutes), and generally observe the code set forth in the Marquess of Queensberry rules (see below *Queensberry rules*). Boxing contestants are matched in weight and ability, each trying to land hard and often with his own fists and, while doing so, attempting to avoid the blows of his opponent.

The terms pugilism and prizefighting in 20th-century usage are practically synonymous with boxing, although the first term indicates the ancient origins of the sport in its derivation from the Latin *pugil,* "a fighter with the cestus [a hand covering]," related to the Latin *pugnus,* "fist," and derived in turn from the Greek *pyx,* "with clenched fist." The term prizefighting emphasizes pursuit of the sport for monetary gain. (For records see SPORTING RECORD and OLYMPIC GAMES in the *Micropædia.*)

HISTORY

Early years. Presumably people used their fists to settle arguments for many centuries before anyone thought of staging such bouts for the entertainment of others. There is evidence that boxing existed by about 1500 BC in ancient Crete. More recent evidence, however, indicates that the sport was being practiced in Africa much earlier, particularly in the region now known as Ethiopia. Hieroglyphic evidence dating to 4000 BC reveals the spread of the newly developed sport throughout the Nile Valley to Egypt, where it was introduced after a series of successful Egyptian campaigns in Ethiopia.

African origins

The spread of boxing followed the expansion of Egyptian civilization through the Mediterranean and the Middle East. By 686 BC boxing had been refined and perfected enough to be included in the Olympic Games. However, the sport bore little resemblance to what is now known as boxing. Matches were held outdoors, with spectators forming the boundaries. The fight continued without pause until one participant was unable to continue. Although the first boxers primarily fought for glory, rewards were abundant for the victors, usually taking the form of gold, livestock, or trophies.

To protect the hands and wrists, fighters wore thongs of soft leather bound around their fists and often around two-thirds of their forearms. By the 4th century BC, the thongs were made of harder leather, transforming them into offensive weapons as well as protective devices. Late in the history of the Roman Empire, the hand covering called the *cestus,* studded with iron or brass nuggets, was developed, and slaves were forced to battle each other to the death for the entertainment of spectators.

The bareknuckle era. With the rise of Christianity and the concurrent decline of the Roman Empire, pugilism as entertainment apparently ceased to exist for some centuries. A formal bout was recorded in Britain as early as 1681, and by 1698 regular pugilistic contests were being held in the Royal Theatre of London. As London grew, prizefighting, as it came to be known, became quite popular there. The fighters performed for whatever purses were agreed upon plus stakes (side bets), and admirers of the combatants wagered on the outcomes. These matches were fought without gloves and, for the most part, without rules. There were no weight divisions; thus there was just one champion. Lighter men were at an obvious disadvantage. Rounds were designated, but a bout was usually fought until one participant could no longer continue. Wrestling was permitted, and it was common to fall on a foe after throwing him to the ground. Until the mid-1700s it was also common to hit a man when he was down.

17th-century prizefighting

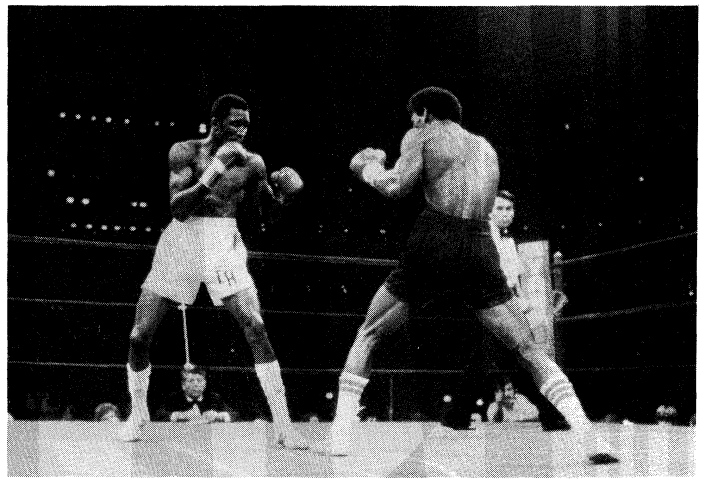
Although boxing was illegal, it became quite popular, and by 1719 the prizefighter James Figg had so captured the public's imagination that he was acclaimed champion of England, a distinction he held for up to 15 years. One of Figg's pupils, Jack Broughton, is credited with taking the first steps leading to boxing's acceptance as a respectable athletic endeavour. Broughton devised the sport's first set of rules in 1743, and those rules, with only minor changes, governed boxing until they were replaced by the more detailed London Prize Ring rules in 1838. Broughton discarded the barroom techniques that his predecessors favoured and relied primarily on his fists. While wrestling holds were still permitted, a boxer could not grab an op-

ponent below the waist. Under Broughton's rules, a round continued until a man went down; after 30 seconds' rest he had to square off a yard from his opponent or be declared beaten. Hitting a downed opponent was also forbidden. Recognized as "The Father of Boxing," Broughton attracted pupils to the sport by introducing "mufflers," the forerunners of modern gloves, to protect one's hands and the opponent's face.

"The Father of Boxing"

After Jack Slack beat Broughton to claim the championship, fixed fights became common and boxing again experienced a period of decline, though pugilists such as Daniel Mendoza and "Gentleman" John Jackson did have success. Mendoza was an English Jew who weighed only 160 pounds and emphasized speed and the left jab. Jackson, who defeated Mendoza for the championship, contributed to the transformation of prizefighting into boxing by gaining friends of distinction for the sport, thus bringing it a degree of respectability.

In 1814 the Pugilistic Society was started in London to try to bring some control to the sport, and by 1838 the London Prize Ring rules had been accepted in both Britain and America. These rules, which were first used in a championship fight in 1839 in which James "Deaf" Burke lost the English title to William Thompson ("Bendigo"), provided for a ring 24 feet (7.32 metres) square and bounded by two ropes. When a fighter went down, the round ended and he was helped to his corner. The next round would begin 30 seconds later, with each boxer required to reach, unaided, a mark in the centre of the ring. If a fighter could not reach that mark by the end of eight additional seconds, he was declared the loser. Kicking, gouging, butting with the head, biting, and low blows were all declared fouls.



Queensberry rules. Though the London Prize Ring rules did much to help boxing, the brawling that distinguished old-time pugilism continued to alienate most of England's upper class, and it became apparent that still more revisions were necessary to attract a better class of patron. John Graham Chambers of the Amateur Athletic Club devised a new set of rules in 1867 which emphasized boxing technique and skill. Chambers sought the patronage of John Sholto Douglas, the 9th marquess of Queensberry, who lent his name to the new guidelines. The Queensberry rules differed from the London rules in four major respects: contestants wore padded gloves; a round consisted of three minutes of fighting followed by a minute of rest; wrestling was illegal; and any fighter who went down had to get up unaided within 10 seconds—if he could not do so, he was declared knocked out, and the fight was over. During this period the introduction of the first weight divisions also took place.

The new rules at first were scorned by professionals, who considered them unmanly, and championship bouts continued to be fought under London Prize Ring rules. But many young pugilists preferred the Queensberry guidelines and fought accordingly. Prominent among these was James ("Jem") Mace, who won the English heavyweight title under the London rules in 1861. Mace's enthusiasm for gloved fighting did much to popularize the Queensberry rules.

John L. Sullivan

It was, however, John L. Sullivan of the United States who made the move that finally aligned professional fighters on the side of the Queensberry rules. Sullivan claimed the world heavyweight championship in 1882 under the London bareknuckle rules. In 1889 Sullivan defended against Jake Kilrain in the last heavyweight championship bareknuckle fight in the United States, despite the London rules by then having been made illegal in every state. The legal complications following the Kilrain match so upset Sullivan that when he agreed to defend his championship against James J. Corbett, he insisted on Queensberry rules.

Economic impetus. By the early 20th century, boxing had become a shortcut to riches and social acceptance for those near the foot of the economic ladder. It was at this time that professional boxing became centred in the United States, with its expanding economy and successive waves of immigrants. Famine had driven thousands of Irish to seek refuge in America, and by 1915 the Irish had become dominant in professional boxing, producing such standouts as Terry McGovern, "Philadelphia" Jack O'Brien, Mike ("Twin") Sullivan and his brother Jack, Packey McFarland, Jimmy Clabby, and Jack Britton, among others. German, Scandinavian, and central European fighters also emerged. Outstanding Jewish fighters such as Joe Choynski, Abe Attell, "Battling" Levinsky, and Harry Lewis were active before 1915 and were followed by a second wave consisting of Barney Ross, Benny Leonard, Sid Terris, Lew Tendler, Al Singer, Maxie Rosenbloom, and Max Baer. Italian-Americans to reach prominence included Tony Canzoneri, Rocky Marciano, Johnny Dundee, and Willie Pep.

Steve Sutton—Duomo

Meanwhile, black Americans also turned to boxing to fight their way to the top, and foreign-born black boxers such as Peter Jackson, Sam Langford, Joe Walcott, and George Dixon came to the United States to capitalize on the opportunities offered by boxing. Joe Gans won the world lightweight championship in 1902, and Jack Johnson became the first black heavyweight champion in 1908. Prejudice against black boxers, however, remained great. Sullivan refused to defend against Jackson, and Jack Dempsey, the "Manassa Mauler," would not fight the black boxer Harry Wills. As champion, Johnson was hounded so relentlessly he was forced to leave the United States. Blacks nevertheless continued to pursue fistic careers, particularly during the Great Depression, which began in 1929. When the black boxer Joe Louis won the world heavyweight championship in 1937 and went on to become one of boxing's most popular champions, blacks became more encouraged, and all-time greats such as Henry Armstrong, "Sugar" Ray Robinson, Archie Moore, Ezzard Charles, "Jersey" Joe Wolcott, Floyd Patterson, Sonny Liston, Muhammad Ali, and Joe Frazier went on to win world championships in various weight divisions. By the last quarter of the 20th century blacks dominated boxing, producing stars such as "Sugar" Ray Leonard, "Marvelous" Marvin Hagler, Thomas Hearns, Larry Holmes, Michael Spinks, and Mike Tyson.

Black American domination

Hispanics also became prominent on the boxing scene, giving the sport such legendary names as Carlos Monzón, Pascual Pérez, Roberto Durán, and Alexis Argüello. Pancho Villa of the Philippines was the first Asian to win a world championship, capturing the flyweight crown in 1923. In the late 20th century East Asia was a boxing hotbed, with many Asians fighting for various world titles.

Organization and tournaments. *Development of amateur boxing.* In 1867 the first amateur boxing championships took place under the Marquess of Queensberry rules. In 1880 the Amateur Boxing Association (ABA), the sport's first amateur governing body, was formed in Britain, and in the following year the ABA staged its first official amateur championships.

In 1888 the Amateur Athletic Union (AAU) of the United States was formed, instituting its annual champi-

onships in boxing the same year. In 1926 the *Chicago Tribune* started another amateur competition called the Golden Gloves. It grew into a national competition rivaling that of the AAU. In 1978 a law was passed in the United States forbidding the AAU from governing more than one Olympic sport. This led to the formation of the United States of America Amateur Boxing Federation (USA/ABF), which now governs U.S. amateur boxing.

Amateur boxing spread rapidly to other countries and resulted in several major international tournaments taking place annually, every two years, or, as in the case of the Olympic Games, every four years. Important events include the European Games, Commonwealth Games, Pan-American Games, All-African Championships, and the World Military Games. All international matches are controlled by the Association Internationale de Boxe Amateur (AIBA), formed in 1946 with headquarters in London.

Boxing in socialist nations

Because of their political and social policies, the Soviet Union and other Communist countries do not have professional boxers. However, the Soviet Union joined the AIBA in 1950 and entered the Olympic Games in 1952; they emerged as one of the strongest amateur boxing nations in the world, along with other Communist countries such as East Germany, Poland, Hungary, and Cuba. Cuba, which had produced many excellent professional boxers before professional sports were banned there by Fidel Castro's government, became a dominating force in international amateur boxing. The Cuban heavyweight Teofilo Stevenson won Olympic gold medals in 1972, 1976, and 1980. African countries advanced considerably in boxing after acquiring independence in the 1950s and 1960s.

Professional purses. The man who made boxing into big business was George ("Tex") Rickard, the sport's first great promoter. After staging the world's lightweight championship bout between Joe Gans and Oscar ("Battling") Nelson to publicize the mining town of Goldfield, Nev., in 1906, he realized the potential of boxing. Rickard made an art of boxing publicity, playing on the public's prejudices to boost interest and ticket sales. Five of the bouts that he promoted for Jack Dempsey, heavyweight champion from 1919 to 1926, each made more than $1,000,000. In the Great Depression years that followed Dempsey's retirement, receipts from boxing dwindled. Then in 1935 promoter Mike Jacobs signed Joe Louis to a contract, launching a new era of prosperity in boxing. Louis' career purses totaled more than $5,000,000.

Impact of television

After World War II, television took on an increasingly important role in professional boxing. Because of its relatively low production costs as compared to other sports, professional boxing became a regular feature of most network programming throughout much of the 1950s and early 1960s. After a period of decline, boxing enjoyed a television revival when five American boxers won gold medals in the 1976 Olympics and turned professional following those games. The advent of cable television in the United States also benefited professional boxing in the 1980s, replacing, in many ways, the small neighbourhood boxing clubs that had been declining as the training ground for novice professionals.

Television also greatly increased boxing revenues. Million-dollar purses for heavyweight championships became commonplace by the 1960s, and the heavyweight champion Muhammad Ali earned an estimated $69,000,000 during his 20-year professional career. Million-dollar purses are no longer restricted to the heavyweight division. When middleweights "Sugar" Ray Leonard and Marvin Hagler fought on April 6, 1987, they shared a purse estimated at $30,000,000. Aside from television, casino gambling has been the biggest influence on modern professional boxing in the United States and, to a lesser degree, in continental Europe. Casinos, especially those in Las Vegas, Nev., and Atlantic City, N.J., have found boxing to be a highly successful marketing tool for increasing gaming revenues. Major bouts at casinos also receive national and international television exposure.

Professional organizations. World professional boxing has no single controlling body that is universally recognized. This situation had its origins in the United States in 1920 when two organizations were set up: the National Boxing Association, a private body, and the New York State Athletic Commission, a state agency. Divided control led to a situation in which competing organizations sometimes recognized different boxers as world champions at the same time. In Europe the ruling body was the International Boxing Union, which in 1948 became the European Boxing Union. Several attempts were subsequently made to induce all major professional boxing organizations to agree to the formation of one international ruling body, but to little avail. In 1963 the World Boxing Council (WBC) was formed. In the early 1960s the National Boxing Association changed its name to the World Boxing Association (WBA). In 1983 the International Boxing Federation (IBF) was formed, adding to an already convoluted situation. By the 1980s it was common for most weight divisions to have three so-called "world" champions, which has considerably diluted the championship class in boxing.

The schism in boxing authority

Weight divisions. During the 19th and again at the beginning of the 20th century the popularity of boxing brought about the formation of weight divisions other than the heavyweight class to eliminate the handicap of smaller contestants having to concede excessive weight to their opponents. Some of these weight divisions originated in the United States, others in Great Britain.

The eight traditional weight divisions that are universally recognized are delimited as follows: flyweight (not more than 112 pounds [50.8 kilograms]), bantamweight (118 pounds), featherweight (126 pounds), lightweight (135 pounds), welterweight (147 pounds), middleweight (160 pounds), light-heavyweight (175 pounds), and heavyweight (any weight over 175 pounds). In all world and national title fights, the above weight limits must be strictly observed. If a boxer is over the limit, he is normally given a short time in which to make the stipulated weight. If he still fails, the bout usually ceases to be regarded as a championship contest and the champion, if he is at fault, forfeits his title.

Proliferation of weight classes

Two additional divisions, junior-lightweight (130 pounds) and junior-welterweight (140 pounds), were introduced in the United States in the 1920s. (The term "junior" in boxing has nothing to do with age.) These divisions were formed for the benefit of boxers who were unable, or unwilling, to make the stipulated weight in one of the eight original divisions. The proliferation of weight classes continued until some governing bodies recognized a total of 17 weight classes. New weight divisions recognized by the WBC are: cruiserweight (195 pounds), super middleweight (165 pounds), super welterweight (154 pounds), super bantamweight (122 pounds), super flyweight (116 pounds), light-flyweight (110 pounds), and strawweight (105 pounds).

RULES, TECHINIQUES, AND STYLES

Ring, rules, and equipment. Because there is no universally accepted world ruling body for professional boxing, each country has its own set of rules, and in the United States there are different rules in different states. Generally bouts take place in a "ring" that is some 18 to 22 feet square (the size may vary slightly) and surrounded by four strands of rope. Professional bouts may be scheduled to last from four to 12 rounds of three minutes' duration, though two-minute rounds are used in some bouts held in Great Britain. Professional championship bouts had traditionally lasted 15 rounds, but by the late 1980s the WBC, WBA, and IBF championships were all being scheduled for 12 rounds.

Scoring

A referee is stationed inside the ring with the boxers and regulates the bout. In some jurisdictions, the referee scores the contest along with two judges outside the ring. In most jurisdictions, however, the referee does not participate in the judging, and three ringside officials score the bout. The officials award points to each boxer for each round, and a boxer must win on two of the three scorecards to earn a decision victory. Padded gloves, ranging from eight to 10 ounces in weight, are worn by the boxers.

A bout ends in a knockout when a boxer is knocked down and cannot get up or is adjudged not ready to resume the contest after the referee has counted to 10. A

fight can be stopped (called a technical knockout) when a boxer is deemed by the referee (and sometimes the ringside physician) to be unable to defend himself, when a boxer is deemed to have sustained a serious injury, or when a boxer or his seconds decide he should not continue. A bout may also end in a decision, when the bout has gone the scheduled number of rounds and the scoring officials decide the winner; in a draw when the officials agree that both boxers fought equally well; in a "no contest" when the referee deems that both men are not giving their best; or in disqualification.

The rules governing amateur boxing are similar in the United States, Great Britain, and continental Europe. Amateur rules, however, differ substantially from those governing professional boxing. Amateur bouts are normally three rounds in duration, and the boxers wear protective headgear. The referee only supervises the boxing, while three to five ringside judges score the bout. The rules are also more stringently enforced in amateur boxing, and disqualification is more more common than in professional boxing.

Techniques. No one phase of boxing is more important than another. An effective offense in boxing depends on the ability to land punches fast and hard enough to penetrate the opponent's guard. Defensive tactics include parrying or warding off punches with one's upraised arms and gloves; stepping backward or sideways out of the arc of a punch; and bending or twisting one's head and upper body out of the blow's path. Footwork is important to both offense and defense. The two generally recognized stances are "orthodox" and "southpaw." The former has the left hand and the left foot forward, the latter the right hand and the right foot forward. "Switch-hitting" boxers are those who change from one stance to another during the course of a bout. In either stance, the lead hand is extended forward in front of the body and the other hand is held near the chin for protection, the chin is tucked into the chest, and the shoulders are hunched. There are variations in individual styles, of course.

The basic punches

There are four basic punches: the jab, hook, uppercut, and cross. All other punches are modifications of these basic punches. The jab, whether thrown from an orthodox or southpaw stance, is a straight punch delivered with the lead hand, which moves directly out from the shoulder. The other punches may be thrown with either hand. The hook is a short lateral movement of arm and fist, with elbow bent and wrist twisted inward at the moment of impact. The uppercut is an upward blow delivered from the direction of the toes. The cross is thrown across the body at shoulder level, usually as a follow-up to a lead from the other hand.

Styles. In bareknuckle fighting the emphasis was on the power of the punch, since bouts usually ended only when one contestant could not continue. The hands were held in front of the body in no particular position, and footwork was practically nonexistent. With the advent of padded gloves and contests decided on points, boxing skills and footwork became more important. James J. Corbett was the first modern heavyweight to concentrate on technique. Ten years after Corbett lost the title, heavyweight champion Jack Johnson showed that he too could box as well as punch. The heavyweight champion Jack Dempsey enjoyed tremendous popularity because he was an aggressive fighter who always sought to knock out his opponent. Dempsey fought from a crouch, bobbing and weaving to leave as little of himself exposed as possible. The heavyweight champion Joe Louis perfected the "stalking" style, a method of patiently pursuing his opponent until he came within range to deliver a knockout blow. Mike Tyson, who won the WBA, WBC, and IBF heavyweight titles in the late 1980s, used a similar style.

Muhammad Ali

Until Muhammad Ali, heavyweights were not expected to move quickly. At his peak, however, Ali was probably the fastest and most skillful heavyweight champion of all time. He danced around the ring with his arm sometimes dangling at his side, but always in position to attack or defend at the right time. Although Ali did not possess a devastating punch, he scored many knockouts by delivering a rapid sequence of blows. Though style remains a matter of individual choice, swift lateral movement and combination punching have, to a large degree, become the two most important aspects of modern boxing technique.

Bowling

Bowling, also called tenpin bowling, is a game in which a ball is rolled down a long, narrow lane toward a group of pins, the object being to knock down more pins than an opponent. The game is quite different from the sport of bowls, or lawn bowls, in which the aim is to bring the ball to rest near a stationary ball called a jack. There are many forms of bowling, but tenpins, the most widely played variation, is the principal form of bowling in the United States, Canada, western Europe, the Far East, Australia, New Zealand, and Latin America. Its many variations include duckpins, candlepins, fivepins, skittles, and ninepins, and differences within the framework of each of the games. For records of Fédération Internationale des Quilleurs and American Bowling Congress championships, see SPORTING RECORD in the *Micropædia*.

HISTORY

Origin and early period. Articles found in the tomb of an Egyptian child buried in 5200 BC included nine pieces of stone, to be set up as pins, at which a stone "ball" was rolled, the ball having first to roll through an archway made of three pieces of marble. The modern sport of bowling at pins probably originated in ancient Germany, not as a sport but as a religious ceremony. As early as the 3rd or 4th century AD, in rites held in the cloisters of churches, parishioners may have placed their ever-present club, or *Kegel* (the implement most Germans carried for sport and, certainly, self-protection), at one end of a runway resembling a modern bowling lane. The *Kegel* was said to represent the *Heide* ("heathen"). A stone was rolled at the *Heide,* and those successfully toppling it were believed to have cleansed themselves of sin. Although the peasants' club evolved into pins, the association remained, and even today bowlers are often called keglers.

German roots

The passage of time brought an increase in the size of the stone rolled at pins, and eventually the ball came to be made of wood. Many variations of the game developed, some played with three pins, others with as many as 17. A biographer of the 16th-century cleric Martin Luther has written that Luther built a bowling lane for his children which he occasionally visited, sometimes throwing the first ball.

Among other significant historical references to bowling are an account of a great feast given the citizenry of Frankfurt in 1463, at which the venison dinner was followed by bowling; notations from 1325 in which "gambling on bowling" in Berlin and Cologne was limited to five shillings; and the award of an ox to the winner of a bowling competition in 1518, given by the city of Breslau (now Wrocław, Pol.).

In the 15th, 16th, and 17th centuries, the game spread into the Low Countries and also into Austria and Switzerland. The playing surfaces were usually cinders or clay, specially treated and sun-baked to a hardness resembling concrete. The roofing over of lanes, first done in London for lawn bowls around 1455, was the beginning of bowling as an all-weather, around-the-clock game. When the lanes were covered or put into sheds (called *Kegelbahns* in Germany and Austria and usually attached to village taverns or guest houses), the playing surfaces ranged from wood or hardened clay to, in later years, asphalt.

Bowls and pins in North America. There is confusion about how and when bowling at pins came to North America, arising from the inconsistent use of the terms bowl, bowler, and bowling. The early British settlers brought lawn bowls with them to America because that was the game they knew best. Dutch explorers under Henry Hudson were said to have brought some form of pin bowling.

Early European pin games

Many of the early European pin games involved rolling the ball along a wooden plank, 12 to 18 inches (30 to 46 centimetres) wide and 60 to 90 feet (18 to 27 metres) long, toward a diamond-shaped formation of nine pins.

The plank still can be found in parts of Europe, notably in eastern European countries, where bowling games called bohle, asphalt, and schere are popular. In these, the nine pins are smaller than tenpins, and the duckpin-type ball, without finger holes, is held in the palm of the hand. The Netherlands has a "plank" game in which a large ball, with only a thumbhole, is rolled on the plank toward the nine pins. The earliest known reference to bowling in the United States was made by Washington Irving in his short story "Rip Van Winkle" (1819–1820).

Emergence of the tenpin game. By the mid-1830s, as bowling at pins was flourishing, the scourge that periodically struck the game in Germany, France, England, and other countries—gambling—became a plague on the U.S. bowling scene. To combat the problem, the state legislature of Connecticut in 1841 banned the playing of "Nine-Pins, whether more or less than nine-pins are used." However, a month before the Connecticut legislation, the town of Perry, N.Y., had enacted a law banning tenpins. There are other earlier signs of tenpin bowling, including a painting, traced to 1810, that shows English dandies playing a game with 10 oddly shaped pins set up outside a factory in Ipswich, Eng., an area that was populated by many Dutch immigrants in the 1700s. Regardless of how tenpins came into being, its popularity spread as German immigrants began populating Chicago; Milwaukee; St. Louis, Mo.; Cincinnati, Ohio; Detroit, and other cities. Although intercity bowling events were becoming common, the lack of uniform playing rules and equipment specifications stifled the development of the game. In 1875 delegates from nine bowling clubs in New York City and Brooklyn, N.Y., organized the National Bowling Association. Some of the legislation agreed upon then is still in effect in modified form, but the group lacked national acceptance.

Organization and tournaments. Disagreement over rules continued, principally as an alignment of New York bowlers against everyone else. On Sept. 9, 1895, the American Bowling Congress (ABC) was organized in New York City. Rules and equipment standards were developed, and the game as it finally was organized remained basically unchanged as the sport grew steadily. An early technological development that helped the sport's progress was the introduction of the hard rubber ball in 1904, its predecessor having been made of lignum vitae, a tropical wood that was durable but that often chipped or otherwise lost its shape. The next big advance was the introduction of the automatic pin-setting machine in the early 1950s. Later, balls made of polyester and urethane were developed and in some cases replaced the hard rubber ball.

The American Bowling Congress

In 1901 the ABC started its national tournament. The Women's International Bowling Congress (WIBC) was organized in 1916 and conducted annual national championships from 1917. While the ABC and WIBC are autonomous organizations, each billing itself as the "world's largest" men's or women's sports organization, respectively, they share a number of functions, including equipment testing and research and the joint issuance of credentials to the mixed leagues that made up more than 70 percent of their late 1980s combined membership of approximately 7,000,000. A third membership organization, the Young American Bowling Alliance (YABA; established in 1982), administers to the league and tournament needs of young bowlers through college age.

In the late 20th century it was estimated that more than 60,000,000 persons bowled at least once or twice a year in the United States. The backbone of the sport continued to be its highly organized, competitive league structure. Most men's and women's leagues consist of eight to 12 teams but some have 40 or more, depending on the number of lanes in the bowling centre. League play is conducted under rules laid down by the three major membership organizations, including the handling of prize funds by the adult leagues. The prize funds are developed from the contestants' entry fees and are distributed to the various teams and individuals on a performance basis.

League structure

Professional bowling. The Professional Bowlers Association of America (PBA) was organized in 1958. It quickly developed a star system and a tournament tour fashioned after that of professional golf. PBA members, helped by a booming television industry, were soon playing for more than $1,000,000 in yearly prize money, a figure that had grown to more than $7,000,000 by the late 1980s. Don Carter became the leading winner in the 1950s, succeeded by Dick Weber in the 1960s and Earl Anthony into the 1980s. The Professional Women Bowlers Association (1959; since 1981 called the Ladies Pro Bowlers Tour [LPBT]) began modest tournament play in the early 1960s. A major influence in development of the game was the Bowling Proprietors' Association of America, founded in 1932. In addition to its trade association functions, it is affiliated with a number of tournaments, most notably the All-Star tournament, a match game event begun in 1941 that in 1971 became the U.S. Open and a part of the PBA tour. The National Bowling Council, founded in 1943 by manufacturers, proprietors, and membership groups, concerns itself with national promotional campaigns and other activities.

Tenpins in other countries. The first tenpin lanes in Europe were installed in Sweden in 1909. Attempts to popularize tenpin bowling elsewhere in Europe were unsuccessful over the next several decades, but the game became popular in Great Britain during World War II, when hundreds of lanes were installed on U.S. military bases.

As league bowling in the United States peaked in the mid-1960s, equipment manufacturers began looking elsewhere for new markets. With assistance from the ABC, the British Tenpin Bowling Association was formed in 1961 and was ready for the boom. With the same ABC assistance, Australia followed suit. Mexico, where Emperor Maximilian had installed a skittles alley in Chapultepec Castle a century earlier, joined the tenpin trend, as did other Latin-American countries.

By the early 1970s the bowling boom had spread to Japan. Leading players for the PBA were invited to compete in an annual Japanese tournament. Unlike the United States, where the male professionals dominated television, however, the most popular bowlers on Japanese television were women. Bowling also became popular in other Asian localities, including Hong Kong, Thailand, Singapore, Korea, and Indonesia.

The bowling boom in Japan

International competition. Documents indicate that an international competition was held in Hannover, Ger., as early as 1891. An early bowling proprietor and promoter in New York City was so taken with the idea of international play that he sponsored an event in Union Hill, N.J., in 1900, but the use of the word international was only thinly justified by the appearance of some teams from Canada. Competitions apparently limited to ninepins and other "small ball" games were held in the German cities of Solingen (1904), Dresden (1908), and Berlin (1914). Few other than German bowlers were entered.

In 1923 a group of American bowlers toured Sweden and were roundly defeated by their hosts. The outcome was the same in 1926, at which time teams from Denmark, Finland, Norway, The Netherlands, and Germany joined the Swedes and Americans in forming the International Bowling Association. In 1929 they held what came to be called the Third International tournament, again in Sweden, followed by a Fourth International held in New York City in 1934. Germany hosted the Fifth International in 1936, as a prelude to, but having no connection with, the Olympic Games in Berlin. It was the last international meet of any consequence until the Fédération Internationale des Quilleurs (FIQ) was formed in 1952 to coordinate international amateur competition. Its headquarters is in Helsinki, and it has grown to more than 70 member nations.

The first world tournament of the FIQ was held in Helsinki in 1954, and from 1967 championships were played every four years. Competition is held in three zones—American, European, and Asian. The organization has four sections, the principal one being devoted to tenpins. The other three are the small-ball games, schere, bohle, and asphalt. FIQ competition is for nonprofessionals; and gold, silver, and bronze medals are awarded to champions and runners-up. Bowling was accepted as a demonstration sport in the summer 1988 Olympic Games in Seoul, South Korea.

PLAY OF THE GAME

Lanes and equipment. The U.S. game of tenpins is played according to the rules and specifications of the American Bowling Congress. The game is played indoors on wooden or synthetic lanes with maximum dimensions of 62 feet $10^{11}/_{16}$ inches (19.17 metres) in length and 42 inches (107 centimetres) in width. The surface, coated with lacquer or plastic-type material, must be free of continuous grooves and must be within 40/1,000th inch (one millimetre) of perfect levelness. The distance from the foul line, past which the player may not slide when delivering the ball, to the centre of the spot on which the headpin stands is 60 feet (18.3 metres). The approach to the foul line has a minimum length of 15 feet (4.6 metres).

The bowling lane

The pins are 15 inches (38 centimetres) tall and arranged in a triangle formation with the point or No. 1 pin at the head of the formation facing the bowler. The centres of the pin spots are 12 inches (30.5 centimetres) apart. The pins have a laminated wood core covered by a plastic coating. The weight ranges between 3.5 and 3.7 pounds (1.6 and 1.7 kilograms).

The ball is of nonmetallic composition—either hard rubber, polyester, or urethane—with a circumference of 27 inches (68.6 centimetres) and a weight limit of 16 pounds (7.3 kilograms). There is no minimum weight.

Principles of play. A game of tenpins consists of 10 frames. Two deliveries (rolls of the ball) per frame are allowed, the ideal being to knock down all pins on the first for a strike. If pins are left standing after the first delivery, the fallen or "dead" wood is removed and a second delivery permitted. If all remaining pins are knocked down, a spare is recorded. A split can occur on the first ball when two or more pins are left standing, separated by at least one fallen pin. Stepping over the foul line is a foul and results in loss of all pins knocked down on that delivery. There are depressed troughs on each side of the lane; a ball falling therein is a gutter ball and out of play, with resulting loss of one delivery.

Scoring

Both a strike and a spare count 10 pins plus additional pins scored on the next two (after a strike) or one (after a spare) deliveries. If two strikes in a row are recorded (a double), the player counts 20 pins in the first frame plus the number of pins he knocks down on his first delivery in the third frame. Should he score another strike, he will have 30 pins in his first frame. A perfect game is 300 and consists of 12 strikes in a row, two additional deliveries being permitted in the 10th, or final, frame (one additional following a spare). Competition in league and tournament play includes individuals, as well as teams of up to five players. Two teams are assigned to a pair of lanes, the bowlers alternating lanes for each frame.

Sri Lanka

Sri Lanka (known as Ceylon until 1972) is an independent island state in the Indian Ocean lying off the southeast coast of peninsular India. The Republic of Sri Lanka has a parliamentary form of government and is a republic within the Commonwealth. The island is pear-shaped, with a maximum length of about 272 miles (435 kilometres) and a maximum width of about 140 miles; it has an area of 25,332 square miles (65,610 square kilometres). A shallow sea, Palk Strait, separates Sri Lanka from India; Talaimannar, on Sri Lanka's Mannar Island, is only 22 miles away from Dhanushkodi on India's Pāmban Island. A line of shoals called Adams Bridge runs between Sri Lanka and India immediately south of this point. Colombo is the capital of Sri Lanka, but Sri Jayawardenepura, about five miles outside Colombo, became the capital designate in 1982.

Sri Lanka is a country of great beauty, with scenery varying from the palm-fringed beaches of its coasts to the highlands of the interior, where the famous Buddhist Temple of the Tooth is located at Kandy, once the capital of an independent kingdom. Sri Lanka has also been traditionally associated with elephants, but their numbers have decreased substantially in recent years. The name Ceylon is an English word derived from the Sanskrit Siṃhaladvīpa, meaning "Island of the Sinhalese." The Sinhalese and Pāli name for the country is Laṅkā, and the prefix *Śri* is an honorific. The Tamil name is Īḻam, or Ilaṅkai.

Physical and human geography

THE LAND

Relief. Like peninsular India, of which it forms a continuation, Sri Lanka is a fragment of an ancient southern continent that geologists call Gondwanaland.

Both peninsular India and Sri Lanka stand on the same continental shelf, the edge of which does not extend beyond 12 miles from Sri Lanka's coastline. This shelf is shallow, lying at a depth of between 30 and 40 feet (nine and 13 metres) in the Palk Strait and attaining a maximum depth of only about 210 feet. Beyond the edge of the continental shelf the depth increases to about 3,000 feet within two miles.

The relief of the island is dominated by a highland massif situated in the southern central part of the island. This is surrounded by an intermediate zone consisting of upland ridges and valleys, which are separated from the massif by well-defined scarps. The intermediate zone, in turn, is surrounded by an outer or lower coastal lowland zone, except in the southwest, where the land abuts directly onto the sea in the form of cliffs. Elsewhere there is a coastal fringe consisting of a series of lagoons, sandbars, peninsulas, dunes, and marshes. Five-sixths of the country lies at an altitude of less than 1,000 feet.

The four physiographic regions

Regions. For convenience Sri Lanka may be divided into four regions—the central highlands, the southwest, the east, and the northern lowlands. The central highlands, which were formed by faulting, have some fine scenery. The highest point is Pidurutalagala, a rounded peak 8,281 feet (2,524 metres) high; more renowned, however, is the pyramidical Adams Peak, 7,360 feet (2,243 metres) high, which lies to the southwest of Pidurutalagala and is a centre for pilgrimages by Buddhists, Hindus, Muslims, and even Christians.

The southern edge of the central massif consists of a rim of steep scarp running east to west and curving southward in the centre; at one point, called the World's End, the scarp wall forms an almost sheer drop of about 5,000 feet. To the north of the central highlands lies Knuckles Mountain, which is separated from the highlands by the valley of the eastward-flowing Mahaweli Ganga, Sri Lanka's largest river.

The southwestern region is also mountainous and includes the Rakwana, or Bulutota, Range, a continuation of the central massif. Its topography consists of elongated ridges, parallel valleys, and a trellis (crisscross) drainage pattern.

The east consists of an undulating plain dotted with isolated hills or inselbergs (steep-sided hills that remained after the landscape had been scoured by erosion). Among these hills are Westminster Abbey (named for its shape), Monaragalla, and Kataragama.

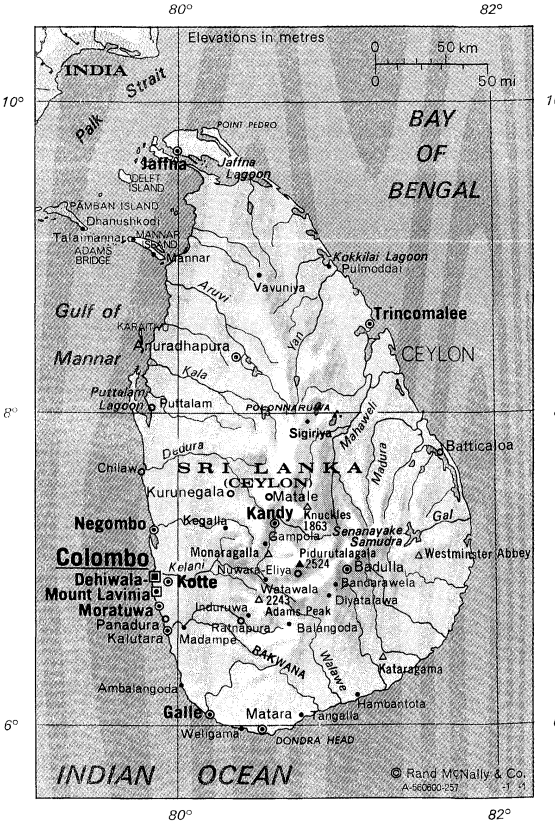
The northern lowlands region consists of rolling countryside intersected by rivers and marked by occasional ridges and isolated hills. In the extreme north, the Jaffna Peninsula, which is made of limestone, is associated with a coral reef. Several offshore islands have the same formation.

Geologic record. Forming part of a very old landmass, Sri Lanka has experienced a long series of geological events, including folding movements as well as uplifting movements that have resulted in the fracturing and faulting of rocks. These movements, in addition to providing differences in rock composition, account for the scarps that separate the different elevation levels. Climate has also exerted an influence upon the sculpturing of the land surface.

Nearly nine-tenths of the island is floored by rocks of Precambrian age (570,000,000 to 4,600,000,000 years old), consisting of schists (rocks changed by heat and pressure at depth and having a banded and foliated structure) and gneisses (imperfectly foliated rocks changed by heat and pressure, with alternating light and dark bands differing in mineral composition, and more coarsely grained than schists), overlain by sediments changed by heat and pressure. Among the sedimentary rocks, only a few outcrops of shale and sandstone of Jurassic age (from 136,000,000 to 190,000,000 years old) are to be found. These occur in the Tabbowa and Andigama areas; some coal has been found in them. The north and northwest areas are floored by sedimentary limestone of Miocene age (from 7,000,000 to 26,000,000 years old). Gravel deposits adjoining this sedimentary limestone belt may have been laid down in periods when the area lay under a shallow sea during the last 2,500,000 years. Sand dunes and alluvium are commonly deposited in coastal areas. Some coral formations occur at Mathagal in the north and in the Madampe-Ambalangoda area in the southwest.

The rivers

Drainage. The rivers of Sri Lanka are noted for their number rather than for their size. They radiate from the central highlands like the spokes of a wheel, except for the upper course of the Mahaweli Ganga, which has developed different characteristics from the fault movements that have shaped the terrain. Most of the rivers, however, tumble down in a series of waterfalls and cascades before reaching the plain. The Mahaweli Ganga is only 206 miles long and Aruvi Aru 104 miles long; the other rivers, of which there are more than 100, are all less than 100 miles in length. The mouths of the rivers are choked with sand.



Climate. Sri Lanka lies between 6° and 10° north of the Equator and consequently might be expected to experience an equatorial type of climate. Its position in relation to the Indian subcontinent and to the neighbouring seas, however, has resulted in modification of the climate, with a regime of monsoons (rain-bearing winds) being superimposed upon the equatorial regime. Further modifications are caused by relief.

Rainfall is the most important element in the climate. Although Sri Lanka is a small island, the distribution of rainfall is not uniform, varying from more than 200 inches (5,000 millimetres) to less than 40 inches a year in different parts. Further climatic variations in different places are the result of the seasonal incidence of rainfall. Because of elevation and aspect, the central and southwestern parts receive the most rain. Some strips along the extreme northwest and southeast coasts are described as arid because they receive less than 50 inches of rainfall a year; while this is a relatively large amount, much of the moisture is lost through evaporation, in addition to which there are several rainless months. Much of the rain is also lost because it runs off the surface. Cultivation in these areas is restricted to the short rainy season, except when irrigation is resorted to.

The southwest monsoon blows from May to October, and from December to March the northeast trade winds—locally known as the northeast monsoon—prevail. The monsoons are often irregular, beginning or ending earlier or later than expected, thus adding to the hazards of agriculture. Between the monsoons—from approximately October to December and again from March to May—normal equatorial conditions prevail.

The five climatic zones

While the north and east of the island are generally drier, and the south and west wetter, five climatic zones may be distinguished in terms of rainfall: the wet lowlands and the wet highlands in the west; the dry lowlands and the dry highlands in the east; and the arid zones, which, as already mentioned, are in the extreme northwest and southeast. At Colombo in the wet lowlands, annual rainfall amounts to 90 inches, and the average annual temperature is 81° F (27° C); at Watawala in the wet highlands, the annual rainfall amounts to 218 inches, and the average temperature is 65° F (18° C); at Trincomalee in the dry lowlands,

annual rainfall averages 64 inches, and the temperature 82° F (28° C); at Mannar, on the island of Mannar in the arid zone, rainfall averages 40 inches a year, and the temperature averages 82° F (28° C). Nuwara Eliya in the wet highlands experiences some night frost but no snow. In Sri Lanka in general, temperatures vary little at different seasons; the annual and diurnal (daily) temperature variation does not exceed about 8° F (4° C). Most places in Sri Lanka have a high relative humidity.

Soils. In the wet zone, climate is the dominant factor in the formation and characterization of soils. Lateritic loams (reddish leached iron-bearing soils, composed of a mixture of clay, silt, sand, and organic matter) are the most common. They are generally well drained, friable when dry, but poor. In the dry zones, the same types of rocks result in semilateritic and nonlateritic earths. In the sedimentary limestone areas, thin mantles of red loams, rich in lime, are common. Along the lower courses of the rivers, and on their floodplains, rich rice soils occur. Sandy soils are prevalent on the coastal dunes and sandbars.

Plant and animal life. As Sri Lanka has been occupied by man for many centuries, the natural vegetation cover has been altered by cultivation. The open, rolling grasslands, known as *patanas,* in the eastern highlands of the Uva region are said to have resulted from the destruction of the forests that previously grew there.

Nearly 50 percent of the island, however, is still covered with forest, natural grassland, and wasteland. The best developed evergreen forests are to be found in the wet zone; the larger part of the dry zone forests are of poor composition.

Animal life, once abundant, is now becoming depleted. The elephant population has dwindled to a few hundred. The common forest animals are deer, leopards, bears, jackals, monkeys, wild boars, cheetahs, and wild buffalo.

Settlement patterns. The present-day pattern of population distribution bears little resemblance to that of the period before the advent of the Europeans, which ended with the arrival of the Portuguese in 1505. Earlier Sinhalese and Tamil settlements were confined to the dry lowlands of the north and were focused on Anuradhapura. This environment resembled that of the settlers' original homelands in South India, where rice cultivation was based on irrigation from water tanks. The forested wet zone of southern Sri Lanka remained almost uninhabited until plantation agriculture was introduced by the British in the early 19th century.

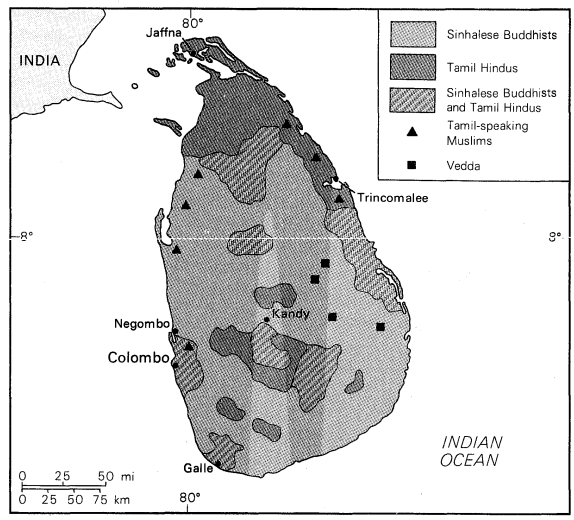
Rural settlement. Individual villages are surrounded with cultivated plots and orchards, from which vegetables, fruits, and spices are obtained. Elsewhere, temporary (shifting) cultivation is practiced; after being used for three to five years, the fields are allowed to revert to forest again.

Urban settlement. In the late 20th century about one-fourth of the total population of Sri Lanka was urban, and nearly half of this number lived in towns in the Colombo region alone. The urban population in other districts is relatively small.

THE PEOPLE

Sri Lanka is inhabited by a varied mixture of peoples who have immigrated to the island at intervals since remote times. The population, while consisting of nationals of Sri Lanka, is divided into several groups. The two principal linguistic groups are the Sinhalese, who generally are Buddhists, and the Tamils, who generally are Hindus. (The Sinhalese are divided between the low-country Sinhalese and the up-country, or Kandyan, Sinhalese. The Tamils are divided between the Sri Lanka Tamils and the Tamils of Indian origin.) A major minority are the Muslims (misnamed Moors), who are partly descended from Arab seafarers and speak Tamil. Relations between Sinhalese and Tamils have deteriorated in recent years, more as a result of current economic maladies than for historic reasons. Linguistic and religious groups—as well as the caste groups into which both Sinhalese and Tamils are divided—vie with one another to secure economic and political advantage, using pseudohistoric race myths and concepts in their struggles. Sri Lanka's ethnic and linguistic plurality is reflected in the design of its flag, which shows a yellow lion—symbolizing the legendary origin of the Sinhalese from a lion—on a red background, with a saffron stripe added to represent the Tamils and a green stripe to represent the Muslim minority.

The Sinhalese and Tamil linguistic groups



Other notable groups are the Burghers, who are of mixed Dutch and Eurasian origin; the Eurasians; the Malays; the Europeans who have adopted Sri Lankan nationality; and the Indians. The Veddas, who are believed to be the aboriginal inhabitants of the island, are very few in number and are now practically indistinguishable from other groups, with whom they have intermarried.

THE ECONOMY

Sri Lanka's economy is still precariously dependent upon the exports of its plantation products, which are subject to severe fluctuations in the world market prices as well as to the influence of other factors beyond national control, such as the development of substitutes, changes in people's tastes abroad, changes in manufacturing practices, or the conclusion of multilateral trade pacts. The necessity of diversifying the economy in the agricultural sector by reducing dependence upon imports, especially of food crops, and encouraging the domestic production of substitutes, and achieving a greater degree of industrialization has been partially realized in recent years. The country remains dependent, however, upon imports of rice, sugar, and other foods, as well as of clothing. The diversification of agriculture has been rendered inevitable by falling prices in the world market for tea and rubber—two of the mainstays of the export sector. Tea, rubber, and coconuts together earn most of Sri Lanka's foreign exchange, while tea alone accounts for the largest proportion. The output of rice has been increased through achieving higher yields. Yields in turn are being increased by irrigation, flood control, the use of artificial fertilizers, intensive cultivation, and the use of better seeds.

Resources. Mineral deposits include iron ore, ilmenite (iron titanate, a common black mineral), graphite, and gemstones. Iron ore deposits of high quality, suitable for electrosmelting and found at a shallow depth, have been located in the Ratnapura, Balangoda, Kalutara-Baddegama, Matara-Akuressa, Matale, and Chilaw areas, all in central or southern Sri Lanka. Ilmenite deposits in the form of beach deposits are located north of Trincomalee at Pulmoddai. Additional deposits exist at Turrukovil, Pamunugama, and elsewhere. Deposits of monazite (the principal ore of thorium, used in alloys) are found with ilmenite in beach sands along the west coast. There is an extensive deposit of ilmenite at Pulmoddai and important concentrations of monazite at Beruwela and Induruwa. Rutile (titanium dioxide, used to coat welding rods), zircon (zirconium silicate, used to line furnaces), and garnet sand (used as an abrasive) also occur as beach deposits. Sri Lanka is famous for its almost inexhaustible deposits of high-grade graphite. It also possesses both a quantity

and a variety of gemstones, including rubies, sapphires, starstones, and cat's-eyes (gemstones that change in lustre or colour, like the eyes of a cat). Other mineral deposits include large quantities of kaolin (china clay); other clays used for making tiles, bricks, and pottery; an inferior quality of mica; quartz, which is used for glassmaking; and limestone suitable for cement manufacture. Sri Lanka's lagoons and other coastal features are favourable for manufacturing salt from seawater by solar evaporation during the rainless period. Prospecting for oil is in progress, but so far without result.

In addition to the climate and soil, which favour such crops as tea and rubber, the forests constitute a substantial resource, although pure stands of timber are rare. Fish and other edible forms of marine life abound in the seas around the island.

More than 50 waterfalls, some perennial and of considerable size, are found in the hill country; in addition, major irrigation projects, such as those on the Gal Oya, Mahaweli, and Walawe rivers, are also capable of yielding much hydroelectric power.

Agriculture, forestry, and fisheries. As mentioned, tea, rubber, and coconut products are the principal sources of foreign exchange earnings. About one-half of the people in the labour force work in subsistence or plantation agriculture, primarily in rice and tea cultivation; rice is the staple food, although only two-thirds of the country's needs are met by domestic production. Rice is cultivated twice each year with one primary growing season, the *maha* (October–March), and one secondary growing season, the *yala* (April–September). The island's climate allows for almost year-round tea production, and tea is exported each month of the year. Some livestock is raised, including cattle, buffalo, sheep and goats, pigs, and chickens. The government is sponsoring a reafforestation program. Local timber production consists mostly of logs and firewood for domestic consumption.

Livestock

Sea fishing is more important than river fishing. Pearl fishing, once of importance, has been unsuccessful in recent years.

Mining and industry. Graphite is the principal mineral export. Most of the ilmenite produced is exported to Japan. The cement industry is based on the deposits of limestone in the northern part of the country. The production of salt is a government monopoly.

Manufacturing is still of minor importance. Several large-scale industries are engaged in the processing of agricultural produce. Cement, textile, leather, and ceramics industries have been developed. The paper industry uses domestic paddy straw, wastepaper, and imported pulp. Steel-rolling, plywood, and tire manufacturing industries are thriving. Industrial estates are being established to promote light industries. Foreign aid is being used to establish sugar-refining, petroleum-refining, chemical, and textile industries.

In 1978 the government established a free-trade zone on the outskirts of Colombo to attract new industry and foreign investment. Entrepreneurs are allowed to import materials into the zone duty free, provided the imports are used to manufacture products for export. The garment industry dominates the zone, but electronic components and appliances also are manufactured there.

Electricity is generated both by hydroelectric plants and by thermal plants, which are fueled by imported oil. Distribution is confined largely to the cities—Colombo, Nuwara Eliya, Diyatalawa, Norton Bridge, Bandarawela—and some villages.

Finance and trade. The Central Bank administers and regulates Sri Lanka's banking and monetary system and also issues the national currency. Commercial banks include some national banks and branches of foreign banks. Government-sponsored credit institutions include the State Mortgage and Investment Bank, the Agricultural and Industrial Credit Corporation, and the Development Finance Corporation. In 1975 all domestic banks were nationalized.

Sri Lanka's unfavourable balance of trade is exacerbated by its dependence upon agricultural products, which are subject to fluctuations in market value. Imports are largely petroleum products, rice and other foodstuffs, manufactured goods, raw materials, and machinery.

Management of the economy. *The public sector.* The state sponsors a wide variety of industrial corporations, among them a cement works, a chemical factory, an industrial estates corporation that provides ready-made factory units to small industry, a pulp and paper mill, a mineral sands processing plant, an oil refinery, and a steel-rolling mill. The government also sponsors numerous small manufacturing plants as a means of increasing employment. During the 1970s the government sought to improve agricultural productivity through major land reform. A limit was placed on the size of small, privately owned farms, and most of the major tea and rubber plantations were nationalized.

The private sector. Private industrial development is encouraged by such measures as tax exemptions, duty-free raw materials, and tax relief on investment. Foreign investment is also encouraged; it occurs mainly in the manufacture of textiles, electric appliances, transport equipment, metal, and glass. More than one-third of private industry is engaged in the production of food, beverages, and tobacco products.

Taxation. Taxes levied include an income tax on individuals and companies, a tax on wealth, a capital gains tax, and various customs and excise duties. Deficit budgeting has become a permanent feature, due to increased governmental expenditure on welfare services. The deficit is partially made up by market and administrative borrowing and foreign aid in the form of grants and loans.

Trade unions and employer associations. There are numerous trade unions, more than half of which are unions for public servants. Sri Lanka is represented in the International Labour Organisation. Industrial disputes are settled by labour tribunals. Employer associations include those for planters and manufacturers.

Tourism. A Ministry of State for Tourism, Broadcasting, and Information helps to promote tourism from abroad, in cooperation with the private sector and with the participation of international airlines and foreign governments. A number of hotels have been established in Colombo, seaside resorts developed, and additional transport facilities supplied.

Transportation. Sri Lanka has a good road system, although the roads are often uneven in quality. The surfaced roads are in the western lowland, the southern central highlands, and the Jaffna Peninsula in the north. There is also a ferry service from Mannar Island to Pāmban Island, India; it runs parallel to Adams Bridge.

The railways are owned and controlled by the government. They serve the flat, low country, the central hill areas, and the Kelani Valley in the southwest.

Colombo is the principal port. Other ports are Trincomalee on the east coast and Galle on the south coast. Galle handles the overflow of commercial shipping from Colombo. Trincomalee is one of the finest and largest natural harbours in the world. It was formerly a British naval base and now handles some of the island's export trade.

There is an international airport at Colombo. Air Ceylon maintains both international and domestic services.

ADMINISTRATIVE AND SOCIAL CONDITIONS

Government. Sri Lanka is an independent republic within the Commonwealth. The Ceylon Independence Order in Council, issued in 1947, was the basic constitutional document until it was superseded by the constitution of 1972. The former 30-member Senate was abolished in September 1971, and under the terms of the constitution of 1972 the House of Representatives was renamed the National State Assembly. This parliamentary system of government was supplanted by a presidential form of government in the constitution of 1978. The president replaced the prime minister as chief of state, with the power to appoint a prime minister and cabinet. The president is elected directly by the people for a six-year term, although an amendment ratified in 1982 allows the president to seek reelection after serving in office for at least four years. The members of the assembly, however, are elected indirectly by a system of modified proportional representation,

The presidential form of government

according to the number of votes cast for each political party. Assembly members also serve a six-year term. The constitution of 1978 transformed the office of president from a ceremonial position to a position of actual power, not accountable to the assembly.

