bsSingle	Single-line border

Do not confuse the line drawn around the panel with the BorderWidth of the panel. The BorderWidth of the panel is the distance between the outer and inner bevels.

See Also

BorderWidth (see page 811)

3.1.32.2.11 TGridPanel.BorderWidth Property

Specifies the distance, in pixels, between the outer and inner bevels.

Pascal

```
property BorderWidth: TBorderWidth;
```

C++

```
__property TBorderWidth BorderWidth;
```

Description

Use BorderWidth to specify how wide the border around the panel should be. A value of 0 (zero) means no border should appear.

The border of a panel is the area between the outer and inner bevels. It is visible only if the inner bevel is raised or lowered, but affects the inset of the caption within the panel even if BevelInner is bvNone. If the Alignment property is not taCenter, the Caption will be aligned to the inner edge of the border. This edge is BorderWidth pixels in from the outer bevel if BevelInner is bvNone. It is the inner edge of the inner bevel otherwise.

Do not confuse the border of the panel with line drawn around the panel itself. The line around the panel is specified by the BorderStyle property.

C++ Examples:

```
/*
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
*/
void __fastcall TForm1::CreateStatusLineClick(TObject *Sender)
{
```

```
  Panel1->Align = alBottom;
  Panel1->BevelInner = bvLowered;
  Panel1->BevelOuter = bvRaised;
  Panel1->BorderWidth = 1;
  Panel1->BevelWidth = 1;
}
```

Delphi Examples:

```
{
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
}
procedure TForm1.CreateStatusLineClick(Sender: TObject);
begin
  with Panel1 do
  begin
    Align := alBottom;
    BevelInner := bvLowered;
    BevelOuter := bvRaised;
    BorderWidth := 1;
    BevelWidth := 1;
  end;
end;
```

Alignment (see page 807)

BevelInner (see page 807)

BevelOuter (see page 808)

BorderStyle (see page 810)

Caption

3.1.32.2.12 TGridPanel.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>
#include <memory>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);  // The owner (toolBar) will clean this up.
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this); // The owner (this) will clean this up.
  myToolBar->Parent = this;
//  TStringList *captions = new TStringList();
  std::auto_ptr<TStringList> captions(new TStringList());

  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions.get());
//  delete captions;
```

```
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long to be the caption of this label';
end;
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
        Caption := ButtonCaptions[I];
        if (ButtonCaptions[I] = '|') then
          Style := tbsSeparator
        else
          Style := tbsButton;
      end;
    end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ToolBar1 := TToolBar.Create(Self);
  ToolBar1.Parent := Self;
  AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
  ToolBar1.ShowCaptions := True;
  ToolBar1.Height := 40;
end;
```

```
procedure TForm1.FormDestroy(Sender: TObject);
var
  I: Integer;
begin
  for I := ToolBar1.ButtonCount - 1 downto 0 do
    ToolBar1.Buttons[I].Free;
  ToolBar1.Free;
end;
```

3.1.32.2.13 TGridPanel.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

ParentColor

3.1.32.2.14 TGridPanel.ColumnCollection Property

Sets the number and size of the columns on the grid panel.

Pascal

```
property ColumnCollection: TColumnCollection;
```

C++

```
__property TColumnCollection ColumnCollection;
```

Description

Use the ColumnCollection property to set the number of columns as well as the size of each column. You can use the SizeStyle property to specify whether column sizes are based on a percentage of the available width, based on an absolute value, or automatically sized.

3.1.32.2.15 TGridPanel.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

OnCanResize

3.1.32.2.16 TGridPanel.ControlCollection Property

Pascal

```
property ControlCollection: TControlCollection;
```

C++

```
__property TControlCollection ControlCollection;
```

Description

This is ControlCollection, a member of class TGridPanel.

3.1.32.2.17 TGridPanel.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

3.1.32.2.18 TGridPanel.DockManager Property

Specifies the control's docking manager interface.

Pascal

```
property DockManager;
```

C++

```
__property DockManager;
```

Description

Use DockManager to specify the control's docking manager. The docking manager handles the layout of docking zones (where controls are docked) and any painting associated with docking zones.

If you set DockSite and UseDockManager to true, but do not assign a value to DockManager, the windowed control generates a default docking manager, using the global DefaultDockTreeClass variable.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/
```

```
void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;
```

```
procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;
```

DefaultDockTreeClass

3.1.32.2.19 TGridPanel.DockSite Property

Specifies whether the control can be the target of drag-and-dock operations.