Sri Lanka is divided into districts, each with an appointed governor and an elected development council. Local authorities consist of municipal councils, town councils, urban councils, and village councils.

Justice. Since independence, the justice system has undergone basic reform in an effort to streamline the colonial judicial and appellate hierarchy and to eliminate some of the judicial vestiges of colonialism. The Administration of Justice Law (1974) simplified the complex system of judicial appeal left from the colonial period; it eliminated the barrister and solicitor system of law practice and instituted in its place the single attorney-at-law practice; and it allowed women to serve as jurors. The system remains elaborate, however, comprising the Supreme Court, the Court of Appeal, the High Court, district courts, magistrate's courts, family courts, and primary courts. The common law of Sri Lanka consists of Roman-Dutch law, but aspects of English law have also been adopted, particularly in commercial matters. Customary law frequently operates in matters concerning the personal status of Kandyans (those living in the former kingdom of Kandy), Tamils, and Muslims. In civil and criminal matters, English procedure generally is followed; the penal code is based on that of India.

The armed forces. The armed services comprise the army, navy, and air force. The army and navy each have a regular force, a regular reserve, a volunteer force, and a volunteer reserve. Service is entirely voluntary; there is no conscription. The navy possesses a frigate, a number of small patrol boats, and smaller craft. The air force possesses a number of aircraft, including jets, light transports, helicopters, and trainers.

Education. Education is free, from kindergarten to university level. Almost all children between the ages of six and 11 attend school, and a high proportion continue until the age of 16 or 18. There are several technical and teacher training schools, colleges, and universities.

Health and welfare. Public health and medical care services are mostly planned and financed by the Ministry of Health, under which is the Department of Health, which is responsible for providing these services. Campaigns are conducted periodically against tuberculosis, cancer, venereal diseases, malaria, and leprosy. In addition to Western medical facilities, Sri Lanka in recent years has revived the practice of traditional medicine, which is conducted under government auspices.

The Ministry of Social Services

The Ministry of Social Services is responsible for public assistance, the relief of distress, the care and welfare of the aged and infirm, the administration of workman's compensation, and the rehabilitation of antisocial persons. Rural development activities include training in the performance of community services and self-help programs. There is a vigorous cooperative movement that is especially active in agriculture, industry, and fisheries.

Wages boards have been established to regulate labour conditions, including conditions of employment, wage rates, industrial safety, and related matters. Wage scales are reviewed periodically in relation to the cost of living index. Unemployment and rising living costs have, nevertheless, caused much labour and student unrest; the increase in the population has been the principal cause of these problems.

CULTURAL LIFE

Sri Lanka has a rich cultural heritage dating from the 3rd century BC. Its artistic tradition centres largely on Buddhist and Hindu religious art and the dance-drama. During the British administration the national arts suffered an eclipse, and since independence there has been a tendency to imitate Indian and Western art forms. The government, however, is aware of the importance of preserving traditional forms.

The national dance-drama

There are three main forms of the national dance-drama. The *kōlam* (a Tamil word for costume) play is a masked dance-drama that is performed annually. The devil dance, an expression of pre-Buddhist beliefs in spirits, is a masked dance performed to alleviate misfortune or illness. Most important is Kandyan dance, the sophisticated national dance. It is performed by elaborately costumed dancers and deals with mythological, historical, and naturalistic themes. It is taught at the National Academy of Dance in Kandy.

Since independence there has been a movement to adapt traditional dramatic forms to the modern stage. Translations of foreign plays are also performed.

Examples of national sculpture, painting, and architecture are seen in the remains of ancient works. These include colossal Buddha images, temples (especially around Kandy), and temple paintings. Other surviving art traditions include ivory carving, metalwork, lacquered woodwork, and basketry.

The Arts Council and the Government College of Fine Arts play an important role in the revival of folk arts and crafts. The national museums contain cultural and artistic collections. The Government Archives are in Colombo. Archaeological reserves, distributed throughout the island, include temples and cities.

The Sri Lanka Broadcasting Corporation provides national, commercial, and educational broadcasting services; it is responsible to the Ministry for Tourism, Broadcasting, and Information. Domestic programs are broadcast in Sinhala, Tamil, and English. There are also broadcasts to Southeast Asia and Europe. (K.Ku.)

History

Sri Lanka has a continuous record of settled and civilized life for more than two millennia. The content and direction of this civilization has been shaped by that of the Indian subcontinent. The island's two major ethnic groups, the Sinhalese and the Tamils, and its two dominant religious cultures, Buddhist and Hindu, made their way onto the island from India. The various expressions of literate culture parallel those of India, and overall the culture and civilization of Sri Lanka are of the Indic pattern.

Relationship with India

Yet it is also clear that in many respects the island's civilization has achieved an individuality and identity that distinguish it from its neighbour. Cultural traits brought from India have undergone independent growth and change. The Sinhalese language, which grew out of Indo-Aryan dialects, exists only in Sri Lanka and has a distinctive and distinguished literary tradition. Likewise, Buddhism, which has had a continuing existence on the island, has all but disappeared from India after a Hindu revival and persists only in the Himalayan kingdoms. Sinhalese Buddhist art shows similar individuality.

A common experience of European colonial rule and its modernizing influences brought Sri Lanka closer to India and, with the attainment of independence in the mid-20th century, both countries developed similar social institutions and ideologies.

The historic connection between Sri Lanka and India was the result mainly of geographic proximity. Geologically an extension of peninsular India, Sri Lanka's separation from the Indian mainland dates from comparatively recent times. Historically, the island has also been influenced by its location along the east–west sea route. Even before the discovery of the oceanic route from Europe to India in the 15th century, Sri Lanka was a meeting point for Eastern and Western trade. The island was known to Greek and Roman cartographers and sailors and later to Persian, Armenian, and Arab navigators. With the coming of the Europeans, the strategic importance of Sri Lanka increased and Western maritime powers fought to control its shores.

Early Sri Lanka

The island's first human settlers were probably tribes of the proto-Australoid ethnic group, akin to the pre-Dravidian hill tribes of southern India. Remnants of these people were absorbed by the Indo-Aryans who immigrated from India around the 5th century BC and developed into

the Sinhalese. The Tamils were probably later immigrants from Dravidian India, their migrations being spread out over a period dating from the early centuries AD to about 1200. The Tamil element was strengthened in the 19th century with the immigration of southern Indians to work on the plantations.

Sri Lanka possesses a continuous historical tradition preserved in written form by Buddhist chroniclers. The core of this tradition—the chronicle called the *Mahāvaṃsa* ("Great Chronicle") and its continuation the *Cūlavaṃsa* ("Little Chronicle")—constitutes a literary record of the establishment and growth of Sinhalese political power and of the Buddhist faith on the island. These works were written at various times by Buddhist monks and are based on other written records and on oral tradition. The *Mahāvaṃsa* accounts, supplemented by commentaries on them and by other historical works in Pāli and Sinhalese, provide a sequential narrative and a chronological framework for the history of the island up to the fall of the Kandyan kingdom in 1815. The excavation of ancient cities and monuments and the deciphering of inscriptions have supplemented and provided a corrective to the evidence from the written records.

PREHISTORIC RECORD

Studies of prehistoric Sri Lanka have not yet achieved a sequence of datable strata. The Stone Age appears to have begun with the Paleolithic, or Old Stone Age (about 1,750,000 years ago), when chert and quartz were abundant because of climatic changes. The earliest Stone Age implements found were made from those materials with a technique similar to that of the Old Stone Age cultures of India, which had identical environmental conditions. The Middle and Upper Paleolithic ages cannot be clearly distinguished because of the difficulty of correlating finds and putting them in a proper sequence. Stone implements of good workmanship, similar to those in India and Europe, have been discovered.

The transformation from food gathering to food producing and some form of settled life marks the transition to the Neolithic Age, or New Stone Age (probably more than 5,000 years ago). The grinding, rubbing, and polishing of stone tools; the use of the ax; and the use of wood, horn, bone, and other materials characterize this period.

The Mesolithic Age, or Middle Stone Age, which preceded the Neolithic Age, has produced rather more artifacts in the island; microliths have been found spread almost throughout, especially among the grasslands in the hill country and the sandy tracts of the coast.

COLONIZATION AND THE SPREAD OF BUDDHISM

According to the earliest Sinhalese tradition, recorded in the *Mahāvaṃsa,* the first Indian colonists on Sri Lanka were Prince Vijaya and his 700 followers, who landed on the west coast near Puttalam (5th century BC). They had been banished for misconduct from the kingdom of Sinhapura by Vijaya's father, King Sinhabāhu, who put them all in a ship and drove them away. According to tradition, when Vijaya's band landed on the island, it was inhabited by *yakṣas* (demons), whom they defeated and chased into the interior. Vijaya married a *yakṣa* princess and had two children by her. Later he drove her and the children away and sent to the Madurai court in India for a Paṇḍu princess and for wives for his 700 followers. Vijaya settled down to reign as king after a ceremonial enthronement and marriage and founded a dynasty. He had no heir to the throne, and toward the end of his reign he sent for his younger brother at Sinhapura. The brother, unwilling to leave his native land, sent his youngest son, Paṇḍuvāsudeva, to Sri Lanka. Paṇḍuvāsudeva landed with 32 followers at Gokaṇṇa (now Trincomalee) on the east coast. He was enthroned at Upatissagama and continued the Vijaya dynasty.

Indo-Aryan settlement. This traditional account contains a kernel of historical fact—the settlement of Sri Lanka by Indo-Aryan tribes from North India. Controversy exists as to the provenance of the early colonists; the legends contain evidence for both the northeastern and the northwestern parts of the Indo-Gangetic Plain. Vijaya's ancestors hailed from Bengal, but his father established himself subsequently in Gujarāt, from where the adventurers were put out to sea. Before arriving in Sri Lanka, their ship called at Supāra on the west coast of India. Their landing in Sri Lanka at Tambapaṇṇi, near Puttalam, would indicate their arrival from western India. Some early tribal names occurring in Sri Lanka also suggest connections with northwestern India and the Indus region.

Early settlements

While considerable evidence points to western India as the home of the first immigrants, it seems probable that a subsequent wave arrived from the east around Bengal and Orissa. One band of settlers landed on the east coast port of Gokaṇṇa, a natural port of disembarkation for vessels arriving from the Bay of Bengal. The traditional accounts of the arrival of Paṇḍuvāsudeva may portray a second wave of migration following the first mentioned in the Vijaya legend. Linguistic affinities between the early Sinhalese and the Prākrits of eastern India strengthen the hypothesis of a migration from this area.

The tradition speaks primarily of colonization by conquest, and tribes of conquerors led by a warrior nobility would have been an important factor in Aryan settlement. But this would have formed only one element of the Aryan migrations. Indo-Aryan traders probably reached Sri Lanka while sailing down the Indian coast; the natural products of Sri Lanka were lucrative items of trade and may have influenced some of these merchants to found settlements. Then there may have been settlements of Buddhist monks, as indicated in the traditional account of Paṇḍuvāsudeva.

The early settlers appear to have encountered a less civilized people, whom they pushed into the interior; some intermarriage probably took place. They also seem to have established contact with the Dravidians of southern India, who helped them in founding the first settlements. This feature is enshrined in the tradition that Vijaya secured a consort for himself and brides for his followers from the Paṇḍu kingdom of Madurai, if this may be presumed to be the Pāṇḍyan Tamil kingdom of southern India.

Indo-Aryan settlements grew in different parts of the island from about the 5th century BC. The settlers came in numerous clans or tribes; the most powerful were the Sinhalas, who eventually gave their name to the descendants of the various groups. The earliest settlers were those on the west-central coast, who pushed inland along the Malwatu Oya and founded a number of riverbank villages. Their seat of government was Upatissagama, where the first kings of the Vijaya dynasty reigned. The settlers of the east coast moved inland along the Mahaweli Ganga. Somewhat later there was perhaps an independent band of immigrants who settled in Ruhuṇa in the southeast, on the mouth of the Walawe Ganga, with Mahāgama as the chief seat of government.

Tradition attributes the founding of the kingdom of Anurādhapura to Paṇḍukābhaya, the third king of the Vijaya dynasty. With its growth as the strongest Sinhalese kingdom, the city of Anurādhapura and the nearby settlements flourished. Kings built up the city and developed it for urban life; they extended royal control over villages and outlying settlements. The establishment of strong government led to population growth and to extensive colonization of the north-central region. The political system was Brahminic, similar to that of Indo-Aryan kingdoms of the Gangetic Plain.

Conversion to Buddhism. According to Sinhalese tradition, Buddhism was first brought to Sri Lanka by a mission sent out under the patronage of the Mauryan emperor Aśoka (*c.* 269–232 BC) and led by his son, Mahinda. Mahinda and his colleagues were transported by air to the island, in the *Mahāvaṃsa* tradition, and landed on the Mihintalē hill, eight miles from the royal capital. There Mahinda chanced to meet the Sinhalese king Tissa and preached the king a sermon on Buddhism. The king was immediately converted and invited the missionaries to the city. The missionaries were settled in a royal pavilion in the city park of Mahāmegha from where they preached, first to members of the royal family and then to the people. Many embraced the new faith, and some took holy orders

and joined the Buddhist *saṅgha* (community of monks). The king donated the Mahāmegha park to the *saṅgha,* and the monastery of Mahāvihāra was established and became the prime centre of Buddhism in Sri Lanka. Mahinda sent for his sister Saṅghamitthā, who arrived with a branch of the Bo tree at Gayā, sacred to Buddhists as the tree under which Buddha attained enlightenment. The sapling was ceremonially planted in the city. Saṅghamitthā founded an order of nuns. A *stūpa* (shrine), the Thūpārāmacetiya, was built by the king for popular worship. Thus, various institutions of Buddhism were founded in the kingdom, and the faith became its established religion.

Though the conversion of King Tissa is of historic importance, the spread of Buddhism among the Sinhalese must have been more gradual, before and after the reign of Tissa. This was the work of many monks, both foreign and local, who went into every village converting people and founding Buddhist institutions among them. By the 2nd century BC the Sinhalese had accepted Buddhism totally, and this faith helped produce a unity and consciousness on which subsequent political and economic strength was founded.

THE CLASSICAL AGE (C. 200 BC–AD 1200)

As Buddhism spread, the Anurādhapura kingdom extended its political control over the rest of Sri Lanka. This age of political centralization began with Duttagāmanī Abhaya (reigned 161–137 BC).

The Anurādhapura period. The Vijaya dynasty of kings continued, with brief interruptions, until AD 65, when Vasabha founded the Lambakaṇṇa dynasty. The Lambakaṇṇas ruled for about four centuries; their most noteworthy king was Mahasena (reigned 276–303), who constructed many major irrigation systems and championed heterodox Buddhist sects.

A Pāṇḍyan invasion from southern India put an end to this dynasty and, briefly, to Sinhalese rule in 432. Dhātusena (reigned 459–477) defeated the Pāṇḍyas and reestablished Sinhalese rule with a line of Moriya kings. His son Kāśyapa I (reigned 477–495) moved the capital from Anurādhapura to the rock fortress of Sigiriya. After Kāśyapa's dethronement the capital was returned to Anurādhapura.

From the 7th century there was an increase in the involvement of South Indian powers in the island's politics and in the presence of Tamil mercenaries in and around the capital. Mānavamma, a Sinhalese royal fugitive, was installed on the throne in 684 with the support of the Pallavas of South India.

Mānavamma founded the second Lambakaṇṇa dynasty, which reigned in Anurādhapura for about 400 years. The dynasty produced a number of distinguished kings who consolidated and extended Sinhalese political power. During this period, Sinhalese involvement with southern India was even closer. Sinhalese kings were drawn into the dynastic battles between the Pāṇḍyas, Pallavas, and Cōḷas. Invasions from South India to Sri Lanka and retaliatory raids were a recurrent phenomenon. The 10th century saw a weakening of political and military power, and the Cōḷas, hostile because of the Sinhalese alliance with Pāṇḍya, attacked and occupied the kingdom in 993 and annexed Rajarata as a province of the Cōḷa empire. The conquest was completed in 1017 when the Cōḷas seized the southern province of Ruhuṇa.

The Polonnaruva period. The Cōḷas occupied Sri Lanka until 1070, when Vijayabāhu liberated the island and reestablished Sinhalese power. He shifted the capital to Polonnaruva (Polonnaruwa), a city that was easier to defend, that controlled the route to Ruhuṇa, and the easterly location of which provided more time to prepare for South Indian attacks. The capital remained there for 150 years. The most colorful king of the Polonnaruva period, and indeed of Sinhalese history, was Parākramabāhu I (reigned 1153–86), under whom the kingdom enjoyed its greatest prosperity. He followed a strong foreign policy, sending a punitive naval expedition to Burma and an army of invasion to the Pāṇḍyan kingdom but achieved no permanent success. After Parākramabāhu, the throne passed to the Kaliṅga dynasty, and the influence of South India increased. Nissaṅkamalla (reigned *c.* 1186–96), a brother of Parākramabāhu's Kaliṅga queen, was the last effective ruler of this period. The last Polonnaruva king was Māgha (reigned 1215–36), an adventurer from South India who seized power and ruled with severity and disrespect for traditional authority.

Government. Kingship was the unifying political institution in the classical period, a symbol of the aims and achievements of the Sinhalese people. The kingship was essentially Brahminic, with strong Buddhist influences. The king's authority was supreme and was elevated by the adoption of Brahminic symbolism. There was a trend toward sanctifying the person of the monarch, with the adoption of extravagant titles and mythical genealogies, and a tendency to style kings as *ḍevas* (gods) and *bodhisattvas* (Buddhas-to-be). Although the absence of a definite law of succession was a weakness leading to many disputes, it had the advantage of ensuring the succession of the ablest candidate; it also gave rise to a strong element of personal despotism, and many kings put the stamp of their personalities on their periods of rule.

Authority of the kings

All of the kings were practicing Buddhists and patrons of Buddhist institutions; the support and blessing of the clergy was essential in a peaceful and continuous reign. This connection between kingship and Buddhism, which continued throughout the period, enabled Buddhism to flourish. Kings built, maintained, and endowed many shrines and monasteries, and intervened to establish order and prevent schism within the Buddhist church. Nobles and commoners too were lavish in their support, and thus Buddhist institutions prospered. Many beautiful temples were built with finely carved sculpture; monasteries throve as centres of learning in the Pāli and Sinhalese languages and in Buddhist philosophy.

The king was supported by an inner administrative hierarchy consisting of members of his family and of influential nobles. A council of state of the highest officers served in a purely advisory capacity. The administration was conducted by various departments whose ministers dealt personally with the king. The *yuvarāja,* the king's chosen heir to the throne, was given responsible office. The army was the major prop of royal absolutism, and the *senāpati,* or commander in chief, was the king's closest counsellor and confidant.

The country was divided into three divisions. Rajarata was the most important, administered under the king's personal control and embracing the most populated, prosperous parts of the country. Ruhuṇa, to the south and southeast, was next in importance and was always ruled by a high officer, often the *yuvarāja;* owing to its remoteness, it sheltered rebels and fugitives and was used by kings under attack to take refuge and organize resistance. Dakkhiṇadesa, to the west, was organized as a province in the mid-Anurādhapura period and was also ruled by a high-ranking viceroy. These divisions were subdivided into cantons (*maṇḍala*) and districts (*rattha*), and they had a descending hierarchy of local officials down to the village headman.

Society was divided into castes, each performing a certain occupation, but the divisions were not as deep as in India. The *govi,* or cultivators, made up the highest caste. Many other castes also engaged in farming. Administrative officials were drawn from the *govi* caste, which was stratified into chiefs, titled men, and peasants. Chiefs were important supporters of royal absolutism and helped administer the government. Nonagricultural people, the *hina,* were considered of lower rank and divided into occupational groups. These caste groups were endogamous; each lived in its own section, along particular streets. Castes were stratified in terms of status, with the lowest on the scale—the *caṇḍālas*—performing the meanest occupation. The nobility owned slaves who worked for them in their fields and also in their homes. Many of the professional castes were self-regulating to a great degree.

Social castes

Irrigation. The Sinhalese civilization was hydraulic, based on the storage and use of water for the regular cultivation of wet fields. The early Indo-Aryan settlers were cultivators of rice, and they settled along river valleys and other suitable lands. They began with simple schemes

for damming rivers and storing water below them. Small village works, which stored water in reservoirs by tapping seasonal streams, spread throughout the country and were characteristic of every village; these were probably undertaken communally by the landowners of the village. With the increase in royal power, the attraction of greater revenue through greater production made kings play an active role in the construction of irrigation schemes. Beginning in the reign of King Vasabha (reigned AD *c.* 65–110), large perennial rivers were blocked with massive earthen dams to create colossal reservoirs. From these, water was led through canals to distant fields and through underground channels into the capital city. From this time the technical knowledge of irrigation became more sophisticated.

Further technical progress was achieved in the reign of King Mahāsena; a number of storage tanks and canals are attributed to him, the most outstanding of which is the Minnēriya tank and its feeder canals. Thenceforth the construction and maintenance of large-scale irrigation works became a regular preoccupation of kings. Reservoirs and canals studded the northern and north-central plains, tapping every source of water. Among the most noteworthy was the magnificent Parākrama Samudra in Polonnaruva, the crowning glory of Parākramabāhu's reign, with a storage area of over 5,000 acres for the irrigation of 18,000 acres.

The large works needed a great deal of coordination and central control; they required the mobilization of labour and technical skill at the construction stage and a bureaucratic machinery to operate them and keep them in repair. Regulations to coordinate cultivation of irrigated plots, to control the flow of water, and to collect water dues from the operators had to be administered effectively. These were major functions of the central administration; and in turn they increased the power of the king, to whom accrued the benefits of the resulting increased productivity.

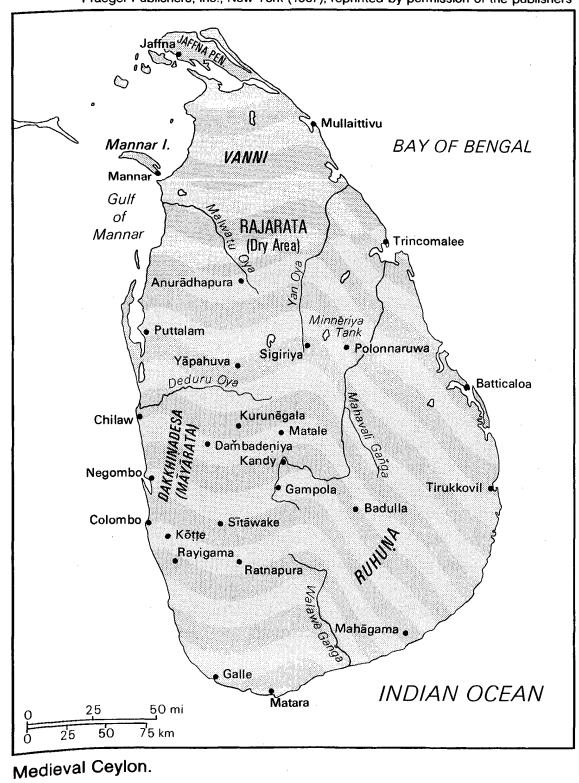
A grain tax, the water dues, and trade in surplus grain were major sources of the king's revenue. They sustained strong political and military power for more than a millennium and enabled the dispatch of expeditions abroad. They also made possible widespread religious building, which culminated in the great age of Parākramabāhu I. His reign also witnessed the high point of Sinhalese creativity in the plastic arts and the greatest strides in irrigation.

DRIFT TO THE SOUTHWEST (1200–1505)

Rise of non-Sinhalese factions

Political changes. After the death of Nissaṅkamalla, the Polonnaruva kingdom was weakened by a succession of ineffective rulers. Non-Sinhalese factions such as the Kaliṅgas and Pāṇḍyas gained power in Sri Lanka as a result of dynastic marriages with South Indian royalty; conflicts between these factions was a common feature. South Indian notables occupied positions of influence under Kaliṅga kings, and their power was buttressed by mercenaries of various races. Māgha's rule was a veritable reign of terror, disregarding traditional authority and established religion. Polonnaruva fell into the hands of non-Sinhalese elements, each vying with the other for power and office.

Central control from Polonnaruva was weakened. Kings of foreign extraction ruling there were unable to exercise political control over outlying provinces. Members of the traditional ruling class gravitated to centres of Sinhalese power located away from the reach of Polonnaruva in strategic terrain relatively inaccessible and defensible from attack; Dakkhiṇadesa, or Māyārata as it was now called, was suitable for this. The first place chosen to reestablish the Sinhalese kingdom was Dambadeṇiya, about 70 miles southwest of Polonnaruva; Vijayabāhu III (reigned 1232–36) and his three successors ruled from there. They made occasional successful raids into Rajarata to attack the Kaliṅga and Tamil rulers but did not attempt to reoccupy Polonnaruva. Under Parākramabāhu II (reigned 1236–70) the Daṁbadeṇiya kingdom achieved great power; it was able to expel the Kaliṅgas from the island with Pāṇḍyan help and to repel an invasion from the Malay Peninsula.



Bhuvanaika Bāhu I (reigned 1272–84) moved the capital northward to Yāpahuva, an isolated rock, which he strengthened with ramparts and trenches. His successors moved the capital southward again to Kurunēgala, and *c.* 1344 to Gampola toward the central highlands. At about the same time, the Alagakōnāra, a powerful Sinhalese family, attained a strong position at Rayigama, near the west coast; the Muslim traveller Ibn Baṭṭūṭah, who visited Sri Lanka in 1344, referred to one of the Alagakōnāras as a sultan named Alkonar. In 1412 the capital was taken by Parākramabāhu VI (reigned 1412–67) to Kōṭṭe, a few miles from present-day Colombo; for a brief period under this king, the Kōṭṭe kingdom expanded and acquired sovereignty over the island.

Generally, the effective control of the Sinhalese kings of the period 1200–1505 did not extend far beyond their capital cities, though they often made extravagant claims. Taking advantage of the collapse of the Polonnaruva kingdom after Māgha's fall and of the drift of Sinhalese political authority to the southwest, a South Indian dynasty called the Ārya Chakaravartis seized power in the north. By the beginning of the 14th century it had founded a Tamil kingdom, its capital at Nallūr in the Jaffna Peninsula. The kingdom of Jaffnapatnam soon expanded southward, initiating a tradition of conflict with the Sinhalese, though Rajarata—by then a largely depopulated country—existed as a buffer between them. Ibn Baṭṭūṭah left a good description of the Jaffna kingdom and its trade.

A politically divided and weakened island was an enticement to foreign invasions in the 13th, 14th, and 15th centuries. The second Pāṇḍyan Empire was constantly interfering in the affairs of Sri Lanka; its forces often supported rival claimants to power and took back considerable sums in payment and booty including, on one occasion, the Tooth Relic—sacred symbol of Sinhalese sovereignty. The Malay ruler Chandrabhānu invaded the island in 1247 and 1258, for reasons not altogether clear. Forces of the Vijayanagar Empire in South India invaded Sri Lanka on a few occasions in the 15th century, and for a brief period the Jaffna kingdom became its tributary. Cheng Ho, the great admiral of the third Ming Emperor of China, led a series of expeditions into the Indian Ocean. In his first expedition (1405–07) Cheng landed in Sri Lanka but withdrew hastily; he returned in 1411, defeated the ruler Vīra Alakeśvara, and took him and his minister captive to China.

Economic changes. The drift of Sinhalese political power to the southwest had drastic social and economic

Consequences of drift to the southwest

consequences. Population gradually shifted in the direction to which the capital was shifting; this led to the neglect of the interconnected systems of water storage. The once-flourishing Rajarata became a devastated ruin of depopulated villages, overgrown jungle, and dried-up tank beds, and the centres of Sinhalese population soon became the monsoon-wasted lands of the south, southwest, and the central highlands. Consequent changes in agricultural techniques, land use, ownership patterns, and ways of life followed swiftly.

Collapse of the dry-zone civilization. A combination of factors had brought about the collapse of Sri Lanka's dry-zone hydraulic civilization. The pursuit of an active foreign policy under Parākramabāhu I and the many wars it involved was a serious burden on the treasury. The Polonnaruva kings had to maintain a strong standing army and navy. The construction and maintenance of the magnificent Buddhist monuments of the Polonnaruva period must have strained the country's economy. The Polonnaruva state was thus carrying a burden of excessive expenditure that only continuous strong government and high productivity could sustain. The later Polonnaruva kings had neither the ability nor the favourable circumstances to maintain such a high level of revenue and expenditure.

The country's productivity depended on the elaborate system of irrigation, the operation of which was the work of a bureaucracy drawn from the landed gentry, both at the centre and at the village level. When the Kaliṅga dynasty came to power and non-Sinhalese factions rose to high office, the traditional Sinhalese aristocracy was eased out of authority. Mercenary military officers were spread out in the country to control law and order and to assume administrative functions. The Sinhalese noble families withdrew from Rajarata to the courts of Sinhalese leaders who had set themselves up in other parts of the country. Thus the traditional officialdom that had maintained the agricultural and irrigation system disappeared, and traditional methods broke down. The new military administrators had neither the capacity nor the interest to attend to this task. Many of the larger reservoirs breached, and smaller tanks that were fed by excess waters from them also lost their supply. (Some of the destruction was deliberate, caused by rival armies to flood a part of the country.) The amount of water stored for cultivation was reduced, which in turn reduced the area of cultivable land. Jungle spread fast into land left uncultivated. Many tanks dwindled into muddy swamps, breeding mosquitoes. Agriculture became dependent on the uncertain rains, and the people waged a losing battle against the advancing forest. The country could not maintain a population of its previous density. People started following their leaders toward areas of greater rainfall.

Changes in farming techniques

New cultivation techniques. Population centres formed in the hospitable areas of the south, southwest, and the central highlands. The marked difference in climate and topography required new techniques of cultivation. Though rice cultivation continued as an important activity, other grains suitable for highland cultivation were adopted to supplement rice. Paddies had to be terraced and the flow of water had to be regulated to suit the undulating land. Irrigation techniques had to be different and could not be attempted on the scale of the dry-zone schemes. Farming was generally of a subsistence character, and in the absence of sufficient rice, garden or highland cultivation became an important peasant activity, helped by excessive rains. Because of the abundance of land, shifting cultivation was practiced along the slopes of the hills. Coconut, easily grown in the wetlands of the coast and the highlands, became an important food. Cattle breeding, a major occupation in the dry zone, became less prevalent, and milk products were not an important constituent in the people's diet. The nutritive value of the popular diet declined.

The growth of trade

Foreign trade. With the decline in agricultural productivity, trade became an important source of state revenue. Spices were the most important exports: cinnamon, indigenous to the southwestern forests, became an export article in the 14th century; pepper and other spices also increased in export value. These articles were royal monopolies; kings entered into contracts with foreign merchants, fixed prices, and derived the revenue. The people of the land were not involved in any aspect of this trade, nor did they benefit directly from it. Colombo and Galle became prominent ports of external trade; smaller ports in the southwest became centres of coastal and Indian trade. Almost all of the traders were foreigners who settled in colonies in and around these ports.

The major international traders were the Arabs. (Arab interest in the luxury products of Sri Lanka dates from about the 10th century. Arab shipping and trade in the Indian Ocean produced Arab and Indo-Arab colonies in western India and coastal Sri Lanka.) Now Arabs became interested in cinnamon and spices, which began to fetch good prices in Western markets. In 1283 the Sinhalese king Bhuvanaika Bāhu I sent an embassy to the Mamlūk sultan of Egypt to seek a commercial agreement. Arab merchants had friendly contact with royal port officials of Colombo and Galle and helped collect customs and port dues. There is no evidence of seaborne trade by the Sinhalese themselves in this period, and the Sinhalese merchant groups of an earlier era appear to have declined.

Land control. Some significant changes took place in land relations and land control. The grain tax, which had been the pivot of the land revenue system—payable directly to the state in cash or kind—was on its way out during this period. This is partly explained by a breakdown in the administration: kings could not now maintain a specialized machinery for the assessment and collection of the grain tax and other miscellaneous land taxes. These were replaced by a system of service tenure, under which a large proportion of the land was held on the basis of service to the state. This service could be used in a multitude of ways beneficial to the state: to cultivate royal land, to be assigned to various officials as payment, or for the upkeep of public utilities. Tithe-paying lands and service lands were gradually merged. Each plot had a fixed obligatory service attached to it, and anyone who enjoyed that land had to perform that service. These services were extensively assigned to village and regional notables in order to attract their support. The commutation of tax for service also meant a decrease in the circulation of money; copper coins replaced those of gold and silver. This trend was further attentuated by the subsistence character of farming, which curtailed internal trade.

Cities. Capitals were now selected for their military defensibility, and cities were constructed with this in mind—relatively small, located in difficult terrain, somewhat isolated from populated areas. Communications from one place to another were difficult, and excessive mobility was discouraged for military reasons. Cities were not centres of economic life as in the past; they no longer attracted large groups of artisans, merchants, servants, and others dependent on the ruling groups. They were primarily of military importance, with a small cluster of buildings around the palace.

Buddhism and society. The Buddhist church had been a beneficiary of the hydraulic system of the dry zone. Lands, taxes, and water dues were assigned to temples, which also invested in land, had their own tanks excavated, and derived benefits therefrom. Now these sources of revenue had declined. Kings continued their patronage of Buddhism, but their wealth and power had diminished. Nobles and commoners were not rich enough to make substantial benefactions. The great monasteries of Anurādhapura and Polonnaruva were disbanded, and new institutions arose in and around the capitals of Daṁbadeṇiya, Kurunegala, Gampola, Rayigama, and Kotte, but they were not of the size or stature of their predecessors in the dry zone.

Changes in Buddhist institutions

The absence of strong political authority also affected the unity and coherence of the Buddhist church. In this period there was a greater incidence of indiscipline and schism than before. Kings were called upon frequently to purge the *saṅgha* of undesirable elements, and its purification had to be undertaken now and then. Close contacts were maintained, however, with Burma and Siam, and Buddhist missions were exchanged with these countries.

The influence of Hinduism on Buddhist institutions,

theology, and ways of life was more marked during this period. The ruling classes mixed extensively with Tamil royal and noble families, and there was an influx of Brahmins from South India to all parts of the country. *Deva* worship became a marked feature of popular Buddhism. Vedic and post-Vedic gods now assumed importance and were worshipped by kings and commoners in elaborate festivals.

One of the consequences of the drift of the Sinhalese kingdoms to the southwest and the establishment of the Tamil kingdom to the north was the division of the island into two ethnolinguistic areas. Before this division occurred, Tamil settlements were interspersed among the Sinhalese throughout the island. Then the northern and eastern areas became predominantly Tamil; their numbers were strengthened by fresh migrations from South India after the collapse of the Pāṇḍyan kingdom in the 14th century. Jaffna, as the capital of the Tamil kingdom, became the seat of Tamil Hindu culture, with a social organization somewhat akin to that of Tamil Nad. The landowning cultivators, or *vellalas,* were the pivot of the social structure and the holders of political and economic power. A number of lesser castes stood in varying degrees of service relationship to the *vellalas.* Hindu institutions were supported by the kings and the people and were strengthened by the influx of Brahmins. Brahminic temples sprang up in many parts of Jaffna, and rituals and public worship were regularly carried on. The Tamil language struck firm roots in the island and became one of its indigenous languages. Tamil literary culture was fostered by the support of the Jaffna kings and was enriched by the constant contact with South India, yet it developed an individuality of idiom and speech and acquired some linguistic characteristics that distinguished it from its South Indian parent.

THE PORTUGUESE IN SRI LANKA (1505–1658)

By 1500 the Portuguese had begun their penetration of the Indian Ocean. In 1505 a Portuguese fleet commanded by Lourenço de Almeida was blown into Colombo by adverse winds. Almeida received a friendly audience from the king of Kōṭṭe, Vīra Parākrama Bāhu, and was favourably impressed with the commercial and strategic value of the island. The Portuguese soon returned and established a regular and formal contact with Kōṭṭe. In 1518 they were permitted to build a fort at Colombo and were given trading concessions.

In 1521 three sons of Vijayabāhu, the reigning king of Kōṭṭe, put their father to death and partitioned the kingdom among themselves. The oldest of the brothers, Bhuvanaika Bāhu, ruled at Kōṭṭe, and the two others set up independent kingdoms at Sītāwake and Rayigama. Māyādunnē, the king of Sītāwake, was an ambitious and able ruler who sought to expand his frontiers at the expense of his brother at Kōṭṭe. Bhuvanaika Bāhu could not resist the temptation of seeking Portuguese assistance. The Portuguese were eager to help the king, and the more he was pressed by Māyādunnē, the greater was his reliance on them. Bhuvanaika Bāhu defended his kingdom against Māyādunnē, who in turn allied himself with the Zamorin of Calicut (in India), an inveterate enemy of the Europeans.

Bhuvanaika Bāhu was succeeded by his grandson Prince Dharmapāla, who was even more dependent on Portuguese support. An agreement (1543) between Bhuvanaika Bāhu and the King of Portugal had guaranteed the protection of the prince on the throne and the defense of the kingdom; in return the Portuguese were to be confirmed in all their privileges and to receive a tribute of cinnamon. The prince was educated by Franciscans; in 1557, when his conversion to Christianity was announced, he became nothing more than a Portuguese protégé. This act undermined the Kōṭṭe dynasty in the eyes of the people. Māyādunnē's wars of aggression were now transformed into a struggle against Portuguese influence and interests in the island, and he annexed a large part of the Kōṭṭe kingdom. After his death, his son Rājasinha continued these wars successfully on land, though like his father he had no way of combating Portuguese seapower.

At the death of Rājasinha in 1593, the Sītāwake kingdom disintegrated for want of a strong successor. The Portuguese captured much of the lands of the Kōṭṭe patrimony and emerged as a strong power in the island. In 1580 Dharmapāla had been persuaded to deed his kingdom to the Portuguese, and, when he died in 1597, they took formal possession of it. Meanwhile a Portuguese expedition to Jaffna in 1560 had no lasting success. A second invasion of 1591, undertaken at the instigation of Christian missionaries, succeeded in installing a Portuguese protégé. Continued unrest and succession disputes made the Portuguese undertake a third expedition, and the kingdom of Jaffna was annexed in 1619.

The Portuguese were now in possession of all Sri Lanka but the central highlands and eastern coast, where an able Sinhalese nobleman, Vimala Dharma Sūrya, had established himself and consolidated his authority. The temptation for the Portuguese to establish hegemony over the entire island was strong, and some attempts were made. These led to protracted warfare and to popular hostility against the foreigners. The Portuguese expanded to the lower reaches of the central highlands and annexed the east coast ports of Trincomalee and Batticaloa.

The Portuguese possessions in Sri Lanka were a part of their *Estado da India;* a captain-general, with his residence at Malwāne, near Colombo, headed the administration and was subordinate to the viceroy at Goa. The most important civil officer was the *vidor da fazenda,* in charge of all revenue matters. An *ouvidor,* or judge, was in charge of all judicial affairs. The administrative structure of the Kōṭṭe kingdom was retained. Sri Lanka was divided into four *dissavanies,* or provinces, each headed by a *dissava.* Other territorial subdivisions were retained. Portuguese held the highest offices, though local officials came from the Sinhalese nobility loyal to the Portuguese.

Portuguese administration

The Sinhalese system of service tenure was retained and used extensively to secure the essential produce of the land such as cinnamon and elephants. The caste system was retained intact and all obligations that had been due to the sovereign now accrued to the Portuguese state. The payment in land to officials was retained and extended to Portuguese officials as well.

The Portuguese lacked a proper understanding of the traditional Sinhalese social and economic structure, and excessive demands put upon it led to hardships and popular hostility. Cinnamon and elephants became articles of monopoly; they provided good profits, as did the trade in pepper and areca nuts (betel nuts). Portuguese officials compiled a *tombo,* or land register, to provide a detailed statement of landholding, crops grown, tax obligations, and nature of ownership.

The period of Portuguese rule was marked by intense Roman Catholic missionary activity. Franciscans established centres in the country from 1543 onward. Jesuits were active in the north. Toward the end of the century Dominicans and Augustinians arrived. With the conversion of Dharmapāla, many members of the Sinhalese nobility followed suit. Dharmapāla endowed missionary orders lavishly, often from the properties of Buddhist and Hindu temples. After the Portuguese secured control of Sri Lanka, they used their extensive powers of patronage and preference in appointments to promote Christianity. Members of the landed aristocracy embraced Christianity and took Portuguese surnames at Baptism. Many coastal communities underwent mass conversion, particularly Jaffna, Mannar, and the fishing communities north of Colombo. Catholic churches with schools attached to them served Catholic communities all over the country. The Portuguese language spread extensively, the upper classes soon gaining proficiency in it.

THE KANDYAN KINGDOM

When Rājasinha I occupied Kandy about 1580, the ruler of that kingdom took refuge with the Portuguese. In 1591 the Portuguese launched an expedition to Kandy to enthrone Dom Philip, an heir of the dispossessed ruler. They were accompanied by an ambitious and distinguished Sinhalese military nobleman, Konnappu Bandāra. Dom Philip was installed as king but died under suspicious circumstances,

and Konnappu Bandāra enthroned himself, proclaiming independence from the Portuguese and taking the regnal name of Vimala Dharma Sūrya. The demise of Sītāwake after Rājasinha's death left Kandy the only independent Sinhalese kingdom.

The Portuguese launched another expedition to Kandy in 1594 under Gen. Pedro Lopes de Sousa, planning to enthrone Dona Catherina, a baptized Sinhalese noblewoman. Popular hostility soon built up toward the continued presence of Portuguese troops. Vimala Dharma Sūrya utilized this to his advantage and, making use of guerrilla warfare tactics, routed the Portuguese army in 1594. He captured Dona Catherina, made her his queen, and legitimized and consolidated his rule. He expanded into the old Sītāwaka kingdom and emerged as leader of resistance to the Portuguese. Subsequently, the Portuguese made a few unsuccessful attempts to subjugate Kandy.

Vimala Dharma realized that without sea power he could not drive the Portuguese out of Sri Lanka. He saw the arrival of the Dutch as an excellent opportunity to get naval support against his adversaries. The first Dutch envoy, Joris van Spilbergen, met the King in July 1602 and made lavish promises of military assistance. A few months later another Dutch official, Sebald de Weert, arrived with a concrete offer of help and, in view of favourable terms offered by the king, decided to launch a joint attack on the Portuguese. But a misunderstanding between the King and de Weert caused an altercation between the Kandyans and the Dutch, and de Weert and his men were killed.

Arrival of the Dutch

King Senarat succeeded to the Kandyan throne in 1604 and continued to solicit Dutch support. In 1612 a Dutch envoy, Marcelis Boschouwer, concluded a treaty with Senarat. The King granted the Dutch extensive commercial concessions and a harbour for settlement on the east coast in return for a promise of armed assistance against Portuguese attack. The Dutch were unable to offer adequate assistance, and Senarat turned to the Danes. But by the time a Danish expedition arrived in May 1620, Senarat had concluded peace with the Portuguese. The truce was short-lived, and in 1630 the Kandyans, taking the offensive, invaded Portuguese territory and laid siege to Colombo and Galle. Again the absence of sea power proved a handicap, and another peace was concluded in 1634.

In 1635 Senarat was succeeded by his son Rājasinha II. The Dutch were now firmly established in Batavia in Java and were developing their trade in southern Asia. The King sent emissaries to meet the admiral of the Dutch fleet, Adam Westerwolt, who was then blockading Goa. The fleet came to Sri Lanka and captured Batticaloa from the Portuguese. Westerwolt and Rājasinha concluded a treaty on May 23, 1638, giving the Dutch a monopoly on most of Sri Lanka's cinnamon and a repayment in merchandise for expenses incurred in assisting the King. In May 1639 the Dutch fleet captured Trincomalee and in February 1640 the Dutch and Kandyans combined to take Negombo. But differences arose between the allies over the occupation of captured forts. The Dutch refused to give Trincomalee and Batticaloa to the King until their expenses were paid in full, and Rājasinha realized that the Dutch really wanted to replace the Portuguese as the rulers of the coast.

He nevertheless continued to work with them to expel the Portuguese. In March 1640 Galle was taken, but the progress of the allies was temporarily halted by a truce declared in Europe between the United Provinces and Spain, which at that time ruled Portugal and its overseas possessions. In 1645, the boundaries between Portuguese and Dutch territory in Sri Lanka were demarcated. Jan Thijssen was appointed the first Dutch governor.

The Dutch peace with the Portuguese and occupation of captured territory incensed the King and strained relations between him and the Dutch. In May 1645 war broke out between them. Though Rājasinha could not conquer the occupied lands, he made them worthless to the Dutch, who realized the advantage of coming to terms with the King. In 1649 a revised treaty was signed. The Dutch agreed to hand over some of the lands but again delayed because of the immense debt the King was held to owe them.

The truce with the Portuguese expired in 1652, leaving the Dutch free to resume the war. Kandyans launched attacks on Portuguese positions in the interior provinces of Seven Korles, Four Korles, and Sabaragamuwa, pushing them back to their coastal strongholds, despite fierce Portuguese resistance. Rājasinha was anxious to attack Colombo, but he was put off by the Dutch. He tried to secure guarantees from them for the return of this city after its conquest, and the Dutch made lavish promises. In August 1655 the Dutch were strengthened by the arrival of a large fleet under Gerard Hulft, and they laid siege to Colombo by sea and by land. In May 1656 the Portuguese surrendered the city to the Dutch, who shut the Kandyans out of its gates. Requests for the cession of Colombo met with evasive replies. Highly incensed, Rājasinha destroyed the lands around Colombo, removed its inhabitants, and withdrew to his mountain kingdom.

After a brief respite the Dutch resumed the expulsion of the Portuguese from Sri Lanka. Adm. Ryckloff van Goens arrived with a fleet to continue the attack on Portuguese strongholds in northern Sri Lanka. The Dutch took Mannar in February 1658 and Jaffna in June. They had replaced the Portuguese as masters of coastal Sri Lanka.

DUTCH RULE IN SRI LANKA (1658–1796)

Though the Dutch East India Company first controlled only the coastal lands, the Dutch gradually pushed inland, occupying considerable territory in southern, southwestern, and western Sri Lanka. In 1665 they expanded to the east coast, and thus controlled most of the cinnamon-growing lands and the points of exit and entry in the island.

Government. The governor, residing in Colombo, was the chief executive; he was assisted by a council of the highest officials. The country was divided into three administrative divisions: Colombo, Galle, and Jaffna. Colombo was ruled by the governor, Galle and Jaffna by commanders. The three divisions were subdivided into dissavanies and districts (*korles*) in the traditional manner. Each dissavani was ruled by a dissava, invariably a Dutch officer; subordinate offices were held by Sinhalese or Tamils loyal to the Dutch.

Dutch administration

Economy. Cinnamon, the most lucrative product derived by the Dutch from Sri Lanka, was collected at little or no cost and fetched high prices in European and Asian markets. The peeling of cinnamon was the obligatory duty of the *chalia* caste, which was sent into the woods by Dutch and native officials to obtain the required quantity of the spice. Similarly, another caste was used to supply elephants, also a valuable commodity of trade.

The Dutch continued the Portuguese policy of respecting the traditional land structure and service relationship, but they used it more methodically to further their interests. Officials were remunerated in land, and obligatory services were used for the state. Taxes in kind were collected for the state and used in trade. The Dutch encouraged agricultural production; they tried to increase rice and cash crop cultivation by land grants and tax concessions as well as through state-owned farms cultivated by slave and serf labour.

The Dutch tried to promote trade with neighbouring countries, but under a strictly controlled system. They sought monopolies in the export of cinnamon, elephants, pearls, areca nuts, and other products. This tended to stifle commerce, and thus trade with India declined, leading to a shortage of such essential commodities as rice and textiles. In the early 18th century some relaxation occurred, and private traders from India were admitted into the Sinhalese trade. But control of trade commodities and prices was sought through a system of passes and inspection, and major articles such as cinnamon, elephants, and pearls remained a strict monopoly. Smuggling of contraband goods was encouraged by local traders, Kandyan authorities, and even by Dutch officials. The directors in Holland sent strict instructions to maintain the restrictions, despite the pleas of officials in Sri Lanka for a freer trade, and much effort was spent to curb smuggling.

Law. The Dutch judicial system was well organized. There were three major courts of justice—in Colombo, Galle, and Jaffna; appeals from these courts were heard

by the Colombo court. A circuit court, the *Land Raad,* was presided over by the dissava and sat in various districts. Native chiefs were invited to sit on cases involving local custom. The customary law of the land was administered in the courts, unless it clashed violently with Dutch jurisprudence.

Some attempt was made to codify customary law. The *Thesavalamai,* or laws and customs of the Tamils of Jaffna, was codified in 1707. A code of Muslim law was applied with the approval of Muslim headmen. Because of the difficulty in codifying Sinhalese law and custom, Roman-Dutch law was increasingly applied to the Sinhalese of the cities and the sea coast, especially to those who professed Christianity.

Religion. The Netherlands state was ardently Calvinist, and in the early years of Dutch rule an enthusiastic effort was made to spread the reformed faith in Sri Lanka. Catholicism was declared illegal and its priests were banned from the country; Catholic churches were given to the reformed faith, with Calvinist pastors appointed to them. Many Sinhalese and Tamil Catholics nominally embraced Protestantism. But the knowledge of the religion was rudimentary because there were not enough ministers, and very few of them could speak either indigenous language fluently. A body of Christian literature in Sinhalese and Tamil was published (after the establishment of a printing press in 1737). Churches had schools attached to them for elementary education, and there were two seminaries for higher education. Protestantism, however, did not have any substantial impact on the people.

THE BRITISH IN CEYLON (1796–1900)

The British East India Company's conquest of Sri Lanka, which it called Ceylon, occurred during the wars of the French Revolution. When the Netherlands came under French control, the British began to move into Sri Lanka from India. The Dutch, after a half-hearted resistance, surrendered the island in 1796. The British had thought the conquest temporary and administered the island from Madras, but the war with France revealed Sri Lanka's strategic value and persuaded the British to make their hold on the island permanent. In 1802 Ceylon was made a Crown Colony and, by the Treaty of Amiens with France, British possession of maritime Ceylon was confirmed.

Control of Kandy. Upon their arrival in 1796, the British established contact with the king of Kandy and contracted to replace the Dutch as protectors of the kingdom. As they began to organize the administration, the British realized that the continuing independence of Kandy posed problems: the frontier with Kandy had to be guarded at much expense, trade with the highlands was hampered by customs posts and political insecurity, land communications between West and East would be quicker if roads could be built through the centre. The advantages of political unification were obvious, but the Kandyans remained deeply suspicious of all foreigners.

Dissensions within the kingdom gave the British an opportunity to interfere in Kandyan affairs. They failed to reduce the kingdom in 1803 but succeeded in 1815 with the help of Kandyan chiefs whose relations with the king had deteriorated when the kingdom had reached an advanced stage of disintegration. They guaranteed Kandyans their privileges and rights and the preservation of customary laws, institutions, and religion. Though Kandy was administered separately, the trend toward reducing the status of its chiefs and of the Buddhist faith was unmistakable; this led to a popular rebellion against British control in 1818. After its suppression the Kandyan provinces were integrated with the rest of the country.

British reforms

Though reluctant to upset traditional Sinhalese institutions, the British quickly set a reform process in motion. They abolished slavery, relieved native officials of judicial authority, paid salaries in cash, and relaxed the system of compulsory service tenure. Agriculture was encouraged, and production of cinnamon, pepper, sugarcane, cotton, and coffee flourished. Internal communications were extended. Restrictions on European ownership of land were lifted. There was intensive Christian missionary enterprise in education.

The early changes under British rule were systematized by a series of reforms enacted in 1833, which laid the foundation for the subsequent political and economic structure of Ceylon. The British adopted a unitary administrative and judicial system for the whole island. They reduced the autocratic powers of the governor and set up Executive and Legislative councils to share in the task of government; unofficial members (not officials of the government) were gradually appointed to the Legislative Council. English became the language of government and the medium of instruction in schools.

Economic changes. The British eliminated restrictions on the economy. They abolished all state monopolies, did away with compulsory labour service, and promoted the liberation of the economy leading to new economic enterprises. Crown land was sold cheaply to cultivators to encourage plantation agriculture, and capital flowed in. Cultivation of coffee was profitable.

Coffee. From 1830 to the 1870s the phenomenal growth of coffee dominated Ceylon's economic development. Acreage under coffee expanded, and roads were constructed to fill the needs of coffee planters. Because of a labour shortage in the plantations, coolie labour under indenture contracts came from southern India in large numbers beginning in the 1840s.

Tea and rubber. In the 1870s coffee was destroyed by a leaf disease. Experiments with tea as a plantation crop in the 1880s were immediately successful, and tea spread along the upper and lower slopes of the hill country. About the same time, rubber plantations were developed both in the highlands and lowlands, and coconut was cultivated as a plantation crop.

Capital investment poured into tea and rubber, which grew as large-scale industries. These products needed a permanent labour force, and steps were taken to settle Indian labour in the plantations. Ancillary services soon arose. Increasing export trade led to the development of the Colombo Harbour and to railway and road construction. Opportunities were created for the Ceylonese entrepreneur, and employment was plentiful for the English educated.

Capitalist enterprise was restricted, however, to the urban areas and the plantation country. The rest of the country continued with subsistence agriculture, using traditional methods, though the isolation of the village was broken somewhat by roads and railways and the people there were brought into the monetary economy by the increased trade.

CONSTITUTIONALISM AND NATIONALISM (1900–48)

In the 19th century Ceylonese nationalist consciousness expended itself on the social, religious, and educational fronts. Revivalist movements in Buddhism and Hinduism sought to modernize their institutions and to defend themselves against Christian inroads by establishing schools to impart Western education unmixed with Christianity.

Constitutional reforms. Gradually this consciousness spread to the political plane. Regional and communal associations were founded in the educationally advanced parts of the country and began to articulate proposals for constitutional reform. They asked for some Ceylonese participation in the executive, a wider representation in the legislature on a territorial basis, and the adoption of the elective principle in place of nomination. These demands showed a common ideology and approach and revealed a desire to advance within the framework of the colonial constitution.

Because demands were not coordinated or vociferous, the imperial government ignored them. Constitutional reforms passed in 1910 retained the old structure with an appointed executive and a legislature with an appointed majority. There was, however, a limited recognition of the elective principle; an "educated Ceylonese" electorate was established to elect one member to the Legislative Council. Other Ceylonese members were to be nominated on a communal basis.

Growth of nationalist power. During World War I the forces of nationalism in Ceylon gathered momentum. Civil disturbances in 1915 and subsequent political repercus-

sions helped the growth of political consciousness. British arrests of prominent Sinhalese leaders during what was at first a minor communal riot provoked widespread opposition. Leaders of all communities, feeling the need for a common platform to voice a common viewpoint, came together for the first political agitation in the island. In 1919 the Ceylon National Congress was formed, uniting existing Sinhalese and Tamil organizations. The Congress drafted proposals for constitutional reforms, demanding an elected majority in the legislature, control of the budget, and partial control of the executive.

A new constitution was promulgated in 1920 under the governor Sir William Manning and modified in 1924 to satisfy nationalist demands. It provided for an elected majority in the legislature, an increase in the number of territorially elected members, and the election of communal representatives. The country thus attained representative government, but no share was given in the executive, which remained under the governor and the official Executive Council. A finance committee of the legislature was formed, consisting of three unofficial and three official members, which could examine the budget.