Pascal

```
property DockSite;
```

C++

```
__property DockSite;
```

Description

Set DockSite to true to allow other controls to be docked to this windowed control.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
```

```
docked control is undocked to its old position and size.
*/
void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
      TWinControl *NewTarget, bool &Allow)
{
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if (Client->ClassNameIs("TDockableForm"))
    dynamic_cast<TDockableForm *>(Client)->DockSite = True;
  if ((DockClientCount == 2) && (NewTarget != this))        // Self?
    PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
}
procedure TConjoinDockHost.FormUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if Client is TDockableForm then
    TDockableForm(Client).DockSite := True;
  if (DockClientCount = 2) and (NewTarget <> Self) then
    PostMessage(Self.Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
end;
```

3.1.32.2.20 TGridPanel.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
```

```
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

3.1.32.2.21 TGridPanel.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

3.1.32.2.22 TGridPanel.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

3.1.32.2.23 TGridPanel.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);

Arranging the Order of Persistent Columns

3.1.32.2.24 TGridPanel.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

Enabling Mouse

3.1.32.2.25 TGridPanel.ExpandStyle Property

Specifies whether rows or columns are added to a filled grid panel to accommodate additional controls.

Pascal

```
property ExpandStyle: TExpandStyle;
```

C++

```
__property TExpandStyle ExpandStyle;
```

Description

Use the ExpandStyle property to specify how a grid panel is expanded when each cell of the grid contains a control, and a new control is added.

3.1.32.2.26 TGridPanel.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

Displaying and Editing Text in a Memo Control

3.1.32.2.27 TGridPanel.FullRepaint Property

Determines how the panel repaints itself when it is resized.

Pascal

```
property FullRepaint: Boolean;
```

C++

```
__property Boolean FullRepaint;
```

Description

FullRepaint controls how the panel responds when it is resized. When FullRepaint is true, the entire panel, including the beveled border repaints when the size changes. When FullRepaint is false, only the area inside the beveled border repaints.

See Also

Invalidate

3.1.32.2.28 TGridPanel.Locked Property

Determines whether a panel that is used as a toolbar is replaced by a toolbar supplied by an OLE server.

Pascal

```
property Locked: Boolean;
```

C++

```
__property Boolean Locked;
```

Description

Set the Locked property to false when the panel is used as a toolbar by a TOleContainer component. Any panels aligned to a TOleContainer are assumed to be replaceable toolbars unless the Locked property is true. Prevent the panel from being

replaced by an OLE server's toolbar by setting the panel's Locked property to true.

Note: An OLE application's toolbars must be in panels aligned to a side of the form (that is, their Align properties must be set to alTop, alBottom, alLeft, or alRight).

See Also

Align

TOleContainer (see page 5969)

3.1.32.2.29 TGridPanel.Padding Property

Specifies the padding of a control.

Pascal

```
property Padding;
```

C++

```
__property Padding;
```

Description

Use Padding to specify the padding of a control. This value is an instance of the class TPadding.

See Also

TPadding

3.1.32.2.30 TGridPanel.ParentBackground Property

Determines whether control uses parent's theme background.

Pascal

```
property ParentBackground;
```

C++

```
__property ParentBackground;
```

Description

If ParentBackground is true, the control uses the parent's theme background to draw its own background. ParentBackground has no effect unless XP themes are enabled.

3.1.32.2.31 TGridPanel.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern

locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent

BiDiMode

3.1.32.2.32 TGridPanel.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

ParentShowHint

3.1.32.2.33 TGridPanel.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

3.1.32.2.34 TGridPanel.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

3.1.32.2.35 TGridPanel.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

Parent

ParentColor

ParentShowHint

3.1.32.2.36 TGridPanel.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

3.1.32.2.37 TGridPanel.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
```

```
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
```

```
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
```

```
    PopupMenu1.AutoPopup := True;
    Edit1.PopupMenu := PopupMenu1;
    Edit2.PopupMenu := PopupMenu1;
  end;

  {
  These are the cut, copy, and paste OnClick events for the commands
  on the pop-up menu. Double click on the pop-up menu and add three
  TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
  The names will be automatically set to "Cut1", "Copy1", and
  "Paste1".  Then double click on the OnClick events and they will
  be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
  Note: only the selected portion of the string in the edit box will
  be copied, cut or replaced.
  }
  procedure TForm1.Copy1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
     Edit1.CopyToClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.CopyToClipboard
    else
      Beep;
  end;

  procedure TForm1.Cut1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
      Edit1.CutToClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.CutToClipboard
    else
      Beep;
  end;

  procedure TForm1.Paste1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
      Edit1.PasteFromClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.PasteFromClipboard
    else
      Beep;
  end;
  {
  This example demonstrates how to add and delete menu items
  to a popup menu at runtime and assign an event handler to
  the OnClick event.  Place a TPopupMenu and three buttons on

OnContextPopup

3.1.32.2.38 TGridPanel.RowCollection Property

Sets the number and size of the rows on the grid panel.

Pascal

```
property RowCollection: TRowCollection;
```

C++

```
__property TRowCollection RowCollection;
```

Description

Use the RowCollection property to set the number of rows as well as the size of each row. You can use the SizeStyle property to specify whether row sizes are based on a percentage of the available width, based on an absolute value, or automatically sized.

3.1.32.2.39 TGridPanel.ShowCaption Property

Pascal

```
property ShowCaption: Boolean;
```

C++

```
__property Boolean ShowCaption;
```

Description

This is ShowCaption, a member of class TGridPanel.

3.1.32.2.40 TGridPanel.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
```

```
      Hint := 'Select an item';
      ShowHint := True;
    end;
    Application.ShowHint := True;
  end;
  {
  Note: To see an example that displays the hints of controls
  in some place other than in a Help Hint box, see the OnHint
  example.
  }

Displaying Fly-over Help

3.1.32.2.41 TGridPanel.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

3.1.32.2.42 TGridPanel.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

3.1.32.2.43 TGridPanel.UseDockManager Property

Specifies whether the docking manager is used in drag-and-dock operations.

Pascal

```
property UseDockManager;
```

C++

```
__property UseDockManager;
```

Description

Use UseDockManager to get or set whether a docking manager is used in drag-and-dock operations.

The docking manager handles the positioning of docked controls and any painting of docking zones around those controls. If you do not use a docking manager, docked controls are aligned to the windowed control based on the closest edge to where they are released. When you do not use a docking manager, there is no region for a user to grab to automatically undock a docked control.

See Also

DockManager

3.1.32.2.44 TGridPanel.VerticalAlignment Property

Sets the vertical position of the caption.

Pascal

```
property VerticalAlignment: TVerticalAlignment;
```

C++

```
__property TVerticalAlignment VerticalAlignment;
```

Description

Use the VerticalAlignment property to control the position of the caption within the panel. Choose one of the following values.

Value	Description
taAlignBottom	The caption displays at the bottom of the panel.
taAlignTop	The caption displays at the top of the panel.

taVerticalCenter	The caption displays at the center of the panel.

Note: Use the Alignment property to control the horizontal position of the caption.

See Also

Caption

3.1.32.2.45 TGridPanel.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the

3.1.32.3 TGridPanel Events

The events of the TGridPanel class are listed here.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 984)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 984)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 985)	Occurs when an attempt is made to resize the control.
	OnClick (see page 986)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 987)	Adjust resize constraints.
	OnContextPopup (see page 988)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 989)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 989)	Occurs when another control is docked to the control.
	OnDockOver (see page 991)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 993)	Occurs when the user drops an object being dragged.

	OnDragOver (see page 996)	Occurs when the user drags an object over a control.
	OnEndDock (see page 999)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 1000)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 1001)	Occurs when a control receives the input focus.
	OnExit (see page 1003)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 1006)	Returns the control's docking information.
	OnMouseActivate (see page 1008)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 1009)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 1011)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 1011)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 1012)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 1014)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnResize (see page 1016)	Occurs immediately after the control is resized.
	OnStartDock (see page 1017)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 1018)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 1018)	Occurs when the application tries to undock a control that is docked to the windowed control.

3.1.32.3.1 TGridPanel.OnAlignInsertBefore Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignInsertBefore;
```

C++

```
__property OnAlignInsertBefore;
```

Description

OnAlignInsertBefore occurs for each pair of child controls with an Align property of **alCustom**.

It can determine the order in which custom-aligned child controls are placed. OnAlignInsertBefore returns true if **C2** should be presented before **C1**, and false otherwise. It holds a TAlignInsertBeforeEvent type.

CustomAlignInsertBefore triggers the OnAlignInsertBefore event. If this event is defined, CustomAlignInsertBefore returns the value returned by OnAlignInsertBefore. Defining this event allows users to define the order of control alignment without overriding CustomAlignInsertBefore.

TAlignInsertBeforeEvent

3.1.32.3.2 TGridPanel.OnAlignPosition Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignPosition;
```

C++

```
__property OnAlignPosition;
```

Description

OnAlignPosition occurs when child controls with an Align property of **alCustom** are aligned.

CustomAlignPosition triggers the OnAlignPosition event. If this event is defined, CustomAlignPosition uses the alignment parameters it obtains from OnAlignPosition. Defining this event allows users to set the alignment parameters without overriding CustomAlignPosition. It holds a TAlignPositionEvent type.

These are the parameters:

Parameter	Meaning
NewLeft | NewTop | NewWidth | NewHeight	Location and size of child control, as determined by container's size and the Anchors TControl_Anchors constraints for the control. OnAlignPosition can modify these values to reposition the control.
AlignRect	The client area in which the control is aligned. OnAlignPosition can modify this value.
AlignInfo	Alignment information in a TAlignInfo.
As implemented in TWinControl, OnAlignPosition does nothing.

3.1.32.3.3 TGridPanel.OnCanResize Event

Occurs when an attempt is made to resize the control.

Pascal