The concession of greater power to the nationalists produced the first fissions among them. Sinhalese leaders wanted to do away with communal representation and make territorial representation universal, but minorities desired to retain it to secure power for their communities. Minorities broke away from the Congress to form their own organizations.

A new constitution, framed in 1931, gave Ceylonese leaders opportunities to exercise political power and to gain governmental experience with a view toward eventual self-government. It provided for a State Council with both legislative and executive functions. Besides being a legislative council with an overwhelming majority of territorially elected members, the State Council was divided for executive work into seven committees, each electing its own chairman. These chairmen, or ministers, formed a board of ministers to coordinate their activities and to present an annual budget. The constitution granted universal franchise, thus for the first time bringing all Ceylonese into the political process. It was in operation for more than 15 years and provided the people and their leaders with valuable experience in democracy.

Preparation for self-government

Dominion status. In response to pressure from Ceylonese nationalist leaders, the British in 1945 appointed the Soulbury Constitutional Commission, which drafted a constitution that gave Ceylon internal self-government, retaining some imperial safeguards in defense and external affairs. In 1947 the Ceylon Independence Act conferred dominion status on the colony. (S.Ara.)

SRI LANKA (CEYLON) SINCE INDEPENDENCE

The constitution of independent Ceylon provided for a bicameral legislature with a popularly elected House of Representatives and a Senate partly nominated and partly elected indirectly. A prime minister and his cabinet, chosen from the largest political group in the legislature, held collective responsibility for executive functions. The governor general, as head of state, represented the British monarch. In matters on which the constitution was silent, the conventions of the United Kingdom were observed.

When the first elections were held in 1947, a number of nationalist and communal parties came together to form the United National Party (UNP); it chose Don Stephen Senanayake as prime minister and advocated orderly and conservative progress. The UNP was dominated by the English-educated leaders of the colonial era, who were familiar with the British type of parliamentary democracy that had been established in the island, and it included people from all the ethnolinguistic groups of Ceylon. Its members were bound by the common ideals of Ceylonese nationalism, parliamentary democracy, and gradual economic progress through free enterprise.

Economically, the island's three export products were doing well in world markets and provided 90 percent of foreign exchange earnings. There was a sizeable sterling balance earned during the war. Politically, the coalition government had a substantial majority in Parliament and attracted support as it went. There were, however, some basic weaknesses in the structure. The political consensus that the government represented embraced the upper 7 percent of the population—the English-educated, westernized elite groups that shared in the values on which the structure was founded. To the great mass of Sinhalese-educated or illiterate people, these values appeared irrelevant and incomprehensible. The continued neglect of traditional culture as embodied in religion, language, and art forms created a gulf that divided the ruling elite from the ruled. Inevitably, leaders and movements arose that articulated the voices of traditionalism and revivalism.

Meanwhile, the country began to face economic difficulties. A rapidly increasing population and free import of consumer goods swiftly ate into the country's foreign exchange. The falling price of Ceylon's rubber and tea and the increase in the price of imported food added to the acute foreign exchange problem. Additionally, the expanded school system produced a large number of educated persons who could not find employment.

These various factors of political and economic discontent converged after 1955, and a new Sinhala nationalism was unleashed. It found a champion in S.W.R.D. Bandaranaike. In the 1956 elections the UNP was swept out of office, and Bandaranaike's Sri Lanka Freedom Party (SLFP) was installed in power at the head of a coalition of like-minded parties—the Mahajana Eksath Peramuna (People's United Front). The new government immediately set about changing the political structure. It made Sinhalese the sole official language and took measures for state support of the Buddhist faith and of Sinhala culture. It wedded the new nationalism to a form of socialism, in which the state was given a positive role in economic development and creation of economic equality.

Sinhala nationalism

The period of Sinhala nationalism was also a time of political instability. The language policy alienated the Tamils, who, under the Federal Party, carried on a bitter opposition. Educational policies alienated the small but influential Christian community. Cultural and Buddhist reforms alienated different factions within the Sinhalese.

Bandaranaike was assassinated in September 1959, and the movement suffered a setback and languished for want of a leader. After a period of political instability, his widow, Sirimavo Bandaranaike, was persuaded to gather together the fragments of the SLFP. In 1960 she formed a government that continued to implement the policies of Sinhala nationalism. All private schools were nationalized, and state-subsidized private schools were abolished, in response to a demand the Buddhists had made consistently because of the dominance of Christian missions in the country's educational system. The policy of nationalization of economic enterprise was carried further.

By 1965 the tide of Sinhala nationalism had begun to recede. Language and religion had become less important as political issues. An economic crisis, caused by increasing unemployment, the rising cost of living, an acute shortage of consumer goods, and the failure of state enterprise in industry and trade, made people look back to the UNP. This party gained the support of minorities, and in 1965 it returned to power under Dudley Shelton Senanayake, who, as the son of Don Stephen Senanayake, had served as prime minister (1952–53) after his father's death and briefly in 1960. Senanayake's government enjoyed a five-year term of office, during which it encouraged private enterprise and made an effort to extend agricultural productivity. These measures, while having moderate success, also tended to create inflation and to increase social inequality. The problem of unemployment of the educated could not be solved. The SLFP formed an alliance with Marxist parties and waged a campaign against the government that called for increased state control of the economy. In 1970 this coalition won a landslide victory, and Bandaranaike again became prime minister.

During its period of office (1970–77), the Bandaranaike government enacted reforms that restricted private enterprise and extended nationalization to a number of private industries, a large part of the wholesale and distributive trade, agency houses, and foreign-owned plantations. Measures aimed at reducing social inequality were enacted,

and an ambitious program of land reform was put under way. These reforms satisfied the vast majority of underprivileged but did nothing to touch basic economic problems. The Sinhala-educated youth, impatient for radical change, were disillusioned within a year. Their discontent was headed by the Jatika Vimukti Peramuna (National Liberation Front), a group of revolutionary youth who launched an unsuccessful armed rebellion.

Constitution of 1972

In a new constitution proclaimed in 1972, Ceylon became the Republic of Sri Lanka, with a president as the formal head of state but with effective executive power continuing in the hands of a prime minister and cabinet. All existing restraints on the lawmaking powers of the new unicameral legislature were removed. Buddhism was given "the foremost place," and Sinhalese was recognized as the official language.

The continuing economic decline, however, could not be arrested. The acquisition of immense economic power by the state provided the party in power with the opportunity for patronage, nepotism, and corruption. By 1977, unemployment had risen to about 15 percent. The SLFP was left to face the polls on its own in July 1977, and it was defeated by a reorganized UNP under the leadership of J.R. Jayawardene, who became prime minister.

Constitution of 1978

The Jayawardene government arrested the drift toward state control of the economy and took steps to revitalize the private sector and to attract foreign capital. One of its innovations was the creation in 1978 of a free-trade zone north of Colombo, where industries would be geared to an export market. The UNP government set about revising radically the constitution of 1972. In a new constitution promulgated in September 1978, the country was renamed the Democratic Socialist Republic of Sri Lanka and a presidential system, somewhat on the French model, was introduced. The president was head of state as well as head of the executive and of government. Sinhalese and Tamil were recognized as national languages, but Sinhalese was to be the official language. Jayawardene in 1978 became the first president under the new constitution.

Political unrest, however, escalated in the 1980s. The Tamil minority in the country campaigned—with increasingly violent acts of terrorism and rioting—for an autonomous state; there were also instances of bloody anti-Tamil rioting. The unrest was damaging to the economy, and Jayawardene's government repeatedly invoked emergency powers in efforts to curb disorder. (S.Ara./Ed.)

Stalin

During the quarter of a century preceding his death in 1953, the Soviet dictator Joseph Stalin probably exercised greater political power than any other figure in history. Stalin industrialized the Union of Soviet Socialist Republics, forcibly collectivized its agriculture, consolidated his position by intensive police terror, helped to defeat Germany in 1941–45, and extended Soviet controls to include a belt of eastern European states. Chief architect of Soviet totalitarianism and a skilled but phenomenally ruthless organizer, he destroyed the remnants of individual freedom and failed to promote individual prosperity, yet he created a mighty military–industrial complex and led the Soviet Union into the nuclear age.

Stalin's biography was long obscured by a mendacious Soviet-propagated "legend" exaggerating his prowess as a heroic Bolshevik boy-conspirator and faithful follower of Lenin, the founder of the Soviet Union. In his prime, Stalin was hailed as a universal genius, as a "shining sun," or "the staff of life," and also as a "great teacher and friend" (especially of those communities he most savagely persecuted); once he was even publicly invoked as "Our Father" by a metropolitan of the Russian Orthodox Church. Achieving wide visual promotion through busts, statues, and icons of himself, the dictator became the object of a fanatical cult that, in private, he probably regarded with cynicism.

The young revolutionary. Of Georgian—not Russian—origin, Joseph Stalin was born on December 21 (December 9, old style), 1879, as Iosif Vissarionovich Dzhugashvili, son of a poor cobbler in the provincial Georgian town of Gori in the Caucasus, then an imperial Russian colony. The drunken father savagely beat his son. Speaking only Georgian at home, Joseph learned Russian—which he always spoke with a guttural Georgian accent—while attending the church school at Gori (1888–94). He then moved to the Tiflis Theological Seminary, where he secretly read Karl Marx, the chief theoretician of international Communism, and other forbidden texts, being expelled in 1899 for revolutionary activity, according to the "legend"—or leaving because of ill health, according to his doting mother. The mother, a devout washerwoman, had dreamed of her son becoming a priest, but Joseph Dzhugashvili was more ruffianly than clerical in appearance and outlook. He was short, stocky, black-haired, fierce-eyed, with one arm longer than the other, his swarthy face scarred by smallpox contracted in infancy. Physically strong and endowed with prodigious willpower, he early learned to disguise his true feelings and to bide his time; in accordance with the Caucasian blood-feud tradition, he was implacable in plotting long-term revenge against those who offended him.

In December 1899, Dzhugashvili became, briefly, a clerk in the Tiflis Observatory, the only paid employment that he is recorded as having taken outside politics; there is no record of his ever having done manual labour. In 1900 he joined the political underground, fomenting labour demonstrations and strikes in the main industrial centres of the Caucasus; but his excessive zeal in pushing duped workers into bloody clashes with the police antagonized his fellow conspirators. After the Social Democrats (Marxist revolutionaries) of the Russian Empire had split into their two competing wings—Menshevik and Bolshevik—in 1903, Dzhugashvili joined the second, more militant, of these factions and became a disciple of its leader, Lenin. Between April 1902 and March 1913, Dzhugashvili was seven times arrested for revolutionary activity, undergoing repeated imprisonment and exile. The mildness of the sentences and the ease with which the young conspirator effected his frequent escapes lend colour to the unproved speculation that Dzhugashvili was for a time an *agent provocateur* in the pay of the imperial political police.

Work with Lenin

Rise to power. Dzhugashvili made slow progress in the party hierarchy. He attended three policy-making conclaves of the Russian Social Democrats—in Tammerfors (now Tampere, Finland; 1905), Stockholm (1906), and London (1907)—without making much impression. But he was active behind the scenes, helping to plot a spectacular holdup in Tiflis (now Tbilisi) on June 25 (June 12, O.S.), 1907, in order to "expropriate" funds for the party. His first big political promotion came in February (January, O.S.) 1912, when Lenin—now in emigration—co-opted him to serve on the first Central Committee of the Bolshevik Party, which had finally broken with the other Social Democrats. In the following year, Dzhugashvili published, at Lenin's behest, an important article on Marxism and the national question. By now he had adopted the name Stalin, deriving from Russian *stal* ("steel"); he also briefly edited the newly founded Bolshevik newspaper *Pravda* before undergoing his longest period of exile: in Siberia from July 1913 to March 1917.

In about 1904 Stalin had married a pious Georgian girl, Ekaterina Svanidze. She died some three years later and left a son, Jacob, whom his father treated with contempt, calling him a weakling after an unsuccessful suicide attempt in the late 1920s; when Jacob was taken prisoner by the Germans during World War II, Stalin refused a German offer to exchange his son.

Reaching Petrograd from Siberia on March 25 (March 12, O.S.), 1917, Stalin resumed editorship of *Pravda.* He briefly advocated Bolshevik cooperation with the provisional government of middle-class liberals that had succeeded to uneasy power on the last tsar's abdication during the February Revolution. But under Lenin's influence, Stalin soon switched to the more militant policy of armed seizure of power by the Bolsheviks. When their coup d'état occurred in November (October, old style) 1917, he played an important role, but one less prominent than that of his chief rival, Leon Trotsky.

Active as a politico-military leader on various fronts during the Civil War of 1918–20, Stalin also held two ministerial posts in the new Bolshevik government, being commissar for nationalities (1917–23) and for state control (or workers' and peasants' inspection; 1919–23). But it was his position as secretary general of the party's Central

Committee, from 1922 until his death, that provided the power base for his dictatorship. Besides heading the secretariat, he was also member of the powerful Politburo and of many other interlocking and overlapping committees—an arch-bureaucrat engaged in quietly outmaneuvering brilliant rivals, including Trotsky and Grigory Zinoviev, who despised such mundane organizational work. Because the pockmarked Georgian was so obviously unintellectual, they thought him unintelligent—a gross error, and one literally fatal in their case.

From 1921 onward Stalin flouted the ailing Lenin's wishes, until, a year before his death, Lenin wrote a political "testament," since widely publicized, calling for Stalin's removal from the secretary generalship; coming from Lenin, this document was potentially ruinous to Stalin's career, but his usual luck and skill enabled him to have it discounted during his lifetime.

Lenin's successor. After Lenin's death, in January 1924, Stalin promoted an extravagant, quasi-Byzantine cult of the deceased leader. Archpriest of Leninism, Stalin also promoted his own cult in the following year by having the city of Tsaritsyn renamed Stalingrad (now Volgograd). His main rival, Trotsky (once Lenin's heir apparent), was now in eclipse, having been ousted by the ruling triumvirate of Zinoviev, Lev Kamenev, and Stalin. Soon afterward Stalin joined with the rightist leaders Nikolay Bukharin and Aleksey Rykov in an alliance directed against his former co-triumvirs. Pinning his faith in the ability of the Soviet Union to establish a viable political system without waiting for the support hitherto expected from worldwide revolution, the Secretary General advocated a policy of "Socialism in one country"; this was popular with the hardheaded party managers whom he was promoting to influential positions in the middle hierarchy. His most powerful rivals were all dismissed, Bukharin and Rykov soon following Zinoviev and Kamenev into disgrace and political limbo pending execution. Stalin expelled Trotsky from the Soviet Union in 1929 and had him assassinated in Mexico in 1940.

The policy of "Socialism in one country"

In 1928 Stalin abandoned Lenin's quasi-capitalist New Economic Policy in favour of headlong state-organized industrialization under a succession of five-year plans. This was, in effect, a new Russian revolution more devastating in its effects than those of 1917. The dictator's blows fell most heavily on the peasantry, some 25,000,000 rustic households being compelled to amalgamate in collective or state farms within a few years. Resisting desperately, the reluctant muzhiks were attacked by troops and OGPU (political police) units. Uncooperative peasants, termed kulaks, were arrested en masse, being shot, exiled, or absorbed into the rapidly expanding network of Stalinist concentration camps and worked to death under atrocious conditions. Collectivization also caused a great famine in the Ukraine. Yet Stalin continued to export the grain stocks that a less cruel leader would have rushed to the famine-stricken areas. Some 10,000,000 peasants may have perished through his policies during these years.

Collectivization of agriculture and industrialization

Crash industrialization was less disastrous in its effects, but it, too, numbered its grandiose failures, to which Stalin responded by arraigning industrial managers in a succession of show trials. Intimidated into confessing imaginary crimes, the accused served as self-denounced scapegoats for catastrophes arising from the Secretary General's policies. Yet Stalin was successful in rapidly industrializing a backward country—as was widely acknowledged by enthusiastic contemporary foreign witnesses, including Adolf Hitler and such well-known writers as H.G. Wells and George Bernard Shaw.

Among those who vainly sought to moderate Stalin's policies was his young second wife, Nadezhda Alliluyeva, whom he had married in 1919 and who committed suicide in 1932. They had two children. The son, Vasily, perished as an alcoholic after rising to unmerited high rank in the Soviet Air Force. The daughter, Svetlana, became the object for her father's alternating affection and bad temper. She emigrated after his death and later wrote memoirs that illuminate Stalin's well-camouflaged private life.

The great purges. In late 1934—just when the worst excesses of Stalinism seemed to have spent themselves—the Secretary General launched a new campaign of political terror against the very Communist Party members who had brought him to power; his pretext was the assassination, in Leningrad on December 1, of his leading colleague and potential rival, Sergey Kirov. That Stalin himself had arranged Kirov's murder—as an excuse for the promotion of mass bloodshed—was strongly hinted by Nikita Khrushchev, first secretary of the party, in a speech denouncing Stalin at the 20th Party Congress in 1956.

Stalin used the show trial of leading Communists as a means for expanding the new terror. In August 1936, Zinoviev and Kamenev were paraded in court to repeat fabricated confessions, sentenced to death, and shot; two more major trials followed, in January 1937 and March 1938. In June 1937, Marshal Mikhail Tukhachevsky, at the time the most influential military personality, and other leading generals were reported as court-martialed on charges of treason and executed.

Such were the main publicly acknowledged persecutions that empowered Stalin to tame the Soviet Communist Party and the Soviet elite as a whole. He not only "liquidated" veteran semi-independent Bolsheviks but also many party bosses, military leaders, industrial managers, and high government officials totally subservient to himself. Other victims included foreign Communists on Soviet territory and members of the very political police organization, now called the NKVD. All other sections of the Soviet elite—the arts, the academic world, the legal and diplomatic professions—also lost a high proportion of victims, as did the population at large, to a semi-haphazard, galloping persecution that fed on extorted denunciations and confessions. These implicated even more victims until Stalin himself reduced the terror, though he never abandoned it. Stalin's political victims were numbered in tens of millions. His main motive was, presumably, to maximize his personal power.

Role in World War II. During World War II Stalin emerged, after an unpromising start, as the most successful of the supreme leaders thrown up by the belligerent nations. In August 1939, after first attempting to form an anti-Hitler alliance with the Western powers, he concluded a pact with Hitler, which encouraged the German dictator to attack Poland and begin World War II. Anxious to strengthen his western frontiers while his new but palpably treacherous German ally was still engaged in the West, Stalin annexed eastern Poland, Estonia, Latvia, Lithuania, and parts of Romania; he also attacked Finland and extorted territorial concessions. In May 1941 Stalin recognized the growing danger of German attack on the Soviet Union by appointing himself chairman of the Council of People's Commissars (head of the government); it was his first governmental office since 1923.

Stalin's prewar defensive measures were exposed as incompetent by the German blitzkrieg that surged deep into Soviet territory after Hitler's unprovoked attack on the Soviet Union of June 22, 1941. Khrushchev claimed that Stalin was shocked into temporary inactivity by the onslaught, but, if so, he soon rallied and appointed himself supreme commander in chief. When the Germans menaced Moscow in the winter of 1941, he remained in the threatened capital, helping to organize a great counteroffensive. The battle of Stalingrad (in the following winter) and the Battle of Kursk (in the summer of 1943) were also won by the Soviet Army under Stalin's supreme direction, turning the tide of invasion against the retreating Germans, who capitulated in May 1945. As war leader, Stalin maintained close personal control over the Soviet battlefronts, military reserves, and war economy. At first overinclined to intervene with inept telephoned instructions, as Hitler did, the Soviet generalissimo gradually learned to delegate military decisions.

Role as supreme commander in chief

Stalin participated in high-level Allied meetings, including those of the "Big Three" with Churchill and Roosevelt at Tehrān (1943) and Yalta (1945). A formidable negotiator, he outwitted these foreign statesmen; his superior skill has been acclaimed by Anthony Eden, then British foreign secretary.

Last years. After the war, Stalin imposed on eastern Europe a new kind of colonial control based on native

Postwar foreign policy

Communist regimes nominally independent but in fact subservient to himself. He thus increased the number of his subjects by about a hundred million. But in 1948 the defection of Titoist Yugoslavia from the Soviet camp struck a severe blow to world Communism as a Stalin-dominated monolith. To prevent other client states from following Tito's example, Stalin instigated local show trials, manipulated like those of the Great Purge of the 1930s in Russia, in which satellite Communist leaders confessed to Titoism, many being executed.

Far from continuing his wartime alliance with the United States and Great Britain, Stalin now regarded these countries—and especially the United States—as the arch-enemies that he needed after Hitler's death. At home, the primacy of Marxist ideology was harshly reasserted. Stalin's chief ideological hatchet man, Andrey Zhdanov, a secretary of the Central Committee, began a reign of terror in the Soviet artistic and intellectual world; foreign achievements were derided, and the primacy of Russians as inventors and pioneers in practically every field was asserted. Hopes for domestic relaxation, widely aroused in the Soviet Union during the war, were thus sadly disappointed.

Increasingly suspicious and paranoid in his later years, Stalin ordered the arrest, announced in January 1953, of certain—mostly Jewish—Kremlin doctors on charges of medically murdering various Soviet leaders, including Zhdanov. The dictator was evidently preparing to make this "Doctors' Plot" the pretext for yet another great terror menacing all his senior associates, but he died suddenly on March 5, 1953, according to the official report; so convenient was this death to his entourage that suspicions of foul play were voiced.

Assessment. A politician to the marrow of his bones, Stalin had little private or family life, finding his main relaxation in impromptu buffet suppers, to which he would invite high party officials, generals, visiting foreign potentates, and the like. Drinking little himself on these occasions, the dictator would encourage excessive indulgence in others, thus revealing weak points that he could exploit. He would also tease his guests, jocularity and malice being nicely balanced in his manner; for such bluff banter Stalin's main henchman, Vyacheslav Molotov, the stuttering foreign minister, was often a target. Stalin had a keen, ironical sense of humour, usually devoted to deflating his guests rather than to amusing them.

Stalin's dinner parties

Foremost among Stalin's accomplishments was the industrialization of a country which, when he assumed complete control in 1928, was still notably backward by comparison with the leading industrial nations of the world. By 1937, after less than a decade's rule as totalitarian dictator, he had increased the Soviet Union's total industrial output to the point where it was surpassed only by that of the United States. The extent of this achievement may best be appreciated if one remembers that Russia had held only fifth place for overall industrial output in 1913, and that it thereafter suffered many years of even greater devastation—through world war, civil war, famine, and pestilence—than afflicted any of the world's other chief industrial countries during the same period. Yet more appallingly ravaged during World War II, the Soviet Union was nevertheless able, under Stalin's leadership, to play a major part in defeating Hitler while maintaining its position as the world's second most powerful industrial—and now military—complex after the United States. In 1949 Stalinist Russia signaled its arrival as the world's second nuclear power by exploding an atomic bomb.

Achievements

Against these formidable achievements must be set one major disadvantage. Though a high industrial output was indeed achieved under Stalin, very little of it ever became available to the ordinary Soviet citizen in the form of consumer goods or amenities of life. A considerable proportion of the national wealth—a proportion wholly unparalleled in the history of any peacetime capitalist country—was appropriated by the state to cover military expenditure, the police apparatus, and further industrialization. It is also arguable that a comparable degree of industrialization would have come about in any case—and surely by means less savage—under almost any conceivable regime that might have evolved as an alternative to Stalinism.

Stalin's collectivization of agriculture did not produce—either during his lifetime or during the decades immediately following his death—positive economic results remotely comparable to those attained by Soviet industry. Considered as a means of asserting control over the politically recalcitrant peasantry, however, collectivization triumphantly justified itself and continues to do so, remaining one of the dictator's most durable achievements. Moreover, the process of intensive urbanization, as instituted by Stalin, continued after his death in what still remained a population more predominantly rural than that of any other major industrial country. In 1937, 56 percent of the population was recorded as engaged in agriculture or forestry; by 1958 that proportion had dropped to 42 percent, very largely as a result of Stalin's policies.

The most lasting of all the dictator's achievements may prove to be his elaborately bureaucratized administrative machinery based on the interlinking of the Communist Party, ministries, legislative bodies, trade unions, political police, and armed forces, as also on a host of other meshing control devices. During the two decades following the dictator's death, these continued to supply the essential management levers of Soviet society, often remaining under the control of individuals who had risen to prominence during the years of the Stalinist terror. But the element of total personal dictatorship did not survive Stalin in its most extreme form. One result of his death was the resurgence of the Communist Party as the primary centre of power, after years during which that organization, along with all other Soviet institutions, had been subordinated to a single man's whim. Yet, despite the great power wielded by Stalin's successors as party leaders, they became no more than dominant figures within the framework of a ruling oligarchy. They did not develop into potentates responsible to themselves alone, such as Stalin was during his quarter of a century's virtually unchallenged rule.

That Stalin's system persists, in all its major essentials, after the death of its creator is partly due to the very excess of severity practiced by the great tyrant. Not only did his methods crush initiative among Soviet administrators, physically destroying many, but they also left a legacy of remembered fear so extreme as to render continuing post-Stalin restrictions tolerable to the population; the people would have more bitterly resented—might even, perhaps, have rejected—such rigours, had it not been for their vivid recollection of repressions immeasurably harsher. Just as Hitler's wartime cruelty toward the Soviet population turned Stalin into a genuine national hero—making him the Soviet Union's champion against an alien terror even worse than his own—so too Stalin's successors owed the stability of their system in part to the comparison, still fresh in many minds, with the far worse conditions that obtained during the despot's sway.

Stalin has arguably made a greater impact on the lives of more individuals than any other figure in history. But the evaluation of his overall achievement still remains, nearly two decades after his death, a highly controversial matter. Historians have not yet reached any definitive consensus of opinion on the worth of his accomplishments, and it is unlikely that they ever will. To the American scholar George F. Kennan, Stalin is a great man, but one great in his "incredible criminality . . . a criminality effectively without limits," while Robert C. Tucker, an American specialist on Soviet affairs, has described Stalin as a 20th-century Ivan the Terrible. To the British historian E.H. Carr, the Georgian dictator appears as a ruthless, vigorous figure, but one lacking in originality—a comparative nonentity thrust into greatness by the inexorable march of the great revolution that he found himself leading. To the late Isaac Deutscher, the author of biographies of Trotsky and Stalin—who, like Carr, broadly accepts Trotsky's version of Stalin as a somewhat mediocre personage—Stalin represents a lamentably deviant element in the evolution of Marxism. Neither Deutscher nor Carr has found Stalin's truly appalling record sufficiently impressive to raise doubts about the ultimate value of the Russian October Revolution's historic achievements.

Reputation

To such views, each illuminating a facet of Stalin's personality, may be added the suggestion that Stalin was anything but a plodding mediocrity, being rather a man of superlative, all-transcending talent. His special brilliance was, however, narrowly specialized and confined within the single crucial area of creative political manipulation. Outside the realm of pioneering political maneuver, in which Stalin's flair remains unsurpassed, his qualities appear in no way superhuman, apart perhaps from the dogged persistence with which he was accustomed to pursue to the death both his manifold goals and his innumerable enemies. BIBLIOGRAPHY. The standard Soviet edition of Stalin's works in Russian is his *Сочинения,* 13 vol. (1946–51), covering publications up to January 1934. His later works have been issued in Russian in similar format by the Hoover Institution; ROBERT H. MCNEAL (ed.), *Сочинения* 3 vol. (1967), is considered to be the extension, as vol. 14–16, of the standard edition. The standard edition has been translated into English and published in Moscow: IOSIF STALIN, *Works,* 13 vol. (1952); a selection of Stalin's works in English is BRUCE FRANKLIN (ed.), *The Essential Stalin: Major Theoretical Writings, 1905–52* (1972). An annotated bibliography by ROBERT H. MCNEAL, *Stalin's Works* (1967), considers the authenticity of material in Russian attributed to Stalin.

There is no definitive biography of Stalin. The most useful of published studies include ROBERT PAYNE, *Rise and Fall of Stalin* (1965, reissued 1968); ISAAC DEUTSCHER, *Stalin: A Political Biography,* 2nd ed. (1966, reissued 1978), Marxist in its approach; LEON TROTSKY, *Stalin: An Appraisal of the Man and His Influence,* new ed. (1967, reprinted 1970), and *The Stalin School of Falsification,* 3rd ed. (1972; originally published in Russian, 1932), both denunciatory; BORIS SOUVARINE, *Stalin: A Critical Survey of Bolshevism* (1939, reprinted 1972); and BERTRAM D. WOLFE, *Three Who Made a Revolution,* 4th rev. ed. (1964, reprinted 1978). *Stalin,* ed. by THOMAS H. RIGBY (1966), is an excellent short anthology of biographical and critical material. Later studies include ADAM B. ULAM, *Stalin: The Man and His Era* (1973); RONALD HINGLEY, *Joseph Stalin: Man and Legend* (1974); and IAN GREY, *Stalin: Man of History* (1979).

Reliable, detailed firsthand accounts of Stalin's domestic background are few, the only family memoirs not subject to Stalinist censorship being those published by Stalin's daughter, SVETLANA ALLILUYEVA, after emigration: *Twenty Letters to a Friend* (1967; originally published in Russian in the United States, 1967) and *Only One Year* (1969; originally published in Russian in the United States, 1969). For Soviet-censored memoirs by other family members, see *The Alliluyev Memoirs,* trans. and ed. by DAVID TUTAEV (1968).

On Stalin's prerevolutionary career, EDWARD ELLIS SMITH, *The Young Stalin: The Early Years of an Elusive Revolutionary* (1967), attempts to prove that the subject was an agent of the Tsarist political police; LAVRENTY BERIA, *On the History of the Bolshevik Organizations in Transcaucasia* (1949, trans. from the 7th Russian ed.), is the chief classic of Stalinist legend-building. For the historical context, see ROBERT C. TUCKER, *Stalin as Revolutionary, 1879–1929: A Study in History and Personality* (1973).

For the political background of Stalin's mature career, LEONARD SCHAPIRO, *The Communist Party of the Soviet Union,* 2nd ed. (1970), is valuable, as is JOHN A. Stars and Star Clusters

Stars are massive, self-luminous objects that shine by radiation derived from internal energy sources. Of the trillions of stars comprising the universe, many occur in pairs, multiple systems, and clusters. The members of such stellar groups are physically related through common origin and are bound by mutual gravitational attraction. Somewhat related to star clusters are stellar associations, which consist of loose groups of physically similar stars that have insufficient mass as a group to remain together as an organization.

This article describes the properties and evolution of both individual stars and stellar aggregates. Included in the discussion are the sizes, energetics, temperatures, masses, and chemical compositions of stars, as well as their distances and motions. The myriad other stars are compared to the Sun, strongly implying that "our" star is in no way special.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* Part One, Division III, especially Section 132.

General considerations

THE SUN AS A POINT OF COMPARISON

Variations in stellar size. With regard to mass, size, and intrinsic brightness, the Sun is a typical star. Its approximate mass is 2×10^{33} grams, its approximate radius 7×10^{10} centimetres, and its approximate luminosity 4×10^{33} ergs per second (or equivalently 4×10^{23} kilowatts of power). Other stars often have their respective quantities measured in terms of those of the Sun.

Table 1 lists data pertaining to the 20 brightest stars, or, more precisely, stellar systems, since some of them are double (binary) or even triple stars. Successive columns give the name of the star, its brightness expressed in units called visual magnitudes and the spectral class or classes (see below *Classification of spectral types*) to which the star or its components belong, the distance in light-years (a light-year being the distance that light waves travel in one Earth year: 9,460,000,000,000 kilometres, or 5,878,000,000,000 miles), and the visual luminosity in terms of that of the Sun (designated by the symbol ⊙). All the primary stars (designated as the A component in the Table) are intrinsically as bright as or brighter than the Sun; some of the companion stars are fainter.

Many stars vary in the amount of light they radiate. Stars such as Altair, Alpha Centauri A and B, and Procyon A are called dwarf stars; their dimensions are roughly comparable to those of the Sun. Sirius A and Vega, though much brighter, also are dwarf stars; their higher temperatures yield a larger rate of emission per unit area. Aldebaran A, Arcturus, and Capella A are examples of giant stars, whose dimensions are much larger than those of the Sun. Observations with an interferometer (an instrument that measures the angle subtended by the diameter of a star at the observer's position), combined with parallax measurements (which yield a star's distance; see below *Determining stellar distances*), give sizes of 12 and 22 solar radii for Arcturus and Aldebaran A. Betelgeuse and Antares A are examples of supergiant stars. The latter has a radius some 560 times that of the Sun, whereas the variable star Betelgeuse oscillates between 600 and 900 solar radii. Several of the stellar class of white-dwarf stars, which have low luminosities and high densities, also are listed in Table 1. Sirius B is a prime example, having a size

of 0.01 solar radius, which is comparable to the size of the Earth. Among other notable stars of Table 1, Rigel A is a young supergiant in the constellation Orion and Canopus a bright beacon in the Southern Hemisphere often used for spacecraft navigation.

Stellar activity and mass loss. The Sun's activity is apparently not unique. It has been found that stars of all types are active and have stellar winds. The importance and ubiquity of strong stellar winds became apparent only through advances in space-borne ultraviolet and X-ray astronomy as well as in radio and infrared ground-based astronomy.

Stellar winds

X-ray observations that were made during the early 1980s yielded some rather unexpected findings. They revealed that nearly all types of stars are surrounded by coronas having temperatures of 1,000,000 kelvins (K) or more. Furthermore, all stars seemingly sport active regions, including spots, flares, and prominences much like those of the Sun. Some stars exhibit star spots so large that an entire face of the star is relatively dark, while others display flare activity thousands of times more intense than that on the Sun.

The highly luminous, hot, blue stars have by far the strongest stellar winds. Observations of their ultraviolet spectra with telescopes on rockets and satellites have shown that their wind speeds often reach 3,000 kilometres per second (roughly 2,000 miles per second), while losing mass at rates up to 1,000,000,000 times that of the solar wind. The corresponding mass-loss rates approach and sometimes exceed 10^{-5} solar masses per year, one entire solar mass (perhaps $1/10$ of the total mass of the star) being carried away into space in a relatively short span of 100,000 years. Accordingly, the most luminous stars are thought to lose substantial fractions of their mass during their lifetimes, as the latter are calculated to be only a few million years.

Ultraviolet radiation from luminous hot stars

Ultraviolet observations have proved that to produce such great winds the pressure of hot gases in a corona, which drives the solar wind, is not enough. Instead, the winds of the hot stars must be driven directly by the pressure of the energetic ultraviolet radiation emitted by these stars. Aside from the simple realization that copious quantities of ultraviolet radiation flow from such hot stars, the details of the process are not well understood. Whatever is going on, it is surely complex, for the ultraviolet spectra of the stars tend to vary with time, implying that the wind is not steady. In an effort to understand better the variations in the rate of flow, theorists are investigating possible kinds of instabilities that might be peculiar to luminous hot stars.

Observations made with radio and infrared telescopes as well as with optical instruments prove that luminous cool stars also have winds whose total mass flow rates are comparable to those of the luminous hot stars, though their velocities are much lower—about 30 kilometres per second. Because luminous red stars are inherently cool objects (having a surface temperature of about 3,000 K, or half that of the Sun), they emit no detectable ultraviolet or X-ray radiation; thus, the mechanism driving the winds must differ from that in luminous hot stars. Winds from luminous cool stars, unlike those from hot stars, are rich in dust grains and molecules. Since nearly all stars more massive than the Sun eventually evolve into such cool stars, their winds, pouring into space from vast numbers of stars, provide a major source of new gas and dust in interstellar space, thereby furnishing a vital link in the cycle of star formation and galactic evolution. As in the case of the hot stars, the specific mechanism that drives the winds of the cool stars is not understood; at this time, investigators can only surmise that gas turbulence and/or magnetic fields in the atmospheres of these stars are somehow responsible.

Strong winds associated with protostars

Strong winds also are found to be associated with objects called protostars, which are huge gas balls that have not yet become full-fledged stars in which energy is provided by nuclear reactions (see below *Star formation and evolution*). Recent radio and infrared observations of deuterium (heavy hydrogen [H_2]) and carbon monoxide (CO) molecules in the Orion Nebula have revealed clouds of gas expanding outward at velocities approaching 100 kilometres per second. Furthermore, high-resolution, very-long-baseline interferometry observations have disclosed expanding knots of natural maser emission of water vapour near the star-forming regions in Orion, thus linking the strong winds to the protostars themselves. The specific causes of these winds remain unknown, but if they generally accompany star formation, astronomers will have to consider the implications for the early solar system. After all, the Sun was presumably once a protostar, too.

DISTANCES TO THE STARS

Determining stellar distances. Distances to stars are basically determined by the technique of trigonometric parallax. When the position of a nearby star is measured from two points on opposite sides of the Earth's orbit (*i.e.*, six months apart), a small angular (artificial) displacement is observed relative to a background of very remote (essentially fixed) stars. Using the radius of the Earth's orbit as the baseline, the distance of the star can be found from the parallactic angle, p. If $p = 1''$ (one second of arc), the distance of the star is 206,265 times the Earth's distance from the Sun—namely, 3.26 light-years. This unit of dis-

Parsec

tance is termed the parsec, defined as the distance of an object whose parallax equals one arc second. Therefore, one parsec equals 3.26 light-years. Since parallax is inversely proportional to distance, a star at 10 parsecs would have a parallax of 0.1″. Stars at greater distances have even smaller parallaxes, and these are more difficult to measure directly. Hence, indirect methods mostly depending on the brightnesses of different classes are used to find the distances for the great majority of stars. The nearest star, Proxima Centauri (a member of the triple system of Alpha Centauri), has a parallax of 0.76″, meaning that its distance is 1/0.76 or 1.32 parsecs, or 4.3 light-years. The parallax of the next closest, Barnard's star, measures 0.55″, so that its distance is nearly six light-years away. Errors of such parallaxes are typically 0.01″, meaning that there is a 50 percent probability that a star whose parallax is 0.065″ lies between 13.3 and 18.2 parsecs (corresponding to parallaxes of 0.075″ and 0.055″, respectively), and an equal chance that it lies outside that range. Thus, measurements of trigonometric parallaxes are useful for only the nearby stars within a few hundred light-years. In fact, of the approximately 100,000,000,000 stars in the Milky Way Galaxy (also simply called the Galaxy), only about 700 are close enough to have their parallaxes measured accurately.

Nearest stars. Table 2 lists information about the 20 nearest known stars. Only Alpha Centauri, Procyon, and Sirius appear in both Tables 1 and 2. Ironically, most of the relatively nearby stars are dimmer than the Sun and are invisible without the aid of a telescope. By contrast, the well-known bright objects often outlining the constellations have parallaxes less than the limiting value of 0.01″ and are therefore well beyond several hundred light-years distance from the Sun. The most luminous stars can be seen at great distances, whereas the intrinsically faint stars can be observed only if they are relatively close to the Earth.

Although Tables 1 and 2 pertain to only a very small number of stars, they nonetheless serve to illustrate some important points. The stars listed fall roughly into three categories: (1) giant and supergiant stars having sizes of tens or even hundreds of solar radii and extremely low average densities—in fact, several orders of magnitude less than that of water (one gram per cubic centimetre); (2) dwarf stars having sizes ranging from 0.1 to five solar radii and masses from 0.1 to about 10 solar masses; and (3) white-dwarf stars having masses comparable to that of the Sun but dimensions appropriate to planets, meaning that their average densities are hundreds of thousands of times greater than that of water.

General categories of stars

These rough groupings of stars correspond to stages in their life histories (see below *Later stages of evolution*). The second category is identified with what is called the main sequence (see below) and includes stars that emit energy mainly by converting hydrogen into helium in their cores. The first category comprises stars that have exhausted the hydrogen in their cores and are burning hydrogen within shells surrounding the core. The white dwarfs represent the final stage in the life of a typical star, embodying that point when most available sources of energy have been exhausted and the star has become relatively dim.

The large number of binary and even multiple systems is notable. These star systems exhibit scales comparable in size to that of the solar system. Some of the nearby single stars have invisible companions detectable only by their gravitational effects on the primary star; this orbital motion of the unseen member causes the visible star to "wobble" or move through space along a wavelike curve rather than following a straight line. The invisible companions do not appear to be self-luminous; some are suspected to have masses on the order of 0.01 solar mass or less, which is in the range of planetary rather than stellar dimensions. Better observations are needed to determine if they are genuine planets or merely extremely dim stars (sometimes called brown dwarfs). Nonetheless, a reasonable inference that can be drawn from these data is that double stars and planetary systems are formed by similar evolutionary processes.

STELLAR POSITIONS

Basic measurements. Accurate observations of stellar positions are essential to many problems of astronomy. Positions of the brighter stars can be measured very accurately in the equatorial system (the coordinates of which are called right ascension [α, or RA] and declination [δ, or DEC] and are given for some epoch, for example, 1950.0 or, nowadays, 2000.0). Fainter stars are measured using photographic plates or some other imaging device (*e.g.*, a charge-coupled device, or CCD) with respect to the brighter stars, and finally the entire group is referred to the positions of known external galaxies. These distant galaxies are far enough away to define an essentially fixed, or immovable, system, whereas positions of both the bright and faint stars are affected over relatively short periods of time by galactic rotation and by their own motions through the Galaxy.

Stellar motions. Accurate measurements of position make it possible to determine the movement of a star across the line of sight—its proper motion. The amount of proper motion denoted by μ (in arc seconds per year) divided by the parallax of the star and multiplied by a factor of 4.74 equals the tangential velocity, V_T, in kilometres per second in the plane of the celestial sphere.

Proper motion

The motion along the line of sight, called radial velocity, is obtained directly from spectroscopic observations. If λ is the wavelength of a characteristic spectral line of some atom or ion present in the star, and λ_L the wavelength of the same line on the Earth, then the difference $\Delta\lambda$, or $\lambda - \lambda_L$, divided by λ_L equals the radial velocity, V_R, divided by the velocity of light, c—namely, $\Delta\lambda/\lambda_L = V_R/c$. Shifts of a spectral line toward the red end of the electromagnetic spectrum (*i.e.*, positive V_R) indicate recession, and those toward the blue end (negative V_R) indicate approach. If the parallax is known, measurements of μ and V_R enable a determination of the space motion of the star. Normally, radial velocities are corrected for the Earth's rotation and for its motion around the Sun, so that they refer to the line-of-sight motion of the star with respect to the Sun.

Consider a pertinent example. The proper motion of Alpha Centauri is about 3.5 arc seconds, which, at a distance of 4.3 light-years, means that this star moves 0.00007 light-year in one year. It thus has a projected velocity in the plane of the sky of 22 km/sec. As for motion along the line of sight, Alpha Centauri's spectral lines are slightly blueshifted, implying a velocity of approach of about 20 km/sec. The true space motion, equal to $(22^2 + 20^2)^{1/2}$ or about 30 km/sec, suggests that this star will make its closest approach to the Sun (three light-years) some 280 centuries from now.

Light from the stars

STELLAR MAGNITUDES

Measuring starlight intensity. Stellar brightnesses are usually expressed by means of their magnitudes, a usage inherited from classical times. A star of the first magnitude is about 2.5 times as bright as one of the second magnitude, which in turn is some 2.5 times as bright as one of the third magnitude, and so on. A star of the first magnitude is therefore 2.5^5 or 100 times as bright as one of the sixth magnitude. The magnitude of Sirius, which appears to an observer on Earth as the brightest star in the sky (save the Sun), is −1.5. Canopus, the second brightest, has a magnitude of −0.7, while the faintest star normally seen without the aid of a telescope is of the sixth magnitude. Stars as faint as the 23rd magnitude have been measured with the five-metre (200-inch) telescope at the Palomar Observatory in California, meaning that this instrument can detect stars several million times fainter than can the human eye alone.

Magnitude scales

The scale of magnitudes comprises a geometric progression of brightness. Magnitudes can be converted to light ratios by letting l_n and l_m be the brightnesses of stars of magnitudes n and m; the logarithm of the ratio of the two brightnesses then equals 0.4 times the difference between them—*i.e.*, $\log(l_m/l_n) = 0.4(n - m)$. Magnitudes are actually defined in terms of observed brightness, a quantity that depends on the light-detecting device employed. Visual magnitudes are measured with the eye, and photographic magnitudes are obtained from images on a photographic plate. There also are various types of photoelectric magnitude systems. All magnitude systems must have a reference, or zero, point. In practice, this is fixed arbitrarily and is essentially based on the star catalogs of the ancient Greek astronomers Hipparchus and Ptolemy.

Absolute magnitude

The actually measured brightnesses of stars give apparent magnitudes. These cannot be converted to intrinsic brightnesses until the distances of the objects concerned are known. The absolute magnitude of a star is defined as the magnitude it would have if it were viewed at the standard distance of 10 parsecs. Since the apparent visual magnitude of the Sun is −26.9, its absolute magnitude corresponds to a diminution in brightness by a factor $(2{,}062{,}650)^2$, and is, using logarithms, $-26.9 + 2.5 \times \log(2{,}062{,}650)^2$, or $-26.9 + 31.6 = 4.7$. This is the magnitude that the Sun would have if it were at a distance of 10 parsecs—an object still visible to the naked eye, though not a very conspicuous one and certainly not the brightest in the sky. In a similar manner, the absolute magnitude of the full Moon can be calculated to be +32; to see it 10 parsecs away would require a ground-based telescope with an aperture about 0.4 kilometre wide. The very brightest stars, such as Deneb, Rigel, and Betelgeuse, have absolute magnitudes of −7 to −9, while the faintest known star, the companion to the star with the catalog name BD + 4°4048, has an absolute visual magnitude of +19—about 1,000,000 times fainter than the Sun. Many astronomers suspect that large numbers of such faint stars exist, but most of these objects have so far eluded detection.

Stellar colours. Stars differ in colour. Most of the stars in the constellation Orion visible to the naked eye are blue-white, most notably Rigel (Beta Orionis), but Betelgeuse (Alpha Orionis) is a deep red. In the telescope, Albireo (Beta Cygni) is seen as two stars, one blue and the other orange. One quantitative means of measuring stellar colours involves a comparison of the visual magnitude of the star with a magnitude measured on a photographic plate. Yellow, the colour to which the human eye is most sensitive, contributes most to visual magnitude. The ordinary photographic plate is insensitive to yellow and red light but is sensitive to blue and violet, so that hot blue stars appear bright, and yellow and red stars are recorded as relatively faint. In all magnitude scales, one magnitude step corresponds to a brightness ratio of 2.5. The zero point is chosen so that white stars with surface temperatures of about 10,000 K have the same visual and photographic magnitudes. The conventional colour index is defined as the photographic magnitude, B, minus the visual magnitude, V; the colour index, $B - V$, of the Sun is thus $+5.46 - 4.84 = 0.62$.

Visual magnitudes also can be determined photographically with the aid of orthochromatic or yellow-sensitive plates and yellow filters. Such photovisual magnitudes differ from visual magnitudes less than naked-eye estimates of visual magnitudes by different observers differ among themselves. Actually, basic measurements of stellar magnitudes and colours are now made photoelectrically, although the photographic plate continues to play a central role as an interpolation device when very large numbers of stars are to be measured.

Magnitude systems. It has been found that the older system of stellar magnitudes, normally employed only for photographic and photovisual (or visual) magnitudes, encounters a number of severe difficulties. Problems also arise when only one colour is observed. If, for instance, a star's colour is found to be red, it is impossible without further information to decide whether the star is red because it is cool or whether it is really a hot star whose colour has been reddened by the passage of light through interstellar matter. Astronomers have overcome these difficulties by measuring the magnitudes of the same stars in three or more colours.

Basis of modern magnitude systems

Modern magnitude systems are based on measurements, usually made photoelectrically, of a few standard stars, the measurement accuracy being limited chiefly by the quality of the atmosphere through which the light must pass. Magnitudes that measure light from only parts of the wavelength range are generally named for the colour of the light. Thus, there are blue magnitudes whose range roughly corresponds to that of the (blue) photographic magnitudes; visual magnitudes whose range is centred in the yellow-green part of the spectrum; red magnitudes, and so on.

Observations of stellar infrared light also have assumed considerable importance. In addition, photometric observations of individual stars from space vehicles and rockets have made possible the measurement of stellar colours over a large range of wavelengths. These data are important for hot stars and for assessing the effects of interstellar attenuation.

Bolometric magnitudes. The measured total of all radiation at all wavelengths from a star is called a bolometric magnitude. The corrections required to reduce visual magnitudes to bolometric magnitudes are large for very cool stars and for very hot ones but are relatively small for stars such as the Sun. A determination of the true total luminosity of a star affords a measure of its actual energy output. When the energy radiated by a star is observed at the Earth, only that portion to which the energy detector is sensitive and that can be transmitted through the atmosphere is recorded. Most of the energy of stars like the Sun is emitted in spectral regions that can be observed from the Earth's surface; but a cool dwarf star with a surface temperature of 3,000 K has an energy maximum on a wavelength scale at 10000 angstroms (Å) in the far-infrared, and most of its energy cannot therefore be measured as light. Bright, cool stars can be observed at infrared wavelengths, however, with special instruments that measure the amount of heat radiated by the star. Corrections for the heavy absorption of the infrared waves by water and other molecules in the Earth's air must be made unless an infrared payload has been lofted by balloon or rocket above the atmosphere.

Determining the actual energy output of a star

The hotter stars pose more difficult problems, since the Earth's atmosphere extinguishes all radiation at wavelengths shorter than 2900 Å. A star whose surface tem-

perature is 20,000 K or above radiates most of its energy in the inaccessible ultraviolet part of the electromagnetic spectrum. Measurements made with detectors flown in rockets or orbited in satellites extend the observable wavelength region down to 1000 Å or less, though most radiation of distant stars is extinguished below 912 Å—a region in which absorption by neutral hydrogen atoms in intervening space becomes effective.

To compare the true luminosities of two stars, the appropriate bolometric corrections must first be added to each of their absolute magnitudes. The ratio of the luminosities can then be calculated.

STELLAR SPECTRA

A star's spectrum contains information about its temperature, chemical composition, and intrinsic luminosity. Spectrograms secured with a slit spectrograph consist of a sequence of images of the slit in the light of the star at successive wavelengths. Adequate spectral resolution (or dispersion) might show the star to be a member of a close binary system, in rapid rotation, or to have an extended atmosphere. Quantitative determination of its chemical composition then becomes possible. Inspection of a high-resolution spectrum of the star may reveal evidence of a strong magnetic field.

Production of spectral lines

Line spectrum. Spectral lines are produced by transitions of electrons within atoms or ions. As the electrons move closer to or farther from the nucleus of an atom (or of an ion), energy in the form of light (or other radiation) is emitted or absorbed. The yellow "D" lines of sodium or the "H" and "K" lines of ionized calcium are produced by discrete quantum jumps from the lowest energy levels (ground states) of these atoms. The visible hydrogen lines (the so-called Balmer series), however, are produced by electron transitions within atoms in the second energy level (or first excited state), which lies well above the ground level in energy. Only at high temperatures are sufficient numbers of atoms maintained in this state by collisions, radiations, and so forth to permit an appreciable number of absorptions to occur. At the low surface temperatures of a red dwarf star, few electrons populate the second level of hydrogen, and thus the hydrogen lines are dim. By contrast, at very high temperatures, for instance that of the surface of a blue giant star, the hydrogen atoms are nearly all ionized and therefore cannot absorb or emit any line radiation whatsoever. Consequently, only faint dark hydrogen lines are observed. The characteristic features of ionized metals such as iron are often weak in such hotter stars because the appropriate electron transitions involve higher energy levels that tend to be more sparsely populated than the lower levels. Another factor is that the general "fogginess," or opacity, of the atmospheres of these hotter stars is greatly increased, resulting in fewer atoms in the visible stellar layers capable of producing the observed lines.

The continuous (as distinct from the line) spectrum of the Sun is produced primarily by the photodissociation of negative hydrogen ions—*i.e.,* atoms of hydrogen to which an extra electron is loosely attached. In the Sun's atmosphere, when H^- is subsequently destroyed by photodissociation, it can absorb energy at any of a whole range of wavelengths and thus produce a continuous range of absorption of radiation. The main source of light absorption in the hotter stars is the photoionization of hydrogen atoms, both from ground level and from higher levels.

Spectral analysis. The physical processes behind the formation of stellar spectra are well enough understood to permit determinations of temperatures, densities, and chemical compositions of stellar atmospheres. The star studied most extensively is, of course, the Sun, but others also have been investigated in detail.

Factors that determine the spectral features of stars

The general characteristics of the spectra of stars depend more on temperature variations among the stars than on their chemical differences. Spectral features also depend on the density of the absorbing atmospheric matter, and density in turn is related to a star's surface gravity. Dwarf stars, with great surface gravities, tend to have high atmospheric densities; giants and supergiants, with low surface gravities, have relatively low densities. Hydrogen absorption lines provide a case in point. Normally, an undisturbed atom radiates a very narrow line. If its energy levels are perturbed by charged particles passing nearby, it radiates at a wavelength near its characteristic wavelength. In a hot gas, the range of disturbance of the hydrogen lines is very high, so that the spectral line radiated by the whole mass of gas is spread out considerably; the amount of blurring depends on the density of the gas in a known fashion. Dwarf stars such as Sirius show broad hydrogen features with extensive "wings" where the line fades slowly out into the background, while supergiant stars, with less dense atmospheres, display relatively narrow hydrogen lines.

Classification of spectral types. Most stars are grouped into a small number of spectral classes. The *Henry Draper Catalogue* lists spectral classes from the hottest to the coolest stars (see below *Photometric catalogs*). These types are designated, in order of decreasing temperature, by the letters O, B, A, F, G, K, and M. This group is supplemented by R- and N-type stars (today often referred to as carbon, or C-type, stars) and S-type stars. The R-, N-, and S-type stars differ from the others in chemical composition; also, they are invariably giant or supergiant stars.

The O–M spectral sequence

The spectral sequence O–M represents stars of essentially the same chemical composition but of different temperatures and atmospheric pressures. This simple interpretation, put forward in the 1920s by the Indian astrophysicist Meghnad N. Saha, has provided the physical basis for all subsequent interpretations of stellar spectra. The spectral sequence is also a colour sequence: the O- and B-type stars are intrinsically the bluest and hottest; the M-, R-, N-, and S-type stars are the reddest and coolest.

In the case of cool stars of type M, the spectra indicate the presence of familiar metals, including iron, calcium, magnesium, and also titanium oxide molecules (TiO), particularly in the red and green parts of the spectrum. In the somewhat hotter K-type stars, the TiO features disappear, and the spectrum exhibits a wealth of metallic lines. A few especially stable fragments of molecules such as cyanogen (CN) and the hydroxyl radical (OH) persist in these stars and even in G-type stars such as the Sun. The spectra of G-type stars are dominated by the characteristic lines of metals, particularly those of iron, calcium, sodium, magnesium, and titanium.

The behaviour of calcium illustrates the phenomenon of thermal ionization. At low temperatures a calcium atom retains all of its electrons and radiates a spectrum characteristic of the neutral, or normal, atom; at higher temperatures collisions between atoms and electrons and the absorption of radiation both tend to detach electrons and to produce singly ionized calcium atoms. At the same time, these ions can recombine with electrons to produce neutral calcium atoms. At high temperatures or low electron pressures, or both, most of the atoms are ionized. At low temperatures and high densities the equilibrium favours the neutral state. The concentrations of ions and neutral atoms can be computed from the temperature, the density, and the ionization potential (namely, the energy required to detach an electron from the atom).