```
property OnCanResize;
```

C++

```
__property OnCanResize;
```

Description

Use OnCanResize to adjust the way a control is resized. If necessary, change the new width and height of the control in the OnCanResize event handler. The OnCanResize event handler also allows applications to indicate that the entire resize should be aborted.

If there is no OnCanResize event handler, or if the OnCanResize event handler indicates that the resize attempt can proceed, the OnCanResize event is followed immediately by an OnConstrainedResize event.

OnResize

3.1.32.3.4 TGridPanel.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
```

```
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;

3.1.32.3.5 TGridPanel.OnConstrainedResize Event

Adjust resize constraints.

Pascal

```
property OnConstrainedResize;
```

C++

```
__property OnConstrainedResize;
```

Description

Use OnConstrainedResize to adjust a control's constraints when an attempt is made to resize it. Upon entry to the OnConstrainedResize event handler, the parameters of the event handler are set to the corresponding properties of the control's Constraints object. The event handler can adjust those values before they are applied to the new height and width that is being applied to the control. (The CanAutoSize method or an OnCanResize event handler may already have adjusted this new height and width).

On exit from the OnConstrainedResize event handler, the constraints are applied to the attempted new height and width. Once the constraints are applied, the control's height and width are changed. After the control's height and width change, an OnResize event occurs to allow any final adjustments or responses.

Note: The OnConstrainedResize handler is called immediately after the OnCanResize handler.

3.1.32.3.6 TGridPanel.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple

times for each context menu invocation.

3.1.32.3.7 TGridPanel.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

3.1.32.3.8 TGridPanel.OnDockDrop Event

Occurs when another control is docked to the control.

Pascal

```
property OnDockDrop;
```

C++

```
__property OnDockDrop;
```

Description

Write code in the OnDockDrop event to perform actions when another control is docked on the control.

OnDockDrop can only occur if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
```

```
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
```

```
      //Modify the DockRect to preview dock area.
      ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
      ARect.BottomRight := LeftDockPanel.ClientToScreen(
        Point(Self.ClientWidth div 3, LeftDockPanel.Height));
      Source.DockRect := ARect;
    end;
  end;

  procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
    NewTarget: TWinControl; var Allow: Boolean);
  begin
    //OnUnDock gets called BEFORE the client is undocked, in order to optionally
    //disallow the undock. DockClientCount is never 0 when called from this event.
    if (Sender as TPanel).DockClientCount = 1 then
      ShowDockPanel(Sender as TPanel, False, nil);
  end;

  procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
    DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
    var CanDock: Boolean);
  begin
    //if CanDock is true, the panel will not automatically draw the preview rect.
    CanDock := DockClient is TDockableForm;
  end;
```

DockSite

OnDockOver

3.1.32.3.9 TGridPanel.OnDockOver Event

Occurs when another control is dragged over the control.

Pascal

```
property OnDockOver;
```

C++

```
__property OnDockOver;
```

Description

Write code in the OnDockOver event to indicate whether a dockable control that is dragged over the windowed control can be accepted as a dock client. OnDockOver occurs after the TDragDockObject has been initialized by an OnGetSiteInfo event.

OnDockOver occurs only if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
```

```
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
```

```
      //Modify the DockRect to preview dock area.
      ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
      ARect.BottomRight := LeftDockPanel.ClientToScreen(
        Point(Self.ClientWidth div 3, LeftDockPanel.Height));
      Source.DockRect := ARect;
    end;
  end;

  procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
    NewTarget: TWinControl; var Allow: Boolean);
  begin
    //OnUnDock gets called BEFORE the client is undocked, in order to optionally
    //disallow the undock. DockClientCount is never 0 when called from this event.
    if (Sender as TPanel).DockClientCount = 1 then
      ShowDockPanel(Sender as TPanel, False, nil);
  end;

  procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
    DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
    var CanDock: Boolean);
  begin
    //if CanDock is true, the panel will not automatically draw the preview rect.
    CanDock := DockClient is TDockableForm;
  end;
```

TDragDockObject

3.1.32.3.10 TGridPanel.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
```

```
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");

3.1.32.3.11 TGridPanel.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
```

```
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:

3.1.32.3.13 TGridPanel.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;

3.1.32.3.14 TGridPanel.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

3.1.32.3.15 TGridPanel.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
```

```
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

procedure TForm1.MaskEdit2Exit(Sender: TObject);
var
  net1, net2, host1, host2,
  netmask1, netmask2, hostmask1, hostmask2,
  sub_net1, sub_net2, sub_host1, sub_host2: Integer;

OnEnter

ActiveControl (see page 2145)

3.1.32.3.16 TGridPanel.OnGetSiteInfo Event

Returns the control's docking information.

Pascal

```
property OnGetSiteInfo;
```

C++

```
__property OnGetSiteInfo;
```

Description

Write code in the OnGetSiteInfo event handler to initialize a TDragDockObject with information about where a dragged object can be docked, if at all. OnGetSiteInfo occurs before the OnDockOver event.

OnGetSiteInfo occurs only if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
```

```
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

3.1.32.3.17 TGridPanel.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the

OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

3.1.32.3.18 TGridPanel.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
```

```
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

3.1.32.3.19 TGridPanel.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

3.1.32.3.20 TGridPanel.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

3.1.32.3.21 TGridPanel.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

Responding to a Mouse-up Action

3.1.32.3.23 TGridPanel.OnResize Event

Occurs immediately after the control is resized.

Pascal

```
property OnResize;
```

C++

```
__property OnResize;
```

Description

Use OnResize to make any final adjustments after a control is resized.

To modify the way a control responds when an attempt is made to resize it, use OnCanResize or OnConstrainedResize.

Note: Some controls call this event handler when the control is first created.

C++ Examples:

```
/*
```

```
/*
The following code keeps the right edge on Button1 against
the right edge of Form1 when Form1 is resized.
*/
void __fastcall TForm1::FormResize(TObject *Sender)
{
  Button1->Left = Form1->ClientWidth - Button1->Width;
}
```

Delphi Examples:

```
{
The following code keeps the right edge on Button1 against
the right edge of Form1 when Form1 is resized.
}
procedure TForm1.FormResize(Sender: TObject);
begin
  Button1.Left := Form1.ClientWidth-Button1.Width;
end;
```

3.1.32.3.24 TGridPanel.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDockDrop

3.1.32.3.25 TGridPanel.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

3.1.32.3.26 TGridPanel.OnUnDock Event

Occurs when the application tries to undock a control that is docked to the windowed control.

Pascal

```
property OnUnDock;
```

C++

```
__property OnUnDock;
```

Description

Write an OnUnDock event handler to adjust the windowed control when a dock client is undocked. The OnUnDock event handler can make any necessary adjustments, or it can block the undock attempt by setting the Allow parameter to false.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
```

```
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/
void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
      TWinControl *NewTarget, bool &Allow)
{
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if (Client->ClassNameIs("TDockableForm"))
    dynamic_cast<TDockableForm *>(Client)->DockSite = True;
  if ((DockClientCount == 2) && (NewTarget != this))        // Self?
    PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
}
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
```

```
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
}
procedure TConjoinDockHost.FormUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if Client is TDockableForm then
    TDockableForm(Client).DockSite := True;
  if (DockClientCount = 2) and (NewTarget <> Self) then
    PostMessage(Self.Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
end;
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
```

```
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;

3.1.33 THeader Class

THeader is a sectioned visual control that displays text and allows each section to be resized with the mouse.

Class Hierarchy

Pascal

```
THeader = class(TCustomControl);
```

C++

```
class THeader : public TCustomControl;
```

File

ExtCtrls

Description

THeader is provided for backward compatibility. New applications should use THeaderControl instead.

3.1.33.1 THeader Members

The following tables list the members exposed by THeader.

Protected Methods

	Name	Description
	CreateParams (see page 1023)	Initializes a window-creation parameter data structure.
	MouseDown (see page 1024)	OnMouseDown event dispatcher.
	MouseMove (see page 1024)	Respond to mouse moving over control area..
	MouseUp (see page 1025)	OnMouseUp event dispatcher.
	Paint (see page 1025)	Renders the image of a custom control.
	Sized (see page 1026)	This is Sized, a member of class THeader.
	Sizing (see page 1026)	This is Sizing, a member of class THeader.

Public Methods

	Name	Description
	Create (see page 1022)	Creates a new THeader (see page 1021) object.
	Destroy (see page 1023)	Frees the memory associated with the THeader (see page 1021) object.

Public Properties

	Name	Description
	SectionWidth (see page 1042)	Determines the width, in pixels, of the sections of a header.

Published Events

	Name	Description
	OnContextPopup (see page 1046)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnSized (see page 1047)	Occurs after the header has been resized.
	OnSizing (see page 1047)	Occurs before the header is resized.

Published Properties

	Name	Description
	Align (see page 1027)	Determines how the control aligns within its container (parent control).
	AllowResize (see page 1030)	Determines if the user can modify the size of the header at runtime with the mouse.
	Anchors (see page 1030)	Specifies how the control is anchored to its parent.
	BorderStyle (see page 1031)	Determines whether the header control has a border.
	Constraints (see page 1031)	Specifies the size constraints for the control.
	DoubleBuffered (see page 1032)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	Enabled (see page 1034)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 1034)	Controls the attributes of text written on or in the control.
	ParentDoubleBuffered (see page 1035)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 1036)	Determines where a control looks for its font information.
	ParentShowHint (see page 1036)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 1037)	Identifies the pop-up menu associated with the control.
	Sections (see page 1042)	Lists the strings that contain the text for the sections of a header.
	ShowHint (see page 1042)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 1044)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 1044)	Determines if the user can tab to a control.
	Visible (see page 1045)	Determines whether the component appears onscreen.

3.1.33.2 THeader.Create Constructor

Creates a new THeader (see page 1021) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall THeader(TComponent * AOwner);
```