The absorption line of neutral calcium at 4227 Å is thus strong in cool M-type dwarf stars, in which the pressure is high and the temperature is low. In the hotter G-type stars, however, the lines of ionized calcium at 3968 and 3933 Å (the "H" and "K" lines) become much stronger than any other feature in the spectrum.

In stars of spectral type F, the lines of neutral atoms are weak relative to those of ionized atoms. The hydrogen lines are stronger, attaining their maximum intensities in A-type stars, in which the surface temperature is about 9,000 K. Thereafter, these absorption lines gradually fade as the hydrogen becomes ionized.

The hot B-type stars, such as Epsilon Orionis, are characterized by lines of helium and of singly ionized oxygen, nitrogen, and neon. In very hot O-type stars, lines of ionized helium appear. Other prominent features include lines of doubly ionized nitrogen, oxygen, and carbon and of trebly ionized silicon, all of which require more energy to produce.

In the more modern system of spectral classification,

MK spectral classification system

called the MK system (after the American astronomers William W. Morgan and Philip C. Keenan who introduced it), luminosity class is assigned to the star along with the Draper spectral class. For example, Alpha Persei is classed as F5 Ia, which means that it falls about halfway between the beginning of type F (*i.e.*, F0) and of type G (*i.e.*, G0). The Ia suffix means that it is a particularly luminous supergiant. The star Pi Cephei, classed as G2 III, is a giant falling between G0 and K0 but much closer to G0. The Sun, a dwarf star of type G2, is classified as G2 V. A star of luminosity class II falls between giants and supergiants; one of class IV is called a subgiant.

BULK STELLAR PROPERTIES

Stellar temperatures. Temperatures of stars can be defined in a number of ways. From the character of the spectrum and the various degrees of ionization and excitation found from its analysis, an ionization or excitation temperature can be determined.

A comparison of the V and B magnitudes (see above) yields a colour index, $B-V$, which is related to the colour temperature of the star. The colour temperature is therefore a measure of the relative amounts of radiation in two more or less broad wavelength regions, while the ionization and excitation temperatures pertain to the temperatures of strata wherein spectral lines are formed.

Provided that the angular size of a star can be measured (see below *Stellar radii*) and that the total energy flux received at the Earth (corrected for atmospheric extinction) is known, the so-called brightness temperature can be found.

The effective temperature, T_{eff}, of a star is defined in terms of its total energy output and radius. Thus, since σT^4_{eff} is the rate of radiation per unit area for a perfectly radiating sphere and if L is the total radiation (*i.e.*, luminosity) of a star considered to be a sphere of radius R, such a sphere (called a blackbody) would emit a total amount of energy equal to its surface area, $4\pi R^2$, multiplied by its energy per unit area. In symbols, $L = 4\pi R^2 \sigma T^4_{eff}$. This relation defines the star's equivalent blackbody or effective temperature.

Since the total energy radiated by a star cannot be directly observed (except in the case of the Sun), the effective temperature is a derived quantity rather than an observed one. Yet, theoretically, it is the fundamental temperature. If the bolometric corrections are known, the effective temperature can be found for any star whose absolute visual magnitude and radius are known.

Stellar masses. Masses of stars can be found only from binary systems and only if the scale of the orbits of the stars around each other is known. Binary stars are divided into three categories, depending on the mode of observation employed: visual binaries, spectroscopic binaries, and eclipsing binaries.

Types of binary stars

Visual binaries. These can be seen as double stars with the telescope. True doubles, as distinguished from apparent doubles caused by line-of-sight effects, move through space together and display a common space motion. Sometimes a common orbital motion can be measured as well. Provided that the parallax, p, and therefore the distance are known, such systems permit a determination of stellar masses, m_1 and m_2, of the two members. The angular radius, a'', of the orbit (more accurately, its semimajor axis) can be measured directly, and, with the distance known, the true dimensions of the semimajor axis, a, can be found. The period, P, of the binary system follows directly. If, in astronomical units, $a = a''/p$, the sum of the masses, $m_1 + m_2$, is, by Kepler's third law, proportional to the cube of the mean distance, a, between them and inversely proportional to the square of the period expressed in years. In symbols, $(m_1 + m_2) = a^3/P^2$ in units of the Sun's mass. For example, for the binary system 70 Ophiuchi, $P = 87.8$ years, $p'' = 0.20''$, and $a'' = 4.55''$, so that $a = 22.8$ astronomical units (the average distance from the Earth to the Sun, approximately 149,597,870 kilometres), and $m_1 + m_2 = 1.56$ solar masses. From a measurement of the motions of the two members relative to the background stars, the orbit of each star has been determined with respect to their common centre of gravity. The mass ratio, $m_2/(m_1 + m_2)$, is 0.42; the individual masses are then 0.90 and 0.66 solar mass.

The star known as 61 Cygni was the first whose distance was measured (via parallax by the German astronomer Friedrich W. Bessel in the mid-19th century) and the first stellar system found to contain a potential planet. Visually, it is a double star separated by 83.2 astronomical units. Its members move around one another with a period of 653 years. The brighter member also seems to have an invisible companion with a mass of about 1 percent that of the Sun; this possible planet (for it would seem too small to ignite nuclear burning on its own) moves about its parent star at a distance of 4,200,000 kilometres, with a period of about 4.8 years.

Though there is currently no clear evidence for Earth-like planets orbiting any other star, minute positional changes in the path of Barnard's star (an M-type dwarf at a distance of some six light-years) do suggest that at least two unseen objects, each having about the mass of Jupiter, accompany it. Careful examination of the motions of a few other stars that are both close to the Sun and of low mass display similar wobbles, but their interpretation is unambiguous. In each case, the wobble could conceivably be caused by a small and dim companion star.

In 1983 an Earth-orbiting infrared satellite observed several nearby stars (including Vega and Fomalhout) around which warm matter was discovered to be spinning in an optically unseen disk. This matter is composed of myriad dust particles mostly a millimetre in size and might be taking part in the first stage of planetary formation. There is now no way, however, to ascertain whether the particles are primordial matter that could develop into planets or are just unpromising bits of interplanetary litter.

Spectroscopic binaries. This type of two-body stellar system is found from radial-velocity observations. At least one member of such a binary has a continuously changing periodic velocity that alters the wavelengths of its spectral lines in a rhythmic way; the velocity curve repeats itself exactly from one cycle to the next, and the motion can be interpreted as orbital motion. In a few cases, rhythmic changes in the lines of both members can be measured. Unlike the case of the visual binaries, the semimajor axes or the individual masses cannot be found for most spectroscopic binaries, since the angle between the orbit plane and the plane of the sky cannot be determined. If spectra from both members are observed, mass ratios can be found. If one spectrum alone is observed, only a quantity called the mass function can be derived, from which is calculated a lower limit to the stellar masses. If a spectroscopic binary is also observed to be an eclipsing system, the inclination of the orbit and often the values of the individual masses can be ascertained.

Rhythmic alteration of wavelengths

Eclipsing binaries. This third category of binaries consists of two close stars moving in an orbit so placed in space in relation to the Earth that the light of one can at times be hidden behind the other. Depending on the orientation of the orbit and sizes of the stars, the eclipses can be total or annular (a ring of one star shows behind the other at the climax of the eclipse) or both eclipses can be partial. The best known example of an eclipsing binary is Algol (Beta Persei), which has a period (interval between eclipses) of 2.9 days. The brighter (B8-type) star contributes about 92 percent of the light of the system, and the eclipsed star provides much less than 8 percent. The system contains a third star that is not eclipsed. Some 20 eclipsing binaries are visible to the naked eye.

Light-curve data

The light curve for an eclipsing binary displays magnitude measurements for the system over a complete light cycle. The light of the variable star is usually compared with that of a nearby (comparison) star thought to be fixed in brightness. Often, a deep, or primary, minimum is produced when a star of higher surface brightness is eclipsed. It represents the total eclipse and is characterized by a flat bottom. A shallower secondary eclipse occurs when the star of higher surface brightness passes in front of the other; it corresponds to an annular eclipse (or transit). In a partial eclipse neither star is ever completely hidden, and the light changes continuously during an eclipse.

The shape of the light curve during an eclipse gives the

ratio of the radii of the two stars and also one radius in terms of the size of the orbit, the ratio of luminosities, and the inclination of the orbital plane to the plane of the sky.

If radial-velocity curves are also available—*i.e.,* if the binary is spectroscopic as well as eclipsing—additional information can be obtained. When both velocity curves are observable, the size of the orbit as well as the sizes, masses, and densities of the stars can be calculated. Furthermore, if the parallax of the system is measurable, the brightness temperatures of the individual stars can be estimated from their luminosities and radii. All of these procedures have been carried out for the faint binary Castor C and for the bright B-type star Mu Scorpii.

Close stars may reflect each other's light noticeably. If a small, high-temperature star is paired with a larger object of low surface brightness and if the distance between the stars is small, the part of the cool star facing the hotter one is substantially brightened by it. Just before (and just after) secondary eclipse, this illuminated hemisphere is pointed toward the observer, and the total light of the system is at a maximum.

The properties of stars derived from eclipsing binary systems are not necessarily applicable to isolated single stars. Systems in which a smaller, hotter star is accompanied by a larger, cooler object are easier to detect than are systems that contain, for example, two main-sequence stars (see below *Hertzsprung–Russell diagram*). In such an unequal system, at least the cooler star has certainly been affected by evolutionary changes and probably so has the brighter one. The evolutionary development of two stars near one another does not exactly parallel that of two well-separated or isolated ones.

Components of eclipsing binaries

Eclipsing binaries include combinations of a variety of stars ranging from white dwarfs to huge supergiants (*e.g.,* VV Cephei), which would engulf Jupiter and all the inner planets of the solar system if placed at the position of the Sun.

Some members of eclipsing binaries are intrinsic variables (see below *Variable stars*). In many such systems, large clouds of ionized gas swirl between the stellar members. In others, such as Castor C, the faint M-type dwarf component might be a flare star, one in which the brightness can unpredictably and suddenly increase to many times its normal value (see below *Peculiar variables*).

The mass of most stars lies within the range of 0.3 to three solar masses. The most massive star determined to date is the O3-type star, HD 93250; this giant contains some 120 solar masses. Though there seems to be no theoretical upper limit on the masses of stars, the physics of instability and fragmentation probably prohibit the formation of stars much more than a couple of orders of magnitude greater than the Sun. On the low mass side, most stars seem to have at least 0.1 solar mass, though, again theoretically, smaller stars could exist. This absolute lower mass limit for a star is about 0.07 solar mass, for below this value an object cannot shine by nuclear energy and simply cools down directly as a black dwarf or even a planet. Jupiter is just such an object. Having 0.001 solar mass, this huge planet was unable to accumulate enough mass to become a star.

Binaries and possible planetary systems. Near the Sun, most stars are members of binaries, and some of the nearest single stars are suspected of having companions. Although some binary members are separated by hundreds of astronomical units while others are contact binaries, binary systems are most frequently built on the same scale as that of the solar system—namely, on the order of 10 astronomical units. The division in mass between two components of a binary seems to be nearly random. A mass ratio of about 1:20 could occur about 5 percent of the time, and under these circumstances a planetary system comparable to the solar system might form.

The formation of double and multiple stars on the one hand and that of planetary systems on the other seem to be different facets of the same process. Planets can presumably be produced as a natural by-product of star formation. Only a small fraction of the original nebula matter is likely to be retained in planets, since much of the mass and angular momentum are swept out of the system. Conceivably, as many as 100,000,000 stars could have bona fide planets in the Milky Way Galaxy.

Stellar radii. Angular sizes of bright red giant and supergiant stars were first measured directly during the 1920s using the principle of interference of light. Only bright stars with large angular size can be measured by this method. Provided the distance to the star is known, the physical radius can be determined.

Eclipsing binaries also provide extensive data on stellar dimensions. The time of eclipse provides the angular size of any occulting object, and so analyzing the light curves of eclipsing binaries can be a useful means of determining the dimensions of either dwarf or giant stars. Members of close binary systems, however, are sometimes subject to evolutionary effects, mass exchange, and other disturbances that change the details of their spectra.

Speckle interferometry

A more recent method, called speckle interferometry, has been developed to reproduce the true disks of red supergiant stars and to resolve spectroscopic binaries such as Capella. The speckle phenomenon is a rapidly changing interference-diffraction effect seen in a highly magnified diffraction image of a star observed with a large telescope.

If the absolute magnitude of a star and its temperature are known, its size can be computed. The temperature determines the rate at which energy is emitted by each unit of area, and the total luminosity gives the total power output. Thus, the surface area of the star and, from it, the radius of the object can be estimated. This is the only way available for estimating the dimensions of white-dwarf stars. The chief uncertainty lies in choosing the temperature that represents the rate of energy emission.

Average stellar values. Table 3 lists surface temperatures, bolometric or total luminosities, and radii in terms of corresponding solar values for main-sequence stars (see below) ranging from very luminous objects to faint M-type dwarf stars. A considerable range exists for each of these quantities. For a given mass (*M,* the fundamental factor), a fair spread in radius (*R*), luminosity (*L*), surface temperature, and spectral class may exist. This spread is produced by stellar evolutionary effects and tends to broaden the main sequence. Masses are obtained from visual and eclipsing binary systems observed spectroscopically. Radii are found from eclipsing binary systems, from direct mea-

Meaningful average values of R, L, and M can be given only for dwarf stars. Giant and subgiant stars all show large ranges in R for a given mass. Conversely, giant stars of very nearly the same radius, surface temperature, and luminosity can have appreciably different masses.

STELLAR STATISTICS

Some of the most important generalizations concerning the nature and evolution of stars can be derived from correlations between observable properties and from certain statistical results. One of the most important of these correlations concerns temperature and luminosity (or, equivalently, colour and magnitude)..

Hertzsprung–Russell diagram. When the absolute magnitudes of stars (or their intrinsic luminosities on a logarithmic scale) are plotted in a diagram against temperature or, what is equivalent, the spectral types, the stars do not fall at random on the diagram but tend to congregate in certain restricted domains. Figure 1 shows such a plot, usually called a Hertzsprung–Russell diagram for Ejnar Hertzsprung of Denmark and Henry Norris Russell of the United States, who independently discovered the relations shown in it. As illustrated, most of the congregated stars are dwarfs lying closely around a diagonal line called the main sequence. These stars range from hot, O- and B-type, blue objects 10,000 times (or more) brighter than the Sun, down through white A-type stars such as Sirius to orange K-type stars such as Epsilon Eridani, and finally to M-type red dwarfs thousands of times fainter than the Sun. The sequence is continuous, the luminosities fall off smoothly with decreasing surface temperature, the masses and radii decrease but at a much slower rate, and the stellar densities gradually increase.

The main sequence

The second group of stars to be recognized was a group of giants—such objects as Capella, Arcturus, and Aldebaran—which are yellow, orange, or red stars about 100 times as bright as the Sun and have radii on the order of 20,000,000 to 30,000,000 kilometres (or 10 to 20 times as large as the Sun). The giants lie above the main sequence in the upper right portion of the diagram. The category of supergiants includes stars of all spectral classes; they show a large spread in intrinsic brightness, and some even approach absolute magnitudes of −7 or −8. A few red supergiants, such as the variable star VV Cephei, exceed in size the orbit of Jupiter or even that of Saturn, although most of them are smaller. Supergiants are short-lived and rare objects, but they can be seen at great distances because of their tremendous luminosity.

Subgiants are stars that are redder and larger than main-sequence stars of the same luminosity. Many of the best known examples are found in close binary systems where conditions favour their detection.

The white-dwarf domain lies about 10 magnitudes below the main sequence. These stars are in the last stages of their evolution (see below *End states of stars*).

The spectrum–luminosity diagram has numerous gaps. Few stars exist above the white dwarfs and to the left of the main sequence. The giants are separated from the main sequence by a gap named for Hertzsprung, who in 1911 became the first to recognize the difference between main-sequence and giant stars. The actual concentration of stars differs considerably in different parts of the diagram. Highly luminous stars are rare, whereas those of low luminosity are very numerous.

Figure 1 applies to the stars in the galactic spiral arm in the neighbourhood of the Sun and represents what would be obtained if a composite Hertzsprung–Russell diagram were constructed combining data for a large number of the star groups called open (or galactic) clusters, as, for example, the double cluster h and χ Persei, the Pleiades, the Coma cluster, and the Hyades (see below *Star clusters*). It includes very young stars, a few million years old, as well as ancient stars perhaps as old as 10,000,000,000 years.

By contrast, Figure 2 exhibits the type of temperature–luminosity (or colour–magnitude) relation characteristic of globular clusters, the central bulge of the Galaxy, and elliptical external galaxies—namely, of the so-called stellar

Population II. (In addition to these oldest objects, Population II includes other very old stars that occur between the spiral arms of the Galaxy and at some distance above and below the galactic plane.) Because these systems are very remote from the observer, the stars are faint, and their spectra can be observed only with difficulty. As a consequence, their colours rather than spectra must be measured. Since the colours are closely related to surface temperature and therefore to spectral classes, equivalent spectral classes may be used; but it is stellar colours, not spectral classes, that are observed in this instance.

Population II stars

The difference between the two Hertzsprung–Russell diagrams in Figures 1 and 2 is striking. In Figure 2 there are no supergiants, and, instead of occurring at $M_v = 0$, the giant branch starts at around −3.5 for very red stars and forms a continuous sequence until an absolute magnitude of about 0 is reached. Then there is a band of stars, all about the same colour, that proceeds downward (*i.e.*, to fainter stars) to about $M_v = +3$. The giant branch is connected to the main sequence at about +4 by a narrow band. The main sequence extends to fainter, redder stars in much the same way as in the spiral-arm Population I objects. (Population I is the name given to the stars found within the spiral arms of the Milky Way system and other galaxies of the same type. Containing stars of all ages, from those in the process of formation to defunct white dwarfs, Population I stars are, nonetheless, always associated with the gas and dust of the interstellar medium.) The main

sequence ends just above the Sun (at about spectral class G), however, and does not extend up through the A, B, and O spectral classes, though occasionally a few such stars are found in the region normally occupied by the main sequence.

The "horizontal branch" falls near magnitude +0.6 and fills the aforementioned Hertzsprung gap, extending to increasingly blue stars beyond the RR Lyrae stars (see below *Variable stars*), which are indicated by the crosshatched area. Among these blue hot stars are found novas and the nuclei of planetary nebulas, the latter so called because their photographic image resembles that of a distant planet. Not all globular clusters show identical colour–magnitude diagrams, which may be due to differences in the cluster ages.

Estimates of stellar ages. The shapes of the colour–magnitude diagrams permit estimates of globular-cluster ages. Stars more massive than about 1.3 solar masses have evolved away from the main sequence at a point just above the position occupied by the Sun. The time required for such a star to exhaust the hydrogen in its core is about 5,000,000,000 to 6,000,000,000 years, and the cluster must be at least as old. More ancient clusters have been identified. In the Galaxy, globular clusters are all very ancient objects, with ages measured in billions of years. In the Magellanic Clouds, there exist globular clusters such as NGC 1866 that contain numerous blue stars and therefore must be relatively young. Exact ages, however, cannot yet be assigned to globular clusters. The details of the evolutionary tracks depend on hydrogen–metal ratios, helium–hydrogen ratios, and the precise theory of stellar evolution.

Open clusters in the spiral arms of the Galaxy—extreme Population I—tell a somewhat different story. Figure 3 shows a colour–magnitude diagram for several different open clusters, the main feature distinguishing these clusters being their ages. The youngest cluster, the pair *h* and χ Persei, which is a few million years old, contains stars ranging widely in luminosity. Some stars have already evolved into the supergiant stage, so that the top of the main sequence is bent over. The stars of luminosity 10,000 times greater than that of the Sun have already largely depleted the hydrogen in their cores and are leaving the main sequence.

The brightest stars of the Pleiades have begun to leave the main sequence and are approaching the critical phase when they will have exhausted all the hydrogen in their cores. There are no giants in the Pleiades. Presumably, the cluster contained no stars as massive as some of those found in *h* and χ Persei.

The Beehive, or Praesepe, cluster is older than the Pleiades. All stars much more luminous than the first magnitude have begun to leave the main sequence; there are some giants. The Hyades, about 1,000,000,000 years old, displays a similar colour–magnitude array. These clusters contain a number of white dwarfs, indicating that the initially most luminous stars have already run the gamut of evolution. Finally, M67 must be the oldest cluster of all; the best data of stellar structure indicate that it is many billions of years old. All of the bright main-sequence stars have disappeared.

The colour–magnitude diagrams for globular and open clusters differ quantitatively because the latter show a wider range of ages and differ in chemical composition. Most globular clusters have smaller metal–hydrogen ratios than do open clusters or the Sun. The gaps between the giants and main-sequence stars of the open clusters (Population I) often contain unstable stars such as variables. The Cepheid stars, for instance, fall in these gaps (see below *Variable stars* and *Star clusters*).

The giant stars of the Praesepe cluster are comparable to the brightest stars in M67. The M67 giants have evolved from the main sequence near absolute magnitude +3.5, whereas the Praesepe giants must have masses about twice as great as those of the M67 giants. Giant stars of the same luminosity may therefore have appreciably different masses.

Numbers of stars versus luminosity. Of great statistical interest is the relationship between the luminosities of the stars and their frequency of occurrence. The naked-eye stars are nearly all intrinsically brighter than the Sun, but the opposite is true for the known stars within 20 light-years of the Sun. The bright stars are easily seen at great distances; the faint ones can be detected only if they are close. Only if stars of magnitude +11 were 1,000,000,000 times more abundant than stars of magnitude −4 could they be observed to some fixed limit of apparent brightness. Table 4 lists the relation between the number of stars and their luminosities in the neighbourhood of the Sun. For a sphere of radius 10 parsecs, about seven stars between the fourth and fifth magnitude, 30 stars between the 10th and 11th, and 67 stars between the 14th and 15th could be expected in such a volume. There would be less than one chance in 1,000 of finding a star brighter than magnitude −5. The luminosity function has a maximum near magnitude 15.5.

Luminosity function and population type

The luminosity function depends on population type. The luminosity function for pure Population II differs substantially from that for pure Population I. There is a small peak near absolute magnitude +0.6, corresponding to the horizontal branch for Population II, and no stars as bright as absolute magnitude −5. The luminosity function for pure Population I is evaluated best from open star clusters, the stars in such a cluster being at about the same distance. The neighbourhood of the Sun includes examples of both Populations I and II.

Mass–luminosity correlations. A plot of mass against bolometric luminosity for visual binaries for which good parallaxes and masses are available shows that for stars with masses comparable to that of the Sun the luminosity,

L, varies as a power, $3+\beta$, of the mass M. This relation can be expressed as $L=(M)^{3+\beta}$. The power differs for substantially fainter or much brighter stars (see Table 3).

This mass–luminosity correlation applies only to unevolved main-sequence stars. It fails for giants and supergiants and for the subgiant (dimmer) components of eclipsing binaries, all of which have changed considerably during their lifetimes. It does not apply to any stars in a globular cluster not on the main sequence, or to white dwarfs that are abnormally faint for their masses.

The mass–luminosity correlation, predicted theoretically in the early 20th century by the English astronomer Arthur Eddington, is a general relationship that holds for all stars having essentially the same internal density and temperature distributions—*i.e.,* for what are termed the same stellar models.

VARIABLE STARS

Intrinsic variables

Many stars are variable. Some are geometric variables, as in the eclipsing binaries considered earlier. Others are intrinsically variable—*i.e.,* their total energy output fluctuates with time. Such intrinsic variable stars are dealt with in this section.

A fair number of stars are intrinsically variable. Some objects of this type were found by accident, but many were detected as a result of carefully planned searches. Variable stars are important in astronomy for several reasons. They usually appear to be stars at critical or short-lived phases of their evolution; detailed studies of their light and spectral characteristics, spatial distribution, and association with other types of stars may provide valuable clues to the life histories of various classes of stars. Certain kinds of variable stars, such as Cepheids (periodic variables) and novas (explosive variables), are extremely important in that they make it possible to establish the distances of remote stellar systems beyond the Galaxy, as, for example, the Magellanic Clouds and some of the nearer external galaxies. If the intrinsic luminosity of a recognizable variable is known and this kind of variable star can be found in a distant stellar system, the distance of the latter can be estimated from a measurement of apparent and absolute magnitudes, provided the interstellar absorption is also known.

Classification. Variables are often classified as behaving like a prototype star, and the entire class is then named for this star; *e.g.,* RR Lyrae stars are those whose variability follows the pattern of the star RR Lyrae. The most important classes of intrinsically variable stars are the following:

Major types

(1) Pulsating variables—*i.e.,* stars whose variations in light and colour are thought to arise primarily from stellar pulsations. These include Cepheids, RR Lyrae stars, and Delta Scuti stars, all with short regular periods up to a few days; long-period variables; semi-regular variables; irregular red variables; and Beta Canis Majoris stars.

(2) Explosive, or catastrophic, variables—in which the variations are produced by the wrenching away of part of the star, usually the outer layers, in some explosive process. They include SS Cygni or U Geminorum stars; novas; and supernovas (which are usually regarded as representing an enormous explosion involving most of the matter in a star [see below *Later stages of evolution*]).

(3) Miscellaneous and special types of variables—R Coronae Borealis stars; T Tauri stars; flare stars; pulsars (neutron stars); spectrum and magnetic variables; X-ray variable stars; and radio variable stars.

Pulsating stars. An impressive body of evidence indicates that stellar pulsations can account for the variability of Cepheids, long-period variables, semi-regular variables, Beta Canis Majoris stars, and even the irregular red variables. Of this group, the Cepheids have been studied in greatest detail, both theoretically and observationally. These stars are regular in their behaviour; some repeat their light curves with great faithfulness from one cycle to the next over periods of many years.

Much confusion existed in the study of Cepheids until it was recognized that different types of Cepheids are associated with different groups, or population types, of stars.

Classic Cepheids

Cepheids, belonging to the spiral-arm Population I, are characterized by regularity in their behaviour. They show continuous velocity curves indicative of regular pulsation. They exhibit a relation between period and luminosity in the sense that the longer the period of the star, the greater is its intrinsic brightness. This period–luminosity relationship has been used to establish the distances of remote stellar systems.

Cepheids with different properties are found in Population II, away from the Milky Way, in globular clusters. They are bluer than classic Population I Cepheids of the same period, and their light curves have different shapes. Studies of the light and velocity curves indicate that shells of gas are ejected from the stars as discontinuous layers that later fall back toward the surface. These stars exhibit no well-defined relation between period and luminosity; consequently, they are worthless as distance indicators. The distance of a Cepheid in a remote stellar system can be determined only if it is known to be a classic Cepheid.

RR Lyrae stars

Closely associated with Population II Cepheids are the cluster-type, or RR Lyrae, variables. Many of these stars are found in clusters, but some, such as the prototype RR Lyrae, occur far from any cluster or the central galactic bulge. The periods are less than a day, and there is no correlation between period and luminosity. Their absolute magnitudes are about 0.6; *i.e.,* they are about 50 times as bright as the Sun. They are useful for determining the distance of star clusters and some of the nearer external galaxies because their short periods permit them to be detected readily.

Long-period variables also probably owe their variations to pulsations. Here, the situation is complicated by the vast extent of their atmospheres, so that radiation originating at very different depths in the star is observed at the same time. At certain phases of the variations, bright hydrogen lines are observed, overlaid with titanium oxide absorption. The explanation is an outward-moving layer of hot, recombining gas, whose radiation is absorbed by strata of cool gases. These stars are all cool red giants and supergiants of spectral classes M (normal composition), R and N (carbon rich), or S (heavy-metal rich). The range in visual brightness during a pulsation can be a hundredfold, but the range in total energy output is much less, because at very low stellar temperatures (1,500–3,000 K) most of the energy is radiated in the infrared as heat rather than as light.

Unlike the light curves of classic Cepheids, the light curves of these red variables show considerable variations from one cycle to another. The visual magnitude of Mira Ceti (Omicron Ceti) is normally about nine to 9.5 at minimum light, but at maximum it may lie between five and two. Time intervals between maxima often vary considerably. In such cool objects, a very small change in temperature can produce a huge change in the output of visible radiation. At the low temperatures of the red variables, compounds and probably solid particles are formed copiously, so that the visible light may be profoundly affected by a slight change in physical conditions. Random fluctuations from cycle to cycle, which would produce negligible effects in a hotter star, produce marked light changes in a long-period variable.

Long-period variables appear to fall into two groups: (1) those with periods of roughly 200 days tend to be associated with Population II; (2) those of periods of about a year belong to Population I.

Red semi-regular variables such as the RV Tauri stars show complex light and spectral changes. They do not repeat themselves from one cycle to the next; their behaviour suggests a simultaneous operation of two or more modes of oscillation. Betelgeuse is an example of an irregular red variable. In these stars the free period of oscillation does not coincide with the periodicity of the driving mechanism.

Finally, among the various types of pulsating variable stars, the Beta Canis Majoris variables are high-temperature stars (spectral class B) that often show complicated variations in spectral-line shapes and intensities, velocity curves, and light. In many cases, they have two periods of variation so similar in duration that complex interference or beat phenomena are observed, both in radial velocities and in the shapes of spectral lines.

A large body of evidence suggests that all members of this first class of variable stars owe their variability to pulsation. The pulsation theory was first proposed as a possible explanation as early as 1879, was applied to Cepheids in 1914, and was further developed by Eddington in 1917–18. Eddington found that if stars have roughly the same kind of internal structure, then the period multiplied by the square root of the density equals a constant that depends on the internal structure.

Pulsation theory

The Eddington theory, though a good approximation, encountered some severe difficulties that have been met through modifications. If the entire star pulsated in synchronism, it should be brightest when compressed and smaller while faintest when expanded and at its largest. The velocity should become zeroed at both maximum and minimum light. Observations contradict these predictions. When the star pulsates, all parts of the main body move in synchronism, but the outer observable strata fall out of step or lag behind the pulsation of the inner regions. Running waves are set up within the outer regions (envelope) of the star. Pulsations involve only the outer part of a star; the core, where energy is generated by thermonuclear reactions, is unaffected.

Many years ago, careful measurements of the average magnitudes and colours of RR Lyrae stars in globular cluster M3 showed that all these stars fell within a narrow range of luminosity and colour (or surface temperature) or, what amounts to the same thing, luminosity and radius. Also, every star falling in this narrow range of brightness and size was an RR Lyrae variable. Subsequent work has indicated that similar considerations apply to classic Cepheids. Variability is thus a characteristic of any star whose evolution carries it to a certain size and luminosity.

In the pulsation theory as now developed, the light and velocity changes of Cepheids can be interpreted not only qualitatively but also quantitatively. The complex light curves of Population II Cepheids, for example, have been precisely predicted by the theory. Stellar pulsation, like other rhythmic actions, may give rise to harmonic phenomena wherein beats reinforce or interfere with one another. Beat and interference phenomena then complicate the light and velocity changes. The RR Lyrae stars supply some of the best examples, but semi-regular variables such as the RV Tauri stars, "dwarf" Cepheids such as Delta Scuti, or SX Phoenicis evidently vibrate simultaneously with two or more periods.

Explosive variables. The evolution of a member of a close double-star system can be markedly affected by the presence of its companion. As the stars age, the more massive one swells up more quickly as it moves away from the main sequence. It becomes so large that its outer envelope falls under the gravitational influence of the smaller star. Matter is continuously fed from the more rapidly evolving star to the less massive one, which still remains on the main sequence. U Cephei is a classic example of such a system for which spectroscopic evidence shows streams of gas flowing from the more highly evolved star to the hotter companion, which is now the more massive of the two. Eventually, the latter will also leave the main sequence and become a giant star, only to lose its outer envelope to the companion, which by that time may have reached the white-dwarf stage.

Novas and supernovas

Novas appear to be binary stars that have evolved from contact binaries of the W Ursae Majoris type. One member may have reached the white-dwarf stage. Matter fed to it from its distended companion appears to produce instabilities that result in violent explosions or nova outbursts. The time interval between outbursts can range from a few score years to hundreds of thousands of years.

In ordinary novas the explosion seems to involve only the outer layers, as the star later returns to its former brightness; in supernovas the explosion is catastrophic. Normally, novas are small blue stars much fainter than the Sun, though very much hotter. When an outburst occurs, the star can brighten very rapidly, 10 magnitudes or more in a few hours. Thereafter it fades; the rate of fading is connected with the brightness of the nova. The brightest novas, which reach absolute magnitudes of about −8, fade most rapidly, whereas a typical slow nova, which reaches an absolute magnitude of −5, can take 10 times as long to decline in brightness. The changes in light are accompanied by pronounced spectroscopic changes that can be interpreted as arising from alterations in an ejected shell that dissipates slowly in space. In its earliest phases, the expanding shell is opaque. As its area grows, with a surface temperature near 7,000 K, the nova brightens rapidly. Then, near maximum light, the shell becomes transparent, and its total brightness plummets rapidly, causing the nova to dim.

The mass of the shell is thought to be rather small, comparable with the mass of the Earth. Only the outer layers of the star seem to be affected; the main mass settles down after the outburst into a state much as before until a new outburst occurs. The existence of repeating novas, such as the star T Coronae Borealis, suggests that perhaps all novas repeat at intervals ranging up to thousands or perhaps millions of years; and probably, the larger the explosion, the longer the interval. There is strong evidence that novas are components of close double stars and, in particular, that they have evolved from the most common kind of eclipsing binaries, those of the W Ursae Majoris type, which are pairs of stars apparently similar to the Sun in size but revolving around one another while almost touching.

Stars of the SS Cygni type undergo novalike outbursts but of a much smaller amplitude. The intervals between outbursts are a few months to a year. Such variables are close binaries. The development of this particular type may be possible only in close binary systems.

Eta Carinae

A peculiar object with no known counterpart is Eta Carinae, which appears in the telescope as a fuzzy red "star" slightly less than two arc seconds in diameter. Surrounding it is a roughly elliptical nonuniform shell or halo about 10 arc seconds in diameter. First observed as a star of about the fourth magnitude in 1677, it brightened irregularly, undergoing an outburst in 1843. Unlike an ordinary nova or supernova, it remained bright for several years, fading out of sight to the naked eye about a century ago. Since then, it has shown irregular variations around the seventh magnitude. The first spectrum obtained of the object resembled that of a somewhat abnormal supergiant, but it now shows very complex emission-line structures dominated by radiations of ionized iron. If a star was present, it may have been blown to bits. Eta Carinae was brighter than normal novas, yet it resembles no known supernova; the star proper (excepting its corona) does not appear to be a source of X rays or non-thermal radio-frequency emission.

Probably all variable stars represent more or less ephemeral phases in the evolution of a star. Aside from catastrophic events of the kind that produce a supernova, some phases of stellar variability might be of such brief duration as to permit recognizable changes during an interval of 50 to 100 years. Other stages may require many thousands of years. The period of Delta Cephei, for example, has not changed by a detectable amount since its variability was discovered.

Peculiar variables. R Coronae Borealis variables are giant stars of about the Sun's temperature whose atmospheres are characterized by excessive quantities of carbon. The brightness of such a star remains constant until the star suddenly dims by several magnitudes and then slowly recovers its original brightness. (The star's colour remains the same during the changes in brightness.) The dimmings occur in a random fashion and seem to be due to the huge concentrations of carbon. At times the carbon vapour literally condenses into soot, and the star is hidden until the smog blanket is evaporated. Similar veiling may sometimes occur in other types of low-temperature stars, particularly in long-period variables.

Flare stars

Flare stars are cool dwarfs (spectral class M) that display flares apparently very much like, but much more intense than, those of the Sun. In fact, the flares are sometimes so bright that they overwhelm the normal light of the star. Solar flares are associated with copious emission of radio waves, and simultaneous optical and radio events appear to have been found in UV Ceti, YZ Canis Minoris, and V371 Orionis.

Spectrum and magnetic variables, mostly of spectral class A, show only small amplitudes of light variation but often pronounced spectroscopic changes. Their spectra typically show strong lines of metals such as manganese, titanium, iron, chromium, and the lanthanides (also called rare earths), which vary periodically in intensity. These stars have strong magnetic fields, typically from a few hundred to a few thousand gauss; one star, HD 215441, has a field on the order of 30,000 gauss. Not all magnetic stars are known to be variable in light; these objects also seem to have variable magnetic fields. The best interpretation is that these stars are rotating about an inclined axis. As with the Earth, the magnetic and rotation axes do not coincide. Different ions are concentrated in different areas (*e.g.*, chromium in one area and the lanthanides in another).

The Sun is an emitter of radio waves, but with present techniques it could not be detected—even in its most active phases—at a distance greater than that of the nearest star, about four light-years away. Most discrete radio-frequency sources have turned out to be objects like old supernovas, radio galaxies, and quasars, though well-recognized radio stars also have been recorded on occasion. These probably include flare stars, possibly red supergiants such as Alpha Orionis, the high-temperature dwarf companion to the red supergiant Antares, and the shells ejected from Nova Serpentis 1970 and Nova Delphini. The radio emission from the latter objects is consistent with that expected from an expanding shell of ionized gas that fades away as the gas becomes attenuated. The central star of the Crab Nebula has been detected as a radio (and optical) pulsar.

Measurements from rockets, balloons, and satellites have revealed distinct X-ray sources outside the solar system. The strongest galactic source, Scorpius X-1, appears to be associated with a hot variable star resembling an old nova. Three radio sources have been observed near the X-ray star. One coincides with the star, which shows rapid irregular time variations, as do the optical and radio sources. The other two radio sources lie on opposite sides of the X-ray source and are constant in brightness. X-ray stars may be massive objects near the end of their evolution and may be closely related to pulsars.

Globular clusters are a notable source of cosmic X rays. Some of this X-ray emission appears as intense fluctuations of radiation lasting only a few seconds but changing in strength by as much as 25 times. These X-ray sources have become known as bursters, and several such objects have been discovered outside of globular clusters as well. Some bursters vary on a regular basis, while others seem to turn on and off randomly. The most popular interpretation holds that bursters are the result of binary systems in which one of the objects—a compact neutron star or black hole (see below *End states of stars*)—pulls matter from the companion, a normal star. This matter is violently heated in the process, giving rise to X rays. That the emission is often in the form of a burst is probably caused by something interrupting the flow of matter onto (or into) the compact object or by an eclipsing orbit of the binary system.

STELLAR ATMOSPHERES

To interpret a stellar spectrum quantitatively, knowledge of the variation in temperature and density with depth in the star's atmosphere is needed. Some general theoretical principles are outlined here.

The gradient of temperature in a star's atmosphere depends on the method of energy transport to the surface. One way to move energy from the interior of a star to its surface is via radiation; photons produced in the core are repeatedly absorbed and reemitted by stellar atoms, gradually propagating to the surface. A second way is via convection, which is a non-radiative mechanism involving a physical upwelling of matter much as in a pot of boiling water. For the Sun, at least, a discriminant is possible.

High-speed photographs of the Sun's disk show that the centre of the disk is brighter than the limb. The difference in brightness depends on the wavelength of the radiation detected; it is large in violet light, small in red light, and nearly vanishes when the Sun is imaged in infrared radiation. This limb darkening arises because the Sun becomes hotter toward its core. At the centre of the disk, radiation is received from deeper and hotter layers (on average) instead of from the limb, and the dependence of temperature on depth can be shown to correspond to the transport of energy by radiation, not by convection, at least in the outer layers of the Sun's atmosphere.

Limb darkening

The amount of limb darkening in any star depends on the effective temperature of the star and on the variation in temperature with depth. Limb darkening is occasionally an important factor in the analysis of stellar observations. For example, it must be taken into account to interpret properly the observed light curves of eclipsing binaries, and here again the results suggest transport of energy via radiation.

The layers of a normal star are assumed to be in mechanical, or "hydrostatic," equilibrium. This means that at each point in the atmosphere, the pressure supports the weight of the overlying layers. In this way, a relation between pressure and density can be found for any given depth.

In addition to the temperature and density gradients, the chemical composition of the atmospheric layers as well as the absorptivity, or opacity, of the material must be known. In the Sun the principal source of opacity is the negative hydrogen ion (H^-), a hydrogen atom with one extra electron loosely bound to it. In the atmospheres of many stars, the extra electrons break loose and recombine with other ions, thereby causing a reemission of energy in the form of light. At visible wavelengths the main contribution to the opacity comes from the destruction of this ion by interaction with a photon (the above-cited process termed photodissociation). In hotter stars, such as Sirius A (temperature = 10,000 K), atomic hydrogen is the main source of opacity, whereas in cooler stars much of the outgoing energy is often absorbed by molecular bands of titanium oxide, water vapour, and carbon monoxide. Additional sources of opacity are absorption by helium atoms and electron scattering in hotter stars, absorption by hydrogen molecules and molecular ions, absorption by certain abundant metals such as magnesium, and Rayleigh scattering (a type of wavelength-dependent scattering of radiation by particles named for the British physicist Lord Rayleigh) in cool supergiant stars.

Opacity of a star's atmospheric layers

At considerable depths in the Sun and similar stars, convection sets in. Though most models of stellar atmospheres (particularly the outer layers) assume plane-parallel stratified layers, photographs of the solar granulation belie this simple picture. Realistic models must allow for rising columns of heated gases in some areas and descent of cooler gases in others. The motions of the radiating gases are especially important when the model is to be used to calculate the anticipated line spectrum of the star. Typical velocities are on the order of two kilometres per second in the Sun; in other stars they can be much larger.

Temperature, density, and pressure all increase steadily inward in the Sun's atmosphere. The Sun has no distinct solid surface, so the point from which the depth or height is measured is arbitrary. The temperature of the visible layers ranges from 4,700 to 6,200 K, the density from about 10^{-7} to 4×10^{-7} gram per cubic centimetre, and the gas pressure from 0.002 to 0.14 atmosphere. The visible layers of stars such as the Sun have very low densities and pressures compared with the Earth's atmosphere, even though the temperature is much higher. The strata of the solar atmosphere are very opaque compared with the terrestrial atmosphere.

For stars other than the Sun, the dependence of temperature on depth cannot be directly determined. Calculations must proceed by a process of successive approximations, during which the flux of energy is taken to be constant with depth. Computations have been undertaken for atmospheres of a variety of stars ranging from dwarfs to supergiants, from cool to hot stars. Their validity can be evaluated only by examining how well they predict the observed features of a star's continuous and line spectrum, including the detailed shapes of spectral-line features. Considering the known complexities of stellar atmospheres, the results fit the observations remarkably well.

Severe deviations exist for stars with extended and expanding atmospheres. Matter flowing outward from a star produces a stellar wind analogous to the solar wind, but one that is often much more extensive and violent. In the spectrum of certain very hot O-type stars (*e.g.,* Zeta Puppis), strong, relatively narrow emission lines can be seen; however, in the ultraviolet, observations from rockets and orbiting spacecraft show strong emission lines with distinct absorption components on the shorter wavelength side. These absorption features are produced by rapidly outflowing atoms that absorb the radiation from the underlying stellar surface. The observed shifts in frequency correspond to ejection velocities of about 100 kilometres per second. Much gentler stellar winds are found in cool M-type supergiants.

Effects of rapid stellar rotation

Rapid stellar rotation also can modify the structure of a star's atmosphere. Since effective gravity is much reduced near the equator, the appropriate description of the atmosphere varies with latitude. Should the star be spinning at speeds near the breakup point, rings or shells may be shed from the equator.

Some of the most extreme and interesting cases of rotational effects are found in close binary systems. Interpretations of the light and velocity curves of these objects suggest that the spectroscopic observations cannot be reconciled with simple, orderly rotating stars. Instead, emission and absorption lines sometimes overlap in such a way as to suggest streams of gas moving between the stars. For example, Beta Lyrae (Figure 4), as an eclipsing binary system, has a period of 12.9 days and displays very large orbital-velocity shifts. The brighter member at visible wavelengths is a B9-type star; the other member appears to be a hot, abnormal object whose spectral lines have not been observed. The spectrum of the B9-type component shows the regular velocity changes expected of a binary star but with an absorption (and associated emission) spectrum corresponding to a higher temperature (near spectral class B5) and a blue continuum corresponding to a very high temperature star. The anomalous B5-type spectrum is evidently excited principally by the hotter source; it envelopes the entire system and shows few changes in velocity with time.

Supergiant stars have very extended atmospheres that are probably not even approximately in hydrostatic equilibrium. The atmospheres of M-type supergiant stars appear to be slowly expanding outward. Observations of the eclipsing binary 31 Cygni show that the K-type supergiant component has an extremely inhomogeneous, extended atmosphere composed of numerous blobs and filaments. As the secondary member of this system slowly moves behind the larger star, its light shines through larger masses of the K-type star's atmosphere. If the atmosphere were in orderly layers, the lines of ionized calcium, for example, produced by absorption of the light of the B-type star by the K-type star's atmosphere, would grow stronger uniformly as the eclipse proceeds. They do not, however.

STELLAR INTERIORS

Models of the internal structure of stars—particularly their temperature, density, and pressure gradients below the surface—depend on basic principles explained in this section. It is especially important that model calculations take account of the change in the star's structure with time as its hydrogen supply is gradually converted into helium. Fortunately, given that most stars can be said to be examples of an "ideal gas," there results a basic simplicity of the relations among temperature, density, and pressure. In fact, these quantities can be calculated for main-sequence and white-dwarf stars with greater confidence than can the values for internal temperature and density of the Earth.

Distribution of matter. Several mathematical relations can be derived from basic physical laws, assuming that the gas is "ideal" and that a star has spherical symmetry; both these assumptions are met with a high degree of validity. Another common assumption is that the interior of a star is in hydrostatic equilibrium, a condition whereby the pressure at each point exactly balances the weight of the overlying layers. This balance is often expressed as a simple relation between pressure gradient and density. A second relation expresses the continuity of mass; *i.e.,* if M is the mass of matter within a sphere of radius r, the mass added, ΔM, when encountering an increase in distance Δr through a shell of volume, $4\pi r^2\Delta r$, equals the volume of the shell multiplied by the density, ρ. In symbols this is expressed as $\Delta M = 4\pi r^2\rho\Delta r$.

Hydrostatic equilibrium

A third relation, termed the equation of state, expresses an explicit relation among the temperature, density, and pressure of a star's internal matter. Throughout the star the matter is entirely gaseous, and, except in certain highly evolved objects, it obeys closely the perfect gas law. In such neutral gases the molecular weight is 2 for molecular hydrogen, 4 for helium, 56 for iron, and so on. In the interior of a typical star, however, the high temperatures and densities virtually guarantee that nearly all the matter is completely ionized; the gas is said to be a plasma, the fourth state of matter. Under these conditions the hydrogen molecules are not only dissociated into individual atoms but also the atoms themselves are broken apart (ionized) into their constituent protons and electrons. Hence, the molecular weight of ionized hydrogen is the average mass of a proton and an electron—namely, $1/2$ on the atom-mass scale noted above. By contrast, a completely ionized helium atom contributes a mass of 4 with a helium nucleus (an alpha particle) plus two electrons of negligible mass; hence, its average molecular weight is $4/3$. As another example, a totally ionized nickel atom contributes a nucleus of mass 58.7 plus 28 electrons; its molecular weight is then $58.7/29 = 2.02$. Since stars contain a preponderance of hydrogen and helium that are completely ionized throughout the interior, the average particle mass, μ, is the (unit) mass of a proton, divided by a factor taking into account the concentrations by weight of hydrogen, helium, and heavier ions. Accordingly, the molecular weight depends critically on the star's chemical composition, particularly on the ratio of helium to hydrogen as well as on the total content of heavier matter.

An interior consisting of plasma

If the temperature is sufficiently high, the radiation pressure, P_r, must be taken into account in addition to the perfect gas pressure, P_g. The total equation of state then becomes, $P = P_g + P_r$. Here, P_g depends on temperature, density, and molecular weight, whereas P_r depends on temperature and on the radiation density constant, $a = 7.5 \times 10^{-15}$ ergs per cubic centimetre per degree to the fourth power. With $\mu = 2$ (as an upper limit) and $\rho = 1.4$ grams per cubic centimetre (the mean density of the Sun), the temperature at which the radiation pressure would equal the gas pressure can be calculated. The answer is 28,000,000 K, much hotter than at the core of the Sun. Consequently, radiation pressure may be neglected for the Sun, but it cannot be ignored for hotter, more massive

stars. Radiation pressure may then set an upper limit to stellar luminosity.

Certain stars, notably white dwarfs, do not obey the perfect gas law. Instead, the pressure is almost entirely contributed by the electrons, which are said to be particulate members of a degenerate gas (see below *White dwarfs*). If μ' is the average mass per free electron of the totally ionized gas, the pressure, P, and density, ρ, are such that P is proportional to a $^5/_3$ power of the density divided by the average mass per free electron; *i.e.*, $P = 10^{13}(\rho/\mu')^{5/3}$. The temperature does not enter at all. At still higher densities the equation of state becomes more intricate, but it can be shown that even this complicated equation of state is adequate to calculate the internal structure of the white-dwarf stars. As a result, white dwarfs are probably better understood than most other celestial objects.

For normal stars such as the Sun, the energy-transport method for the interior must be known. Except in white dwarfs or in the dense cores of evolved stars, thermal conduction is unimportant because the heat conductivity is very low. One significant mode of transport is an actual flow of radiation outward through the star. Starting as X rays near the core, the radiation is gradually "softened" as it works its way to the surface (typically, in the Sun, over the course of about 1,000,000 years) to emerge as ordinary light and heat. The rate of flow of radiation is proportional to the thermal gradient—namely, the rate of change of temperature with interior distance. Providing yet another relation of stellar structure, this equation uses the following important quantities: a, the radiation constant noted above; c, the velocity of light; ρ, the density; and κ, a measure of the opacity of the matter. The larger the value of κ, the smaller the transparency of the material and the steeper the temperature fall required to push the energy outward at the required rate. The opacity, κ, can be calculated for any temperature, density, and chemical composition and is found to depend in a complex manner largely on the two former quantities.

In the Sun's outermost (though still interior) layers and especially in certain giant stars, energy transport takes place by quite another mechanism: large-scale mass motions of gases, namely convection. Huge volumes of gas deep within the star become heated, rise to higher layers, and mix with their surroundings, thus releasing great quantities of energy. The extraordinarily complex flow patterns cannot be followed in detail, but when convection occurs a relatively simple mathematical relation connects density and pressure. Wherever convection does occur, it is a much more efficient means to move energy than radiative transport.

Source of stellar energy. The most basic property of stars is that their radiant energy must derive from internal sources. Given the great length of time that stars endure (some 10,000,000,000 years in the case of the Sun), it can be shown that neither chemical nor gravitational effects could possibly yield the required energies. Instead, the cause must be nuclear events wherein lighter nuclei are fused to create heavier nuclei, an inevitable by-product being energy.

In the interior of a star, the particles move rapidly in every direction because of the high temperatures present. Every so often a proton moves close enough to a nucleus to be captured, and a nuclear reaction takes place. Only protons of extremely high energy (many times the average energy in a star such as the Sun) are capable of producing nuclear events of this kind. A minimum temperature required for fusion is roughly 10,000,000 K. Since the energies of protons are proportional to temperature, the rate of energy production rises steeply as temperature increases.

For the Sun and other normal main-sequence stars, the source of energy lies in the conversion of hydrogen to helium. The nuclear reaction thought to occur in the Sun is called the proton–proton cycle. In this fusion reaction, two protons (^{1}H) collide to form a deuteron (^{2}H), with the liberation of a positron (the electron's positively charged antimatter counterpart, denoted e^+). Also emitted is a neutral particle of very small (or possibly zero) mass called a neutrino, ν. While the helium ash remains in the core where it was produced, the neutrino escapes from the solar interior within seconds. The positron encounters an ordinary negatively charged electron, and the two annihilate each other with much energy being released. This annihilation energy amounts to 1.02 megaelectron volts (MeV), which accords well with the Einsteinian relation, $E = mc^2$ (where m is the mass of the two particles, c the velocity of light, and E the liberated energy).

Proton–proton cycle

Next, a proton collides with the deuteron to form the nucleus of a light helium atom of atomic weight 3, ^{3}He. A "hard" X ray (one of higher energy) or gamma ray also is emitted. The most likely event to follow in the chain is a collision of this ^{3}He nucleus with a normal ^{4}He nucleus (or α particle) to form the nucleus of a beryllium atom of weight 7, ^{7}Be, with the emission of another gamma (γ) ray. The ^{7}Be nucleus in turn captures a proton to form a boron nucleus of atomic weight 8, ^{8}B, with the liberation of yet another gamma ray.

Boron-8, however, is very unstable. It almost immediately decays into beryllium of atomic weight 8, ^{8}Be, with the emission of another positron and a neutrino. The nucleus itself thereafter decays into two α particles (the helium nucleus, ^{4}He). These nuclear events can be represented by the following equations:

$$^3\text{He} + {}^4\text{He} \rightarrow {}^7\text{Be} + \gamma \quad \text{(rather slow reaction)}$$
$$^7\text{Be} + {}^1\text{H} \rightarrow {}^8\text{B} + \gamma \quad \text{(rapid reaction)}$$
$$\left.\begin{array}{l} {}^8\text{B} \rightarrow {}^8\text{Be} + e^+ + \nu \\ {}^8\text{Be} \rightarrow 2\,{}^4\text{He} \end{array}\right\} \quad \text{(instantaneous reactions)}$$

In the course of these reactions, four protons are consumed to form one helium nucleus, while two electrons perish.

The mass of four hydrogen atoms is

$$4 \times 1.00797 = 4.03188 \text{ atomic mass units;}$$

that of a helium atom is 4.0026. Hence, 0.02928 atomic mass units, or 0.7 percent of the original mass, have disappeared. Some of this has been carried away by the elusive neutrinos, but most of it has been converted to radiant energy. In order to keep shining at its present rate, a typical star (*e.g.*, the Sun) needs to convert 674,000,000 tons of hydrogen to 670,000,000 tons of helium every second. According to the formula $E = mc^2$, more than 4,000,000 tons of matter literally disappear into radiation each second.

This theory provides a good understanding of solar-energy generation except for one potential problem. Attempts have been made to detect the neutrino flux from the Sun by means of an intricate experimental apparatus. Fewer neutrinos than expected have been detected so far, and no consensus has been reached regarding this discordance.