Description

Call Create to instantiate a header at runtime. Headers added to forms at design time are created automatically.

The AOwner parameter initializes the Owner property of the header.

See Also

Owner

3.1.33.3 THeader.Destroy Destructor

Frees the memory associated with the THeader (see page 1021) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~THeader();
```

Description

Do not call Destroy directly. Instead, use the Free method, which checks whether the THeader (see page 1021) reference is nil before calling Destroy.

See Also

System::TObject::Free

3.1.33.4 THeader Methods

The methods of the THeader class are listed here.

Protected Methods

	Name	Description
	CreateParams (see page 1023)	Initializes a window-creation parameter data structure.
	MouseDown (see page 1024)	OnMouseDown event dispatcher.
	MouseMove (see page 1024)	Respond to mouse moving over control area..
	MouseUp (see page 1025)	OnMouseUp event dispatcher.
	Paint (see page 1025)	Renders the image of a custom control.
	Sized (see page 1026)	This is Sized, a member of class THeader.
	Sizing (see page 1026)	This is Sizing, a member of class THeader.

3.1.33.4.1 THeader.CreateParams Method

Initializes a window-creation parameter data structure.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. Override CreateParams to customize the way a control creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

CreateParams fills in the parameter that is passed as the value of the Params parameter. This data structure holds information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call

to the CreateWindowEx API function.

TWinControl implements CreateParams by setting all the fields of Params to generic base values. A number of the standard controls override CreateParams to change one or more of the default values in Params.

CreateWnd

AddBiDiModeExStyle

3.1.33.4.2 THeader.MouseDown Method

OnMouseDown event dispatcher.

Pascal

```
procedure MouseDown(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer);
override;
```

C++

```
virtual __fastcall MouseDown(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

Override the protected MouseDown method to provide other responses in addition to calling the OnMouseDown event handler when the user presses the mouse button down while the cursor's hotspot is over the control.

The Button parameter determines which mouse button the user pressed. Shift indicates which shift keys (Shift, Ctrl, or Alt) were down when the user pressed the mouse button. X and Y are the pixel coordinates of the mouse pointer within the client area of the control.

A control calls MouseDown in response to any of the Windows mouse-down messages (WM_LBUTTONDOWN, WM_MBUTTONDOWN, WM_RBUTTONDOWN), decoding the message parameters into the shift-key state and position, which it passes in the Shift, X, and Y parameters, respectively. The value of the Button parameter indicates which mouse button was pressed down: left, right, or middle.

MouseMove

MouseUp

OnMouseDown

3.1.33.4.3 THeader.MouseMove Method

Respond to mouse moving over control area..

Pascal

```
procedure MouseMove(Shift: TShiftState; X: Integer; Y: Integer); override;
```

C++

```
virtual __fastcall MouseMove(TShiftState Shift, int X, int Y);
```

Description

Override the protected MouseMove method to provide other responses in addition to calling the OnMouseMove event handler when the user moves the mouse.

A control calls MouseMove in response to any of the Windows mouse-move messages (WM_MOUSEMOVE), decoding the message parameters into the shift-key state and position, which it passes in the Shift, X, and Y parameters, respectively.

As the mouse cursor moves across a control, this method is called repeatedly. Each time it is called, it is with the new coordinates that reflect the continuous path of the mouse cursor across the screen real estate covered by the control's visual representation.

MouseDown

MouseUp

OnMouseMove

3.1.33.4.4 THeader.MouseUp Method

OnMouseUp event dispatcher.