Carbon cycle

The main source of energy in hotter stars is the carbon cycle (also called the CNO cycle for carbon, nitrogen, and oxygen), in which hydrogen is transformed into helium, with carbon serving as a catalyst. The reactions proceed as follows: First, a carbon nucleus, ^{12}C, captures a hydrogen nucleus or proton, ^{1}H, to form a nucleus of nitrogen, ^{13}N, a gamma ray being emitted in the process; thus, $^{12}\text{C} + {}^1\text{H} \rightarrow {}^{13}\text{N} + \gamma$. The light ^{13}N nucleus is unstable, however. It emits a positron, e^+, which encounters an ordinary electron, e^-, and the two annihilate one another. A neutrino also is released, and the resulting ^{13}C nucleus is stable. Eventually the ^{13}C nucleus captures another proton, forms ^{14}N, and emits another gamma ray. In symbols the reaction is represented by the equations: $^{13}\text{N} \rightarrow {}^{13}\text{C} + e^+ + \nu$; then $^{13}\text{C} + {}^1\text{H} \rightarrow {}^{14}\text{N} + \gamma$. This ordinary nitrogen, ^{14}N, is stable, but when it captures a proton to form a nucleus of light oxygen-15, ^{15}O, the resulting nucleus is unstable against beta decay. It therefore emits a positron and a neutrino, a sequence of events expressed by the symbols: $^{14}\text{N} + {}^1\text{H} \rightarrow {}^{15}\text{O} + \gamma$; then $^{15}\text{O} \rightarrow {}^{15}\text{N} + e^+ + \nu$. Again, the positron meets an electron and the two annihilate each other while the neutrino escapes. Eventually the ^{15}N nucleus encounters a fast-moving proton, ^{1}H, and captures it, but the formation of an ordinary ^{16}O nucleus by this process occurs only rarely. The most likely effect of this proton capture is a breakdown of ^{15}N and a return to the ^{12}C nucleus, that is: $^{15}\text{N} + {}^1\text{H} \rightarrow {}^{12}\text{C} + {}^4\text{He} + \gamma$. Thus, the original ^{12}C nucleus reappears and the four protons that have been added permit the formation of an alpha

particle (or helium nucleus). The same amount of mass has disappeared, though a different fraction of it may have been carried off by the neutrinos.

Only the hottest stars that lie on the main sequence shine with energy produced by the carbon cycle. The faint red dwarfs use the proton–proton cycle exclusively, whereas stars such as the Sun shine mostly by the proton–proton reaction but derive some contribution from the carbon cycle as well.

The aforementioned mathematical relationships permit the problem of stellar structure to be addressed notwithstanding the complexity of the problem. An early assumption that stars have a uniform chemical composition throughout their interiors simplified the calculations considerably, but it had to be abandoned when studies in stellar evolution proved that the compositions of stars change with age (see below *Later stages of evolution*). Computations need to be carried out by a step-by-step process known as numerical integration. They must take into account that the density and pressure of a star vanish at the surface, whereas these quantities and the temperature remain finite at the core. A common procedure is to make the computations from the surface inward and from the centre outward; the two solutions can then be adjusted, giving the same values for the temperature, density, and pressure when they come together.

Resulting models of a star's interior, including the relation among mass, luminosity, and radius, are determined largely by the mode of energy transport. In the Sun and the fainter main-sequence stars, energy is transported throughout the outer layers by convective currents, whereas in the deep interior, energy is transported by radiation. Among the hotter stars of the main sequence, the reverse appears to be true. The deep interiors of the stars that derive their energy primarily from the carbon cycle are in convective equilibrium, whereas in the outer parts the energy is carried by radiation. The observed masses, luminosities, and radii of most main-sequence stars can be reproduced with reasonable and uniform chemical composition.

Chemically homogeneous models of giant and supergiant stars cannot be constructed. If a yellow giant such as Capella is assumed to be built like a main-sequence star, its central temperature turns out to be so low that no known nuclear process can possibly supply the observed energy output. Progress has been made only by assuming that these stars were once main-sequence objects that, in the course of their development, exhausted the hydrogen in their deep interiors. Inert cores consequently formed, composed mainly of the helium ash left from the hydrogen-fusion process. Since no helium nuclear reactions are known to occur at the few tens of millions of kelvins likely to prevail in these interiors, no thermonuclear energy could be released from such depleted cores. Instead, energy is assumed to be generated in a thin shell surrounding the inert core where some fuel remains and is presumably produced by the carbon cycle. Such models are called shell-source models. As a star uses up increasing amounts of its hydrogen supply, its core grows in mass, all the while the outer envelope of the star continues to expand. These shell-source models explain the observed luminosities, masses, and radii of giants and supergiants (see below *Later stages of evolution*).

Shell-source models

The depletion of hydrogen fuel is appreciable even for a dwarf, middle-aged star such as the Sun. The Sun seems to have been shining at its present rate for about the last 20 percent of its current age of 5,000,000,000 years. For its observed luminosity to be maintained, the Sun's central temperature must have increased considerably since the formation of the solar system, largely as a consequence of the depletion of the hydrogen in its interior along with an accompanying increase in molecular weight and temperature. During the past 5,000,000,000 years, the Sun probably brightened by about half a magnitude; in the early Precambrian (about 2,000,000,000 years ago), the solar luminosity must have been some 20 percent less than it is today.

Table 5 gives the results of a typical calculation of the internal structure of the Sun. The carbon and proton–proton cycles as well as evolutionary effects are all accounted for in this model. Temperature, density, and the fraction of the total mass within a radius r (shown in Table 5 as a fraction of the Sun's radius, R) are listed. Nearly all the matter within the Sun is hotter than 1,000,000 K; the central temperature attains a value of about 15,000,000 K.

Star formation and evolution

Throughout the Milky Way Galaxy (and even near the Sun itself), astronomers have discovered stars that are well evolved or even approaching extinction, or both, as well as occasional stars that must be very young or still in the process of formation. Evolutionary effects on these stars are not negligible, not even for a middle-aged star such as the Sun. More massive stars must display more spectacular effects because the rate of conversion of mass into energy is higher. While the Sun produces energy at the rate of about two ergs per gram per second, a more luminous main-sequence star can release energy at a rate some 1,000 times greater. Consequently, effects that require billions of years to be easily recognized in the Sun might occur within a few million years in highly luminous and massive stars. A supergiant star such as Antares, a bright main-sequence star such as Rigel, or even a more modest star such as Sirius cannot have endured as long as the Sun has endured. These stars must have been formed relatively recently.

Rates of energy production

BIRTH OF STARS AND EVOLUTION TO THE MAIN SEQUENCE

Stars form from the gas and dust of the interstellar medium. The matter between stars is not uniformly distributed in space but is spread in a patchy fashion. Occasionally, a massive cloud will accumulate sufficient matter for its own gravitational attraction to draw it still further together. The details of this process are only beginning to be understood.

As the core of the cloud begins pulling itself together, its internal temperature and density rise until the protostar within reaches incandescence with a faint red glow. At this stage, the protostar is not yet shining by nuclear processes but rather by the energy released via its gravitational contraction. As the internal temperature rises to a few million kelvins, deuterium (heavy hydrogen) is first destroyed. Then lithium, beryllium, and boron are broken down into helium as their nuclei are bombarded by protons moving at increasingly high speeds.

Dwarf stars of the T Tauri type (see below *OB and T associations*) have been observed in the clouds of dark obscuring matter in Taurus as well as in numerous other regions of the Milky Way. These objects might represent stars in the actual process of formation. In fact, several galactic regions in which stars were actually "turned on" may have been observationally identified. Other evidence is provided by colour–magnitude diagrams such as that obtained for the cluster NGC 2264 associated with the star S Monocerotis. In this cluster the brighter part of the main sequence is well defined by stars somewhat more luminous than the Sun. The fainter redder stars whose colours correspond to spectral classes G, K, and M all fall above the main sequence defined by the normal dwarf stars. Presumably, they are contracting toward the main sequence, shining mostly by liberation of gravitational

Sites of possible star formation

energy; however, they might be burning the light helium isotope helium-3 before they reach the main sequence and the proton–proton reaction is ignited.

Many additional sites of possible star formation have been identified in the Milky Way and are being investigated carefully for possible changes. Radio and infrared observations have provided, for example, some sketchy evidence for more advanced pre-stellar objects. The Orion complex, shown in Figure 5, is one such region. Illuminated by several O-type stars, the bright Orion Nebula is partly engulfed by a vast molecular cloud. This dark cloud extends well beyond the few light-years bordered by the photograph and has been studied by means of the radio radiation emitted and absorbed by carbon monoxide and formaldehyde.

The Orion molecular cloud also houses several smaller sites of intense radiation emitted by molecules under very special conditions. Molecules such as hydroxyl (OH) and water vapour (H_2O) have been found by radio techniques to be buried within the core of the cloud fragment. Their extent measures about 10^{10} kilometres, or roughly $^1/_{1,000}$ of a light-year, which is approximately the full diameter of the solar system. While astronomers cannot currently determine whether these regions will eventually form stars more or less like the Sun, it does seem certain that such intensely emitting regions are on the threshold of becoming protostars.

Detailed calculations show that a protostar originally appears on the Hertzsprung–Russell diagram well above the main sequence because it is too bright for its colour. As it continues to contract, it moves downward and to the left toward the main sequence.

SUBSEQUENT DEVELOPMENT ON THE MAIN SEQUENCE

As the central temperature and density continue to rise, the proton–proton and carbon cycles become active, and the development of the (now genuine) star is stabilized. The star then reaches the main sequence where it remains for most of its active life. The time required for the contraction phase depends on the mass of the star. A star of the Sun's mass generally requires tens of millions of years to reach the main sequence, whereas one of much greater mass might take a few hundred thousand years.

By the time the star reaches the main sequence, it is still chemically homogeneous. With additional time, the hydrogen fuel in the core is converted to helium, and the temperature slowly rises. If the star is sufficiently massive to have a convective core, the matter in this region has a chance to be thoroughly mixed, but the outer region does not mix with the core. The Sun, by contrast, has no convective core and the helium-to-hydrogen ratio is maximum at the centre and decreases outward. Throughout the life of the Sun, there has been a steady depletion of hydrogen, so that the concentration of hydrogen at the centre today is probably only about one-third of the original amount. The rest has been transformed into helium.

Relationship between the mass of a star and its rate of evolution

Like the rate of formation of a star, the subsequent rate of evolution on the main sequence is proportional to the mass of the star; the greater the mass, the more rapid the evolution. Whereas the Sun is destined to endure for some 10,000,000,000 years, a star of twice the Sun's mass burns its fuel at such a rate that it lasts about 3,000,000,000 years, and a star of 10 times the Sun's mass has a lifetime measured in tens of millions of years. By contrast, stars having a fraction of the mass of the Sun seem to be able to endure for trillions of years, which is much greater than the current age of the universe.

The spread of luminosities and colours of stars within the main sequence can be understood as a consequence of evolution. At the beginning of their lives as hydrogen-burning objects, stars define a nearly unique line in the Hertzsprung–Russell diagram called the zero-age main sequence. Without differences in initial chemical composition or in rotational velocity, all the stars would start exactly from this unique line. As the stars evolve, they adjust to the increase in the helium-to-hydrogen ratio in their cores and gradually move away from the zero-age main sequence. When the core fuel is exhausted, the internal structure of the star changes rapidly; it quickly leaves the main sequence and moves toward the region of giants and supergiants.

Effects of composition changes

As the composition of its interior changes, the star departs the main sequence slowly at first and then more rapidly. When about 10 percent of the star's mass has been converted to helium, the structure of the star changes drastically. All of the hydrogen in the core has been burned out, and this central region is composed almost entirely of inert helium, with trace admixtures of heavier elements. The energy production now occurs in a thin shell where hydrogen is consumed and more helium added to a growing but inert core. The outer parts of the star expand outward because of the increased burning there, and as the star swells up its luminosity gradually increases. The details of the evolutionary process depend on the metal-to-hydrogen ratio, and the course of evolution differs for stars of different population types.

LATER STAGES OF EVOLUTION

The great spread in luminosities and colours of giant, supergiant, and subgiant stars is also understood to result from evolutionary events. When a star leaves the main sequence, its future evolution is precisely determined by its mass, rate of rotation (or angular momentum), chemical composition, and whether or not it is a member of a close binary system. Giants and supergiants of nearly the same radius and surface temperature may have evolved from main-sequence stars of different ages and masses.

Evolution of low-mass stars. Theoretical calculations suggest that, as the star evolves from the main sequence, the hydrogen-helium core gradually increases in mass but shrinks in size as more and more "ash" is fed in through the outer hydrogen-burning shell. Energy is carried out-

ward from the shell by rapid convection currents. The temperature of the shell rises, the star becomes more luminous, and it finally approaches the top of the giant domain. By contrast, the core shrinks by gravitational contraction, becoming hotter and denser until it reaches a central temperature of about 120,000,000 K. At that temperature the previously inert helium is consumed in the production of heavier elements.

Helium burning

When two helium (He) nuclei each of mass 4 atomic units are jammed together, it might be expected that they would form a nucleus of beryllium, Be, of mass 8 atomic units. In symbols, the reaction would be $^4He + {}^4He \rightarrow {}^8Be$. Actually, however, ^8Be is unstable and breaks down into two helium nuclei. If the temperature and density are high enough, though, the short-lived beryllium nucleus can (before it decays) capture another helium nucleus in what is essentially a three-body collision to form a nucleus of carbon-12—namely, $^8Be + {}^4He \rightarrow {}^{12}C$.

Provided that the central temperature continues to rise as the core shrinks, increasingly heavy nuclei can be fused. In particular, further reactions can occur by capturing additional helium nuclei, producing in turn oxygen (oxygen-16), neon (neon-20), magnesium (magnesium-24), and so on. (The Sun, being rather small in mass, will probably never reach the core temperature of approximately 600,000,000 K required to fuse carbon and will thus move toward its final state in roughly 5,000,000,000 years, when helium is depleted at its core.) During each of these stages of element production, energy is released, and the star once again establishes hydrostatic equilibrium, at least for a relatively short period of time. Since the energy output of helium fusion (per ton of matter) is much less than for hydrogen burning, the star's lifetime in the helium-burning phase is relatively short; in fact, it is considerably less than 1 percent of the duration of hydrogen fusion.

Ultimately, as the core of the star contracts, the overlying layers expand. The star, aged and severely unbalanced, is on its way to becoming a giant star. The gases making up the interior envelope literally recede away, creating a cooler, distended star called a red giant. These are real stars, and, as noted earlier, such red giants (*e.g.*, Betelgeuse) actually are observed in the sky.

Eventually, the outermost layers reach so far from the source of nuclear burning that they cool to a few thousand kelvins. The result is a weird-looking object having two distinct parts: a well-defined core of mostly carbon ash (a white dwarf; see below) and a swollen spherical shell of cooler and thinner matter spread over a volume roughly the size of the solar system. Such planetary nebulas also are actually observed in large numbers in the sky. Of the nearly 1,000 examples known in the Milky Way Galaxy alone, NGC 7027 is the most intensively studied to date.

Planetary nebulas

Origin of the chemical elements. The relative abundances of the chemical elements provide significant clues regarding their origin. The Earth's crust has been affected severely by erosion, fractionation, and other geologic events, so that its present varied composition offers few clues as to its early stages. The composition of the matter from which the solar system formed is deduced from that of stony meteorites called chondrites and from the composition of the Sun's atmosphere, supplemented by data acquired from spectral observations of hot stars and gaseous nebulas. Table 6, compiled from the efforts of many workers, lists the most abundant chemical (nonterrestrial) elements. This tabulation represents an average pertaining to all cosmic objects in general.

The most obvious feature is that the light elements tend to be more abundant than the heavier ones. That is to say, a plot of abundance against atomic mass, A, shows a decline with increasing A up to about $A = 100$. Thereafter the abundance is more nearly constant. Furthermore, this "curve of cosmic abundances" is not smooth. Among the lighter elements, those of even atomic number tend to be more abundant, and those with atomic numbers divisible by four are especially favoured. The abundance of lithium, beryllium, and boron is very rare compared with carbon, nitrogen, and oxygen. There is a pronounced abundance peak for iron and a relative maximum for lead, the most stable of the heavy elements.

The overwhelming preponderance of hydrogen suggests that all the nuclei were built from this simplest element, a hypothesis first proposed many years ago and widely accepted. It is now agreed, however, that the various elements could not have been formed in the aftermath of the "big bang" that created the universe some 15,000,000,000 years ago. According to this now-defunct idea, all matter was initially compressed into one huge ball of neutrons. As the universe began to expand, its density decreased and the neutrons decayed into protons and electrons. The protons then captured neutrons, one after another, underwent beta decay (ejection of electrons), and synthesized the heavy elements. A major difficulty with this hypothesis, among various other problems, is that atomic masses 5 and 8 are unstable, and there is no known way to build heavier nuclei by successive neutron capture.

Synthesis of heavy elements in massive stars

A large body of evidence supports the idea that the heavy elements have been, and are being, produced in stars. The majority of them, however, are fashioned only in the most massive stars and even for a short period of time after some stars have exploded as supernovas (see below *Evolution of high-mass stars*).

The splitting in the spectral sequence among the cooler stars can be understood in terms of composition differences. The M-type stars appear to have a normal (*i.e.*, solar) makeup, with oxygen more abundant than carbon and the zirconium group of elements much less abundant than the titanium group. The R-type and N-type stars often contain more carbon than oxygen, whereas the S-type stars appear to have an enhanced content of zirconium as compared with titanium. Other abundance anomalies are found in a peculiar class of higher temperature stars, called Wolf-Rayet (or W) stars, in which objects containing predominantly helium, carbon, and oxygen are distinguished from those containing helium and nitrogen, some carbon, and little observed oxygen. Significantly, all these abundance anomalies are found in stars thought to be well advanced in their evolutionary development. No main-sequence dwarfs display such effects.

A most critical observation is the detection of the unstable element technetium, Tc, in the S-type stars. This element has been produced synthetically in nuclear laboratories on Earth, and its longest-lived isotope, technetium-99 is known to have a half-life of 200,000 years. The implication is that this element must have been produced within the past few hundred thousand years in the stars where it has been observed, suggesting furthermore that this nucleosynthetic process is at work at least in some stars today. How the star upwells this heavy element from the core (where it is produced) to the surface (near where it is observed) in such a short time without the star exploding provides an impressive challenge to theoreticians.

During the past few decades, researchers have demon-

strated how elements might be created in stars by nuclear processes occurring at very high temperatures and densities. No one mechanism can account for all the elements; rather, several distinct processes occurring at different epochs during the late evolution of a star have been proposed.

After hydrogen, helium is the most abundant element. Most of it was probably produced in the initial big bang, by which the universe was created. Furthermore, as described earlier, helium is the normal ash of hydrogen consumption, and in the dense cores of highly evolved stars, helium itself is consumed to form, successively, carbon-12, oxygen-16, neon-20, and magnesium-24. By this time in the core of a sufficiently massive star, the temperature has reached some 700,000,000 K. Under these conditions, fragments such as protons, neutrons, and alpha particles also can interact with the newly created nuclei to produce a variety of other elements such as fluorine and sodium. As these "uneven" elements are produced in lesser quantities than those divisible by four, both the peaks and troughs in the curve of cosmic abundances can be explained.

With the core still shrinking and the central temperature and density forced even higher, a fundamental difficulty is soon reached. A temperature of roughly 1,000,000,000 K is sufficient to create silicon (silicon-28) by the usual method of helium capture. This temperature, however, is also high enough to begin to break apart silicon as well as some of the other newly synthesized nuclei. A kind of semi-equilibrium is set up in the star's core—a balance of sorts between the production and destruction (photodisintegration) of silicon. Ironically, though destructive, this situation is also suitable for the production of even heavier nuclei up to and including iron (iron-56) again through the successive capture of helium nuclei.

Evolution of high-mass stars. If the temperature and the density continue to rise, the iron-group nuclei tend to break down into alpha particles, but a large amount of energy is suddenly consumed in the process. The star then suffers a violent implosion, or collapse, after which it soon explodes as a supernova. In the catastrophic events leading to a supernova explosion and for roughly 1,000 seconds thereafter, a great variety of nuclear reactions can take place. And these processes seem to be able to explain the trace abundances of all the known elements heavier than iron.

Supernova explosions as a source of elements heavier than iron

Two situations have been envisioned, and both involve the capture of neutrons. When a nucleus captures a neutron, its mass increases by one atomic unit and its charge remains the same. Such a nucleus is often too heavy for its charge and might emit an electron (or beta ray) to attain a more stable state. It then becomes a nucleus of the next higher element in the periodic table of the elements. In the first such process, called the slow, or *s*, process, the flux of neutrons is low. A nucleus captures a neutron and leisurely emits a beta ray; its nuclear charge then increases by one.

Beta decay is often very slow, and, if the flux of neutrons is high, the nucleus might capture another neutron before there is time for it to undergo decay. In this rapid, or *r*, process, the evolution of a nucleus can be very different from that in a slow process. In supernova explosions, vast quantities of neutrons can be produced, and these could result in the rapid buildup of massive elements. One interesting feature of the synthesis of heavy elements by neutron capture at a high rate in a supernova explosion is that nuclei much heavier than lead or even uranium can be fashioned. These in turn can decay by fission, releasing additional amounts of energy.

The superabundant elements in the S-type stars come from the slow neutron process. Moreover, the observation of technetium-99 is ample evidence that these processes are at work in stars today. Even so, some low-abundance atomic nuclei are proton rich (*i.e.*, neutron deficient) and cannot be produced by either the *s* or *r* process. Presumably, they have been created in relatively rare events—*e.g.*, one in which a quantum of hard radiation, a γ ray, causes a neutron to be ejected.

In addition, no known nuclear process is capable of producing lithium, beryllium, and boron in stellar interiors. These lightweight nuclei are probably produced by the breakdown or "spallation" of heavier elements, such as iron and magnesium, by high-energy particles in stellar atmospheres or in the early stages of star formation. Apparently, these high-energy particles (called cosmic rays) originate by means of electromagnetic disturbances in the neighbourhood of star spots and stellar flares, and they also might arise from supernova explosions themselves. Some of these light-element nuclei also might be produced by cosmic rays shattering atoms of carbon, nitrogen, oxygen, and other elements in the interstellar medium.

Origin of cosmic rays

Finally, the peculiar A-type stars comprise a class of cosmic objects with strange abundance anomalies. These

might arise from mechanical effects—selective radiation pressure, photospheric diffusion and element separation, and so on—rather than from nuclear effects. Some stars show enhanced silicon, others enhanced lanthanides. The so-called manganese stars show great overabundances of manganese and gallium, usually accompanied by an excess of mercury. The latter stars exhibit weak helium lines, low rotational velocities, excess amounts of gallium, strontium, yttrium, mercury, and platinum, as well as absences of such elements as aluminum and nickel. When these types of stars are found in binaries, the two members often display differing chemical compositions. It is most difficult to envision plausible nuclear events that can account for the peculiarities of these abundances, particularly the strange isotope ratios of mercury.

END STATES OF STARS

The final stages in the evolution of a star depend on its mass, its angular momentum, and whether it is a member of a close binary.

White dwarfs. All stars seem to evolve through the red-giant phase to their ultimate state along a straightforward path. In most instances, especially among low-mass stars, the distended outer envelope of the star simply drifts off into space, while the core settles down as a white dwarf. Here, the star (really the core) evolves on the horizontal branch to bluer colours and lower luminosities. In other cases, where the star has several solar masses or more, the star may explode as a supernova. Even for these more massive stars, if the residual mass in the core is less than 1.4 solar masses (the Chandrasekhar limit), the stellar remnant will become a white dwarf. The matter in such a dwarf becomes a degenerate gas, wherein the electrons are all stripped from their parent atoms. Gas in this peculiar state is an almost perfect conductor of heat and does not obey the ordinary gas laws. It can be compressed to very high densities, typical values being in the range of 10^7 grams per cubic centimetre. Such a white dwarf no longer has any source of energy and simply cools down forever, becoming in turn a yellow dwarf, a red dwarf, a brown dwarf, and, eventually, perhaps a black dwarf.

Degenerate gas

The energy output of a white dwarf is so small that the object can go on shining mainly by radiating away its stored energy until virtually none is left to emit. How long this might take is unknown, but it would seem to be on the order of trillions of years. The final stage of this kind of low-mass star is typically a ball not much larger than the Earth but with a density perhaps 50,000 times that of water, covered possibly with a thin layer of ice and surrounded by an atmosphere a few metres thick.

The Sun is destined to perish as a white dwarf. But before that happens, it will evolve into a red giant, engulfing Mercury and Venus in the process. At the same time, it will blow away the Earth's atmosphere and boil its oceans, making the planet uninhabitable. None of these events will come to pass locally for several billion years.

The first white dwarf to be recognized was the companion to Sirius. It was originally detected by its gravitational attraction on the larger, brighter star and only later observed visually as a faint object (now called Sirius B), about 10,000 times fainter than Sirius (now called Sirius A) or 500 times fainter than the Sun. Its mass is slightly less than that of the Sun and its size a little less than that of the Earth. Its colour and spectrum correspond roughly to spectral class A, with a surface temperature of 8,000 to 10,000 K. Hence, the energy emission per unit area from the surface must be much greater than that of the Sun. Since Sirius B is so faint, its surface area and thus its volume must be very small, and its average density is on the order of 100,000 times that of water.

Another well-known white dwarf, designated BD +16°516, is paired with a much cooler K0V dwarf in an eclipsing system. The two stars, whose centres are separated by 2,092,000 km, revolve around each other with a period of 12.5 hours. The white dwarf produces pronounced excitation and heating effects in the K-type star's atmosphere. The white dwarf's mass is about 0.6 that of the Sun, but its diameter is only 16,000 km; hence, its density is about 650,000 times that of water.

Neutron stars. When the mass of the remnant core lies between 1.4 and two solar masses, it apparently becomes a neutron star with a density more than 1,000,000 times greater than even that of a white dwarf. Having so much mass packed within a ball on the order of 50 km in diameter, a neutron star's density can reach that of nuclear values, which is roughly 10^{14} times the average density of solar matter or of water. Such a star is predicted to have a crystalline solid crust, wherein bare atomic nuclei would be held in a lattice of rigidity and strength some 18 orders of magnitude greater than that of steel. Below the crust, the density is similar to that of an atomic nucleus, so the residual atomic cores lose their individuality as their nuclei are jammed together to form a nuclear fluid.

Although neutron stars were predicted in the 1930s, it was not until the late 1960s that observers accidentally discovered a radio source emitting weak pulses, each lasting about 0.3 second with a remarkably constant period of approximately 1.337 seconds. Other examples of such an object, dubbed a pulsar for "pulsating radio star," were soon found. Many of them were detected in the skies of the Southern Hemisphere, where a pulsar was first identified with a supernova remnant.

A large body of evidence now identifies pulsars as rotating neutron stars. All the energy emitted in the pulses derives from a slowing of the star's rotation, but only a small fraction is released in the form of radio-frequency pulses. The rest goes into pulses observed elsewhere in the electromagnetic spectrum and into cosmic rays, with perhaps some into the emission of gravitational energy, or gravity waves. For example, the pulsar at the centre of the Crab Nebula (Figure 7), the most famous of the modern supernovas, has been observed not only at radio frequencies but also at optical and X-ray frequencies, where it emits 100 and 10,000 times, respectively, as much radiation as in the radio spectrum. The slowing of the pulsar's spin also supplies the energy needed to account for the nonthermal, or synchrotron, emission from the Crab Nebula, which ranges from X rays to radio waves.

Pulsars as rotating neutron stars

Pulsar radiation is polarized, both linearly and circularly, and can be understood in terms of a rotating star having a powerful magnetic field of 10^{12} gauss. (By contrast, the Earth's magnetic field is on the order of one gauss.) Various mechanisms have been proposed whereby charged particles can be accelerated to velocities close to that of light itself. Possibly most, if not all, galactic cosmic rays originate from pulsars.

More recently, sudden changes have been observed in the rotation rates of pulsars. The Vela pulsar, for instance, abruptly decreased its spin rate. Such a period change or "glitch" can be explained if the pulsar altered its radius by about one centimetre; this sudden shrinkage of the crust has been called a "star quake" by some researchers. Pulsar phenomena apparently last much longer than the observable supernova remnants in which they were born, since hundreds of pulsars are now cataloged and only a few are associated with well-known remnants. Even so, the statistics of pulsars are likely to be observationally biased, since signals from pulsars at great distances in the Galaxy become distorted by ionized regions of interstellar space.

Black holes. If the core remnant of a supernova exceeds about two solar masses, it continues to contract. The gravitational field of the collapsing star is predicted to be so powerful that neither matter nor light can escape it. The "star" then collapses to what is called a Schwarzschild singularity—or, in popular terms, a black hole. Bodies trapped in its gravity field, or a beam of light directed at such an object, would seemingly just disappear—pulled into a "bottomless pit."

Schwarzschild singularity

Theory aside, astronomers remain unsure if black holes really exist. For further information on the subject, see COSMOS: *Black-hole model for active galactic nuclei.*

Star clusters

GENERAL DESCRIPTION AND CLASSIFICATION

Star clusters fall into two main types: open (or galactic) and globular. Open clusters contain from a dozen to

many hundreds of stars, usually in an unsymmetrical arrangement. By contrast, globular clusters are old systems containing thousands to hundreds of thousands of stars closely packed in a symmetrical, roughly spherical form.

Stellar associations

In addition, groups called associations, made up of a few dozen to hundreds of stars of similar type and common origin whose density in space is less than that of the surrounding field, are also recognized.

Four open clusters have been known from earliest times: the Pleiades and Hyades in the constellation Taurus, Praesepe (the Beehive) in the constellation Cancer, and Coma Berenices. The Pleiades was so important to some early peoples that its rising at sunset determined the start of their year. The appearance of the Coma Berenices cluster to the naked eye led to the naming of its constellation for the hair of Berenice, wife of Ptolemy Euergetes of Egypt (3rd century BC), the only constellation named after a historical figure.

Though several globular clusters, such as Omega Centauri and Messier 13 in the constellation Hercules, are visible to the unaided eye as hazy patches of light, attention was paid to them only after the invention of the telescope. The first record of a globular cluster, in the constellation Sagittarius, dates to 1665 (it was later named Messier 22); the next, Omega Centauri, shown in a modern photograph in Figure 8, was recorded in 1677 by the English astronomer and mathematician Edmund Halley.

Investigations of globular and open clusters greatly aided the understanding of the Milky Way Galaxy. In 1917, from a study of the distances and distributions of globular clusters, the American astronomer Harlow Shapley, then of the Mount Wilson Observatory, California, determined that the galactic centre lies in the Sagittarius region. In 1930, from measurements of angular sizes and distribution of open clusters, Robert J. Trumpler of Lick Observatory, California, showed that light is absorbed as it travels through many parts of space.

The discovery of stellar associations depended on knowledge of the characteristics and motions of individual stars scattered over a substantial area. In the 1920s it was noticed that young, hot blue stars (spectral types O and B) apparently congregated together. In 1949 Victor A. Ambartsumian, a Soviet astronomer, suggested that these stars are members of physical groupings of stars with a common origin and named them O associations (or OB associations, as they are often designated today). He also applied the term T associations to groups of dwarf, irregular T Tauri variable stars, which were first noted at Mount Wilson Observatory by Alfred Joy.

The study of clusters in external galaxies began in 1847, when Sir John Herschel at the Cape Observatory (in what is now South Africa) published lists of such objects in the nearest galaxies, the Magellanic Clouds. During the 20th century the identification of clusters has been extended first to more remote galaxies by the use of large reflectors and other more specialized instruments—Schmidt telescopes.

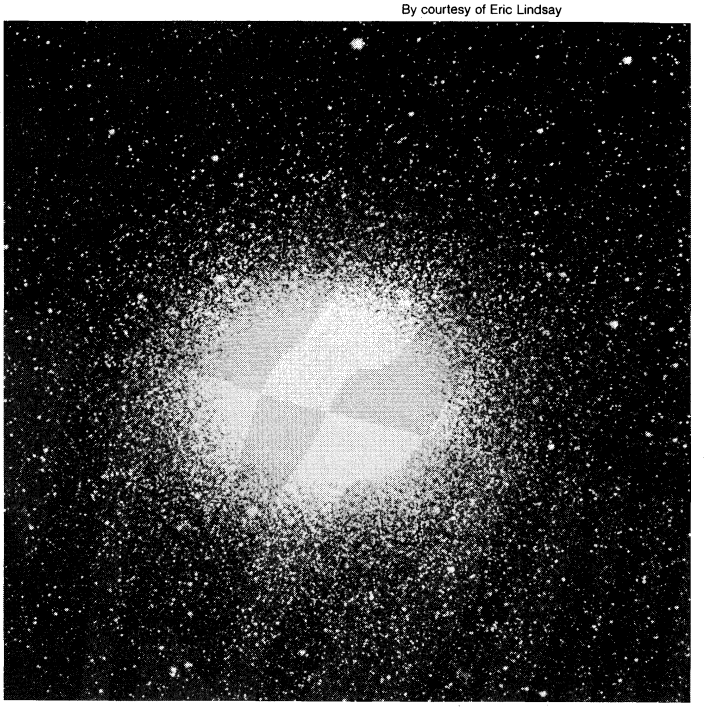

Figure 8: Globular cluster Omega Centauri (NGC 5139).

The number of open clusters identified, in particular, has in recent years tripled, totaling by the late 1980s an estimated 40,000 such objects in about 1,000 associations.

Distribution within the Milky Way system

Globular clusters. Although globular clusters are widely scattered in galactic latitude (Figure 9), about a third of them are concentrated around the galactic centre, as satellite systems in the rich Sagittarius–Scorpius star fields. Individual cluster masses include up to 1,000,000 suns, and their linear diameters can be several hundred light-years; their apparent diameters range from one degree for Omega Centauri down to knots of one minute of arc. In a cluster such as M3, 90 percent of the light is contained within a diameter of 100 light-years, but star counts and the study of RR Lyrae member stars (whose intrinsic brightness varies regularly within well-known limits) include a larger one of 325 light-years. The clusters differ markedly in the degree to which stars are concentrated at their centres. Most of them appear circular and are probably spherical, but a few (*e.g.*, Omega Centauri) are noticeably elliptical. The most elliptical cluster is M19, its major axis being about double its minor axis.

Globular clusters are composed of Population II objects (*i.e.*, old stars). As noted above, the brightest stars are the red giants, bright red stars with an absolute magnitude of −2, about 600 times the Sun's brightness or luminosity. In only six globular clusters have stars as intrinsically faint as the Sun been photographed, and in no such clusters have the faintest stars yet been recorded. The luminosity function for M3 shows that 90 percent of the visual light comes from stars at least twice as bright as the Sun, but more than 90 percent of the cluster mass is made up of fainter stars. The density near the centres of globular clusters is two stars per cubic light-year, compared with one star per 300 cubic light-years in the solar neighbourhood. Studies of 50 globular clusters showed a difference in spectral properties from stars in the solar neighbourhood—a difference that proved to be due to a deficiency of metals in the clusters, which have been classified on the basis of increasing metal abundance. Globular cluster stars are two to 300 times poorer in metals than stars of the solar neighbourhood. The ratio of metals is higher for clusters near the galactic centre than for those in the halo (the outermost reaches of the Galaxy extending far above and below its plane). The amounts of other elements, such as helium, also differ from cluster to cluster. Radio astronomical studies have set a low upper limit on the amount of neutral hydrogen in globular clusters. Puzzling features in some of these clusters are dark lanes of nebulous matter. Though it is difficult to explain the presence of distinct, separate masses of unformed matter in old systems, the nebulosity cannot be foreground material between the cluster and the observer.

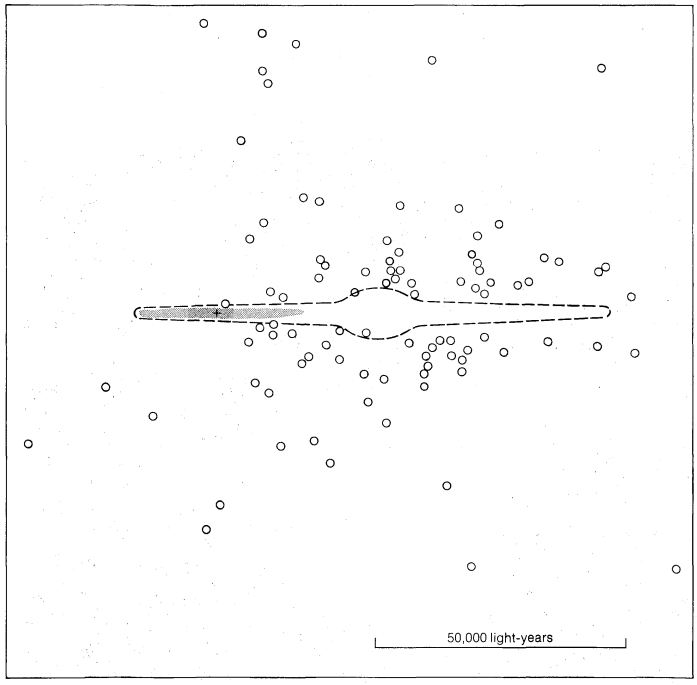

Figure 9: *Distribution of open and globular star clusters in the Galaxy.*

Some of the known open star clusters are scattered among the stars in shaded region. Small circles represent globular clusters.

Nearly 2,000 variable stars are known in the 100 globular clusters that have been examined. Of these, perhaps 90 percent are members of the class called RR Lyrae variables (see above). Other variables that occur in globular clusters are W Virginis, RV Tauri, and U Geminorum stars, as well as Cepheids, Mira stars, eclipsing binaries, and novas.

Constituent stars

The colour of a star, as previously noted, has been found generally to correspond to its surface temperature, and in a somewhat similar way the type of spectrum shown by a star depends on the degree of excitation of the light-radiating atoms in it and, therefore, also on the temperature. All stars in a given globular cluster are, within a very small percentage of the total distance, at equal distances from the Earth so that the effect of distance on brightness is common to all. Colour–magnitude and spectrum–magnitude diagrams can thus be plotted for the stars of a cluster, and the position of the stars in the array, except for a factor that is the same for all stars, will be independent of distance.

All such arrays show a major grouping of stars along the main sequence, and the categories range from hot, bright, bluer stars to cool and redder ones. In many cases, a giant branch containing very luminous stars also is present (Figure 10), as are some other minor groupings, but the extent and concentration of the stars in the various parts of the diagram can be quite different from cluster to cluster.

In 1917 a more distinct difference between open and globular clusters was noticed in colour–magnitude diagrams. This was later explained as a result of differences in the courses of evolutionary change that stars with similar compositions but different masses would follow after long intervals of time. The magnitude at which the brighter stars leave the main sequence (the turnoff point or knee) is a measure of the age of the cluster, assuming that most of the stars formed at the same time. RR Lyrae variables, when present, lie in a special region, called the variable gap, near the mean visual magnitude and the blue end of the horizontal (giant) branch of the colour–magnitude diagram. The hydrogen in cluster stars is thought to amount to 70 to 75 percent by mass, helium 25 to 30 percent, and the heavier elements 0.01 to 0.1 percent. Globular clusters prove to be nearly as old as the universe, perhaps 12,000,000,000 to 13,000,000,000 years.

Age of globular clusters

Integrated magnitudes (measurements of the total brightness of the cluster), their diameters, and the mean magnitude of the 25 brightest stars made possible the first distance determinations on the basis of the assumption that the apparent differences were due entirely to distance. The colour–magnitude diagram, or the apparent magnitudes of the variables, if their absolute magnitude is known, however, leads to the best distance estimates. The correction factor for interstellar reddening, due to intervening matter that absorbs and reddens stellar light, is substantial for many globular clusters but small for those in high galactic latitudes away from the plane of the Milky Way, the irregular luminous band of stars and gas clouds for which the Galaxy is named. Distances range from about 8,000 light-years for M71 and NGC 6397 to intergalactic distances of 270,000 light-years for the highly luminous NGC 2419 and 325,000 light-years for the clusters called Palomar 3 and 4.

Velocities and orbits of globular clusters

The radial velocities (the speed at which objects approach or recede from an observer, taken as positive when the distance is increasing) measured by the Doppler effect have been determined from integrated spectra for some 70 globular clusters. The largest negative velocity is −360 km/sec for NGC 6934, while the largest positive velocity is +493 km/sec for NGC 3201. These velocities suggest that the globular clusters are moving around the galac-

tic centre in highly elliptical orbits. The globular cluster system as a whole has a rotational velocity of about 140 km/sec relative to the Sun, or 110 km/sec on an absolute basis. For one cluster, Omega Centauri, motions of the individual stars around the massive centre have actually been observed and measured. Though proper motions of the clusters are very small, those for individual stars provide a useful criterion for cluster membership.

The two globular clusters of highest absolute luminosity are in the Southern Hemisphere in the constellations Centaurus and Tucana. Omega Centauri, with an (integrated) absolute blue magnitude of −9.4, is the second richest cluster in variables, with 171. From this large group, three types of RR Lyrae stars were first distinguished in 1902. Omega Centauri is relatively nearby at a distance of 17,000 light-years, and it lacks a sharp nucleus. The cluster designated 47 Tucanae (NGC 104), with an absolute magnitude of −9.5 at a similar distance of 16,000 light-years, has a different appearance with strong central concentration. It is located near the Small Magellanic Cloud but is not connected with it. For an observer situated at the centre of this great cluster, the sky would have the brightness of twilight on the Earth because of the light of the thousands of stars nearby. In the Northern Hemisphere, M13 in the constellation Hercules is the easiest to see and is the best known. At a distance of 20,000 light-years, it has been thoroughly investigated and is relatively poor in variables. M3 in Canes Venatici, 35,000 light-years away, is the cluster richest in variables, with 189 known. Investigation of these variables resulted in the placement of the RR Lyrae stars in a special region of the colour–magnitude diagram.

Open clusters. Open clusters are strongly concentrated toward the Milky Way. They form a flattened disklike system 3,000 light-years thick with a diameter of about 30,000 light-years. The younger clusters serve to trace the spiral arms of the Galaxy, since they are found invariably to lie in them. Very distant clusters are hard to detect against the rich Milky Way background. A classification based on central concentration and richness (Figure 11) is used and has been extended to nearly 1,000 open clusters. Probably about half the known open clusters contain fewer than 100 stars, but the richest have 1,000 or more. The largest have apparent diameters of several degrees, the diameter of the Taurus cluster being 400 arc minutes (nearly seven arc degrees), and that of the Perseus cluster being 240 arc minutes.

Concentration within the Galaxy

The linear diameters range from the largest, 75 light-years, down to five light-years. Increasingly, it has been found that a large halo of actual cluster members surrounds the more noticeable core and extends the diameter severalfold. Cluster membership is established through common motion, common distances, and so on. Tidal forces and stellar encounters lead to the disintegration of open clusters over long periods of time, as stars "evaporate" from the cluster.

Stellar content

Stars of all spectral classes from O to M (high to low temperatures) are found in open clusters, but the frequency of types varies from one cluster to another, as does concentration near the centre. In some (O or OB clusters), the brightest stars are blue, very hot spectral types O or B. In others, they are whitish yellow, cooler spectral type F. High luminosity stars are more common than in the solar neighbourhood, and dwarfs are much more scarce. The brightest stars in some open clusters are 150,000 times as bright as the Sun. The luminosity of the brightest stars at the upper end of the main sequence varies in clusters from about −8 to −2 visual magnitude. (As noted above, visual magnitude is that seen by the eye, as opposed to that registered on ordinary photographs.)

Because of the high luminosity of their brightest stars, some open clusters have a total luminosity as bright as that of some globular clusters (absolute magnitude of −8), which contain thousands of times as many stars. In the centre of rich clusters, the stars may be only one light-year apart. The density can be 100 times that of the solar

neighbourhood. In some, such as the Pleiades and the Orion clusters, nebulosity is a prominent feature, while others have none. In clusters younger than 25,000,000 years masses of neutral hydrogen extending over three times the optical diameter of the cluster have been detected with radio telescopes. Many of the OB clusters mentioned above contain globules—relatively small, apparently spherical regions of absorbing matter. The most numerous variables connected with open clusters are the T Tauri type (see below) and related stars that occur by the hundreds in some nebulous regions of the sky. Conspicuously absent from open clusters is the type most common in globular clusters, the RR Lyrae stars. Other variables include eclipsing binary stars (both Algol type and contact binaries), Cepheids, flare stars, and spectrum variables, such as Pleione. The last named star, one of the Pleiades, is known to cast off shells of matter from time to time, perhaps as a result of its high rotational speed (up to 322 kilometres per second).

The colour- or spectrum-magnitude diagram derived from the individual stars holds vital information. Colour-magnitude diagrams are available for about 200 clusters on the UBV photometric system, in which colour is measured from the amount of light radiated by the stars in the ultraviolet, blue, and visual (yellow) wavelength regions. In young clusters, stars are found along the luminous bright blue branch, whereas in old clusters, beyond a turnoff only a magnitude or two brighter than the Sun, they are red giants and supergiants (Figure 12).

Distance determinations

Distances can be determined by many methods—geometric, photometric, and spectroscopic—with corrections for interstellar absorption. For the very nearest clusters, direct (trigonometric) parallaxes may be obtained, and these are inversely proportional to the distance. Distances can be derived from proper motions, apparent magnitudes of the brightest stars, and spectroscopically from individual bright stars. Colour-magnitude diagrams, fitted to a standard plot of the main sequence, provide a common and reliable tool for determining distance. The nearest open cluster is the nucleus of the Ursa Major group at a distance of 75 light-years; the farthest clusters are thousands of light-years away.

Motions, including radial velocities and proper motion, have been measured for thousands of cluster stars. The radial velocities of open cluster stars are much smaller than those of globular clusters, averaging tens of kilometres per second, but their proper motions are larger. Open clusters share in the galactic rotation. Used with galactic rotation formulas, the radial velocities provide another means of distance determination.

Moving clusters

A few clusters are known as moving clusters because the convergence of the proper motions of their individual stars toward a "convergent point" is pronounced. The apparent convergence is caused by perspective: the cluster members are really moving as a swarm in almost parallel directions and with about the same speeds. The Hyades is the most prominent example of a moving cluster. (The Hyades stars are converging with a velocity of 45 kilometres per second toward the point in the sky with position coordinates right ascension 94 arc degrees, declination +7.6 arc degrees.) The Ursa Major group, another moving cluster, occupies a volume of space containing the Sun, but the Sun is not a member. The cluster consists of a compact nucleus of 14 stars and an extended stream.

Stellar groups are composed of stars presumed to have been formed together in a batch, but the members are now too widely separated to be recognized as a cluster.

Of all the open clusters, the Pleiades is the best known and perhaps the most thoroughly studied. This cluster, with a diameter of 35 light-years at a distance of 400 light-years, is composed of about 500 stars and is 150,000,000 years old. Near the Pleiades in the sky but not so conspicuous, the Hyades is the second nearest cluster at 130 light-years. Its stars are similar to those in the solar neighbourhood, and it is an older cluster (about 2,000,000,000 years in age). Measurements of the Hyades form a basis for astronomical determinations of distance and age because its thoroughly studied main sequence is used as a standard. Coma Berenices, located 260 light-years away, is an example of a "poor" cluster, containing only about 40 stars. There are some extremely young open clusters. Of these, the one associated with the Orion Nebula, which is some 3,000,000 years old, is the closest at a distance of 1,500 light-years. A still younger cluster is NGC 6611, which formed only about 800,000 years ago. At the other end of the scale, some open clusters have ages approaching those of the globular clusters and seem to be of intermediate type. M67 in the constellation Cancer is 5,500,000,000 years old, and NGC 188 in Cepheus, the oldest known open cluster, is 8,000,000,000 or 9,000,000,000 years of age.

OB and T associations. The chief distinguishing feature of the members of a stellar association is that the large majority of constituent stars have similar physical characteristics. An OB association consists of many hot, blue giant stars, spectral classes O and B, and a relatively small number of other objects. A T association consists of cooler dwarf stars, many of which exhibit irregular variations in brightness. The stars clearly must be relatively close to each other in space, though in some cases they might be widely dispersed in the sky and are less closely placed than in the open clusters.

Distinguishing characteristics

The existence of an OB association is usually established through a study of the space distribution of early O- and B-type stars. It appears as a concentration of points in a three-dimensional plot of galactic longitude and latitude and distance. Approximately 70 have been cataloged and are designated by constellation abbreviation and number (*e.g.*, Per OB 1 in the constellation Perseus). In terms of dimensions, they are larger than open clusters, ranging from 100 to 700 light-years in diameter, and usually contain one or more open clusters as nuclei. They frequently contain a special type of multiple star, the Trapezium (named for its prototype in Orion), as well as supergiants, binaries, gaseous nebulas, and globules. Associations are relatively homogeneous in age. The best distance determinations are from spectroscopic parallaxes of individual stars—*i.e.*, estimates of their absolute magnitudes made from studies of their spectra. Most of those known are closer than 10,000 light-years, with the nearest, named Sco OB 1, at 650 light-years.

Associations appear to be almost spherical, though rapid elongation would be expected from the shearing effect of differential galactic rotation. Expansion, which is on the order of 10 km/sec, may well mask the tendency to elongate, and this is confirmed in some. Tidal forces break up an association in less than 10,000,000 years through differences in the attraction by an outside body on members in different parts of the association.

A good example of an OB association is Per OB 1 at a distance of some 6,000 light-years, which spreads out

from the double cluster h and χ Persei. A large group of 20 supergiant stars of spectral type M belongs to Per OB 1. Associations with red supergiants may be in a relatively advanced evolutionary stage, almost ready to disintegrate.

T Tauri stars

The T associations (short for T Tauri associations) are formed by groups of T Tauri stars associated with the clouds of interstellar matter (nebulas) in which they occur. About three dozen are recognized. A T Tauri star is characterized by irregular variations of light, low luminosity, and hydrogen line (H-alpha) emission. It is a newly formed star of intermediate mass that is still in the process of contraction from diffuse matter. The small motions of T Tauri stars relative to a given nebula indicate that they are not field stars passing through the nebula. They are found in greatest numbers in regions with bright O- and B-type stars.

T associations occur only in or near regions of galactic nebulosity, either bright or dark, and only in obscured regions showing the presence of dust. Besides T Tauri stars, they include related variables, nonvariable stars, and Herbig-Haro objects, small nebulosities 10,000 astronomical units in diameter, each containing several starlike condensations in configurations similar to the Trapezium, Theta Orionis, in the sword of Orion. These objects are considered to be star groups at the very beginning of life.

The constellation of Cygnus has five T associations, and Orion and Taurus have four each. The richest is Ori T2 with more than 400 members; it has a diameter of 50 by 90 light-years and lies at a distance of 1,300 light-years around the variable star T Ori.

DYNAMICS OF STAR CLUSTERS

Seen from intergalactic space, the Milky Way Galaxy would appear as a giant luminous pinwheel, with more than 100 globular clusters dotted around it. The richest parts of the spiral arms of the pinwheel would be marked by dozens of open clusters. If this panorama could be seen as a time-lapse movie, the great globular clusters would wheel around the galactic centre in elliptical orbits with periods of hundreds of millions of years. The open clusters and stellar associations would be seen to form out of knots of diffuse matter in the spiral arms, gradually disperse, run through their life cycle, and fade away, while the Sun pursued its course around the galactic centre for billions of years.

Young open clusters and associations, occupying the same region of space as clouds of ionized hydrogen (gaseous nebulas), help to define the spiral arms. A concentration of clusters in the bright inner portion of the Milky Way between galactic longitudes 283° and 28° indicates an inner arm in Sagittarius. Similarly, the two spiral arms of Orion and Perseus are defined between 103° and 213°, with a bifurcation of the Orion arm. Associations show the existence of spiral structure in the Sun's vicinity. Older clusters, whose main sequence does not reach to the blue stars, show no correlation with spiral arms because in the intervening years their motions have carried them far from their place of birth.

Origin of galactic O- and B-type stars

All the O- and B-type stars in the Galaxy might have originated in OB associations. The great majority, if not all, of the O-type stars (5,000) were formed and still exist in clusters and associations. Though only 10 percent of the total number of B-type stars are now in OB associations or clusters, it is likely that all formed in them. At the other (fainter) end of the range of stellar luminosities, the number of dwarf variable stars in the nearby T associations is estimated at 12,000. These associations are apparently the main source of low luminosity stars in the neighbourhood of the Sun.

While large numbers of associations have formed and dispersed and provided a population of stars for the spiral arms, the globular clusters have survived relatively unchanged except for the evolutionary differences that time brings. They are too massive to be disrupted by the tidal forces of the Galaxy, though their limiting dimensions are set by these forces when they most closely approach the galactic centre. Impressive as they are individually, their total mass of 10,000,000 suns is small compared to the mass of the Galaxy as a whole—only about 1/10,000. Their substance is that of the Galaxy in a very early stage. The Galaxy probably collapsed from a gaseous cloud composed almost entirely of hydrogen and helium. Between 12,000,000,000 and 13,000,000,000 years ago, before the last stages of the collapse, matter forming the globular clusters may have separated from the rest. The fact that metal-rich clusters are near the galactic nucleus while metal-poor clusters are in the halo or outer fringes may indicate a nonuniform distribution of elements throughout the primordial mass.

In a study of star clusters, a time panorama unfolds—from the oldest objects existing in the Galaxy, the globular clusters, through clusters in existence only half as long, to extremely young open clusters and associations that have come into being since humans first trod the Earth.

CLUSTERS IN EXTERNAL GALAXIES

Clusters have been discovered and studied in at least eight external galaxies, mostly members of the Local Group (a group of about 20 stellar systems to which the Galaxy belongs). At their great distances classification is difficult. Attempts at classification are made from studies of the colours of the light from an entire cluster (integrated colours) or, for a few, from colour–magnitude diagrams. An electronograph (image tube) on a large telescope in the uniquely good observing conditions of Chile has extended studies to cluster stars of apparent magnitude 23, which is a factor of 10^{10} fainter than the bright star Sirius.

Clusters have been found by the hundreds in some of the nearest galaxies. At the distance of the Magellanic Clouds, a cluster like the Pleiades would appear as a faint 15th magnitude object, subtending 15 seconds of arc instead of several degrees.

Clusters and associations in the Magellanic Clouds

In the Small Magellanic Cloud, at a distance of 200,000 light-years, about 120 clusters are known. In the Large Magellanic Cloud, at a distance of 180,000 light-years, nearly 1,200 have been cataloged. Most of them are young blue-giant open clusters such as NGC 330 and NGC 1866. The open clusters contain some Cepheid variables and in chemical composition are similar to, but not exactly the same as, those of the Galaxy. The globular clusters fall into two distinct groups. Those of the first group, the red, have a large metal deficiency similar to the globular clusters in the Galaxy, and some are known to contain RR Lyrae variables. The globular clusters of the second group are large and circular in outline, with colours much bluer than normal galactic globular clusters and with ages of about 1,000,000 to 1,000,000,000 years. They are similar to the open clusters of the Magellanic Clouds but are very populous. The observed differences between clusters in the Galaxy and the Magellanic Clouds result from small differences in helium or heavy-element abundances. There are at least 122 associations with a mean diameter of 250 light-years, somewhat richer and larger than in the Galaxy. Sixteen of the associations contain coexistent clusters. Also, 15 star clouds (aggregations of many thousands of stars dispersed over hundreds or even thousands of light-years) are recognized.

Discoveries in the Andromeda Galaxy

In the great Andromeda spiral galaxy (M31) some 2,200,000 light-years away, more than 300 clusters are known, of which perhaps two-thirds are globular. Colour studies of about 50 of these clusters reveal that they have a higher metal content than globular clusters of the Galaxy. Nearly 200 OB associations are known with distances up to 80,000 light-years from the nucleus. The diameters of their dense cores are comparable to those of galactic associations. NGC 206 (OB 78) is the richest star cloud in M31, having a total mass of 200,000 suns and bearing a strong resemblance to the double cluster in Perseus. Some globular clusters have been found around the dwarf elliptical companions to M31, NGC 185, and NGC 205.