Pascal

```
procedure MouseUp(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer); override;
```

C++

```
virtual __fastcall MouseUp(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

Override the protected MouseDown method to provide other responses in addition to calling the OnMouseDown event handler when the user releases a previously pressed mouse button while the cursor's hotspot is over the control.

A control calls MouseUp in response to any of the Windows mouse-up messages (WM_LBUTTONUP, WM_MBUTTONUP, WM_RBUTTONUP), decoding the message parameters into the shift-key state and position, which it passes in the Shift, X, and Y parameters, respectively. The value of the Button parameter indicates which mouse button was released: left, right, or middle

MouseMove

OnMouseUp

3.1.33.4.5 THeader.Paint Method

Renders the image of a custom control.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

The Paint method for TCustomControl does nothing other than provide the interface for a method that responds to WM_PAINT messages. Paint is called by the PaintWindow method, after that method has supplied the Canvas with the handle to a device context. When creating a custom control, always override Paint to draw the image of the control.

Tip: To determine which portions of the control's canvas need to be repainted when Paint is called, use the ClipRect property of the canvas.

3.1.33.4.6 THeader.Sized Method

Pascal

```
procedure Sized(ASection: Integer; AWidth: Integer); dynamic;
```

C++

```
__fastcall Sized(int ASection, int AWidth);
```

Description

This is Sized, a member of class THeader.

3.1.33.4.7 THeader.Sizing Method

Pascal

```
procedure Sizing(ASection: Integer; AWidth: Integer); dynamic;
```

C++

```
__fastcall Sizing(int ASection, int AWidth);
```

Description

This is Sizing, a member of class THeader.

3.1.33.5 THeader Properties

The properties of the THeader class are listed here.

Public Properties

	Name	Description
	SectionWidth (see page 1042)	Determines the width, in pixels, of the sections of a header.

Published Properties

	Name	Description
	Align (see page 1027)	Determines how the control aligns within its container (parent control).
	AllowResize (see page 1030)	Determines if the user can modify the size of the header at runtime with the mouse.
	Anchors (see page 1030)	Specifies how the control is anchored to its parent.
	BorderStyle (see page 1031)	Determines whether the header control has a border.
	Constraints (see page 1031)	Specifies the size constraints for the control.
	DoubleBuffered (see page 1032)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	Enabled (see page 1034)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 1034)	Controls the attributes of text written on or in the control.
	ParentDoubleBuffered (see page 1035)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

	ParentFont (see page 1036)	Determines where a control looks for its font information.
	ParentShowHint (see page 1036)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 1037)	Identifies the pop-up menu associated with the control.
	Sections (see page 1042)	Lists the strings that contain the text for the sections of a header.
	ShowHint (see page 1042)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 1044)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 1044)	Determines if the user can tab to a control.
	Visible (see page 1045)	Determines whether the component appears onscreen.

3.1.33.5.1 THeader.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
```

```
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];

  for i := Low(TabTitles) to High(TabTitles) do
  begin
    pts[i]:= TTabSheet.Create(PageControl1);
    with pts[i] do
    begin
      PageControl := PageControl1;
      Name := 'ts' + TabTitles[i];
      Caption := TabTitles[i];
      Brush.Color := colorPalette[i];
   end;
  end;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  i: Integer;
begin
  for i := Low(TabTitles) to High(TabTitles) do
  begin
    pts[i].Free;
  end;
  PageControl1.Free;
end;
```

See Also

Parent

Anchors

3.1.33.5.2 THeader.AllowResize Property

Determines if the user can modify the size of the header at runtime with the mouse.

Pascal

```
property AllowResize: Boolean;
```

C++

```
__property Boolean AllowResize;
```

Description

If AllowResize is false, the sections within a header can't be resized. If AllowResize is true, clicking a border of a header section and dragging it left or right changes the width of the section. The default value is true.

3.1.33.5.3 THeader.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Align

3.1.33.5.4 THeader.BorderStyle Property

Determines whether the header control has a border.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

These are the possible values:

Value	Meaning
bsNone	No visible border
bsSingle	Single-line border

3.1.33.5.5 THeader.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

AutoSize

Align

Anchors

OnConstrainedResize

OnCanResize

3.1.33.5.6 THeader.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
```

```
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
```

```
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

3.1.33.5.7 THeader.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

3.1.33.5.8 THeader.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
```

```
  the memo or Rich Edit control font is set to the
  corresponding font name in the combo box.
  */
  void __fastcall TForm1::FormCreate(TObject *Sender)
  {
    for (int i = 0; i < Screen->Fonts->Count; i++)
     ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
  //  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
  }

  void __fastcall TForm1::ComboBox1Change(TObject *Sender)
  {
    RichEdit1->Font->Name = ComboBox1->Text;
  }
```

Delphi Examples:

```
  {
  To use this example, place a TComboBox and TRichEdit or
  TMemo on a form.  During form creation, a list of font names
  is loaded into the combo box. When the combo box is clicked,
  the memo or Rich Edit control font is set to the
  corresponding font name in the combo box.
  }
  procedure TForm1.FormCreate(Sender: TObject);
  var
    i : Integer;
  begin
    for i := 0 to Screen.Fonts.Count - 1 do
     ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
  //  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
    RichEdit1.Lines.Text := 'How is it to be you?';
  end;

  procedure TForm1.ComboBox1Click(Sender: TObject);
  begin
    RichEdit1.Font.Name := ComboBox1.Text;
  end;
```

3.1.33.5.9 THeader.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

3.1.33.5.10 THeader.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

ParentShowHint

3.1.33.5.11 THeader.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

3.1.33.5.12 THeader.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
```

```
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
```

```
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
```

```
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

OnContextPopup

3.1.33.5.13 THeader.Sections Property

Lists the strings that contain the text for the sections of a header.

Pascal