M33 in the constellation Triangulum—a spiral galaxy with thick, loose arms (an Sc system in the Hubble classification scheme)—has about 300 known clusters, not many of which have globular characteristics. Of the six dwarf spheroidal galaxies in the Local Group, only the one in the constellation Fornax has clusters. Its five globular clusters are similar to the bluest globular clusters of the Galaxy. No clusters have been discovered in the irregular galaxies NGC 6822 and IC 1613.

Globular clusters in galaxies beyond the Local Group

Beyond the Local Group, at a distance of 45,000,000 light-years, the giant elliptical galaxy M87 in the Virgo cluster of galaxies is surrounded by an estimated 2,000 globular star clusters. Inspection of other elliptical galaxies in Virgo shows that they too have globular clusters whose apparent magnitudes are similar to those in M87, though their stellar population is substantially smaller. It appears that the mean absolute magnitudes of globular clusters are constant and independent of the absolute luminosity of the parent galaxy.

The total number of clusters now known in external galaxies far exceeds the number known in the Milky Way system. For additional information on this and related matters, see GALAXIES: *The external galaxies.*

Astronomical maps

NATURE AND SIGNIFICANCE

The brighter stars and star groupings are easily recognized by a practiced observer. The much more numerous fainter celestial bodies can be located and identified only with the help of astronomical maps, catalogs, and in some cases almanacs.

The first astronomical charts, globes, and drawings, often decorated with fantastic figures, depicted the constellations, recognizable groupings of bright stars known by imaginatively chosen names that have been for many centuries both a delight to man and a dependable aid to navigation. Several royal Egyptian tombs of the 2nd millennium BC include paintings of constellation figures, but these cannot be considered accurate maps. Classical Greek astronomers used maps and globes; unfortunately, no examples survive. Numerous small metal celestial globes from Islāmic makers of the 11th century onward remain. The first printed planispheres (representations of the celestial sphere on a flat surface) were produced in 1515, and printed celestial globes appeared at about the same time.

Use of the telescope in stellar mapping

Telescopic astronomy began in 1609, and by the end of the 17th century the telescope was applied in mapping the stars. In the latter part of the 19th century, photography gave a powerful impetus to precise chart making, culminating in the 1950s in the publication of *National Geographic Society–Palomar Observatory Sky Survey,* a portrayal of the part of the sky visible from Palomar Observatory in California.

Many modern maps used by amateur and professional observers of the sky show stars, dark nebulas of obscuring dust, and bright nebulas (masses of tenuous, glowing matter). Specialized maps show sources of radio radiation, sources of infrared radiation, and quasi-stellar objects having very large redshifts (the spectral lines are displaced toward longer wavelengths) and very small images. Astronomers of the 20th century have divided the entire sky into 88 areas, or constellations; this international system codifies the naming of stars and star patterns that began in prehistoric times. Originally only the brightest stars and most conspicuous patterns were given names, probably based on the actual appearance of the configurations. Beginning in the 16th century, navigators and astronomers have progressively filled in all the areas left undesignated by the ancients.

THE CELESTIAL SPHERE

To any observer, ancient or modern, the night sky appears as a hemisphere resting on the horizon. Consequently, the simplest descriptions of the star patterns and of the motions of heavenly bodies are those presented on the surface of a sphere.

The daily eastward rotation of the Earth on its axis produces an apparent diurnal westward rotation of the starry sphere. Thus, the stars seem to rotate about a northern or southern celestial pole, the projection into space of the Earth's own poles. Equidistant from the two poles is the celestial equator; this great circle is the projection into space of the Earth's Equator.

Figure 13 illustrates the celestial sphere as viewed from some middle northern latitude. Part of the sky adjacent to a celestial pole is always visible (the shaded area in the diagram), and an equal area about the opposite pole is always invisible below the horizon; the rest of the celestial sphere appears to rise and set each day. For any other latitude the particular part of sky visible or invisible will be different and the diagram must be redrawn. An observer situated at the Earth's North Pole could observe only the stars of the northern celestial hemisphere. An observer at the Equator, however, would be able to see the entire celestial sphere as the daily motion of the Earth carried him around.

In addition to their apparent daily motion around the Earth, the Sun, Moon, and planets of the solar system have their own motions with respect to the starry sphere. Since the Sun's brilliance obscures the background stars from view, it took many centuries before observers discovered the precise path of the Sun through the constellations that are now called the signs of the zodiac. The great circle of the zodiac traced out by the Sun on its annual circuit is the ecliptic (so called because eclipses can occur when the Moon crosses it).

The zodiac and the ecliptic

As viewed from space, the Earth slowly revolves about the Sun in a fixed plane, the ecliptic plane. A line perpendicular to this plane defines the ecliptic pole, and it makes no difference whether this line is projected into space from the Earth or from the Sun. All that is important is the direction, because the sky is so far away that the ecliptic pole must fall on a unique point on the celestial sphere (Figure 14).

The principal planets in the solar system revolve about the Sun in nearly the same plane as the Earth's orbit, and their movements will therefore be projected onto the celestial sphere nearly, but seldom exactly, on the ecliptic. The Moon's orbit is tilted by about five degrees from this plane, and hence its position in the sky deviates from the ecliptic more than those of the other planets with the exception of Pluto.

Because the blinding sunlight blocks some stars from view, the particular constellations that can be seen depend on the position of the Earth in its orbit—*i.e.,* on the apparent place of the Sun. The stars visible at midnight will shift westward by about one degree each successive midnight as the Sun progresses in its apparent eastward motion. Stars visible at midnight in September will be concealed by the dazzling noontime Sun 180 days later in March.

Why the ecliptic and celestial equator meet at an angle of 23° 26.6′ is an unexplained mystery originating in the past history of Earth. The angle gradually varies by small amounts as a result of Moon- and planet-caused gravitational perturbations on the Earth. The ecliptic plane is comparatively stable, but the equatorial plane is continually shifting as the Earth's axis of rotation changes its direction in space. The successive positions of the celestial poles trace out large circles on the sky with a period of about 26,000 years. This phenomenon, known as precession of the equinoxes, causes a series of different stars to become pole stars in turn. Polaris, the present pole star, will come nearest to the north celestial pole around

Precession of the equinoxes

Dotted lines are all perpendicular to the plane of Earth's orbit, and all intersect the celestial sphere at the north ecliptic pole. the year AD 2100. At the time the pyramids were built, Thuban in the constellation Draco served as the pole star, and in about 12,000 years the first-magnitude star Vega will be near the north celestial pole. Precession also makes the coordinate systems on precise star maps applicable only for a specific epoch.

CELESTIAL COORDINATE SYSTEMS

The horizon system. The simple altazimuth system, which depends on a particular place, specifies positions by altitude (the angular elevation from the horizon plane) and azimuth (the angle clockwise around the horizon, usually starting from the north). Lines of equal altitude around the sky are called almucantars. The horizon system is fundamental in navigation, as well as in terrestrial surveying. For mapping the stars, however, coordinates fixed with respect to the celestial sphere itself (such as the ecliptic or equatorial systems) are far more suitable.

The ecliptic system. Celestial longitude and latitude are defined with respect to the ecliptic and ecliptic poles. Celestial longitude is measured eastward from the ascending intersection of the ecliptic with the equator, a position known as the "first point of Aries," and the place of the Sun at the time of the vernal equinox around March 21. The first point of Aries is symbolized by the ram's horns (♈).

Widespread use of the ecliptic system in early Western astronomy

Unlike the celestial equator, the ecliptic is fixed among the stars; however, the ecliptic longitude of a given star increases by 1.396° per century owing to the precessional movement of the equator—similar to the precessional movement of a child's top—which shifts the first point of Aries. The first 30 degrees along the ecliptic is nominally designated as the sign Aries, although this part of the ecliptic has now moved forward into the constellation Pisces. Ecliptic coordinates predominated in Western astronomy until the Renaissance. (In contrast, Chinese astronomers always used an equatorial system.) With the advent of national nautical almanacs, the equatorial system, which is better suited to observation and navigation, gained ascendancy.

The equatorial system. Based on the celestial equator and poles, the equatorial coordinates, right ascension and declination, are directly analogous to terrestrial longitude and latitude (Figure 15). Right ascension, measured eastward from the first point of Aries (see above), is customarily divided into 24 hours rather than 360°, thus emphasizing the clocklike behaviour of the sphere. Precise equatorial positions must be specified for a particular year, since the precessional motion continually changes the measured coordinates.

Galactic coordinates. For problems relating to the structure of the Galaxy, astronomers have introduced the galactic equator, a great circle girdling the sky and centred in the Milky Way. Galactic longitude is measured from a specified location in Sagittarius in the direction of the nucleus of the Galaxy and is taken as positive in a direction obliquely northward in the sky (increasing declination). Galactic latitude is measured from the galactic equator and is positive toward the north galactic pole in Coma Berenices.

THE CONSTELLATIONS AND OTHER SKY DIVISIONS

Ancient references to the constellations

Recognition of the constellations can be traced to early civilization. The oldest astronomical cuneiform texts, from the second half of the 2nd millennium BC, record the Sumerian names of the constellations still known as the lion, the bull, and the scorpion. Drawings of these astronomical animals appear on Babylonian boundary stones of the same period, and the earlier occurrence of these motifs on prehistoric seals, Sumerian vases, and gaming boards suggests that they may have originated as early as 4000 BC. In China a handful of configurations show similarity to those of the West, including the scorpion, lion, hunter (Orion), and northern dipper, suggesting the possibility of a very old common tradition for a few groups, but, otherwise, almost complete independence.

Greek literature reflects the impact of the stars on the life of an agricultural and seafaring people. Homer (*c.* 9th century BC) records several constellations by the names used today, and the first mention of circumpolar stars is in the *Odyssey.* Odysseus is

> Gazing with fixed eye on the Pleiades,
> Boötes setting late and the Great Bear,
> By others called the Wain, which wheeling round,
> Looks ever toward Orion and alone
> Dips not into the waters of the deep.
>
> *Odyssey,* V

In England the Great Bear (Ursa Major), or Big Dipper, was still called Charles's Wain (or Wagon) in Shakespeare's day:

> An't be not four by
> The day I'll be hanged; Charles' Wain is over
> The new chimney and yet our horse not pack'd.
>
> *King Henry IV,* Part I, Act ii, Scene 1

This form derives from Charlemagne, and according to *The Oxford English Dictionary,* apparently from a verbal association of the name of the bright nearby Arcturus with Arturus, or Arthur, and the legendary association of Arthur and Charlemagne.

The earliest systematic account of the constellations is contained in the *Phaenomena* of Aratus, a poet of the 3rd century BC, who described 43 constellations and named five individual stars. Cicero recorded that

> The first Hellenic globe of the sky was made by Thales of Miletus, having fallen into a ditch or well while star-gazing. Afterwards Eudoxos of Cnidus traced on its surface the stars

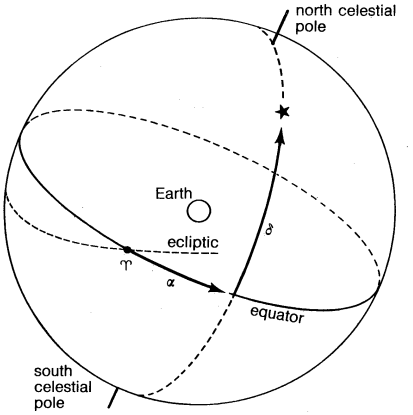

Figure 15: *Equatorial system of coordinates: right ascension (α) and declination (δ) of a star.* Both are angular measurements, though right ascension is usually given in hours rather than degrees of arc and is measured eastward from the "first point of Aries" (♈), where the Sun crosses the celestial equator in March. Declination is considered positive (+) north of the celestial equator and negative (−) south of it.

> that appear in the sky; and . . . many years after, borrowing from Eudoxos this beautiful design and representation, Aratos had illustrated it in his verses, not by any science of astronomy, but by the ornament of poetical description.

The *Almagest*

By far the most important list of stars and constellations still extant from antiquity appears in the *Almagest* of Ptolemy (flourished 2nd century AD). It contains ecliptic coordinates and magnitudes (measures of brightness) for 1,022 stars, grouped into 48 constellations. Numerous writers have stated that Ptolemy simply borrowed his material from a now-lost catalog of Hipparchus compiled in 129 BC. A critical analysis of the Hipparchian fragments still extant, including his commentary on the *Phaenomena* of Aratus, indicates that (1) the catalog of Hipparchus did not include more than 850 stars and (2) Ptolemy most likely obtained new coordinates for even those 850 stars. The evidence suggests that Ptolemy, who for over a century has been considered a mere compilator, should be placed among the first-rank astronomical observers of all ages.

Nevertheless, Ptolemy's star list presents a curious puzzle. The southernmost heavens, invisible at the latitude of Alexandria, naturally went unobserved. On one side of the sky near this southern horizon, he tabulated the bright stars of the Southern Cross (although not as a separate constellation) and of Centaurus, but on the opposite side a large area including the first-magnitude star Achernar had been left unrecorded. Because of precession, before 2000 BC this region would have been invisible from Mesopotamia. Perhaps neither Hipparchus nor Ptolemy considered that part of the heavens unnamed by their ancient predecessors. Ptolemy's catalog of 1,022 stars remained authoritative until the Renaissance.

Ptolemy divided his stars into six brightness, or magnitude, classes. He listed 15 bright stars of the first magnitude but comparatively few of the faint, much more numerous but barely visible sixth magnitude at the other limit of his list. Aṣ-Ṣūfī, a 10th-century Islāmic astronomer carried out the principal revision made to these magnitudes during the Middle Ages. Ulugh Beg, grandson of the Mongol conqueror Tamerlane, is the only known Oriental astronomer to reobserve the positions of Ptolemy's stars. His catalog, put together in 1420–37, was not printed until 1665, by which time it had already been surpassed by European observations.

Constellations of the zodiac. The Mesopotamian arrangement of constellations has survived to the present day because it became the basis of a numerical reference scheme—the ecliptic, or zodiacal, system. This occurred around 450 BC, when the ecliptic was clearly recognized and divided into 12 equal signs of the zodiac. Most modern scholars take the zodiac as a Babylonian invention; the oldest record of the zodiacal signs as such is a cuneiform horoscope from 419 BC. However, as Greek sources attribute the discovery of the ecliptic to Oenopides in the latter part of the 5th century BC, a parallel development in both Greece and Babylon should not be excluded.

At the time the zodiac was established, it was probably necessary to invent at least one new constellation, Libra. Centuries later Ptolemy's *Almagest* still described the stars of Libra with respect to the ancient figure of the scorpion.

The decans. Two other astronomical reference systems developed independently in early antiquity, the lunar mansions and the Egyptian decans. The decans are 36 star configurations circling the sky somewhat to the south of the ecliptic. They make their appearance in drawings and texts inside coffin lids of the 10th dynasty (around 2100 BC) and are shown on the tomb ceilings of Seti I (1318–04 BC) and of some of the Rameses in Thebes. The decans appear to have provided the basis for the division of the day into 24 hours.

Besides representing star configurations as decans, the Egyptians marked out about 25 constellations, such as crocodile, hippopotamus, lion, and a falcon-headed god. Their constellations can be divided into northern and southern groups, but the various representations are so discordant that only three constellations have been identified with certainty: Orion (depicted as Osiris), Sirius (a recumbent cow), and Ursa Major (foreleg or front part of a bull). The most famous Egyptian star map is a 1st-century-BC stone chart found in the temple at Dandarah and now in the Louvre. The Zodiac of Dandarah illustrates the Egyptian decans and constellations, but since it incorporates the Babylonian zodiac as well, many stars

must be doubly represented, and the stone can hardly be considered an accurate mapping of the heavens.

Hsiu and *nakṣhatra*

Lunar mansions. Called *hsiu* in China and *nakṣhatra* in India, the lunar mansions are 28 divisions of the sky presumably selected as approximate "Moon stations" on successive nights. At least four quadrantal *hsiu* that divided the sky into quarters or quadrants were known in China in the 14th century BC, and 23 are mentioned in the *Yüeh Ling,* which may go back to 850 BC. In India a complete list of *nakṣhatra* are found in the Atharvaveda, providing evidence that the system was organized before 800 BC. The system of lunar mansions, however, may have a common origin even earlier in Mesopotamia.

Relationship of the bright stars and their constellations. Ancient peoples sometimes named individual bright stars rather than groups; sometimes the name of the group and its brightest star were synonymous—as in the case of the constellation Aquila and the star Altair (Alpha Aquilae), both names meaning "flying eagles"—or were used interchangeably as in the case of both the star Arcturus (Alpha Boötis, "bear watcher") and the constellation Boötes ("plowman"). In the star list of the *Almagest,* Ptolemy cites only about a dozen stars by name, describing the others by their positions within the constellation figures. Most star names in current use have Arabic forms, but these are usually simply translations of Ptolemy's descriptions; for example, Deneb, the name of the brightest star in the constellation Cygnus (Swan), means literally "tail" of the bird.

The earliest astronomical globes and ancient maps

Ptolemy's placement of the stars within apparently well-known figures indicates the earlier existence of star maps, probably globes. An example survives in the so-called Farnese Globe at Naples, the most famous astronomical artifact of antiquity. This huge marble globe, supported by a statue of Atlas, is generally considered to be a Roman copy of an earlier Greek original. It shows constellation figures but not individual stars, although the stars may have been painted on the stone.

A unique hemispherical celestial map, which furnishes a remarkable connecting link between the classical representation of the constellations and the later Islāmic forms, is painted in the dome of a bath house at Quṣayr 'Amra, an Arab palace built in Jordan around AD 715. The surviving fragments of the fresco show parts of 37 constellations and about 400 stars.

Circumstantial evidence suggests that a flat representation of the sky, in the form of a planisphere using a stereographic projection, had come into use by the beginning of the present era. This provided the basis for the astrolabe, the earliest remaining examples of which date from the 9th century AD. The open metalwork of the top moving plate (called a spider or rete) of an astrolabe is essentially a star map, and these instruments together with associated manuscript lists provide the basic documentation for Arabic star names.

If astrolabes are excluded, the oldest existing portable star map from any civilization is the Chinese Tunhuang manuscript in the British Museum, dating from about AD 940 (Figure 16). A Latin document of about the same age, also in the British Museum, shows a planisphere to illustrate the *Phainomena* of Aratus, without, however, indicating individual stars. The oldest illuminated Islāmic astronomical manuscript, an AD 1009–10 copy of aṣ-Ṣūfī's book on the fixed stars, shows individual constellations, including stars (Figure 17).

The earliest known western maps of the skies of the Northern and Southern Hemispheres with both stars and constellation figures date from 1440; preserved in Vienna, they may have been based on two now-lost charts from 1425 once owned by the German astronomer and mathematician Regiomontanus. In 1515 the noted German painter Albrecht Dürer drew the first printed star maps, a pair of beautiful planispheres closely patterned on the Vienna manuscripts. Dürer and his collaborators numbered the stars on the charts according to the order in Ptolemy's list, a nomenclature that gained limited currency in the 16th century. The first book of printed star charts, *De le stelle fisse* (1540) of the Italian Alessandro Piccolomini, introduced a lettering system for the stars; although frequently reprinted, application of its nomenclature did not spread.

New constellations: 16th–20th centuries. Star charts contained only the 48 constellations tabulated by Ptolemy until the end of the 16th century. Then Pieter Dircksz Keyser, a navigator who joined the first Dutch expedition to the East Indies in 1595, added 12 new constellations in the southern skies, named in part after exotic birds such as the toucan, peacock, and phoenix.

The southern constellations were introduced in 1601 on

a celestial globe by J. Hondius and in 1603 on the globe of Willem Blaeu and on a single plate in the *Uranometria* of Johann Bayer. The *Uranometria,* the first serious star atlas, has a plate for each of the 48 traditional figures (Figure 17). Its scientific integrity rests on Tycho Brahe's newly determined stellar positions and magnitudes (see below).

In his *Uranographia* of 1687, the German astronomer Johannes Hevelius devised seven new constellations visible from mid-northern latitudes that are still accepted, including Sextans (the sextant), named for one of his own astronomical instruments. Fourteen additional southern constellations were formed by Nicolas Louis de Lacaille after his visit to the Cape of Good Hope in 1750. They appeared in the *Memoires* of the Académie Royale des Sciences for 1752 (published in 1756). All other attempts to invent constellations have failed to win acceptance.

The classic atlases of Bayer and Hevelius as well as John Flamsteed's *Atlas Coelestis* (1729) showed only the brighter naked-eye stars. Johann Elert Bode's *Uranographia* of 1801 was the first reasonably complete depiction of the stars visible to the unaided eye. It included an early use of constellation boundaries, a concept accepted and refined by 19th-century cartographers (Figure 18). Friedrich W.A. Argelander's *Uranometria Nova* (1843) and Benjamin A. Gould's *Uranometria Argentina* (1877–79) standardized the list of constellations as they are known today. They divided Ptolemy's largest constellation, Argo Navis (the ship), into four parts: Vela (the sail), Pyxis (the compass), Puppis (the stern), and Carina (the keel).

The list of constellations

The definitive list of 88 constellations was established in 1930 under the authority of the International Astronomical Union. Its rectilinear constellation boundaries preserve the traditional arrangements of the naked-eye stars. The smallest of the constellations, Equuleus ("the Little Horse") and Crux ("the [Southern] Cross"), nestle against constellations that are more than 10 times larger, Pegasus and Centaurus, respectively. The standard boundaries define an unambiguous constellation for each star.

STAR NAMES AND DESIGNATIONS

Of approximately 5,000 stars visible to the unaided eye, only a few hundred have proper names, and less than 60 are commonly used by navigators or astronomers. A few names come almost directly from the Greek, such as Procyon, Canopus, and Antares—the latter derived from "anti-Ares" or "rival of Mars" because of its conspicuous red colour. The stars Sirius ("Scorcher") and Arcturus ("Bear Watcher") are mentioned both by Homer and Hesiod (8th century BC?). Aratus names those two as well as Procyon ("Forerunner of the Dog"), Stachys ("Ear of Corn"?, now Spica), and Protrugater ("Herald of the Vintage," now Latinized to Vindemiatrix).

The *Al* that begins numerous star names indicates their Arabic origin, *al* being the Arabic definite article "the": Aldebaran ("the Follower"), Algenib ("the Side"), Alhague ("the Serpent Bearer"), and Algol ("the Demon"). A conspicuous exception is Albireo in Cygnus, possibly a corruption of the words *ab ireo* in the first Latin edition of the *Almagest* in 1515. Most star names are in fact Arabic and are frequently derived from translations of the Greek descriptions. The stars of Orion illustrate the various derivations: Rigel, from *rijl al-Jawzah,* "Leg of Orion," Mintaka, the "Belt," and Saiph, the "Sword," all follow the Ptolemaic figure; Betelgeuse, from *yad al-Jawzah,* is an alternative non-Ptolemaic description meaning "hand of Orion"; and Bellatrix, meaning "Female Warrior," is either a free Latin translation of an independent Arabic title, *an-najid,* "the conqueror," or is a modification of an alternative name for Orion himself. Only a handful of names have recent origins—for example, Cor Caroli, the brightest star in Canes Venatici, named in 1725 by Edmond Halley.

Arabic names

Bayer's *Uranometria* of 1603 introduced a system of Greek letters for designating the principal naked-eye stars. In this scheme, the Greek letter is followed by the genitive form of the constellation name, so that alpha (*α*) of Canes Venatici is Alpha Canum Venaticorum. Bayer's letters and their extension to newer constellations apply to about 1,300 stars. In *Historia Coelestis Britannica* (published posthumously in 1725), Flamsteed numbered the stars within each of 54 constellations consecutively according to right ascension, and the Flamsteed numbers are customarily used for the fainter naked-eye stars such as 61 Cygni.

An astronomer wishing to specify an even fainter star will usually take recourse to a more extensive or more specialized catalog. Such catalogs generally ignore constellations and list all stars by right ascension. Thus, astronomers learn to recognize that BD +38°3238 refers to a star in the *Bonner Durchmusterung* and that HD 172167 designates one in the *Henry Draper Catalogue* of spectral classifications; in this case, both numbers refer to the same bright star, Vega (Alpha Lyrae). Vega can also be specified as GC 25466, from Benjamin Boss's *General Catalogue of 33,342 Stars* (1937), or as ADS 11510, from Robert Grant Aitken's *New General Catalogue of Double Stars* (1932). These are the most widely used numbering systems. For more obscure names, such as Ross 614 or Lalande 21185, most astronomers would have to consult a bibliographical aid to discover the original listing.

Designations of faint and variable stars

Variable stars have their own nomenclature, which takes precedence over designations from more specialized catalogs. Variable stars are named in order of discovery within each constellation by the letter R to Z (providing they do not already have a Greek letter). After Z the double from RR to RZ, SS to SZ, . . . is used; after ZZ come the letters AA to AZ, BB to BZ, and so on, the letter J being omitted. After the letters QX, QY, and QZ, the names V335, V336, and so on are assigned. Hence, the first lettered variable in Cygnus is R Cygni, and the list reached V1761 by the end of 1981. The names were assigned by the Soviet authors of the *General Catalogue of Variable Stars* (3rd edition, 1969), with the approval of the Commission on Variable Stars of the International Astronomical Union.

Two catalogs are frequently used for designating star clusters, nebulas, or galaxies. The shorter list of these, which includes about 100 of the brighter objects, was compiled in three installments by the French astronomer Charles Messier in the latter part of the 18th century; M1 and M31 are examples of this system, being, respectively, the Crab Nebula and the great galaxy in Andromeda. A much more extensive tabulation in order of right ascension is the *New General Catalogue* (NGC; 1890), followed by the *Index Catalogue* (IC; 1895, 1908); examples are NGC 7009 or IC 1613.

MODERN STAR MAPS AND CATALOGS

Near the end of the 16th century, Tycho Brahe of Denmark resolved to provide an observational basis for the renovation of astronomy. With his large and sturdy (but pre-telescopic) quadrants and sextants, he carefully measured the positions of 777 stars, to which he later added

enough hastily observed stars to bring the catalog up to exactly 1,000. A comparable catalog of southern stars was not available until 1678, when the young Edmond Halley published positions of 350 stars measured during a British expedition to St. Helena.

The first Astronomer Royal, John Flamsteed, pioneered the use of telescopic sights for measuring stars' positions. His aforementioned *Historia Coelestis Britannica* listed 3,000 stars, exceeding all former catalogs in number and accuracy. These observations provided the basis for his great *Atlas Coelestis*. Measurements of the third Astronomer Royal, James Bradley, achieved a precision within a few seconds of arc; as reduced by the German astronomer Friedrich W. Bessel in 1818, his positions are the oldest still considered useful in modern astronomy.

Survey and zone maps and catalogs. The German word *Durchmusterung,* literally a "scanning through," was introduced by Argelander, who undertook to list all the stars visible in the eight-centimetre Bonn refractor. Keeping the telescope fixed, he recorded the stars, zone by zone, as the Earth's rotation carried the stars past the field of view. The resulting *Bonner Durchmusterung* (1859–62), or *BD* catalog, contains 324,189 stars to about the ninth magnitude between declinations +90° and −2°. The accompanying charts, published in 1863, far surpassed all former maps in completeness and reliability. These maps are still of great value. The Bonn survey was extended to −23° in 1886, and at Córdoba, Arg., it was carried to the parallel of −62° by 1908, and to the South Pole by 1930. Because observing conditions changed over the many years required, the resulting *Córdoba Durchmusterung,* or *CD,* lacks the homogeneity of its northern counterpart.

The *Bonner Durchmusterung*

In 1867 Argelander proposed to the Astronomische Gesellschaft (German Astronomical Society) a massive project to document stellar positions with far greater precision. Although the observing of selected star positions with meridian circle telescopes had become well established by observers during the 18th and early 19th centuries, the new plan called for meridian observations of all stars down to the ninth magnitude. A score of observatories on four continents, each responsible for a specific zone of declination, cooperated to complete the catalog and its southern supplements. The northern sections, known as the *AGK1,* were published by zones; not until 1912 was the *AGK1* complete to −18°.

Meanwhile, in quite another way, the Dutch astronomer Jacobus Cornelius Kapteyn completed an inventory of the southern sky by the measurement of the positions and magnitudes of about 454,000 stars from a set of photographic plates taken in Cape Town. Known as the *Cape Photographic Durchmusterung* (1896–1900), or *CPD,* the result covers the sky from declination −19° to the South Pole, down to the 11th magnitude.

Beginning in 1924, the Astronomische Gesellschaft catalog was repeated photographically by the Bonn and Hamburg-Bergedorf observatories; published in 1951–58, the new catalog is called the *AGK2.* Neither the *AGK1* nor the *AGK2* provided information on proper motions (see above). Therefore, another set of photographic plates was obtained in Hamburg during the 1950s in order to obtain the motions; the resulting *AGK3* was distributed on magnetic tape in 1969.

Astronomische Gesellschaft catalog

In 1966 the Smithsonian Astrophysical Observatory in Cambridge, Mass., issued a reference star catalog for use in finding artificial satellites from photographs. Although the *SAO Star Catalog* of 258,997 stars contains no new basic data, it does present the information in a particularly useful form. An accompanying computer-plotted atlas (1968), which includes more than 260,000 stars in addition to galaxies and nebulas, achieves an unprecedented accuracy for celestial cartography.

Fundamental catalogs. The measurements of accurate places for vast numbers of stars rests on painstakingly and independently determined positions of a few selected stars. A list of positions and proper motions for such selected stars well distributed over the sky is called a fundamental catalog, and its coordinate system is a close approximation to a fixed frame of reference. When the German astronomers began the *AGK2* in the 1920s, they first required a fundamental reference system that by the following decade was defined in the *Dritter Fundamentalkatalog des Berliner Astronomischen Jahrbuchs,* or *FK3. The Fourth Fundamental Catalogue* (1963), or *FK4,* published by the Astronomisches Rechen-Institut in Heidelberg, contains data for 1,535 stars and has now superseded the *FK3.*

Photometric catalogs. A complete mapping of the sky includes magnitudes (and colours) as well as positions and motions. The great survey catalogs furnished magnitude estimates, but since photometric procedures are

quite different from astrometric ones, a separate family of photometric catalogs has developed. Visual observations provided the basis for major tabulations published at Oxford, Harvard, and Potsdam around the turn of the century, but these were soon superseded by photographic work. Studies of galactic structure, which required accurate magnitudes for at least some very faint stars as well as the bright ones, led to the establishment of the plan of 206 selected areas. These were well-defined areas of sky with stars of many representative kinds that could be used as standards of comparison, and the *Mount Wilson Catalogue of Photographic Magnitudes in Selected Areas* (1930), made about 20 years later, was for many years a leading reference for celestial photometry. Today, several catalogs of photoelectric measurements in three or more colours set the standards for precision magnitudes.

The Mount Wilson Catalogue

Another important quantity that can be measured is a star's spectral type (see above). One of the greatest collections of astronomical data is the *Henry Draper Catalogue* (1918–24), formed at Harvard by Annie Jump Cannon and Edward Charles Pickering. The *HD* lists spectra of 225,300 stars distributed over the entire sky, and the *Henry Draper Extension* (1925–36, 1949) records 133,782 additional spectra.

Photographic star atlases. Astronomical photography was scarcely past its infancy when an international conference in Paris in 1887 all too hastily resolved to construct a photographic atlas of the entire sky down to the 14th magnitude, the so-called *Carte du Ciel,* and an associated *Astrographic Catalogue,* with measured star places down to the 12th magnitude. The original stimulus had come in 1882 with the construction of a 33-cm astrographic objective lens at Paris. For decades the immense *Carte du Ciel* enterprise sapped the energies of observatories around the world, especially in France, and even now is incomplete in the form originally planned. Nowadays such a program could be speedily completed with the use of computerized measuring instruments.

Carte du Ciel

The first photographic atlas of the entire sky (if a set of 55 glass plates offered by Harvard in 1903 be excepted) was initiated by an energetic British amateur. Issued in 1914, the (John) *Franklin-Adams Charts* comprise 206 prints with a limiting magnitude of 15.

The monumental *National Geographic Society–Palomar Observatory Sky Survey,* released in 1954–58, reaches a limiting photographic magnitude of 21, far fainter than any other atlas. (The southernmost band has a slightly brighter limiting magnitude of 20.) Each field was photographed twice with a 124-cm Schmidt telescope at Mount Palomar to produce an atlas consisting of 935 pairs of prints made from the original blue-sensitive and red-sensitive plates, each about 6° square. The atlas proper extends to a declination of −33°, but 100 additional prints from red-sensitive plates now carry the coverage to −45° (Figure 19). Photographic mapping of the southern skies by the United Kingdom's 124-cm Schmidt telescope at Siding Spring Observatory in Australia and by the European Southern Observatory's 100-cm Schmidt at La Silla in Chile has penetrated to stars fainter than magnitude 22.

Atlases for stargazing. Three modern atlases have gained special popularity among amateur and professional observers alike. *Norton's Star Atlas,* perfected through numerous editions, plots all naked-eye stars on eight convenient charts measuring 25 by 43 cm. The *Tirion Sky Atlas 2000.0* (1981) includes some 43,000 stars to magnitude eight and is based primarily on the *SAO Star Catalog.* Its 26 charts, measuring 47 by 33 cm, include bright star names, boundaries of the Milky Way, and about 2,500 star clusters, nebulas, and galaxies. The companion to the *Tirion Atlas—Sky Catalogue 2000.0* (1982, 1985)—summarizes the essential characteristics of 45,269 stars. The second volume of this work catalogs double stars, variable stars, and various kinds of nonstellar objects, including radio and X-ray sources. The German astronomer Hans Vehrenberg's *Photographischer Stern-Atlas* (1962–64), covering the entire sky in 464 sheets, each 12° square, has probably reached wider use than any other photographic atlas because of its quality and comparatively modest cost.

Norton's Star Atlas

There are several handbooks that serve as useful supplements to such atlases. *Burnham's Celestial Handbook* (1978) contains comprehensive descriptions of thousands of astronomical objects. *The Observer's Handbook,* published annually by the Royal Astronomical Society of Canada, lists valuable information for locating and observing a wide range of astronomical phenomena.

Statistics

Statistics is the art and science of gathering, analyzing, and making inferences from data. Originally associated with numbers gathered for governments, the subject now includes large bodies of method and theory.

Applied fields have stimulated extensive theoretical and practical work. Trying to improve the accuracy of physical measurements, for example, led the 19th-century German mathematician Carl Friedrich Gauss to develop the method of least squares (a method of analyzing experimental data; see below), which today has evolved to a flexible general theory that is applied and adapted to nearly every quantitative area. This work also contained the seeds of what the 20th-century British statistician Sir Ronald Aylmer Fisher later developed into the design of experiments, a branch of statistics widely used in agriculture for the improvement of crop yield and used to improve the precision of the results obtained in medical, biological, and industrial experimentation.

The ideas of effective design for data gathering are also basic to the construction of sample surveys, a branch of statistics most popularly known for its contributions to public opinion polling, to pre-election forecasting, and to market research. Perhaps even more significant is this branch's service to government through, for example, estimates of amount of unemployment and cost of living, which have become indispensable in attempts to regulate the economy. Sample survey methods have found uses in accounting, inventory control, and other areas.

For modern manufacturing, methods of controlling the quality of manufactured product have been essential. The statistical foundations of sequential analysis were provided by Abraham Wald in 1947 in order to handle problems in quality control. In psychology and education, the statistical theory of tests and measurements has been extensively developed to compare achievement by individuals from diverse places and backgrounds.

THE BASIC PRINCIPLES OF STATISTICAL INFERENCE

Statistical experiments. The basic principles of statistical inference involve the notions of experiment, outcome, sample space, event, and probability. The idea of an experiment includes such examples as tossing a coin, measuring a length, or asking a person which party he or she will vote for at an election. Such experiments have a number of possible outcomes, perhaps infinitely many. When an ordinary die is thrown there are six possible outcomes, corresponding to the numbers 1, 2, 3, 4, 5, and 6. In statistics this collection of all possible outcomes is called a sample space. For the die the sample space can be written as the set {1, 2, 3, 4, 5, 6}. Any single outcome of an experiment, such as the throwing of a 6, is called a point. Certain specified sets of outcomes are called events. The throwing of an even number on a die would be an event, denoted by {2, 4, 6}.

Die throwing and coin tossing

Sets of events are frequently studied. For example, in tossing a coin twice, one possible outcome is "heads first time, tails second time," which is abbreviated to (H, T). Four possible outcomes make up the sample space—(H, T), (H, H), (T, H), and (T, T). If the experimenter asks only whether he gets the same result on both throws, the natural events chosen would be {(H, H), (T, T)} and {(H, T), (T, H)}.

In statistics the results of a large number of experiments form the data used. Sometimes it is assumed that each outcome is independent of any preceding one, as the number thrown on a die is independent of any preceding throws. It is also assumed that there is an underlying probability mechanism determining the nature of the data, as the probability of a coin's coming up heads determines the outcomes of experiments in which a coin is thrown twice. If the underlying probability mechanism is known, then the probability that certain outcomes occur can be calculated. This is the concern of probability theory (see PROBABILITY THEORY).

Statistics is concerned with the application of probability theory to data. If only partial information is available—for example, if the underlying mechanism is one of several—it may be possible to use the data to infer which mechanism generated it and to associate probabilities or degrees of confidence with the various mechanisms. It is possible to perform the experiment a number of times and obtain a sequence of outcomes. Dividing the number of times an outcome of an experiment falls in event A by the number of experiments gives an estimate of the probability of event A. As the number of experiments grows large, the estimate becomes more likely to be close to the true probability $\mathbf{P}(A)$. In mathematical terms, if $x_1, x_2, \cdots$ is a sequence of outcomes and A an event, and $N(x_1, x_2, \cdots, x_n; A)$ denotes the number of times the outcome falls in A during the first n experiments, then as n tends to infinity, the chance that $N(x_1, x_2, \cdots, x_n; A)/n$ is close to $\mathbf{P}(A)$ tends to certainty.

Although this fact, known as the law of large numbers, tells the experimenter that he will arrive at the right answer eventually, it does not tell him how close he will be to the right answer after having performed the experiment a certain number of times. This is where statistical methods come in. Under certain conditions statistical methods give an estimate of the error that might possibly be made by performing the experiment a finite number of times.

An experiment is described completely by its sample space S, which is the set of possible outcomes, by a family B of events, and by a probability assignment $\mathbf{P}$ that governs the outcome of the experiment. The independence of two events means that the outcome of one does not imply anything about the outcome of the other. As a practical matter, separation of events in space and time often ensures independence. The concept of statistical or probabilistic independence is intended to extend the common meaning of independence to chance situations in which the occurrence of one event does not change the probability of occurrence of another event.

When events are independent, the probability that they jointly occur is the product of their probabilities: If the events are $A_1, \cdots, A_n$ and the associated probabilities are $\mathbf{P}(A_i)$, $i = 1, \cdots, n$, the probability that all occur is $\mathbf{P}(A_1) \cdots \mathbf{P}(A_n)$.

When a die is tossed twice, for example, the sample space can be written as the set {(1, 1), (1, 2), · · · , (1, 6), (2, 1), · · · , (2, 6), · · · , (6, 6)}; each of the 36 points in this sample space is composed of an outcome on the first toss and an outcome on the second. Thus, (4, 3) denotes a 4 on the first toss and a 3 on the second. The events A_1 and A_2 are independent and the probability of "A_1 and A_2" may be computed as the product of the individual probabilities (see Box, calculation 1), yielding a probability of $1/3$.

These ideas of independence apply to statistical investi-

(1) $\begin{cases} A_1 = \{\text{first toss even}\}, \\ A_2 = \{\text{second toss 4 or less}\} \\ \mathbf{P}(A_1 \cap A_2) = \mathbf{P}(A_1)\mathbf{P}(A_2) = \frac{3}{6} \times \frac{4}{6} = \frac{1}{3} \end{cases}$

(2) $\mathbf{P}(X=1) = \mathbf{P}(X=0) = \frac{1}{2}$

(3) $f(x) = \mathbf{P}(X=x), \quad x \in S$

(4) $\mathbf{P}(A) = \sum_{x \in A} f(x)$

(5) $f(x) = \dfrac{n!}{x!(n-x)!} p^x (1-p)^{n-x}, \qquad 0 \leq x \leq n$

(6) $F(x) = \mathbf{P}(X \leq x), \qquad -\infty < x < +\infty$

(7) $F(b) - F(a) = \mathbf{P}(a < X \leq b)$

(8) $\int_a^b f(x)\,dx = F(b) - F(a) = \mathbf{P}(a < X \leq b)$

(12) $\mu_r = \int_{-\infty}^{+\infty} (x-\mu)^r f(x)\,dx$

gations in which the data are generated by repetitions of the same elementary operation, each carried out independently of the others.

To develop models for numerical data, a real number or a vector with real components is associated with each outcome in the sample space. The function mapping the outcome to the number or vector is called a random variable. Capital letters are often used to designate the random variable itself and lower-case letters for an unspecified value of a random variable. Thus $\mathbf{P}(X=x)$ represents the probability that the random variable X takes the value x. It is often convenient to forget the functional origin of the idea of random variable and regard the set of values of X as the basic sample space.

Random variables

For example, when a coin is tossed, the outcome may be heads or tails, and heads may be associated with $X=1$ and tails with $X=0$. X, the number of heads, is called a random variable and its values are 0 and 1 with equal probabilities of ½ (see 2).

Using random variables to describe outcomes of experiments gives systematic ways to describe the assignment of probability to sets. In practice, the sample space of the random variable is either a discrete set of values (as in tossing a die) or a continuous set (as in measuring a length). In both cases the sample space consists of a set on the real line. In the discrete case, it may be convenient to give a probability for each point x in the sample space S. Thus for the random variable X a probability mass function f is defined such that its value at x is a probability (see 3). Then the probability of an event A may be computed by summing $f(x)$ for all values of x in A (see 4). For all x, $f(x) \geq 0$ and $\mathbf{P}(S) = 1$.

For example, if p is the probability of success on a single trial, if the outcomes of trials are independent, and if the random variable X is the number of successes in n trials, then (as mentioned in PROBABILITY THEORY) the value of f at x is a term in a binomial expansion (see 5). The probability that the experiment produces all successes or all failures is $p^n + (1-p)^n$. The distribution of probability represented by the values of $f(x)$ is called the binomial distribution. A more complete representation would use $f(x \mid n, p)$ (read "f of x given n and p") rather than $f(x)$ so as to specify the parameters n and p of the distribution.

When probability is smoothly distributed over continuous sample spaces, a difficulty in representing the probabilities is that each point has probability zero, yet the total probability must be one: a line segment consists of points, each of zero length, and yet it has a nonzero length. Developing probability through measures on Borel sets resolves such difficulties (see ANALYSIS: *Real analysis*).

Distribution functions and their properties. For the continuous random variable X with values $x \in S$, a cumulative distribution function F is defined so that its value at x is the probability (see 6) for the random variable to be less than or equal to x. $F(-\infty)$ and $F(+\infty)$ are also defined by: $F(-\infty) = 0$ and $F(+\infty) = 1$ (the symbol ∞ denotes infinity). The probability in an interval, say $a < x \leq b$, is given by the difference in the values of F evaluated at the endpoints of the interval (see 7).

If F has a derivative $dF(x)/dx = f(x)$ for almost all x, then f is called the probability density function of the random variable X, or more briefly the density function. This brings the integral calculus into play because now, from the fundamental theorem of calculus, the definite integral of f is a probability (see 8). For example, for the uniform distribution on the interval $a < x \leq b$, the density and cumulative are given by specific functions (see 9) that are constant and of constant slope, respectively, over the interval.

The approach via the cumulative distribution function F makes it possible to unify mathematically discrete and continuous distributions as well as mixed ones by employing the Lebesgue-Stieltjes integral.

The problem of finding the value of x such that $F(x) = p$ often arises. Such a value of x is called the pth quantile, or $100p$th percentile, of the distribution; the notation x_p is used. The median of the distribution is $x_{0.5}$, and $x_{0.25}$ and $x_{0.75}$ are the first and third quartiles.

When the random variable X has a distribution with density f, the mean of the distribution, if it exists, is given by the integral (see 10) over the whole real line of the product $xf(x)$. Its value μ is also called the first moment of the distribution. More generally, if it exists, the integral (see 11) of the product $x^r f(x)$ is the rth raw moment of the distribution. Moments about the mean are also used, and the rth moment about the mean is obtained from a similar integral (see 12) involving the rth power of $(x-\mu)$. In the discrete case the integrations are replaced by summations over $x \in S$.

The second moment about the mean is much used in both statistics and probability. It is called the variance of the distribution, or the variance of the random variable X, abbreviated var X, or σ_X^2, or when the name of the random variable is understood, σ^2. Its square root, σ, is the standard deviation.

Variance

In addition to moments defined as average values of the functions X^r and $(X-\mu)^r$, the average values of other functions of random variables frequently arise. If h is a function of X, then when it exists, the expected value of $h(X)$ is defined to be the integral over the whole real line (see 13) of the product of $h(x)$ and the probability density function. Therefore, the mean is $\mathbf{E}(X)$, and $\sigma^2 = \mathbf{E}[(X-\mu)^2]$. It should be noted that $\mathbf{E}$ is an operator, not a notation for a function.

For example, the expected value of the number of successes, X, for the binomial distribution is the product of the number of trials n and the constant probablity p of success in each trial (see 14), derived by evaluating a binomial summation. The variance of X is $(1-p)$ times the mean (see 15).

For the normal distribution (see 16a), upon integration the mean μ of the random variable X is θ_1 (see 17), and the variance σ^2 is θ_2 (see 18). Consequently, the parameters of the normal distribution are said to be μ and σ^2. These results (see 16b) make clear that the normal density decreases exponentially, the exponent being proportional to the square of $(x-\mu)/\sigma$, the distance from x to the mean

measured in standard deviation units. The coefficient $1/\sqrt{2\pi}\sigma$ assumes that the total density integrates to unity so that the total probability is 1. [In (16a), (16b), and (16c), π (pi) equals 3.14159 · · · .]

If $Y = aX + b$, in which a and b are constants and X any random variable with mean μ and variance σ^2, then the mean of Y, written μ_Y, bears the same linear relation to the mean of X that Y bears to X, and the variance of Y is the product of a^2 and the variance of X (see 19).

From any random variable X with mean μ and variance σ^2 a new random variable $Y = (X-\mu)/\sigma$ with mean 0 and variance 1 can be constructed. Such a Y is called a standardized random variable, and, if X is normally distributed, it is said to have the standard normal distribution (see 16c).

To generalize the concept of distribution function to several random variables $X_1, \cdots, X_k$ in a k-dimensional Euclidean space, the joint cumulative distribution function F is used. By definition the joint cumulative distribution function (see 20) is the probability of the common occurrence of k events of the type $(x_k \leq x_k)$. If any x_i is replaced by $-\infty$, then F takes the value zero. When all x_i are replaced by $+\infty$, $F = 1$. If F is differentiable with respect to all the variables, then there is a joint probability density function f such that F is the indefinite multiple integral (see 21) of f. If A is a set in the sample space and $x = (x_1, \cdots, x_k)$, then the probability that x belongs to the set A is the multiple integral (see 22) of the density extended over A. Formally the same equality is expressible in terms of a Stieltjes integral (see 23). When integration is performed over all variables but x_i, the cumulative gives $F(+\infty, \cdots, +\infty, x_i, +\infty, \cdots, +\infty)$, which represents the marginal cumulative distribution of X_i alone. More generally, when exactly r $(1 \leq r < n)$ coordinates are set at $+\infty$, the $(k-r)$ th-order marginal distribution of the remaining $k-r$ random variables is obtained.

When the X_i are independent with $F_i(x_i) = \mathbf{P}(X_i \leq x_i)$, $i = 1, \cdots, k$, and have probability density functions $f_i(x_i)$, then the joint cumulative can be represented as the product of the separate distribution functions (see 24), and the joint density as the product of the separate densities (see 25). To represent the distribution of repeated measurements, X_i is allowed to represent the ith measurement, and the f_i is taken to be equal to f_0, so that the products above take a particularly simple form, expressible as a product extended over k index values (see 26) of $f_0(x_i)$.

If two random variables X and Y have a joint density f and if their means are μ_X and μ_Y, the covariance between X and Y (if it exists) is defined as an integral of the product of the differences $(x-\mu_X)$ and $(y-\mu_Y)$, weighted with the joint density (see 27).

Sums of random variables have special interest for statisticians. If X_i has mean μ_i and variance $\sigma_i^2 = \sigma_{ii}$ and if $\operatorname{cov}(X_i, X_j) = \sigma_{ij}$, then if $Y = \Sigma X_i$, the mean of Y is the sum of the means of the X_i (see 28) and the variance of Y is the double sum over σ_{ij} (see 29). (In the summation defining Y the sum is from 1 to n.) In other words, the mean of a sum is the sum of the means, and the variance of a sum is the sum of the variances plus twice the covariances. The correlation coefficient between variables X_i and X_j is defined as the ratio of σ_{ij} to the product $\sigma_i\sigma_j$ (see 30).

The correlation coefficient

When all pairs of variables have $\rho_{ij} = 0$, then $\sigma_Y^2 = \sum_{i=1}^{n} \sigma_i^2$. Independence between all the random variables guarantees $\rho_{ij} = 0$, but having all $\rho_{ij} = 0$, $i \neq j$, does not guarantee independence.

An important exception is the joint multivariate normal distribution, the only parameters of which are the means, variances, and covariances of the variables. When $\rho_{ij} = 0$ for all i, j, $i \neq j$, the joint density can be represented by a product (see 31) of normal densities with typical mean μ_i and variance σ_i^2. For the general joint multivariate normal distribution density is proportional to the exponent of a quadratic form (see 32). If $\| \sigma_{ij} \|$ is the covariance matrix of the n random variables ($\| a_{ij} \|$ denotes the matrix with elements a_{ij}) and σ^{ij} the elements of its inverse, then the quadratic form is expressible (see 33) in terms of the collection $\{\sigma^{ij}\}$, and the constant factor that multiplies the exponential is expressible (see 34) in terms of $| \sigma^{ij} |$, in which $| a_{ij} |$ is the determinant of the matrix with elements a_{ij}. If $\Sigma = \| \sigma_{ij} \|$ and the vector $(x-\mu)$ is defined (see 35), the quadratic form Q can be written more simply in vector and matrix notation, in which T stands for transpose.

$$(32)\quad \begin{cases} f(x_1, \cdots, x_n|\mu_i, \sigma_i^2, \sigma_{ij}, i,j=1, \cdots, n) \\ \quad = K\exp(-\frac{1}{2}Q) \end{cases}$$

$$(33)\quad Q=\sum_i \sum_j \sigma^{ij}(x_i-\mu_i)(x_j-\mu_j)$$

$$(34)\quad K=[|\sigma^{ij}|/(2\pi)^n]^{1/2}$$

$$(35)\quad \begin{cases} (x_1-\mu_1, \cdots, x_n-\mu_n)=(x-\mu) \\ Q=(x-\mu)^T\Sigma^{-1}(x-\mu) \end{cases}$$

$$(36)\quad Z_n=\frac{Y_n-\mu_n}{\sqrt{\text{var } Y_n}}$$

$$(37)\quad \lim_{n\to\infty} \mathbf{P}(Z_n<z)=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{z} e^{-\frac{1}{2}x^2}\,dx$$

$$(38)\quad Z_1^2+\cdots+Z_k^2$$

$$(39)\quad t_k=\frac{Z}{\sqrt{\chi_k^2/k}}$$

$$(40)\quad f(x|\theta)=\theta e^{-\theta x}, \qquad x\geqslant 0, \theta>0$$

$$(41)\quad \mu=\mathbf{E}(X)=\theta\int_0^\infty xe^{-\theta x}\,dx=1/\theta$$

$$(42)\quad L(x_1, \cdots, x_n|\theta)=\prod_{i=1}^{n} f(x_i|\theta)$$

Under a variety of conditions, the distribution of sums of random variables tends to a normal distribution as the number of random variables tends to infinity. The statements of conditions leading to these distributions are called central limit theorems. To illustrate, if X_1, X_2, $\cdots$ is a sequence of random variables and $Y_n=X_1+\cdots+X_n$, and if $\mathbf{E}(Y_n)=\mu_n$ and var Y_n exists, then as n becomes large the sequence of distributions of the standardized random variables Z_n (see 36; each with mean 0 and variance 1) has a limit that is the standard normal distribution (see 37). One set of conditions guaranteeing this limiting distribution is independence of the X_i and identical distributions with finite variances, but other conditions are also available that do not require identical distributions, equal variances, or even independence.

This limiting distribution is also shared by many functions of random variables and is one reason for the importance of the Gaussian or normal distribution in statistical theory. In applications, sums of even a few random variables of the types ordinarily met have distributions the central portions of which can be well approximated by normal distributions.

If Z_1, $\cdots$, Z_k are independent standard normal random variables, the sum of their squares (see 38) forms a new random variable, χ_k^2; its distribution is called the chi-square distribution with k degrees of freedom.

If Z, a standard normal random variable, and χ_k^2 a chi-square random variable with k degrees of freedom, are independent, then the new random variable, written t_k, which is proportional to Z divided by the square root of the chi-square (see 39), has the distribution known as Student's t distribution with k degrees of freedom. Student was the scientific pseudonym of William Sealy Gosset, the statistician and chemist who discovered the form of the distribution by a combination of mathematical work and empirical work with random numbers, an early application of what is now called the Monte-Carlo method.

The chi-square and t distributions are frequently used in interval estimation and in testing hypotheses.

ESTIMATION

Point estimation. For a random sample with values x_1 $\cdots$ x_n independently drawn from a distribution F the parameter of which is θ, the problem of estimation is to find a function of the x's, $\hat{\theta}$, that comes close to θ. Here "close" is a vague word that can be given many meanings. If the sample is regarded as composed of random variables X_1, $\cdots$, X_n, and the estimator $\hat{\theta}$ as a function of those random variables, then $\hat{\theta}$ is itself a random variable. Some desirable properties for an estimator $\hat{\theta}$ are (A) that its average error be small: indeed, if the average error vanishes, $\mathbf{E}(\hat{\theta}-\theta)=0$, and the estimator is said to be unbiassed; (B) that the mean square error $\mathbf{E}(\hat{\theta}-\theta)^2$ be small: this measure combines, in a somewhat arbitrary way, variability of $\hat{\theta}$ with its bias $b=\mathbf{E}(\hat{\theta}-\hat{\theta}$, because $\mathbf{E}(\hat{\theta}-\theta)^2=$ var $\hat{\theta}+b^2$. (C) Another attractve property is small variance. If, among several unbiassed estimators, one has smallest variance, it is known as the minimum-variance unbiassed estimator. Which of several estimators may be more desirable depends, among other things, upon the costs of errors $(\hat{\theta}-\theta)$ of various sizes.

Small variance

Samples contain information about the parameters of a family of distributions, but different families can profitably use different functions to extract this information. Several methods of estimation offer general techniques for finding estimators for parameters. Three techniques are considered here: the method of moments, the method of maximum likelihood, and Bayesian methods.

Method of moments. The moments of a family of distributions are functions of the parameters of the family. If there are only a few parameters, it may be possible to use the first few moments of the distributions together with the sample moments to get estimates of the parameters. If the observed values of the sample moments are equated with the corresponding population moments, expressed as functions of the parameters, the resulting equations for estimates of the parameters may be solved. Thus the estimators choose that member of the family whose moments match the sample moments.

The method of moments may be used, for example, to estimate the parameter θ of an exponential distribution having probability density function proportional to the exponential of $-\theta x$, the values of x being non-negative (see 40). The population mean is calculated (see 41) to be $1/\theta$. The value of the sample mean is $\bar{x}=(x_1+\cdots+x_n)/n$, and so the method of moments would derive the estimate of θ from $\bar{x}=1/\hat{\theta}$ and give $\hat{\theta}=1/\bar{x}$.

The method of maximum likelihood. A widely used method that has attractive large-sample properties is the method of maximum likelihood. For families of discrete distributions, the probability of getting the particular sample that has been observed can be computed, and then those values of the parameters that maximize the probability can be chosen as estimates. If the sample x_1, $\cdots$, x_n has been independently chosen from a distribution with probabilities $\mathbf{P}(X=x\mid\theta)=f(x\mid\theta)$, in which θ may be a vector, then that probability, called the likelihood, is defined as the product of n probability mass functions, one evaluated at each sample value (see 42).

For continuous distributions the corresponding approach is again to maximize the likelihood function, which is given above (see 42) except that the righthand side is the product of the values, $f(x_i\mid\theta)$, of the density function evaluated at the sample points. Although symbolically the same, the likelihood in the discrete situation is a probability, but in the continuous case it is a measure of the density of probability at the sample point. The one-parameter case is considered. Under broad regularity conditions (dealing with the differentiability of f with respect to θ, and the existence of integrals of functions of f and its derivatives), the estimator θ, the value of θ that maximizes L for the given sample, is the maximum likelihood estimator of θ. Asymptotically (*i.e.*, as n tends to infinity) $\hat{\theta}$ tends to be normally distributed with asymptotic mean θ and asymptotic variance expressed in a simple formula (see 43) in terms of the reciprocal expectation of the second derivative (with respect to θ) of the log of the density.

For example, a sample of size n from the normal distribution with mean 0 and variance θ (or σ^2) has a likelihood

$$(43)\quad \operatorname{var}\hat{\theta}=\frac{1}{-n\mathbf{E}\left[\dfrac{\partial^2 \log f(x|\theta)}{\partial\theta^2}\right]}$$

$$(44)\quad \begin{cases} L(x_1,\cdots,x_n|\theta)=[2\pi\theta]^{-\frac{n}{2}}\,e^{-\frac{1}{2}\Sigma x_i^2/\theta} \\ \dfrac{\partial \log L}{\partial\theta}=-\dfrac{n}{2\theta}+\dfrac{\Sigma x_i^2}{2\theta^2} \end{cases}$$

$$(45)\quad \hat{\theta}=\sum_{i=1}^{n} x_i^2/n$$

$$(46)\quad \frac{\partial^2 \log f(x|\theta)}{\partial\theta^2}=\frac{1}{2\theta^2}-\frac{x^2}{\theta^3}$$

$$(47)\quad \operatorname{var}\hat{\theta}=\frac{2\theta^2}{n}$$

$$(48)\quad \hat{\sigma}=\sqrt{\hat{\theta}}=\sqrt{\Sigma x_i^2/n}$$

$$(49)\quad L(x_1,\cdots,x_n|\theta)=\prod_{i=1}^{n} f(x_i|\theta)$$

$$(50)\quad B_{pq}=-\mathbf{E}\frac{\partial^2 \log f(x|\theta)}{\partial\theta_p\partial\theta_q},\qquad p,q=1,\cdots,n$$

$$(51)\quad \begin{cases} f(x|\theta_1,\theta_2)=(2\pi\theta_2)^{-1/2}\exp[-(x-\theta_1)^2/2\theta_2] \\ -\infty<x<\infty,\qquad -\infty<\theta_1<\infty,\qquad 0<\theta_2<\infty \end{cases}$$

$$(52)\quad \hat{\theta}_1=\frac{\Sigma x_i}{n}=\bar{x},\qquad \hat{\theta}_2=\frac{\Sigma(x_i-\bar{x})^2}{n}$$

$$(53)\quad \begin{Vmatrix} \dfrac{\theta_2}{n} & 0 \\ 0 & \dfrac{2\theta_2^2}{n} \end{Vmatrix}$$

$$(54)\quad \theta_2/n=\sigma_X^2/n$$

$$(55)\quad \mu-|z_{\frac{1}{2}\alpha}|\sigma/\sqrt{n}\leq\bar{X}\leq\mu+|z_{\frac{1}{2}\alpha}|\sigma/\sqrt{n}$$

$$(56)\quad \bar{X}-|z_{\frac{1}{2}\alpha}|\sigma/\sqrt{n}\leq\mu\leq\bar{X}+|z_{\frac{1}{2}\alpha}|\sigma/\sqrt{n}$$

function and its derivative given by the equations that are exponential and algebraic in form, respectively (see 44). If the derivative is set equal to zero and the equation solved for θ, the maximum likelihood estimate of θ is given by the sum of the squares of the x_i divided by n (see 45). Because the second derivative of the log of the density is a simple expression that is linear in the square of the variable (see 46), and $\mathbf{E}(X^2)=\theta$, the asymptotic variance is proportional to the reciprocal of n (see 47).

Some attractive asymptotic properties of the maximum likelihood estimator when the regularity conditions are met are:

A. That it converges in probability to the true value of θ as $n\to\infty$. (Estimators that do this are said to be consistent.)

B. That it is asymptotically unbiassed.

C. That among asymptotically unbiassed estimators, no other has smaller asymptotic variance. (Unbiassed estimators having finite variance at least as small as that of any other estimator are said to be efficient.)

D. The maximum likelihood estimator of a function of θ is the same function of the maximum likelihood estimator of θ.

In the example given above the maximum likelihood estimate of θ (or σ^2) was $\Sigma x_i^2/n$. The maximum likelihood estimate of σ is the square root of this expression (see 48).

The extension of this method to vector random variables and vector parameters is straightforward providing further regularity conditions hold. If a sample point consists of the vector $x_i=(x_{1i},\cdots,x_{ri})$, and the joint distribution of the r variables has k parameters $\theta=(\theta_1,\cdots,\theta_k)$, then one forms the likelihood function that is formally the same as before but now involving vectors (see 49). To find the relative maximum (assumed unique), the partial derivatives with respect to θ_i are taken, they are set equal to zero, and the resulting equations for the maximum likelihood estimates $\hat{\theta}_i$ are solved. Asymptotically the estimators are jointly normally distributed with mean $(\theta_1,\cdots,\theta_k)$ and covariance matrix $\|nB_{pq}\|^{-1}$, in which the $\{B_{pq}\}$ are expectations of second partial derivatives of the log of the density (see 50). The vectorial nature of the observations is not central to maximum likelihood estimation, and so the method is illustrated by a one-variable probability distribution with two parameters.

As an example, consider the vector parameter. If the sample is drawn from the normal distribution with mean θ_1 and variance θ_2, so that the normal density is specified (see 51) as before, then it is found that the maximum likelihood estimator of the population mean is the sample mean, and of the population variance is the sample variance (see 52). Furthermore, the covariance matrix is diagonal (see 53), so that asymptotically $\hat{\theta}_1$ and $\hat{\theta}_2$ are independently normally distributed with means (θ_1,θ_2) and variances θ_2/n and $2\theta_2^2/n$, respectively.

For a sample of n independent normally distributed observations, the sample mean $\bar{X}$ is exactly, not just asymptotically, normally distributed with mean θ_1 and variance θ_2 as before (see 54).

Interval estimation. The discussion of estimation has emphasized point estimates for parameters, but it may also be useful to give an interval within which a parameter is likely to lie, together with the chance that the interval includes the parameter. More generally, if the parameter were a vector, a region would be given.

The confidence interval

An important illustration gives the confidence interval, based on a sample size of n, for the unknown mean μ of a normal distribution with known standard deviation σ. The probability is $1-\alpha$ that the sample mean $\bar{X}$ falls (see 55) within a specified distance, $|z_{\alpha/2}|\,\sigma/\sqrt{n}$, of μ, in which $z_{\alpha/2}$ is the $100\alpha/2$ percentage point of the standard normal distribution.

The sample mean $\bar{X}$ is normally distributed with mean μ and standard deviation $\sigma/\sqrt{n}$, so that a rearrangement of the inequalities gives upper and lower bounds for the parameter μ that involve the random variable $\bar{X}$ (see 56). This statement (in 56) is true $100(1-\alpha)$ percent of the time. If the random variable $\bar{X}$ is replaced by the observed sample mean $\bar{x}$, then the statements (in 56) are true or false. They are true in $100(1-\alpha)$ percent of the times this method is used. The limits $\bar{x}\pm|z_{\alpha/2}|\,\sigma/\sqrt{n}$ are called upper and lower $100(1-\alpha)$ percent confidence limits, and $100(1-\alpha)$ is called the confidence level or confidence coefficient and is expressed either as a percent or a proportion, $1-\alpha$. The interval composed of the points (see 57) between the upper and lower confidence limits is called a confidence interval. A commonly used confidence level is 0.95, and then $|z_{\alpha/2}|=1.96$, or about 2.

If, in general, an upper function $\hat{\theta}_u$ and a lower function $\hat{\theta}_l$ of the sample values can be found—so that the probability for these functions to bound θ is $1-\alpha$ (see 58), then the values of $\hat{\theta}_u$ and $\hat{\theta}_l$ obtained from the sample provide upper and lower $100(1-\alpha)$ confidence limits for θ.

In a sample of size n drawn from a normal distribution with unknown mean μ and unknown variance σ^2, having sample mean $\bar{x}$ and variance $s_{\bar{x}}^2$ of the mean given by $\Sigma(x_i-\bar{x})^2/n(n-1)$, symmetrical $1-\alpha$ confidence limits on μ are given by $\bar{x}\pm|t_{\alpha/2}|\,s_{\bar{x}}$, in which $t_{\alpha/2}$ is the $\alpha/2$ percentage point of the t distribution with $n-1$ degrees of freedom.

In some investigations, the researcher continues sampling

(57) $(\bar{x} - |z_{\frac{1}{2}\alpha}|\sigma/\sqrt{n}, \bar{x} + |z_{\frac{1}{2}\alpha}|\sigma/\sqrt{n})$

(58) $\mathbf{P}(\hat{\theta}_l \leq \theta < \hat{\theta}_u|\theta) = 1 - \alpha$

(59) $\operatorname{var} X' = \dfrac{1}{4n[f(x_{0.5})]^2}$

(60) $c(x|\mu, \sigma^2, \gamma) = (1-\gamma)n(x|\mu, 1) + \gamma n(x|\mu, \sigma^2)$
$\sigma > 1$

(61) $L(x_1, \cdots, x_n|\theta) = \prod_{i=1}^{n} f(x_i|\theta)$

(62) $h(x_1, \cdots, x_n, \theta) = g(\theta) \prod_{i=1}^{n} f(x_i|\theta)$

(63) $p(\theta|x_1, \cdots, x_n) = kg(\theta) \prod_{i=1}^{n} f(x_i|\theta)$

until his confidence limits have been reduced to a preset size. Finding appropriate stopping rules and setting the limits are problems in sequential estimation.

Interval estimation can be used not only for reporting uncertainty in the value of the parameter, but also for hypothesis testing. If a specific value of the parameter θ, say θ_0, has a reasonable chance of being the true value, and if $1 - \alpha$ confidence limits can be set on θ, then if θ_0 is in the confidence region, it can be accepted as possibly being the true value. Otherwise this hypothesis can be rejected.

For example, in a sample of size $n = 3$ from a normal distribution, $\bar{x} = 2$, $S_{\bar{x}} = 0.5$, symmetrical 95 percent confidence limits are set on μ, and a test applied as to whether $\mu = 0$ is a reasonable value. This problem has two degrees of freedom, and $t_{0.025} = -4.30$. From the above formulas, the confidence limits are $2 \pm 4.30(0.5) = -0.15, +4.15$, and the hypothetical value 0 is in the interval (though barely). Consequently, 0 is not rejected as the value for μ at the 5 percent level of significance.

Robust estimation. In real data, the appearance of observations that seem not to belong with the rest of the measurements (such as 22.19 in the set 10.01, 10.04, 10.03, 22.19) is so commonplace that systematic methods are required to defend the analyses against them. Setting observations aside has always been a touchy step, especially to those who believe that good work never leads to bad data. One reasonable attitude is that wild observations should be set aside and studied separately so as not to destroy the information in the main body of the data. A few standard methods are applied to afford protection against temptation to make a special analysis to reach a foregone conclusion—and against the criticism that this has been done.

One estimator of location is the sample median, the middle-sized observation if the sample size is odd, or the average of the middle two if it is even. The large-sample distribution of the sample median X' is approximately normal with asymptotic mean $x_{0.5}$, the 50th percentile point of the distribution, and asymptotic variance expressed in terms of the density function evaluated at $x_{0.5}$ (see 59). When f is a normal density function, the population mean and median are both μ. The sample mean $\bar{X}$ is exactly, and the sample median X' approximately, normally distributed. As n grows large, $\operatorname{var} \bar{X} \approx \dfrac{2}{\pi} \operatorname{var} X'$, and X' is said to have asymptotic efficiency $2/\pi \approx 0.63$ compared with $\bar{X}$. Thus it takes a sample of 100 using the median to get the accuracy of a sample of 63 with the mean. If wild observations contaminate a distribution, however, the efficiency soon favours the median.

For example, a density function c formed as the weighted sum of two normal densities is expressed in terms of a function n and a weighting parameter γ (see 60), in which $n(x \mid \mu,\sigma^2)$ is the ordinate at x of a normal probability density function with mean μ and variance σ^2. For small γ, c is said to be a contaminated distribution, and γ is the fraction of contamination by data having variance σ^2. When $\gamma = 0.09$ and $\sigma = 3$, X' has a smaller variance than $\bar{X}$, and thus X' would be preferred to $\bar{X}$ as an estimator of μ.

Trimmed means are also resistant to contamination; they are formed by setting aside a fraction a of the largest and smallest measurements, $2a$ in all, and averaging the middle $1 - 2a$. Empirical studies suggest that, for a large class of distributions, trimming with $a \approx 0.25$ seems to be satisfactory for estimating location. For the normal this trimmed mean has asymptotic efficiency of about 0.83 compared with $\bar{X}$ before contamination. For a contaminated distribution c with $\gamma = 0.05$ and $\sigma = 3$, the mean $\bar{X}$ has efficiency only 0.92 of that of the trimmed mean. With $a = 0.25$ and $\gamma = 0.10$ this decreases to 0.775.

Trimmed means

Bayesian methods. The methods of estimation described above are often referred to as classical in the sense of standard. The Bayesian approach offers an alternative that gives an especially convenient way of incorporating prior information about the parameters and also of adding further information when it arrives. One disadvantage is that the method apparently cannot proceed without a prior distribution for the parameters. The main device for inference is the posterior distribution of θ, given the data.

For a distribution of the random variable X given parameter θ with probability density function f, the likelihood of a sample of size n is, as before, a product of densities (see 61) each evaluated at sample points. If the prior distribution of θ has density $g(\theta)$, then the joint density of the sample and θ can be represented as the product (see 62) of this density and the likelihood of a sample. The posterior distribution of θ is required, given the sample. It has the density constructed as k times the joint density of the sample and θ (see 63), in which k is a normalizing constant that makes the integral of the function $p(\theta \mid x_1, \cdots, x_n)$ equal to 1, the integral extending over the possible values of θ.

In this present discussion θ is a random variable, whereas in methods of estimation discussed earlier it was regarded as a constant. The interpretation of $p(\theta \mid x)$ is of interest. It tells what the thoughtful observer who provided the prior distribution would believe about the state of the world after he received the data x. If his prior was largely based on personal subjective judgment, then the degree-of-belief interpretation is paramount, and others may prefer different priors and therefore different $p(\theta \mid x)$. When the prior comes from substantial frequency-based observations closely related to the real world, the posterior distribution may well approximate an objective relative frequency distribution. Many practical situations fall between these extremes.

Much of the controversy over Bayesian methods has concentrated on the philosophy of the choice of the prior distribution and the difficulty of attaining agreement or unanimity. After completing a large Bayesian study, the U.S. statisticians Frederick Mosteller and David L. Wallace (1964) concluded that a neglected difficulty in Bayesian inference, as in methods of inference based on likelihood, is the sensitivity of the conclusions to the chosen family of data distributions; that is, to the functional form of f.

For a given $p(\theta \mid x)$, point or interval estimates can be obtained, or $p(\theta \mid x)$ can be used to make decisions. For example, the mean, mode, or median of the posterior distribution might be used as a point estimate for the true value. Alternatively, an interval (u, v) could be set up, like a confidence interval, that includes most of the probability, so that the integral with respect to θ from u to v of $p(\theta \mid x)$ equals $1 - a$.

An example is a machine setup in which the proportion of defective parts produced in the initial setting is π and prior data suggest that π is distributed according to a beta distribution $g(\pi) = c\pi^{a-1}(1-\pi)^{b-1}$, in which c is the normalizing constant and $a > 0$, $b > 0$, $0 \leq \pi \leq 1$. After a setup, a sample of size n with x defectives has likelihood $f(x \mid \pi) = \pi^x(1-\pi)^{n-x}$. The posterior distribution of π given x defectives in the sample is proportional to

(64) $$p(\pi|x)=k\pi^{a+x-1}(1-\pi)^{b+n-x-1}$$

(65) $$\mu_{post}=\frac{a+x}{a+b+n}, \qquad \sigma^2_{post}=\frac{\mu_{post}(1-\mu_{post})}{a+b+n+1}$$

(66)

State of Nature	Action a_0 (accept H_0)	Action a_1 (accept H_1)
θ_0 (H_0 true)	$l(\theta_0, a_0)$	$l(\theta_0, a_1)$
θ_1 (H_1 true)	$l(\theta_1, a_0)$	$l(\theta_1, a_1)$

(67) $$\begin{cases}\text{Risk}(\theta_0)=l(\theta_0, a_0)\,\mathbf{P}(a_0|\theta_0)+l(\theta_0, a_1)\,\mathbf{P}(a_1|\theta_0)\\ \qquad\quad =\mathbf{P}(a_1|\theta_0)=\alpha\end{cases}$$

(68) $$\begin{cases}\text{Risk}(\theta_1)=l(\theta_1, a_0)\,\mathbf{P}(a_0|\theta_1)+l(\theta_1, a_1)\,\mathbf{P}(a_1|\theta_1)\\ \qquad\quad =\mathbf{P}(a_0|\theta_1)=1-\gamma\end{cases}$$

(69) $$\frac{L(x|H_0)}{L(x|H_1)}\leqslant c$$

(70) $$\int_W L(x|H_0)\,dx=\alpha$$

(71) $$f(x)=\frac{1}{\sqrt{2\pi}}e^{-\frac{1}{2}(x-\mu)^2}, \qquad -\infty<x<+\infty$$

the product of g and f (see 64). The posterior mean and variance of π are then calculable (see 65).

If both the prior distribution and the data distribution are normal with prior mean and variance μ_0 and σ_0^2, and the data observation and variance are x and σ^2, then the posterior distribution is again normal with mean μ_1 and variance σ_1^2. Their values can be computed from the relations $\mu_1=\dfrac{h_0\mu_0+hx}{h_0+h}$, and $h_1=h_0+h$, in which $h_i=1/\sigma_i^2$, $h=1/\sigma^2$, so that $\sigma_1^2=1/h_1$.

When little information about θ is available, prior distributions for θ might be diffuse so that in the neighbourhood of any particular value of θ, the distribution is nearly flat. This would give the data greater weight in determining the posterior. Such a distribution is called a gentle prior distribution.

One's prior distribution of the length of a dimly seen and unfamiliar distant object would have a very large standard deviation compared to that of one direct measurement taken with a steel tape. If measurement errors were normally distributed with $\sigma=0.1$ in inches and a gentle prior were used on the true value, the posterior distribution would be approximately normal with mean x and standard deviation 0.1.

HYPOTHESIS TESTING

When the probability model for the mechanism generating the observed data is known, hypotheses about the model can be tested. This involves the question: Could the present set of data reasonably have come from the model if the hypothesis is correct? Usually a decision must be made on the basis of the available data, and some degree of uncertainty is tolerated about the correctness of that decision. These four components (data, model, hypothesis, and decision) are basic to the statistical problems of hypothesis testing.

Use of the null hypothesis

In such problems a null hypothesis is formed (usually denoted H_0) that the assumption to be tested is correct. Then a significance level $\alpha(0<\alpha<1)$ is chosen to indicate how improbable a set of data must be if H_0 is to be rejected. The particular samples to be considered improbable make up the critical region W, a subset of the sample space that has $\mathbf{P}(W\mid H_0)\leq\alpha$. In developing a test of a hypothesis, the central task is to construct the critical region.

When the null hypothesis is rejected, an alternative hypothesis, usually denoted H_1, is accepted in its place. The probability that a sample will lead to this action when the true value of the parameter is in H_1 is called the power, γ, of the test. If testing a hypothesis is viewed as a decision problem, there are two possible actions—"accept H_0" and "accept H_1"—and each has a corresponding loss depending on the true state of nature. (The terms "accept" and "reject" may give a rather unrealistic impression of finality, but they are the ones conventionally used in statistics as standard labels for the two actions; they owe part of their currency to one development of these ideas in the field of quality control, in which manufactured lots of material are accepted or rejected on the basis of samples.)

Many hypotheses concern values of a parameter (θ) in the probability model. In the most basic case both H_0 and H_1 involve a single value of θ (θ_0 and θ_1, respectively) and are said to be simple hypotheses. In this case the loss function may easily be displayed in a table: the two states of nature and the two possible actions determine four distinct values of the loss function (see 66). Here the concepts of decision theory provide a generalization of the classical formulation of hypothesis testing in which the losses are $l(\theta_0, a_0)=l(\theta_1, a_1)=0$ and $l(\theta_0, a_1)=l(\theta_1, a_0)=1$.

Risk is defined as the expected loss, given the state of nature. In that formulation the values of the risk are α at θ_0 (see 67) and $1-\gamma$ at θ_1 (see 68). Thus among all tests with significance level α in a given problem, the one with the greatest power γ has the least risk.

To construct a test of H_0 with maximum power against H_1, a general technique, given in 1933 by the Romanian-born U.S. statistician Jerzy Neyman and the British statistician Egon Sharpe Pearson, may be used. The basis for this technique is the likelihood function $L(x\mid H)$, in which x denotes the sample and H a simple hypothesis. The critical region W for the test is that subset of the sample space for each element of which the ratio of the likelihood function for H_0 to the likelihood function for H_1 is less than or equal to c (see 69), with c chosen to give the desired significance level: the probability of W, assuming H_0 to be true (see 70), is required to be α. The quotient $L(x\mid H_0)/L(x\mid H_1)$ is referred to as the likelihood ratio.

For example, a hypothesis about the value of the mean μ of

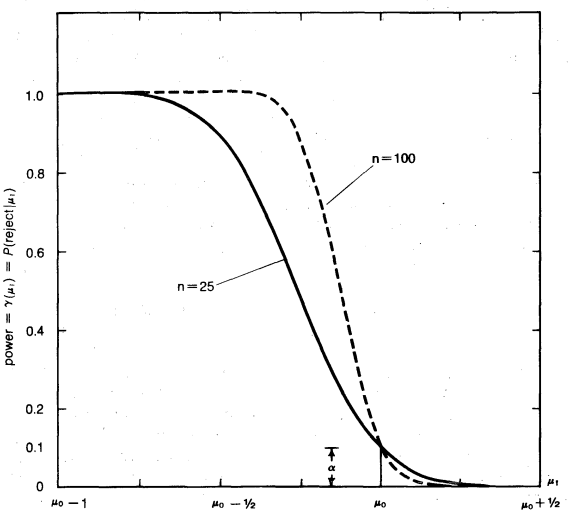
(72) $$\begin{aligned}L(x_1,\cdots,x_n|\mu)&=\prod_{i=1}^{n}f(x_i)\\&=(2\pi)^{-n/2}\exp\left[-\tfrac{1}{2}\sum_{i=1}^{n}(x_i-\mu)^2\right]\end{aligned}$$

(73) $$\frac{L(x_1,\cdots,x_n|\mu_0)}{L(x_1,\cdots,x_n|\mu_1)}$$

(74) $$-\tfrac{1}{2}\sum_{i=1}^{n}(x_i-\mu_0)^2+\tfrac{1}{2}\sum_{i=1}^{n}(x_i-\mu_1)^2\leqslant\log_e c$$

(75) $$\sum_{i=1}^{n}x_i\leqslant\frac{\log_e c}{\mu_0-\mu_1}+\frac{n}{2}(\mu_0+\mu_1)$$

(76) $$W=\left\{(x_1,\cdots,x_n):\bar{x}\leqslant\frac{z_\alpha}{\sqrt{n}}+\mu_0\right\}$$



(77) $$\begin{cases}\mathbf{P}(W|H_1)=\mathbf{P}\left(\overline{X}\leqslant\dfrac{z_\alpha}{\sqrt{n}}+\mu_0|\mu=\mu_1\right)\\ \qquad\quad =\mathbf{P}(\sqrt{n}(\overline{X}-\mu_1)\leqslant z_\alpha+\\ \qquad\qquad +\sqrt{n}(\mu_0-\mu_1)|\mu=\mu_1)\\ \qquad\quad =\Phi(z_\alpha+\sqrt{n}(\mu_0-\mu_1))\end{cases}$$

(78) $$\begin{aligned}&\lambda(x_1,\cdots,x_n;\theta_{01},\cdots,\theta_{0r})\\&\quad=L_0(x_1,\cdots,x_n|\theta)/L_1(x_1,\cdots,x_n|\theta)\end{aligned}$$

(79) $$W=\{\lambda:\lambda\leqslant c\}$$

a Gaussian (normal) distribution with variance 1 might be tested (see 71). On the basis of a random sample of n observations $X_1, \cdots, X_n$, the null hypothesis H_0 that $\mu = \mu_0$ is tested against the alternative hypothesis H_1 that $\mu = \mu_1 < \mu_0$. If a prescribed significance level α is used, $\alpha = 0.1$, say, then the appropriate critical region may be constructed. The likelihood function for any value of μ is formed from a product of normal densities each evaluated at sample points (see 72), and the likelihood ratio for the test is a ratio of two such products that differ in the value selected for the parameter μ (see 73). It is more convenient to work with the logarithm of the likelihood ratio, so that $(x_1 \cdots x_n)$ lies in the critical region when the difference of two sums of squares (namely the quadratics that appear in the exponentials of the normals) yields a value that is less than or equal to $\log_e c$ (see 74). An algebraically equivalent condition is an inequality that sets an upper bound (dependent on c, μ_0, μ_1, and n) on the sum of sample values (see 75). Here c remains unspecified, but that causes no difficulty. In this problem the critical region does not require any distinction between samples that have the same sum. The critical region is described in terms of the sample mean $\bar{x}$: it is composed of the set of n-dimensional points for which the mean is less than or equal to a simple function of z_α (see 76).

As might be expected from the assumption that $\mu_1 < \mu_0$, the critical region is composed of samples with means to the left of μ_0. For this test, the power is calculated (see 77) to be the function Φ evaluated at the sum of z_α and $\sqrt{n}(\mu_0 - \mu_1)$, in which Φ is the standard Gaussian cumulative distribution function. In the Figure power curves are plotted showing how the power depends on the separation between μ_1 and μ_0 and on the sample size n.

Plot of power curves for the example for $\alpha = 0.10$ and $n = 25$ (solid curve) and 100 (dashed curve; see text).

In the example, the critical region W depends only on having $\mu_1 < \mu_0$. Thus, in this problem the alternative hypothesis H_1 that $\mu < \mu_0$ could be used. Such hypotheses, involving more than one value of the parameter, are called composite. The power γ of the test is now a function of the true value of the parameter within the set of alternatives.

The curves in the Figure represent the power function $\gamma(\mu)$ for the two values of n. In general any attempt to construct a test with maximum power against a composite alternative hypothesis involves the formation of a power function $\gamma(\theta)$ that lies above other possible power functions for all values of θ within H_1. In some problems this is not feasible, and a considerable body of theory has been created to deal with such problems in great generality.

The descriptive level of significance

In practical significance testing, instead of presetting the significance level, the investigator may report the level of significance that would have just rejected the null hypothesis for his data. This level, called the descriptive level of significance or the nominal level of significance, has the advantage of giving a more complete report on the test and allows the reader to set his own significance level.

In more complicated situations a critical region in the original sample space may often be difficult to use because the region is defined by complicated functions of the data. When this happens, a technique that is based directly on a likelihood ratio may be used. The following illustration suggests some of the generality of the technique.

Suppose the parameter is $\theta = (\theta_1, \cdots, \theta_k)$, the null hypothesis is H_0: $(\theta_1, \cdots, \theta_r) = (\theta_{01}, \cdots, \theta_{0r})$ with $r \leq k$, and the alternative is H_1: $(\theta_1, \cdots, \theta_r) \neq (\theta_{01}, \cdots, \theta_{0r})$. These hypotheses are not concerned with $\theta_{r+1}, \cdots, \theta_k$. The approach is to determine the maximum value of the likelihood subject to the constraint imposed by H_0 and then use its ratio to the unconstrained maximum as the test statistic. This procedure, known as the likelihood ratio test, plays a role in hypothesis testing analogous to the role of maximum likelihood in estimation. For a random sample of n the test statistic is a function λ that is a ratio of likelihood functions L_0 and L_1 (see 78), in which L_0 is maximized over θ with the constraints that $\theta_i = \theta_{0i}$, $i = 1, \cdots, r$, and L_1 over all θ. From this definition it is clear that $0 \leq \lambda \leq 1$, and the critical region contains values of λ that are too small for H_0 to be reasonable: it is composed of values of λ that are less than or equal to c (see 79), with c chosen so that $\mathbf{P}(W \mid H_0) \leq \alpha$. When the exact distribution of λ is a function of the random sample $X_1, \cdots, X_n$, it is easy to choose c for the desired significance level. Otherwise the distribution of λ must be approximated. Fortunately, a remarkable asymptotic result may be employed: as n becomes large, the distribution of $-2 \log_e \lambda(X_1, \cdots, X_n; \theta_{01}, \cdots, \theta_{0r})$ when H_0 is true approaches a chi-square distribution with r degrees of freedom.

When data can be collected on a continuing basis, the techniques for testing a hypothesis should attempt to reach a decision as soon as the evidence is strong enough. Considered as a decision problem, this situation has three actions: "accept H_0" "accept H_1," and "continue sampling." Such methods are part of the field of sequential analysis.

When hypothesis testing was first mentioned, it was assumed that the probability model underlying the data was known. There is no reason to expect that this will always be the case; the reasonableness of a particular model may be exactly what is to be tested. Alternatively, it may be necessary to test whether the mean of one population is equal to the mean of another, without assuming a particular probability model for either. These are typical of the problems that form the subject of nonparametric hypothesis testing. Ordinarily, nonparametric methods depend less on the detailed shape of the sampling distributions than do methods called parametric. Nonparametric methods when used with measurements typically depend on signs of differences, or on counts, ranks, and permutations, rather than on the specific values.

STRUCTURE IN DATA

Many sets of data arising in actual practice are more complex than the situations and examples that have been described. The data may be collected according to a plan, and its structure must be considered in any analysis. Several properties may be measured for each observation in the sample, and their relationship may be of central importance. A process may be observed over a period of time, and it may be desired to discover or correct for cyclical aspects of its behaviour. These three types of situation are examples, respectively, of experimental design, of regression and correlation analysis, and of timeseries and spectrum analysis. There are almost as many techniques of analysis as kinds of structure in data, but the most widely used are those of linear regression.

Regression analysis

The general setting for regression analysis is as follows. Each observation consists of a value of Y, which is regarded as a response, and a value of each of $X_1, \cdots, X_k$, which are regarded as factors affecting the response. A model that restricts Z to equal a linear combination of $\{U_i\}$ plus ε (see 80) is built, for example, in which Z is some function of Y, the U's are functions of the X's, and ε is random error, attributable to measurement error or natural variation. Z may be regarded as a response; it is often called the dependent variable. The

$$(80) \quad Z = \beta_1 U_1 + \cdots + \beta_r U_r + \varepsilon$$

$$(81) \quad \sum_{i=1}^{n} [z_i - (b_1 U_{1i} + \cdots + b_r U_{ri})]^2$$

$$(82) \quad z_i - (b_1 U_{1i} + \cdots + b_r U_{ri})$$

$$(83) \quad \hat{y} = A(b_1 x_1 + \cdots + b_k x_k) + B$$

U's, which are called carriers, may depend on the X's in ways prescribed by theory or suggested by preliminary examination of the data; they are often called independent variables, even when they may not be probabilistically or functionally independent. The parameters $\beta_1, \cdots, \beta_r$ in the model are usually called regression coefficients. Such a model is said to be linear because Z depends linearly on the U's.

At an early stage in analyzing data according to this linear or multiple regression model the β's are estimated, whether or not their numerical values are the primary goal of the analysis. One standard method for fitting the model to the data is least squares: given n observations $(y_i, x_{1i}, \cdots, x_{ki})$, estimates ($b$'s) for the β's are chosen that result in the smallest value of the sum of squared deviations from the fitted model (see 81). This sum is differentiated with respect to each of the b's, and the minimization problem is reduced to one of solving a set of r simultaneous linear equations in r unknowns. This can be done without consideration of the probability model for the random error ε, but when that error follows a normal distribution, the least-squares estimates of the b's are the same as the maximum-likelihood estimates.

Ordinarily, it is assumed that the random errors $\varepsilon_1, \cdots, \varepsilon_n$ are independent and have mean 0 and common variance σ^2; it is also assumed that they are the only source of random variation in the data. As a result, the estimated coefficients $b_1, \cdots, b_r$ vary randomly with mean values $\beta_1, \cdots, \beta_r$. When the ε's are normally distributed, the vector $b = (b_1, \cdots, b_r)$ will have a multivariate normal distribution. This fact can be used in setting a confidence region for β or a confidence interval for any single β_j.

Certain hypotheses about the model may be tested: is the carrier U_j necessary (usually posed as H_0: $\beta_j = 0$ versus H_1: $\beta_j \neq 0$)? Does the model adequately describe the data? The basis for many such tests is the component of the data that remains when the fitted model is subtracted. For each observation this component is called the residual: it is a typical term (see 82) that appears squared in the sum of squared deviations. The relationship between the residuals and other elements of the model is often examined graphically. Systematic patterns in such plots can show that assuming a common variance σ^2 for the ε's is suspect, that the data have additional structure (to be fitted by adding a carrier to the model), that some U's should have a different form, or that another function of Y is more nearly linear in the U's than the present Z.

While fitting by ordinary least squares, assuming the common variance σ^2 for the ε's, is usually the first step in regression, it is quite sensitive to the presence of contamination or wild observations in the data. Consequently, a different analysis can be undertaken, based on a pattern of unequal variances or fitting the model by minimizing the sum of absolute-value deviations instead of the sum of squares. For these calculations, as well as in graphical examination of the data and the model, the computer has become an indispensable tool.

The discriminant function illustrates one use of linear regression in biology, medicine, the humanities, and the social sciences. When no one property correctly classifies objects into their populations, measures on several properties may improve the process. The linear discriminant function applies multiple regression for this purpose. If $X_1, \cdots, X_k$ are the variables used to aid the classification, $Y = 0$ is defined for objects in population Π_0 and $Y = 1$ for those in population Π_1. Using data for objects that can be correctly assigned to Π_0 and Π_1, least squares is applied to predicting y from $(x_1, \cdots, x_k)$. The discriminant function is a linear function, with parameters A and B, of a linear combination of the $\{x_i\}$ in which the coefficients are $\{b_i\}$ (see 83). The parameters A and B are arbitrary scaling factors chosen for convenience, and the b_i are the least squares regression coefficients. These b_i, it can be shown, separate the y scores of the populations as widely as possible. To classify new objects, one chooses a cutoff score y_0, and values above it are classified as belonging to Π_1, below it to Π_0.

For example, the rates of use of the words *and, in, of, the,* and *to* by Alexander Hamilton and James Madison in political writing led to the discriminant function

$$\hat{y} = -3.014 - 0.0195x_1 + 0.0301x_2 + 0.0547x_3 - 0.0167x_4 + 0.0420x_5.$$

Here a piece of writing by Hamilton is scored 1 and a piece by Madison 0. The rate of use per 1,000 words of the word numbered i above is x_i. A cut-point, here 0.5, is chosen, and a piece of writing scoring higher is assigned to Hamilton, lower to Madison. Thus a new paper known to be written by one of these two authors having rates $x_1 = 30$, $x_2 = 20$, $x_3 = 60$, $x_4 = 100$, $x_5 = 40$ would score $\hat{y} = 0.295$ and be classified as by Madison.

The History of the Eurasian Steppe

The Eurasian Steppe is a belt of grassland that extends some 5,000 miles (8,000 kilometres), from Hungary in the west, through the Ukraine and Central Asia, to Manchuria in the east. Mountain ranges interrupt the steppe, dividing the grassland into distinct segments; but horsemen could cross such barriers easily, so that steppe peoples could and did interact across the entire breadth of the Eurasian grassland throughout most of recorded history. Yet the unity of steppe history is difficult to grasp since the steppe peoples left very little writing behind them for historians to use, and Chinese, Middle Eastern, and European records tell only what happened within a restricted range across their respective steppe frontiers. Archaeology offers real but limited help (grave relics from chieftains' tombs abound but, of course, say little about everyday life and leave political, military, and linguistic alignments to inference). As a result, until about AD 1000, information concerning the rise and fall of steppe empires and the relation between events in the eastern and western portions of the steppe remains fraught with great uncertainty.

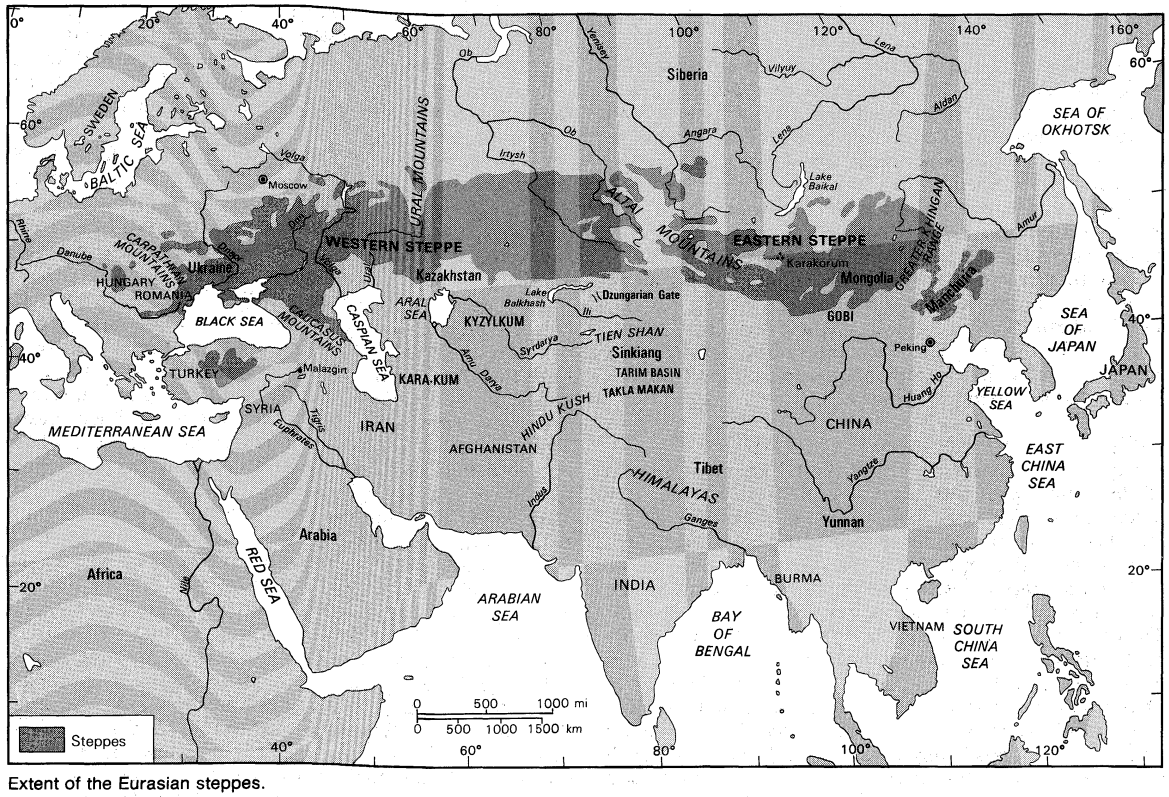
PHYSICAL AND HUMAN GEOGRAPHY

Physical features. The lay of the land divides the Eurasian Steppe into two major segments. The first of these may be called the Western Steppe. It extends from the grassy plains at the mouth of the Danube River along the north shore of the Black Sea, across the lower Volga, and eastward as far as the Altai Mountains. The conventional division between Europe and Asia at the Ural Mountains is completely meaningless for steppe history and geography. The grasslands extend continuously south of the Ural Mountains on either side of the Ural River. The Western Steppe therefore constitutes one vast region, some 2,500 miles from east to west and between 200 and 600 miles from north to south. Within its bounds, a vast sea of grass made cross-country movement easy for anyone with a horse to ride. Rivers and streams cut through the grasslands, with trees growing along the banks. Streams flow slowly, trending, for the most part, either north or south and providing an easy mode of transport by river boat in summer and by sleigh in winter. Consequently, animal caravans and river transport made the steppe accessible to commerce even before modern roads and railroads transformed travel conditions.

Climate of the steppes

Hot summers and cold winters divide the year into sharply contrasting seasons. Temperatures are slightly more extreme in the east, but a more critical variable is rainfall, which diminishes as the rain-bearing winds from the Atlantic become increasingly erratic east of the Don. These temperature and precipitation gradients make the Ukraine and adjacent parts of Romania far richer natural pastureland than the land farther east. Peoples of the Western Steppe therefore tended to migrate westward along the steppe, seeking better grass and milder temperatures, whenever political conditions allowed them to do so.



The second major segment of the Eurasian Steppe extends from the Altai Mountains on the west to the Greater Khingan Range on the east, embracing Mongolia and adjacent regions. It is higher, colder, and drier than the Western Steppe, with greater seasonal extremes of temperature than are found anywhere else in the world. Some 1,500 miles from east to west and about 400 to 500 miles from north to south, the Eastern Steppe is in every way a harsher land for human habitation than the Western Steppe. All the same, lower temperatures counteract lower precipitation by reducing evaporation, so that sparse grass does grow, at least seasonally, even where rainfall is only between 10 and 20 inches (250 and 500 millimetres) a year. At higher elevations precipitation increases, and the mountaintops accumulate snow caps from which streams descend into the dry lands below. Irrigated cultivation is possible along such streams. Oasis dwellers, whose skills and goods complemented those of pastoralists, played important roles in steppe history.

Early patterns of migration. These geographical conditions meant that nomads of the Eastern Steppe, living as they did in one of the most severe climates of the Earth, were under constant temptation to move in one of two directions: either southward and eastward toward Manchuria and northern China or westward, passing between the Altai and Tien Shan along the valley of the Ili River and the shores of Lake Balkhash, toward the more inviting grasslands of the Western Steppe. Migrations and conquests funnelling through this Dzungarian Gate, as it is often called, gave the peoples of all the steppe a common history from the onset of horse nomadism. Warfare techniques, life-styles, religious ideas, artistic styles, languages, etc., spread widely across the steppes, never erasing local variations completely but making a single whole of the entire region in a more intimate way than the fragmentary records left by civilized scribes reveal.

The Dzungarian Gate

Manchuria on the east and Hungary on the west are separated from the two main portions of the Eurasian Steppe by the Greater Khingan and Carpathian mountains, respectively, and are also distinguished by relatively benign climates favourable to agriculture. Hence, before modern times, a mixed economy of pastoral and agricultural activities had greater scope in Hungary and Manchuria than in the main areas of the steppe.

The same marginal participation in steppe history prevailed in the interior of Asia Minor, where open grassland, like that of the main portion of the steppe, was contiguous to similar grasslands in northern Syria and on southward into Arabia. On these southern grasslands arose another historically important style of nomad pastoralism that extended across the Red Sea deep into Africa as well. Since bypassing the Caucasus was easy for horsemen, movement from the northern to the southern grasslands occurred repeatedly. As a result, Eurasia's two great pastoral tradi-

tions—Semitic in the south, Indo-European, Turkish, and Mongol in the north—met and mingled in Asia Minor and on steppe lands south of the Caucasus and therefore shared common traditions. In all likelihood, horses were first domesticated in the north, for example, but came to play important roles in Arabia and even in Africa; while the spread of Islām across the northern steppe attested to the impact of southern nomad ideals upon northerners.

Mingling of northern and southern nomadism

Geography of adjacent regions. Boundaries of the steppe are imprecise. Toward the north the Eurasian grasslands fade into forested landscapes, and because of long winters and short, cool summers, even scant rainfall can sustain scrub growth of spruce and other conifers. The Russian name for such forests is taiga, as steppe is the Russian word for grasslands; and it is convenient to use these terms to describe the two zones of vegetation that set narrow limits on human life in northern Eurasia even today.

The taiga

The taiga was, for the most part, even more forbidding for human beings than the grasslands that lay to the south. In European Russia, a milder climate allowed deciduous forests to grow in some regions. There crops grew better than in the taiga, where agriculture could only be marginally successful, on account of poor soils and short growing seasons. In Asia, where taiga abutted directly on the steppe, hunters and gatherers of the forest were prone to migrate into the open grasslands. There they could establish themselves as nomads, and, being inured to the cold, heat, and hardship of the climate, they were in a good position to compete for a place on even the most forbidding steppe lands of Outer Mongolia. Similar migration from the forested north also occurred sporadically farther west. For example, Goths from southern Sweden penetrated the Ukraine in the early Christian centuries and swiftly adopted the habits and accoutrements of steppe nomads.

Desert areas

To the south the Eurasian Steppe fades into desert; but the deserts of Central Asia are dissected by mountain ranges in far more complicated fashion than the steppe proper. Since rainfall usually increases with elevation, mountains become islands of greenery in otherwise dry landscapes; and streams descending from mountaintops can sustain oasis cultivation in low-lying desert land. Grassland, sometimes merely seasonal, exists in all the mountainous areas of the Central Asian deserts. Complex, locally variable landscapes result. Hence the desert region that extends from the lower Volga and central Iranian plateau eastward through the Kara-Kum and Kyzylkum deserts to the Takla Makan and Gobi in the east is uninhabitable only in some salt-encrusted lowlands. Even in the most barren reaches of unsalted soil, some herbage is occasionally available for animals to pasture on, and oases are often densely populated.

Inhabitants of adjacent regions. Interaction between steppe nomads and the various oasis dwellers of Central Asia was prolonged and intimate. Cities of the oases were often subjected to nomad rule; on the other hand, city dwellers' superior skills regularly captivated unfriendly nomads, and suitably fortified cities could sometimes preserve their independence, even against nomad assault. Looked at from a steppe point of view, China and Europe, together with the cultivable areas of the Middle East, were no more than unusually large oases fed by moisture from adjacent oceans and from the Mediterranean and other inland seas.

Resources available for human life in these favoured regions were obviously more plentiful than in the steppe; and nomadic peoples, even when attached to their own ways of life, were strongly attracted by the wealth and ease that agricultural societies afforded. Movement southward from the steppe into one or another civilized zone was therefore a recurrent feature of Eurasian history. Nomads came as slaves, as traders and transport personnel, or as raiders and rulers. In this latter capacity, they played a politically prominent and often dominant part in Eurasian history. Because of their way of life, steppe peoples found it relatively easy to assemble large, mobile cavalry forces that could probe any weakness in civilized defenses and swiftly exploit whatever gaps they found. The political history of Eurasia consists very largely of nomad raids and conquests and the countervailing efforts by agricultural societies to defend themselves with an appropriate mix of armed force and diplomacy.

The Gobi

Geography did much to shape the pattern of these interactions. In the east the Gobi, dividing Outer Mongolia from China proper, constituted a considerable barrier. Successful raiding across the Gobi required a larger scale organization and more centralized command than was needed further west, where no such geographical obstacles existed. Thus, nomad impact on China was both sporadic and drastic. In Central Asia the complex borderlands be-

tween the contiguous steppe in the north and Iran and Turan (*i.e.*, modern Sinkiang and most of Soviet Central Asia), with their tangled mix of desert, mountain, grassland, and cultivated fields, made interpenetration between nomad populations and settled agriculturalists easy and inevitable. There more than elsewhere civilized traditions of life and those of steppe tribesmen blended through the centuries of recorded history down to the present. To the west, in Europe, the boundary between steppe and sown land was far clearer than in Central Asia so that massed agricultural populations were more often able to protect themselves effectively from nomad harassment. As a result, nomad impact on European history was far less significant than in Central Asia and the Middle East, where, of course, pressure from the northern steppe was compounded by raiders and conquerors coming from Tibet and the southern grasslands.

EMERGENCE OF THE PASTORAL WAY OF LIFE

Critical developments. The earliest human occupants of the Eurasian Steppe seem not to have differed very much from neighbours living in wooded landscapes. As elsewhere in Eurasia, hunters and gatherers using Paleolithic tools and weapons were succeeded on the steppes by Neolithic farmers who raised grain, kept domesticated animals, and decorated their pottery with painted designs. The critical development that eventually distinguished life on the steppes was the domestication of horses; but it is impossible to say when that development took place. Early Mesopotamian figurines showing equine animals pulling a cart probably record the domestication of donkeys and onagers, not horses. Only a few horse bones have been identified at early sites, and they may attest to successful hunting rather than domestication. But some time before 2000 BC steppe dwellers learned to keep herds of horses in addition to cattle, sheep, and goats, which were the principal domestic animals in more southerly lands.

Domestication of horses

Maximizing the size of domesticated herds necessitated a migratory way of life because animals kept together for protection and control ate the grass faster than it could grow, especially in the semiarid regions of the steppe. This made it hard to combine grain-growing with herding, as had been customary among Neolithic food producers. Eventually a clear break occurred between peoples who raised crops and animals and others who depended solely on the products of their flocks and herds and moved from pasture to pasture throughout the year.

In all probability nomadism developed into a fully independent way of life only after human beings had learned to live largely on animal milk and milk products, thus tapping a new food source and, in effect, discovering a new ecological niche by displacing male lambs, calves, and colts from their mothers' teats. Lactating animals had to be tamed to allow human beings to milk them by hand, and human populations also had to adjust physiologically by continuing as adults to secrete the enzymes children need to digest their mother's milk. Such adaptations surely took considerable time, but how they proceeded remains unknown.

Adaptation to milk consumption

The great dispersal. Nevertheless, by about 2000 BC these fundamental adjustments had probably been made, since a notable movement of peoples off the steppe and into the forested regions of Europe was underway. Herdsmen and warriors, speakers of Indo-European tongues, carried a distinctive battle-axe and, with the milk of their cattle and other animals, enjoyed a food supply that was clearly superior to those of other peoples. These advantages allowed the newcomers to overrun older farming and fishing populations of the European peninsula, so that their languages and cultures became dominant among later generations of Europeans. Other, related peoples remained on the steppe, occupying the grasslands as far east as the Altai Mountains. Some Indo-European tribes also penetrated the Eastern Steppe, where, however, they presumably shared the landscape with peoples of other tongues. Such remarkable migrations suggest that by around 2000 BC the speakers of Indo-European languages had attained a formidably efficient nomadic way of life.

It is very likely that behaviour patterns observed only later date back to this great dispersal. At any rate, the critical feature of later steppe nomadism was that only small groups could conveniently manage flocks and herds. In emergencies, manpower might have to be concentrated to protect people and animals against raiders from afar; but in ordinary times, to have more than 50 to 100 persons camped at the same location made daily travel between pastures unbearably lengthy for lactating animals. Accordingly, during most of the year, steppe pastoralists dispersed into small kinship groups. Hundreds of animals were tended by dozens of persons. Every few days or weeks the group had to move to a new location where the herbage had not yet been eaten down. Only portable goods, therefore, were of much value to nomads, though of course their animals allowed them to transport heavier loads than human strength alone could support. Still, tents and leather containers, compared to the mud huts and pottery of settled folk, leave little trace for archaeologists. The possibility of learning much about how and when nomad patterns of life arose and spread across the steppe remains correspondingly slim.

Kinship groups

Dependence on animals meant that relatively few human beings could make a living from the vast expanse of the Eurasian Steppe. Just how numerous ancient pastoralists may have been is impossible to say. The sudden appearance of large numbers of raiding horsemen often gave agricultural peoples the impression that vast hordes roamed the steppelands, waiting to pounce on undefended villages and towns. But because of the mobility of horsemen, raiding parties could gather from great distances, and their size (even if that were known) did not provide a reliable index of population density since their origins were unknown. The fact that a very large number of kurgans—*i.e.*, mounds of earth raised atop chieftains' graves—exist in the Western Steppe attests to the availability of relatively abundant manpower in ancient times; but again, such monuments were raised by a chieftain's followers, gathered for the purpose from afar and temporarily. In general, there can be no doubt that nomadic populations always remained far sparser than agricultural populations. Nomad conquerors, however numerous they seemed at the moment of attack, were always far fewer than the settled populations they overran and, partly for that reason, were nearly always absorbed into the conquered society within a few generations.

In historic times, yearly migrations followed a more or less fixed pattern, up and down mountain slopes with the season or north and south across open country for as much as 400–500 miles. When migratory herdsmen lived near cultivators, they often were able to pasture their animals on the stubble left behind after grain had been harvested. Exchanging grain for cheese and other animal products could also be mutually advantageous, even when rents or tribute payments skewed the simple economic symmetry of the relationship.

The rise of confederations. Dispersal across the steppe to maximize milk and meat production could be, and in historic times was, punctuated by occasional assemblages of large numbers of nomads for an annual roundup and slaughter of wild animals, for warlike undertakings against other communities, and for various ceremonial purposes as well. Real or fictitious kinship bonds united adjacent families of herdsmen into tribes; and tribal confederations, built upon ceremonial recognition of the primacy of a high king, were constructed and confirmed at such periodic assemblages.

Prowess in protecting the herds from animal predators had been necessary from the beginning of domestication, but as pastoralism became an established way of life, prowess was redirected toward rival herdsmen. Quarrels over rights to grass and water were perennial, since boundaries between adjacent herding groups were necessarily imprecise and unpoliced. Infringement invited retaliation in the form of raids, and raids provoked counter-raids. Warfare skills were thus inculcated by the nomads' way of life, and their mobility made it possible to concentrate large numbers of experienced warriors wherever a tribal chieftain or high king might decree.

On the other hand, tribes and tribal confederations were

Precarious nature of leadership

always liable to break apart if the constituent groups felt aggrieved or merely distrusted the leader's luck or military skill. Grounds for quarrels over precedence and dignity as well as over grass and water were always present within every steppe polity; and diplomats from civilized states were often able to exploit such weaknesses by pursuing a policy of "divide and rule."

Nomadic customs and institutions thus superimposed fragile political structures on the migratory herding of small kinship groups. The formation of a far-flung war federation around the charismatic figure of a successful captain could occur very quickly. Division came even faster, since the passing of a high kingship from father to son was always precarious. Great men consolidated their power by marrying as many wives as the diversity of their following required, so whenever a great chieftain died, competition to the death among sons of different wives was likely. In effect, tribal confederations had to be reestablished every few generations.

Perhaps not all of these features of nomad life were evident when civilized peoples first experienced the military might that steppe peoples could exert. For example, occupation of the Eastern Steppe by skilled horse nomads had not yet occurred when Indo-European conquerors first arrived in the Middle East, about 1700 BC. Thereafter, scattered texts allow us to infer something about what happened on the Eurasian Steppe, although steppe peoples themselves did not begin to keep records in writing until about 2,300 years later.

MILITARY AND POLITICAL DEVELOPMENTS AMONG THE STEPPE PEOPLES TO 100 BC

The military advantages of nomadism became apparent even before the speed and strength of horses had been harnessed for military purposes. The early conquests of Sargon of Akkad (*c.* 2250 BC) and the Amorite invasions of Mesopotamia before 1800 BC attest to the superior force that nomadic or seminomadic peoples held, even when fighting only on foot. But the full effect of their military strength came with the use of horses, some time around 1700 BC. Military primacy shifted to the northern steppes, where horses were easy to raise. The southern grasslands were less suited to horses, and the nomads of those regions therefore lost the dominance they once had.

Horsepowered warfare. Horses were first used in war to pull light, two-wheeled chariots that carried a two-man crew. A driver held the reins and controlled the team of horses while his companion shot arrows from the chariot's platform. No foot soldiers could stand against this form of attack when it was new. Warriors who had access to horses and chariots therefore enjoyed an easy superiority in battle for nearly five centuries.

The principal beneficiaries were Indo-European tribesmen, speaking languages akin to Sanskrit, who already possessed horses. Along the southern fringe of the Central Asian portion of the steppe, where cultivated lands intermingled with pasture—perhaps in Azerbaijan or farther east in Iran—wheelwrights learned to make spoked wheels that were accurately circular and strong enough to withstand the impact of a human cargo bouncing across natural land surfaces at a gallop. This invention must have occurred about 1700 BC, for soon after that date chariot conquerors overran the entire Middle East. Others invaded India around 1500 BC and extinguished the Indus civilization. Chariots also spread throughout Europe. Even in distant China, by the 14th century BC, rulers of the Shang dynasty (traditional date *c.* 1766–1122 BC) were using chariots and bows very similar to those of the Aryans further west.

Invention of the chariot

Other peoples, of course, soon learned to use chariots in battle. Consequently, the Indo-European incursions of the second millennium BC had only transitory importance in the Middle East. In India, however, the Aryans spread their language and culture throughout most of the Indian subcontinent in subsequent centuries, just as other Indo-European tribesmen had done in Europe some 500 years before.

The specialized artisan skills needed to build light, sturdy chariots were probably lacking among the steppe dwellers. At any rate there is no sign that large numbers of northern nomads ever owned such expensive devices. Chariot warfare, therefore, never affected steppe life profoundly, though it did revolutionize civilized states, inaugurating a militarized, aristocratic Bronze Age that lasted in the Middle East until about 1200 BC.

Then the rise of iron metallurgy cheapened arms and armour sufficiently to allow common foot soldiers to overthrow the chariot aristocracies of the Middle East. But this, too, had no immediate impact upon steppe peoples. Iron arrowheads were not notably better than arrowheads made of flint or obsidian; and the new metal, even if cheaper than bronze, remained too expensive for ordinary herdsmen. Soon after 900 BC, however, another revolution came to ancient patterns of warfare that did affect the steppe profoundly. Men quite simply learned how to ride horseback, thus dispensing with cumbersome, costly chariots and unleashing the full agility and speed of a galloping horse for military purposes.

Development of cavalry

Assyrians may have pioneered the cavalry revolution. A few wall carvings from the 9th century BC show paired cavalrymen, one of whom holds the reins for both horses while the other bends a bow. This was just the technique charioteers had long been practicing. Riders soon discovered that once their mounts were accustomed to carrying men, it was safe to drop the reins and rely on voice and heel to direct the horse's movements, freeing both hands for shooting with a bow.

This extraordinary synergy of man and horse became routine between 900 and 700 BC. As the new art of horsemanship spread, nomads of the northern steppe found themselves in a position to take full advantage of the mobility and striking power a cavalry force could exert. Mounted raiding parties from the steppes became difficult indeed for sedentary peoples to combat, since horsemen could move far faster than foot soldiers and were therefore able to concentrate greater numbers at will and then flee before a superior countervailing force manifested itself. Cavalry was necessary to repel such raids, but raising horses in landscapes where grass did not grow abundantly was very expensive since the grain came directly from stocks that would otherwise feed human beings.

On the steppes, however, nomads could easily increase their supply of horses, if necessary, at the expense of cattle. Mare's milk could be substituted for cow's milk; horseflesh for beef; and horse nomads, who spent most of their waking hours in the saddle, could exploit through enhanced mobility a wider range of pastures from any given encampment. As a result, the primacy early Indo-European peoples had accorded to cattle gave way to a dependence on horses among later steppe peoples. Sheep, goats, camels, and even (in Europe and Manchuria) pigs also had a place in the steppe economy; as did, in favoured locations, the cultivation of grain. But the cavalry revolution of the 9th and 8th centuries BC put horses first because of their usefulness in war.

Scythian successes. The first sign that steppe nomads had learned to fight from horseback was a great raid into Asia Minor launched from the Ukraine about 690 BC by a people whom the Greeks called Cimmerians. Some, though perhaps not all, of the raiders were mounted. Not long thereafter, tribes speaking an Iranian language, whom the Greeks called Scythians, conquered the Cimmerians and in turn became lords of the Ukraine. According to Herodotus, who is the principal source of information on these events, the Scyths (or at least some of them) claimed to have migrated from the Altai Mountains at the eastern extreme of the Western Steppe. This may well be so; and some modern scholars have even surmised that the barbarian invasions of China that brought the Western Chou dynasty to an end in 771 BC may have been connected with a Scythian raid from the Altai a generation or two before Scythian migration westward to the Ukraine.

The Eastern Steppe was, however, too barren and cold for invaders to linger. Consequently, the spread of cavalry skills and of the horse nomads' way of life to Mongolia took several centuries. We know this from Chinese records clearly showing that cavalry raids from the Mongolian steppe became chronic only in the 4th century BC. China

was then divided among warring states, and border principalities had to convert to cavalry tactics in order to mount successful defenses. The first state to do so developed its cavalry force only after 325 BC.

Long before then, however, the Scythians had erected a loose confederacy that spanned all of the Western Steppe. The high king of the tribe heading this confederacy presumably had only limited control over the far reaches of the Western Steppe. But on special occasions the Scythians could assemble large numbers of horsemen for long-distance raids, such as the one that helped to bring the Assyrian Empire to an end. After sacking the Assyrian capital of Nineveh in 612 BC, the booty-laden Scyths returned to the Ukrainian steppe, leaving Medes, Babylonians, and Egyptians to dispute the Assyrian heritage. But the threat of renewed raids from the north remained and constituted a standing problem for rulers of the Middle East thereafter.

The sacking of Nineveh

Persian defenses. The Persians, who took over political control of the Middle East in 550 BC, met with little success in punishing steppe incursions. Cyrus the Great, founder of the Persian Empire, was killed in 530 BC while leading a punitive expedition against the Massagetai, who lived north and east of the Caspian; and Darius the Great met with indifferent success in 512 BC when he tried to subdue the Scyths from Europe by crossing the Danube. On the other hand, diplomatic arrangements whereby border tribesmen were paid to guard against raids from deeper in the steppe worked well as long as Persian tax collectors provided a suitable assortment of goods with which to subsidize the friendly borderers. No massive incursions or large-scale infiltrations from the steppe into the Middle East took place, therefore, until after the overthrow of the Persian Empire at the hands of Alexander the Great in 330 BC.

In the next century, however, the collapse of the Persian frontier guard in Central Asia and the consolidation of a new steppe empire based in Mongolia combined to provoke large-scale displacements of peoples westward along the steppe and southward from the steppe onto cultivated ground. For the first time, the natural gradient of the Eurasian Steppe came fully into play when a tribal confederation, called Hsiung-nu by the Chinese, attained an unmatched formidability. This happened at the very end of the 3rd century BC. Neighbours on the steppe, fleeing from the Hsiung-nu, moved south and west, generating in turn a wave of migration that eventually reached from the borders of China as far as northwestern India and the Roman limes along the Danube.

Emergence of the Hsiung-nu

The Hsiung-nu Empire. Just as the Scythian Empire of the Western Steppe was a mirror image of the Persian Empire to the south, the empire of the Hsiung-nu (late 3rd century BC–2nd century AD) mirrored the Chinese empire that had been consolidated in 221 BC by Ch'in Shih Huang Ti and was subsequently stabilized under the Han dynasty (206 BC–AD 221). To judge from Chinese accounts, which are the only ones available, the Hsiung-nu modelled themselves quite closely on Chinese principles, regarding their ruler as the Son of Heaven, just as the Chinese did. Organized warfare across the Gobi alternated with periods of peace, when formalized exchanges of tribute-gifts allowed the rulers on each side to strengthen themselves by acquiring rare and valuable goods to distribute as they saw fit. The Chinese obtained horses for the army and other Imperial uses, while the Hsiung-nu ruler acquired grain, silks, and other luxuries with which to reward his followers.

CLOSURE OF THE IRANIAN BORDERLAND TO STEPPE RAIDERS AND ITS CONSEQUENCES, 100 BC–AD 550

Domination by the Parthians. Initially, the displacements westward that were precipitated by the consolidation of the Hsiung-nu confederacy took the form of a series of migrations into Iran and across the Hindu Kush into India. Various Iranian tribes—Śakas and Kushāns chief among them—were the protagonists of these displacements. Their vacated grazing lands came under the control of Turkish tribes, so that the frontier of Indo-European languages began to shrink back as the Turks advanced.

This pattern of migration altered by the end of the 2nd century BC. At that time the Iranian borderland was again effectually defended by new guardians, the Parthians. They were another Iranian people of the steppe who began to move southward during the 3rd century BC when Alexander's successors, the Seleucids, proved incapable of safeguarding their frontiers against such incursions. Once established on cultivated ground, the Parthians prevented other steppe nomads from following hard on their heels by developing a superior cavalry force and inventing a means for supporting it at relatively little cost.

The key change was the introduction of alfalfa (lucerne) as a cultivated crop. Alfalfa, if planted on fallowed fields, provided a fine fodder for horses, and nitrogen-fixing bacteria that grew on its roots enhanced the fertility of the soil for subsequent grain crops. Moreover, horses stall-fed on alfalfa (with some additional grain) could be bred bigger and stronger than the steppe ponies that had only grass to eat. Big horses in turn could support armoured men on their backs and even carry armour to protect their own bodies. Such armoured cavalrymen, scattered out across the agricultural landscape as lords and local protectors of village communities, could readily assemble a formidable force to oppose nomad raiding parties. Their armour permitted them to withstand enemy arrows while returning shot for shot; and when steppe intruders sought to withdraw, the heavy cavalrymen could pursue farther and faster than ever before, making it hard for a raiding party to find a safe camping ground for the night or a place to graze their horses. In this way cultivated land could support an effective frontier guard against the steppe for the first time since the cavalry revolution had tipped the balance so sharply in favour of steppe dwellers. Even so, big horses and armour were always expensive, and an aristocratic and decentralized (*i.e.*, feudal) political and social system invariably developed with this kind of military establishment.

Introduction of alfalfa

The fame of the Parthian horses soon reached the Chinese Imperial court and led the emperor Han Wu Ti to send an expedition westward as far as Fergana to bring back specimens of the new breed in 101 BC. By that time, enough armoured cavalrymen stood guard over the villages of the Parthian Empire to make further nomad incursions unprofitable. As a result, migration routes along the steppe shifted north of the Caspian. The new balance of forces was registered by the collapse of the Scythian Empire in the 1st century AD. Iranian-speaking Sarmatians took over the lordship of the westernmost regions of the steppe. They presented the Roman army with a new and formidable challenge along the Danube frontier, since at least some of the Sarmatian cavalrymen were armoured in the Parthian fashion. But such warriors were comparatively few in number, and their feudal polity made them unable to organize large-scale raids. As a result, the Roman limes held for another two centuries.

The Sarmatians

Flourishing trade in the east. Relations between the steppe and cultivated lands of Eurasia therefore entered upon a new phase that lasted from approximately 100 BC to about AD 200. Raiding being unprofitable, trading intensified; and nomads found a new or enhanced role as caravan personnel, carrying goods along the Silk Road, which connected China with Syria, after Han Wu Ti's exploratory expedition of 101 BC. North–south caravan routes fed into and supplemented the east–west movement of goods, connecting northern India with Central Asia and Central Asia with the entire expanse of the Eurasian Steppe from Hungary to Manchuria.

The consequences of these intensified communications were considerable. The taste for transparent silk clothing that spread among Roman women of high fashion was less important than the propagation of Buddhism, Judaism, Manichaeism, and Christianity across Asia by missionaries and traders who moved with the caravans. Literary records do not reveal much about the process, but the comparatively abundant information surrounding the birth of Islām in Arabia (AD 610–32) casts much light on the sorts of religious exchanges that must have occurred in caravansaries and around innumerable campfires, where strangers met, telling tales and expounding divergent beliefs.

The spread of religions

About AD 200 this relatively peaceful period of steppe history drew to a close. A new era of upheaval manifested itself at both ends of the Eurasian grassland. In the east, the empire of the Hsiung-nu and the Han dynasty both disintegrated during the first two decades of the 3rd century AD. For three and a half centuries thereafter, political fragmentation on the Eastern Steppe matched the fragmentation of China proper. Barbarian regimes arose in northern China, lasting until the reunification of the country by the Sui dynasty in AD 589.

New barbarian incursions. Throughout this chaotic period in the east, the Iranian borderland with the steppe remained firmly defended. The Sāsānian dynasty (AD 224–651), which supplanted the Parthians after a successful rebellion by a great feudatory, like the previous regime, maintained armoured cavalrymen to guard against steppe marauders. The effect was to funnel all the flights and migrations provoked by the disorders on the Eastern Steppe north of the Caspian and into Europe. This put sporadic strain on the Roman frontier, until, in the 4th century, the limes at the Rhine and Danube collapsed, never to be fully reconstituted.

The Huns

The precipitating factor in this collapse was the arrival of a new people from the east, known in European history as the Huns. They crossed the Don about AD 370 and quickly defeated the Sarmatian and Gothic tribes that were then occupying the westernmost steppe. (The Goths had migrated from the forested north earlier in the 4th century, just as Mongols did far to the east perhaps at nearly the same time.) The Huns incorporated the fighting manpower of their defeated enemies into their expanding confederation by making them subject allies. This new and formidable predatory power provoked the flights and raids that broke through the Roman frontiers in 376, starting a migration of peoples that lasted, on and off, for half a millennium and brought far-reaching changes to Europe's ethnic boundaries.

What, if any, relation may have existed between the Huns of European history and the Hsiung-nu of Chinese records is an unsolved, probably insoluble, conundrum. Even the language spoken by the Huns is in dispute, though most experts believe they were of Turkish speech. For a short time a new empire of the Western Steppe took form under the Huns' most famous ruler, Attila (reigned 434–53); but on his death the subject German tribes revolted, and soon thereafter the Huns as a distinct political or ethnic entity disappeared from Europe. The abrupt rise and fall of Hunnish power, nevertheless, set all the peoples of the Western Steppe in motion; and by the time the flights, migrations, and conquests were over, the Roman Empire in the West had come to an end (AD 476), and Germanic peoples had become rulers of all the Western provinces.

China experienced equally drastic barbarian incursions in the same centuries, submitting to various Turkish, Tungusic, Tibetan, and Mongolian invaders. At the end of the 4th century AD a new confederation, the Juan-juan, arose on the Eastern Steppe; a century later a similar group, the Hephthalites, established their supremacy between the Volga River and the Altai Mountains. After the collapse of the Huns, however, no single confederation arose to dominate the rest of the Western Steppe until a people known as Avars set up headquarters in Hungary in 550 and proceeded to raid far and wide in all directions, exercising hegemony over various Slavic and Germanic tribes until submitting to Charlemagne in 805.

All of these confederations probably embraced more than one language group. Evidence is too scant to tell just how Turkish intermingled with Mongolian, Finno-Ugric, Tungusic, Indo-European, Tibetan, and perhaps still other languages across the length and breadth of the steppe. Linguistic differences were not really of great importance. Life-styles among Eurasian horse nomads had attained a fine adjustment to the grasslands; and with the invention of stirrups in about 500, symbiosis between man and mount achieved a precision that defied further improvement. Accurate shooting on the run became possible for the first time when a rider could stand in his stirrups absorbing in his legs the unsteadiness of his galloping mount. But stirrups also made cavalry lances far more formidable, since a rider, by bracing his feet in the stirrups, could put the momentum of a galloping horse and rider behind the thrust of his spearhead. Thus the enhancement of steppe archery through the use of stirrups was counteracted by a parallel improvement in the effectiveness of the heavy armoured cavalry that guarded Middle Eastern and European farmlands against the steppe nomads.

The invention of stirrups

THE ERA OF TURKISH PREDOMINANCE, 550–1200

A new Turkish confederacy. A new period of steppe history began in 552 when a powerful new Turkish confederacy, headquartered in the Altai Mountains, suddenly developed. Its geographic range was great, extending from the frontiers of China to the Caspian Sea. The new masters of the Asian steppe were skilled in ironwork and used their own runic script, of which a few examples survive. Some of the critical skills of civilization with which steppe peoples had become more familiar through the expanding trade patterns of preceding centuries were thus exploited by a nomad confederacy for the first time. Buddhism and then Islām also penetrated among the Turks, bringing steppe peoples still more closely into touch with other aspects of civilized life.

Nonetheless, the Turkish confederacy remained a tribal nomad polity with both the ferocious formidability and fragility associated with such systems of command. Disputed successions tore it apart more than once before its ultimate dissolution in 734; but prior to that time two principal consequences of the consolidation of Turkish power may be discerned. First, raids and rivalry with the Chinese helped to stimulate China's reunification under the Sui (581–618) and early T'ang (618–907) dynasties, thus renewing the mirror relationship that had previously existed between the Han and Hsiung-nu empires. Second, the rise of an aggressive Turkish power provoked recurrent flights and migrations across the steppe itself. As long as the prowess of Sāsānian barons made the Iranian borderlands impenetrable, refugees from steppe warfare continued to be funnelled north of the Caspian into Europe. Consequently, hordes of Avars, Bulgars, Khazars, Pechenegs, and Magyars—to name only the most successful—followed one another in rapid succession onto the Western Steppe. Each of these peoples established a powerful raiding confederation and exercised domination for varying periods of time over adjacent cultivated lands in the Balkans and central Europe. Two of the tribes were ancestral to the modern states of Bulgaria and Hungary, but the rest, like the Huns before them, dissolved into the general population soon after their military power broke down.

Reunification of China

Shift of attention from Europe to the Middle East. Encroachment by peoples of the steppe onto the cultivated lands of eastern Europe slackened in the 9th century and was reversed by the end of the 10th when more efficient protectors allowed European peasantries to begin moving out into grasslands along the Danube. Armoured cavalrymen on the Parthian model, known to the Byzantines as cataphracts and to the English as knights, reversed the balance between steppe raiders and settled folk in eastern Europe. The gradual rise of knighthood after 732, when Charles Martel first tried the experiment in western Europe, involved a drastic feudal decentralization of political power—decentralization that lasted longer in the east of Europe than in the west and has distracted such marcher states as Hungary and Poland down to modern times.

The rise of knighthood

Yet the rise of knighthood along the European steppe frontier was not the only factor reversing the balance between nomads and settled agriculturalists. Nomad pressure on European cultivators also slackened in the 10th century because the Iranian borderland against the steppe had once again become permeable. Exactly why this happened is unclear. Nothing in military technology seems to explain the fact that Turkish tribesmen as well as detribalized slaves began to arrive within the realm of Islām in such numbers as to be able, after about 900, to exercise decisive military force throughout the Middle East. Perhaps the attractions of city life induced Sāsānian barons to abandon their villages for the easy life of absentee landlords and to allow their military habits to decay. But no

one really knows what altered the balance between steppe warriors and Iranian defenders of cultivated lands in such a way as to divert the pattern of steppe migration southward once again. The effect, nonetheless, was to spare eastern Europe from the sort of recurrent invasions it had been experiencing since the 2nd century AD.

The expansion of Islām. Consequences for the Middle East were far-reaching. Islām itself was transformed by the rise of Ṣūfism. How much the Ṣūfis owed to the pagan past of Turkish converts to Islām is unclear, though some practices of dervish orders, which were the main carriers of the Ṣūfi movement, very likely did stem from shamanistic rites and practices of the steppes. In any case, Turkish languages were added to the Arabic and Persian that had previously been the carriers of Middle Eastern high culture; and a proud Turkish consciousness persisted among soldiers and rulers to complicate older ethnic patterns within the heartlands of Islām.

Islām in India

By submitting to Turkish warriors, the realm of Islām acquired a new cutting edge. Rapid expansion at the expense of both Christendom and Hindustan resulted. Raids into India, beginning in the year 1000, led within two centuries to the establishment of Muslim control over the plains of the north. Expansion continued off and on until, by the end of the 17th century, the whole of India had been subjected to Muslim overlordship. On the other flank of Islām, a decisive breakthrough occurred in 1071 when Seljuq tribesmen defeated the Byzantines at Manzikert (modern Malazgirt), thereby confirming their occupation of the grasslands in the interior of Asia Minor. Thus, modern Turkey became Turkish for the first time. This expansion triggered the First Crusade (1095–99), but the crusaders' success only checked, without permanently stemming, the Turkish advance. Instead, toward the end of the 13th century the Ottomans succeeded the Seljuqs as leaders of the struggle against Christendom and continued to advance their frontiers as late as 1683, by which time all of the Balkans and Hungary were under Turkish rule.

Muslim principles deplored strife among the faithful while admiring military success against unbelievers. This belief encouraged newcomers from the steppes to migrate toward the two expanding frontiers of Islām, where they could exercise their military skills, expect rich booty, and win new lands while enjoying the respect and admiration of fellow Muslims. As a result, the mainstream of steppe migration gravitated toward Islām's Christian and Indian frontiers. Arab tribesmen had done the same in the Middle East and North Africa during the first century (632–732) of Muslim history. Thus, after about 900, the military manpower and skills of the northern nomads took over the role that had been played by Bedouins from the south during Islām's first, extraordinary period of expansion.

Developments on the steppe proper. The tribes that remained behind on the Eurasian Steppe were of course affected by this massive Turkish influx into the Middle East. Trade connections with Islāmic lands intensified, and traders from Middle Eastern cities spread Islām far and wide among steppe peoples. To be sure, full compliance with Muslim law was scarcely compatible with pastoral routines of life; but after the 11th century most of the Western Steppe had become, at least superficially, incorporated into the realm of Islām. Along with the religion, heightened familiarity with civilized ways penetrated deep into the steppe. Miniature cities arose at river crossings and at the headquarters of powerful chieftains, where merchants gathered and urban artisan skills began to find limited scope.

Chinese influence

In the Eastern Steppe, Chinese civilization played the same role, although the oasis cities of the Tarim Basin continued to offer steppe peoples alternatives to a purely Chinese pattern of higher culture until long after this period. Collapse of the Turkish Empire in 734, swiftly followed by a drastic weakening of the T'ang dynasty after a massive rebellion in 755, hastened rather than hindered the infiltration of new skills into the Eastern Steppe. The T'ang dynasty recovered control of China only by calling on barbarians for aid, which they received from a newly powerful Uighur confederacy (745–1209) that had started as one of the successor states to the older Turkish Empire of the steppes. But the Uighur horsemen who rescued the T'ang dynasty from its domestic difficulties did so only in return for handsome trade-tribute payments. Once begun, the flow of tribute from China continued as long as Uighur power endured. The Uighurs, of course, consumed some of the goods they carried out of China themselves but traded the rest with neighbours and neighbours' neighbours for grain, slaves, and special goods such as jade, gold, and furs. A far-flung caravan network thus attained greater importance than ever before, binding steppe peoples to oasis cultivators in the south and forest peoples in the north and joining the parallel Muslim trade net of the Western Steppe.

The Uighur confederacy

Such exchanges involved more than simple export and import of goods. Religions continued to travel the caravan routes as they had done for centuries. Buddhism rivalled Islām in the Eastern Steppe, but the Uighurs, interestingly, asserted and maintained their spiritual independence of both of the great civilizations they touched by espousing the Manichaean faith. They also used a Sogdian script, derived from Persian, that supplanted the Turkish runic script and allowed them to create a more thoroughly literate society than earlier steppe peoples had attained.

THE MONGOL EMPIRE, 1200–1368

Emergence of bureaucratic states. The next important transformation of steppe life occurred when nomad peoples began to supplement their age-old tribal organization by borrowing Chinese bureaucratic principles for the management of armed forces. Such experiments first appeared among rising states in northern China after the collapse of the T'ang dynasty in 907. During the next two centuries China's political weakness allowed various barbarian peoples to overrun parts of the north once more while continuing to control ancestral steppe lands. The resulting hybrid states were known to the Chinese as the Khitan (907–1124), Tangut (990–1227), and Juchen (1122–1234) empires. It was natural for them to combine nomad tribal and Chinese bureaucratic principles of management in military and other departments of administration. The Khitan, for example, supplemented their horsemen with foot soldiers and developed combined tactics for using infantry and cavalry together in battle. Even more significant was the way in which their successors in northern China, the Juchen, set up a command structure on bureaucratic principles. The Juchen rulers divided their army into tens, hundreds, and thousands and put appointed officers over each unit. Consequently, among the Juchen, hereditary tribal standing did not necessarily coincide with ascribed military rank. For a brave and lucky man, army service became a career open to talent.

The Chinese had relied on appointed officers to command their soldiers for centuries. By applying the idea to steppe armies, a ruler could at least hope to transcend the fragility previously inherent in tribal confederations. No matter how solemn the binding oaths of blood brotherhood might be, because steppe horsemen had always followed their own tribal leaders to war, any quarrel among chiefs could immediately dissolve a formidable army into its original warring fragments. But in a bureaucratic system, hereditary chieftains no longer had their own tribesmen always at their beck and call. Before a chief contemplating rebellion against central authorities could count on support, he had to overcome his tribesmen's loyalty to appointed commanders. Divided and uncertain loyalties in the ranks therefore made traditional tribal rebellion chancy at best and suicidal if the rebel chieftain's tribesmen failed to follow. Sudden dissolution of steppe confederacies therefore became much less likely.

The decline of the chieftains

The superior stability of steppe polities organized along bureaucratic lines was evident when overthrow resulted not from internal disruption, in the old way, but from conquest at the hands of another bureaucratically organized armed force. The Juchen, for example, supplanted the Khitan only after improving on their rivals' half-hearted efforts to appropriate Chinese patterns of military management; and the Juchen in turn were overthrown by the Mongols under Genghis Khan (1162–1227), whose armies were led by men appointed on the basis of demonstrated

Genghis Khan

efficiency in battle, regardless of birth or hereditary rank.

The triumph of the Mongols. Genghis Khan started his victorious career as a solitary fugitive, and his first followers were men who, like himself, lacked any powerful kindred ties because their clans had met with ill fortune in war. Among such a collection of more or less detribalized warriors, the bureaucratic principle had free rein from the start. Genghis never had to make the compromises with traditional status that would have been necessary if he had not started as a refugee, deprived of the supporting ties so vital to traditional steppe life.

Uninhibited application of the bureaucratic principle endowed Genghis Khan's armies with a remarkable capacity to expand. Instead of simply incorporating tribal war bands into his following, as earlier steppe conquerors had done, Genghis reorganized his defeated foes into tens and hundreds and put his own men in command over each of the units. This practice assured rapid promotion to men of demonstrated ability. A career open to talent allowed an ordinary tribesman to rise to the command of as many as 10,000 men. As in modern armed forces, striving to earn promotion presumably became a way of life for ambitious individuals, whose loyalties were thereby most effectively shifted away from kinship groupings and harnessed to their hope for bureaucratic advancement. By the same token, the Mongol army became capable of indefinite expansion, until literally all of the peoples of the Eurasian Steppe had joined its ranks, from Manchuria in the east to the Ukraine in the west. This remarkable and very rapid military-bureaucratic unification of the steppe was complemented by conquest of most of the civilized lands adjacent to the steppe. Thus, all of China (by 1279), most of the Middle East (by 1260), and all the Russian principalities except Novgorod (by 1241) were brought under the Mongol sway.

Full domination of the steppe

The Mongols, of course, were experienced traders by the time of their conquests. Caravans moved freely throughout their domains, and thousands, perhaps tens of thousands, of persons travelled between Europe and China. Marco Polo's account of his remarkable career in the service of Kublai Khan in China shows how readily the Mongols employed strangers and welcomed merchants from distant lands. Chinese skills were then superior to those of other parts of the world. Consequently, intensified communications under the Mongols allowed the diffusion of certain Chinese skills and tastes to the rest of Eurasia. Gunpowder, the compass, and printing were especially important for Europe. In the Middle East it was Chinese luxuries such as silk, porcelain, and styles of painting that had the most obvious impact.

Mongol religious policy puzzled both Muslim and Christian believers. The early Khans preferred to keep open multiple lines of communication with supernatural powers and therefore encouraged rival faiths—Christian, Muslim, and Buddhist—to coexist at their courts. Eventually a form of Buddhism coming from Tibet won primacy among the Mongols, but this upshot was not finally secured until the 18th century.

Genghis Khan died in 1227, long before the tide of Mongol expansion had reached its height. Down to the end of the century, the Mongol armies remained on the offensive, invading Japan (1281), Annam (modern Vietnam), and Burma (1285–87), and distant Java (1292–93). Throughout this expension, they showed remarkable readiness to exploit new technological possibilities. Even in Genghis Khan's lifetime, the conquest of northern China had required them to master siege techniques; and the conquest of southern China required them to learn to fight from ships as well. They excelled at scouting and logistics and never met a military equal in their extraordinary era of conquest except, perhaps, the Japanese, who turned them back with the help of a typhoon in 1281.

Fragmentation of the empire. The Mongol assault on Europe and the Middle East stopped short of completion due not to military failure but to dissension over the succession—a weakness of steppe empires that Genghis Khan's bureaucratic organization of the armies failed to remedy. A fourfold division among his immediate heirs went along with ceremonial recognition of the primacy of one, who became the great khan, based first at Karakorum in Mongolia and then, after 1267, at Ta-tu (modern Peking) in China.

As time passed, however, cooperation among the separate segments of the Mongol Empire became more and more precarious. With the end of rapid expansion, promotion within army ranks slowed, and the high morale and tight discipline that had been attained in the days of initial success slackened. More important still was the way in which the separate parts of the empire adopted the diverse cultural coloration of their subject peoples. Thus, the Golden Horde in Russia became Muslim and Turkish; the Il-Khans in the Middle East became Persian and Islāmic; and the great khan of China became Sinicized. The steppe way of life survived best in the central region of the empire where the Chagatai khans reigned until 1324. Yet this was the poorest of the four khanates into which Genghis Khan's empire had been partitioned and could not possibly dominate the rest.

Nevertheless, until the end of the 13th century, political unity, at least of a ceremonial kind, was maintained despite sporadic outbreaks of fighting among rival candidates for the supreme power. But after the death of Genghis' grandson Kublai (reigned 1260–94), the separate parts of the empire went their separate ways and soon began to break up internally as subject peoples asserted their independence once again.

DECLINE OF STEPPE POWER

The most important subject people to rise against the Mongol yoke were the Chinese. Rebellions broke out in the south and became so threatening that the remnant of the Mongol army withdrew to the steppe in 1368, intending to reconquer China with help from the distant Golden Horde of Russia. That never happened, but the Mongols did remain a formidable foe for the new Ming dynasty (1368–1644) and in 1449 actually captured a Chinese emperor who had inadvisedly ventured deep into the steppe.

In the Western Steppe, tribal patterns reasserted themselves within the framework of Mongol administration, so hereditary status once again made political confederations precarious. Sometimes a charismatic leader like Timur (died 1405) was able to gather a new confederacy under his banner and terrify the world again; but all such structures were short-lived. More significant were tribal confederations that espoused a special religious faith, such as the followers of Esmāʿīl I, who in 1501 founded a regime that consolidated its power over Iran and part of Iraq in the name of a sectarian version of Shīʿah Islām. The incandescence of Esmāʿīl's faith allowed him to bind nomad tribesmen and believing city folk together into a new and enduring amalgam from which the special character of contemporary Iran descends.

Resurgence under Timur

Yet these and other manifestations of the political-military power that steppe peoples could exert were no more than receding surges of a diminishing tide. In retrospect it is clear that the Mongol Empire constituted the apex of steppe history. The fundamental register of this fact was the slackening of human migration from the steppe—a pattern that had played such a dominating role in Eurasian history since 2000 BC. Recurrent exposure to plague, as a result of the spread of bubonic infection among burrowing rodents of the steppe, may have diminished steppe populations drastically. This is not attested in any known records; all that is sure is that bubonic plague invaded Europe and the Middle East in 1347 via the steppe. Moreover, as late as the 18th century outbreaks of plague in Mediterranean ports continued to occur in connection with the arrival of caravans from the interior. Further indirect evidence of demographic disaster on the steppe in the 14th and 15th centuries is the almost total lack of habitation found on the rich pastures of the Ukraine when settlers from the Russian forestlands began to move southward in the early 16th century. A remnant of the tribesmen who had once pastured their animals in the Ukraine had withdrawn into the Crimean Peninsula, where they retained their political identity as subject-allies of the Ottoman Empire until 1783. Other nomads tended their flocks and herds along the Volga, leaving Eurasia's

The role of the plague

best pasturelands unoccupied. Some catastrophe seems necessary to explain such behaviour; and the fact that rodents in the Ukraine and in Manchuria were discovered to be chronic carriers of bubonic infection in the 20th century suggests what may have happened to steppe populations in the 14th and subsequent centuries.

Whether or not the forays of Mongol horsemen into plague regions of Burma and Yunnan resulted in the transfer of bubonic infection to their native steppe lands at the end of the 13th century, a second by-product of their restless pursuit of military efficiency certainly did contribute in the long run to the overthrow of steppe power. Mongol armies learned about gunpowder from the Chinese and carried it with them for use in sieges wherever they went. Hence after the 14th century both European and Chinese artificers were able to begin elaboration of more and more efficient guns. By about 1650 handguns had become powerful enough to make nomad bows obsolete. Nomads found it hard to acquire guns and harder still to maintain a stock of powder and shot for the guns. Hence their accustomed advantage vis-à-vis infantrymen was undermined when gunfire became decisive on the battlefield, as it did throughout Eurasia by the beginning of the 18th century.

Before nomad military resources suffered this final blow, China experienced another and final conquest from the steppe, when Manchu armies overthrew the Ming dynasty in 1644. The new rulers of China quickly proceeded to extend their power into the Mongolian steppe, where they encountered agents of the Russian tsar. The Russians had begun to overrun the steppe and forest peoples of northern Eurasia after 1480, when the Grand Duke of Moscow formally renounced the suzerainty of the Golden Horde. By 1556 Russian soldiers controlled the length of the Volga. Others crossed the Urals and as early as 1639 had penetrated all the way to the Pacific. Russian and Chinese diplomats therefore had to begin demarcating a border between their respective spheres of influence on the Eastern Steppe as early as 1689; but a definitive border was not achieved until late in the 19th century when Russian soldiers pushed southward in Central Asia to the borders of Afghanistan, while recognizing Chinese authority over adjacent Sinkiang Uighur.

Russian and Chinese advances

Russian and Chinese victories over the steppe nomads and the rulers of Central Asian oases depended on the superiority of firearms wielded by bureaucratically organized armies. The Russian advance also depended on a demographic upsurge that provided a stream of settlers to move out into the steppe lands of the Ukraine and Siberia, beginning about 1550. This agricultural tide continued to advance as recently as the 1950s, when millions of acres in Kazakhstan were put to the plow for the first time, in the hope of increasing Soviet grain harvests.

The Eastern Steppe offered less opportunity for cultivation, except in Manchuria. There, however, the Ch'ing dynasty forbade Chinese settlement until 1912, when the collapse of their rule opened Manchuria to a wave of Chinese settlers. Pioneers from China's crowded hinterland soon brought all of Manchuria's readily cultivable land under crops. As a result, by the 1950s agriculture had reached, or perhaps exceeded, its climatic limits throughout the Eurasian steppe lands, spelling the final eclipse of steppe peoples as a serious factor in world affairs. Some nomadic tribes continue to wrest a hard living from marginal grasslands in Outer Mongolia and other parts of Asia; but the handful who still follow a pastoral mode of existence are no more than a tattered remnant of the steppe peoples who for millennia had played a leading role in Eurasia's political and military history.

Subatomic Particles

Subatomic particles are, literally, particles that are smaller than atoms. The physical study of such particles became possible only during the 20th century, with the development of increasingly sophisticated apparatus to probe matter at scales of 10^{-15} metre and less; yet the basic philosophy of the subject now known as subatomic particle physics dates to at least 500 BC when the Greek philosopher Leucippus and his pupil Democritus put forward the notion that matter consists of invisibly small, indivisible particles, which they called atoms. For more than 2,000 years, however, the idea of atoms lay largely neglected, while the opposing view that matter consists of four elements—earth, fire, air, and water—held sway.

It was in the early years of the 19th century that the atomic theory of matter returned to favour, strengthened in particular by the work of John Dalton, an English chemist, whose studies suggested that each chemical element consists of its own unique kind of atom. As such, Dalton's atoms are still the atoms of modern physics. By the close of the century, however, the first indications began to emerge that atoms are not indivisible, as Leucippus and Democritus had imagined, but that they instead contain smaller subatomic particles.

In 1896 the French physicist Henri Becquerel discovered radioactivity, and in the following year J.J. Thomson, a professor of physics at Cambridge University, England, demonstrated the existence of tiny particles much smaller in mass than hydrogen, the lightest atom. Thomson had discovered the first subatomic particle, the electron. Six years later, Ernest Rutherford and Frederick Soddy, working at McGill University in Montreal, found that radioactivity occurs when atoms of one type transmute into those of another kind. The idea of atoms as immutable, indivisible objects had become completely untenable.

The basic structure of the atom became apparent in 1911, when Rutherford, who had moved to Manchester University, showed that most of the mass of an atom lies concentrated at its centre, in a tiny nucleus. Rutherford postulated that the atom resembled a miniature solar system, with light, negatively charged electrons orbiting around the dense, positively charged nucleus, just as the planets orbit around the Sun. The Danish theorist Niels Bohr soon refined this model by incorporating the new ideas of quantization that had been developed by the German physicist Max Planck at the turn of the century. Planck had theorized that electromagnetic radiation, such as light, occurs in discrete bundles, or "quanta," of energy known as photons. By 1913, Bohr's theory of the atom already incorporated some of the basic elements of modern ideas about subatomic particles.

BASIC CONCEPTS

Subatomic particles play two vital roles in the structure of matter. They are both the basic building blocks of the universe and the mortar that binds the blocks together. Although the particles that fulfill these different roles are of two distinct types, they do share some common characteristics, foremost of which is size.

Subatomic particles are very small. The particles that inhabit the nucleus, for example, are called nucleons. Nucleons can be either positively charged protons or electrically neutral neutrons. A single nucleon has a diameter of about 10^{-15} metre (a distance known as a fermi in honour of the Italian physicist Enrico Fermi, who did much experimental and theoretical work on understanding the nature of the nucleus and its contents). In comparison an atom is typically 10^{-10} metre across, and the distance across an atomic nucleus of average size is roughly $^{1}/_{10,000}$ the diameter of an atom, or 10^{-14} metre.

The sizes of atoms, nuclei, and nucleons are measured by firing a beam of electrons at an appropriate target. The higher the energy of the electrons, the farther they penetrate before being deflected by the electric charges within the atom. A beam with an energy of a few hundred electron volts (eV), for example, scatters from the electrons in an atom. The way in which the beam is scattered can then be studied to determine the general distribution of the atomic electrons.

At energies of a few hundred megaelectron volts (MeV; 10^6 eV), electrons in the beam are little affected by atomic electrons; they penetrate the atom and are scattered by the positive nucleus. Therefore, if such a beam is fired at liquid hydrogen, whose atoms contain only single protons in their nuclei, the pattern of scattered electrons reveals the size of the proton. At energies greater than a gigaelectron volt (GeV; 10^9 eV), the electrons penetrate within the protons and neutrons, and their scattering patterns indicate an inner structure. Thus, protons and neutrons are no more indivisible than atoms are; instead, they contain still smaller particles, which are called quarks.

Elementary particles. Quarks are as small as or smaller than physicists can measure. In experiments at very high energies, equivalent to accelerating electrons to nearly 1,000 GeV, quarks appear to behave as points in space, with no measurable size; they must therefore be smaller than 10^{-18} metre, or less than one-thousandth the size of the individual nucleons they form. Similar experiments show that electrons, too, are smaller than it is possible to measure.

Electrons and quarks contain no discernible structure; they cannot be reduced or separated into smaller components. It is therefore reasonable to call them "elementary" particles, a name that in the past was mistakenly given to particles such as the proton, which is in fact a complex particle that contains quarks. The term subatomic particle refers both to the true elementary particles, such as quarks and electrons, and to the larger particles that quarks form.

Although both are elementary particles, electrons and quarks differ in some respects. Whereas quarks together form nucleons within the atomic nucleus, the electrons generally circulate toward the periphery of atoms. Indeed, electrons are regarded as distinct from quarks and are classified in a separate group of elementary particles called leptons. There are several types of lepton, just as there are several types of quark (see below). Only two types of quark are contained within protons and neutrons, however, and these together with the electron and one other elementary particle are all the "blocks" that are necessary to build the everyday world. The last block required is an electrically neutral particle called the neutrino.

Neutrinos

Neutrinos do not exist within atoms in the sense that electrons do, but they play a crucial role in certain types of radioactive decay. In the basic process of one type of radioactivity, known as beta decay, a neutron changes into a proton. In making this change, the neutron increases its electric charge by one unit. To keep the overall charge constant, and thereby conform to the fundamental physical law of charge conservation, the neutron must emit a negatively charged electron. In addition, according to the fundamental law of energy conservation, the sum of the energies of the final particles must equal the energy of the initial particle. The combined energy of the electron and proton is less than the energy of the neutron, however, because the neutron emits not only an electron but also a neutrino, which has little or no mass but does have energy. Beta decays are important in the transitions that occur when unstable atomic nuclei change to become more stable, and for this reason neutrinos are a necessary component in establishing the nature of matter.

The neutrino, like the electron, is classified as a lepton. Thus it seems, at first sight, that only four kinds of elementary particles—two quarks and two leptons—should exist. In the 1930s, however, long before the concept of quarks was established, it became clear that matter is more complicated.

Spin. The success of Bohr's model of the atom and its implementation of quantization led during the 1920s to the development of quantum mechanics, which appeared to provide physicists with the correct method of calculating the structure of the atom. In his model, Bohr had taken Planck's ideas of quantization a step further by postulating that the electrons in the atom move only in orbits in which the angular momentum (angular velocity multiplied by mass) has certain fixed values. Each of these allowed values is characterized by a quantum number that can have only integer values. In the full quantum mechanical treatment, developed in the 1920s, three quantum numbers relating to angular momentum arise because there are three independent variable parameters in the equation describing the motion of atomic electrons.

In 1925, however, two Dutch physicists, Samuel Goudsmit and George Uhlenbeck, realized that in order to explain fully the spectra of light emitted by the atoms of alkali metals, such as sodium, which have one outer electron beyond the main "core," there must be a fourth quantum number that can take only two values, $-1/2$ and $+1/2$. Goudsmit and Uhlenbeck proposed that this quantum number refers to an internal angular momentum, or spin, that the electrons possess. This implies that the electrons, in effect, behave like spinning electric charges. Each therefore creates a magnetic field and has its own magnetic moment. The internal magnet of an atomic electron orients itself in one of two directions with respect to the magnetic field due to the rest of the atom. It is either parallel or antiparallel; hence, there are two quantized states—and two possible values of the associated spin quantum number.

Antiparticles. Two years after the work of Goudsmit and Uhlenbeck, the English theorist P.A.M. Dirac provided a sound theoretical background for the concept of electron spin when he introduced the German physicist Albert Einstein's special theory of relativity into quantum mechanics in order to describe the behaviour of an electron in an electromagnetic field. Dirac's relativistic theory showed that the electron must have spin and a magnetic moment, but it also made what seemed a strange prediction. The basic equation describing the allowed energies for an electron would admit two solutions, one positive and one negative. The positive solution apparently described normal electrons. The negative solution was more of a mystery; it seemed to describe electrons with positive, rather than negative, charge.

The mystery was resolved in 1932, when Carl Anderson, an American physicist, discovered the particle called the positron. Positrons are very much like electrons: they have the same mass and the same spin but opposite electric charge. Positrons, then, are the particles predicted by Dirac's theory, and they were the first example of the so-called antiparticles to be discovered. Dirac's theory, in fact, applies to any subatomic particle with spin $1/2$; therefore all spin-$1/2$ particles should have corresponding antiparticles. Matter cannot be built from both particles and antiparticles, however. When a particle meets an appropriate antiparticle, the two disappear in an act of mutual destruction known as annihilation. Atoms can exist only because there is an excess of electrons and protons in the everyday world, with no corresponding positrons and antiprotons.

The positron

Positrons do occur naturally, however, which is how Anderson discovered their existence. High-energy subatomic particles—cosmic rays—rain down on the Earth's atmosphere from outer space, colliding with atomic nuclei to generate showers of particles that cascade toward the ground. In these showers, the enormous energy of the incoming cosmic ray is converted to matter, in accordance with Einstein's special theory of relativity, which states that $E = mc^2$, where E is energy, m is mass, and c is the velocity of light. Among the particles created are pairs of electrons and positrons (see Figure 1). The positrons survive until they come close enough to electrons to annihilate. The total mass of each electron-positron pair is then converted to energy, in the form of a gamma-ray photon.

Using particle accelerators, physicists can mimic the ac-

tion of cosmic rays, creating collisions at high energy. In 1955 a team led by the Italian scientist Emilio Segrè and the American Owen Chamberlain found the first evidence for the existence of antiprotons in the collisions of high-energy protons produced by the Bevatron, an accelerator at what is now the Lawrence Berkeley Laboratory, in California. Shortly afterward, a different team working on the same accelerator discovered the antineutron.

THE PRESENT STATE OF SUBATOMIC PARTICLE THEORY

Since the 1950s physicists have discovered that protons and neutrons consist of quarks with spin 1/2 and that antiprotons and antineutrons consist of antiquarks. Neutrinos, too, have spin 1/2 and corresponding antineutrinos. Indeed, it is an antineutrino, rather than a neutrino, that emerges when a neutron changes by beta decay into a proton. This reflects a basic law of nature regarding the production and decay of quarks and leptons: in any interaction the total number of quarks and leptons must separately remain constant. Thus, the appearance of a lepton—the electron—in the decay of a neutron must be balanced by the simultaneous appearance of an antilepton, in this case the antineutrino.

Conservation of quarks and leptons

In addition to such familiar particles as the nucleons and the electron, studies have slowly revealed the existence of more than 200 other subatomic particles. These "extra" particles do not appear in the low-energy environment of everyday human experience; they emerge only at the higher energies found in cosmic rays or particle accelerators. Moreover, they soon decay to the more familiar particles after brief lifetimes of only fractions of a second. The variety and behaviour of these extra particles initially bewildered scientists but have since come to be understood in terms of the quarks and leptons. In fact, only six quarks, six leptons, and their corresponding antiparticles seem to be necessary to explain the variety and behaviour of all the subatomic particles, including those that form normal atomic matter.

These quarks and leptons are the building blocks of matter, but they require some sort of mortar to bind themselves together into more complex forms, whether on a nuclear or a universal scale. The particles that provide this mortar are associated with four basic forces.

On the largest scales, the dominant force is gravity, which governs the aggregation of matter to form stars and galaxies and which influences the way that the universe is evolving from its initial big bang. The best understood force, however, is the electromagnetic force, which underlies the related phenomena of electricity and magnetism. The electromagnetic force binds negatively charged electrons to positively charged atomic nuclei and gives rise to the bonding between atoms to form matter in bulk.

Both gravity and electromagnetism are well known at the macroscopic level. The other two forces act only on subatomic scales, indeed on subnuclear scales. The strong nuclear force keeps quarks bound together within protons, neutrons, and other subatomic particles; and rather as the electromagnetic force is ultimately responsible for holding bulk matter together, so the strong nuclear force keeps protons and neutrons together within atomic nuclei. The fourth force is the weak nuclear force. Unlike the strong force, which acts only between quarks, the weak force acts on both quarks and leptons. This is the force that is responsible for the beta decay of a neutron into a proton and for the nuclear reactions that fuel the Sun and other stars.

Since the 1930s physicists have recognized that they can use field theory for all the four basic forces. In mathematical terms, a field describes something that varies continuously through space and time. A familiar example is the field that surrounds a piece of magnetized iron. The magnetic field maps the way that the force varies in strength and direction around the magnet. The appropriate fields for the four basic forces appear to have an important property in common: they all exhibit what is known as gauge symmetry. Put simply, this means that certain changes can be made that do not affect the basic structure of the field. It also implies that the relevant physical laws are the same in different regions of space and time.

At a subatomic, quantum level, these field theories display a significant feature. They describe the action of a force in terms of subatomic particles, called gauge bosons, which in a sense carry the force. These particles differ from the building blocks—the quarks and leptons—by having integer values of the spin quantum number, rather than a value of 1/2. The most familiar gauge boson is the photon, which transmits the electromagnetic force between electrically charged objects, such as the electrons and protons within the atom. The photon acts as a private, invisible messenger between these particles, influencing their behaviour with the information it conveys, rather as a ball influences the actions of children playing catch. Other gauge bosons, with varying properties, are involved with the other basic forces.

Gauge bosons

In developing a gauge theory for the weak nuclear force in the 1960s, physicists discovered that the best theory, which would always yield sensible answers, must also incorporate the electromagnetic force. The result was what is now called electroweak theory. It was the first workable example of a unified theory linking forces that manifest themselves differently in the everyday world. The unified theory reveals the outwardly diverse forces as separate facets of a single underlying force. The search for a unified theory of everything, which incorporates all four fundamental forces, is one of the major goals of particle physics. It is leading theorists to an exciting area of study that involves not only subatomic particle physics but also cosmology and astrophysics.

THE BASIC FORCES AND THEIR MESSENGER PARTICLES

Gravity. The weakest, and yet the most pervasive, of the four basic forces is gravity. It acts on all forms of mass and energy and thus acts on all subatomic particles, including the gauge bosons that carry the forces. The 17th-century English scientist Isaac Newton was the first to develop a quantitative description of the force of gravity. He argued that the force which binds the Moon in orbit around the Earth is the same force which makes apples and other objects fall to the ground, and he proposed a universal law of gravitation.

According to Newton's law, all bodies are attracted to each other by a force that depends directly on the mass of each body and inversely on the square of the distance between them. For a pair of masses, m_1 and m_2, a distance r apart, the strength of the force, F, is given by $F = Gm_1m_2/r^2$. G is called the constant of gravitation and is equal to 6.67×10^{-11} newton-metre^2-kilogram^{-2}.

The constant G gives a measure of the strength of the gravitational force, and its smallness indicates that gravity is weak. Indeed, on the scale of atoms the effects of gravity are negligible compared with the other forces at work. To compare the strengths of the different forces, physicists prefer to use constants that have no dimensions. For gravity, the appropriate pure number is given by the product of G and the square of the mass of the proton, divided by two other fundamental constants of nature, the velocity of light and Planck's constant. The result is about 5×10^{-39}, a very small number that reflects the relative weakness of the gravitational force on the atomic scale.

Although the gravitational force is weak, its effects can be extremely long-ranging. Newton's law shows that at some distance the gravitational force between two bodies becomes negligible but that this distance depends on the masses involved. Thus, the gravitational effects of large, massive objects can be considerable, even at distances far outside the range of the other forces. The gravitational force of the Earth, for example, keeps the Moon in orbit some 384,400 kilometres distant.

The range of the gravitational force

Newton's theory of gravity proves adequate for many applications. In 1915, however, Einstein developed the general theory of relativity, which incorporates the concept of gauge symmetry and yields subtle corrections to Newtonian gravity. Despite its importance, Einstein's general relativity remains a classical theory in the sense that it does not incorporate the ideas of quantum mechanics. In a quantum theory of gravity, the gravitational force must be carried by a suitable messenger particle, or gauge boson. No workable quantum theory of gravity has yet been developed, but general relativity determines some of

Electromagnetism. The first proper understanding of the electromagnetic force dates to the 18th century, when a French physicist, Charles Coulomb, showed that the electrostatic force between electrically charged objects follows a law similar to Newton's law of gravitation. Coulomb found that the force F between one charge q_1 and a second charge q_2 is equal to the product of the charges divided by the square of the distance r between them, or $F = q_1q_2/r^2$. The force can be either attractive or repulsive, because the source of the force, electric charge, exists in two varieties, positive and negative. The force between opposite charges is attractive, whereas bodies with the same kind of charge experience a repulsive force. Coulomb also showed that the force between magnetized bodies varies inversely as the square of the distance between them. Again, the force can be attractive (opposite poles) or repulsive (like poles).

Magnetism and electricity are not separate phenomena; they are the related manifestations of an underlying electromagnetic force. Experiments in the early 19th century by, among others, Hans Ørsted (in Denmark), André-Marie Ampère (in France), and Michael Faraday (in England) revealed the intimate connection between electricity and magnetism and how the one can give rise to the other. The results of these experiments were synthesized in the 1850s by the Scottish physicist James Clerk Maxwell in his electromagnetic theory. Maxwell's theory predicted the existence of electromagnetic waves—undulations in intertwined electric and magnetic fields, traveling with the velocity of light.

Maxwell's electromagnetic theory

Planck's work at the turn of the century, in which he explained the spectrum of radiation from a perfect emitter, led to the concept of quantization and photons. In the quantum picture, electromagnetic radiation has a dual nature, existing both as Maxwell's waves and as streams of particles called photons. The quantum nature of electromagnetic radiation is encapsulated in quantum electrodynamics, the quantum field theory of the electromagnetic force. Both Maxwell's classical theory and the quantized version contain gauge symmetry, which now appears to be a basic feature of the fundamental forces.

The pure number that characterizes the strength of the electromagnetic force is given by $e^2/\hbar c$, where e is the electric charge of the electron (or proton), $\hbar$ is Planck's constant divided by 2π, and c is the velocity of light. The result, known as the fine structure constant because of its relationship to certain effects in atomic spectra, is approximately $1/137$, or 7.3×10^{-3}. It shows that the electromagnetic force is intrinsically much stronger than the gravitational force—some 10^{36} times as strong. At an atomic level the electromagnetic force is almost completely in control; gravity dominates on a large scale only because matter as a whole is electrically neutral.

The gauge boson of electromagnetism is the photon, which has zero mass and a spin quantum number of 1. Photons are exchanged whenever electrically charged subatomic particles interact. The photon has no electric charge, so it does not experience the electromagnetic force itself—in other words, photons cannot interact with one another. Photons do carry energy and momentum, however, and in transmitting these properties between particles they produce the effects known as electromagnetism.