```
property Sections: TStrings;
```

C++

```
__property TStrings Sections;
```

Description

The number of lines of the string list determines the number of sections of the header. If the string list is empty, the header has one blank section. If this string list contains one or more lines, the text of each line is in its own section. The first line is in the leftmost section, the second line is in the next section to the right, and so on.

3.1.33.5.14 THeader.SectionWidth Property

Determines the width, in pixels, of the sections of a header.

Pascal

```
property SectionWidth [X: Integer]: Integer;
```

C++

```
__property int SectionWidth[int X];
```

Description

Use SectionWidth to specify the width of each header section. X is an index into the sections, from 0 to the number of sections - 1. For example, the index of the first section is 0, the second section is 1, and so on.

3.1.33.5.15 THeader.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

ParentShowHint

ShowHint (see page 1986)

Displaying Fly-over Help

3.1.33.5.16 THeader.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

3.1.33.5.17 THeader.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

3.1.33.5.18 THeader.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;
```

```
procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

3.1.33.6 THeader Events

The events of the THeader class are listed here.

Published Events

	Name	Description
	OnContextPopup (see page 1046)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnSized (see page 1047)	Occurs after the header has been resized.
	OnSizing (see page 1047)	Occurs before the header is resized.

3.1.33.6.1 THeader.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

TPopupMenu (see page 4935)

PopupMenu

AutoPopup (see page 4942)

3.1.33.6.2 THeader.OnSized Event

Occurs after the header has been resized.

Pascal

```
property OnSized: TSectionEvent;
```

C++

```
__property TSectionEvent OnSized;
```

Description

Write an OnSized event handler to perform special processing after the header has been resized. In this event, the AWidth parameter is the width of the section before it was resized. Use the SectionWidth (see page 1042) property to determine the new size of the section.

See Also

OnSizing (see page 1047)

SectionWidth (see page 1042)

3.1.33.6.3 THeader.OnSizing Event

Occurs before the header is resized.

Pascal

```
property OnSizing: TSectionEvent;
```

C++

```
__property TSectionEvent OnSizing;
```

Description

Write an OnSizing event handler to perform special processing immediately before the header is resized. In this event, AWidth is the width that the section will have after it is resized. Use the SectionWidth (see page 1042) property to determine the current size of the section.

See Also

OnSized (see page 1047)

SectionWidth (see page 1042)

3.1.34 TImage Class

TImage displays a graphical image.

Class Hierarchy

Pascal

```
TImage = class(TGraphicControl);
```

C++

```
class TImage : public TGraphicControl;
```

File

ExtCtrls

Description

Use TImage to display a graphical image on a form. Use the TPicture (see page 2812) object in the Picture (see page 1066) property to specify the actual bitmap, con, metafile, or other graphic object displayed by TImage. Properties and methods of TPicture (see page 2812) can be used for such things as loading an image from file, clearing the image in the TImage, and assigning an image for another control. TImage introduces several properties to determine how the image is displayed within the boundaries of the TImage object.

To add an image to a form or data module so that it is available for display by other controls, such as action lists and bitmap buttons, use a TImageList control instead.

A TImage may hold a bitmap, icon, PNG, GIF or JPEG image. A TImageList may hold any image type a TImage holds.

Images

3.1.34.1 TImage Members

The following tables list the members exposed by TImage.

Protected Methods

	Name	Description
	CanAutoSize (see page 1051)	Indicates whether the control can resize itself automatically to accommodate its contents.
	DestRect (see page 1052)	This is DestRect, a member of class TImage.
	DoPaletteChange (see page 1052)	This is DoPaletteChange, a member of class TImage.
	GetPalette (see page 1052)	Returns the handle to a palette for use by the control.
	Paint (see page 1052)	Render control surface.
	Progress (see page 1053)	This is Progress, a member of class TImage.

Public Methods

	Name	Description
	Create (see page 1050)	Creates and initializes an instance of TImage (see page 1048).
	Destroy (see page 1050)	Destroys an instance of TImage (see page 1048).

Public Properties

	Name	Description
	Canvas (see page 1058)	Provides a drawing surface for embellishing bitmap images.

Published Events

	Name	Description
	OnClick (see page 1079)	Occurs when the user clicks the control.
	OnContextPopup (see page 1081)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 1082)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 1082)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 1085)	Occurs when the user drags an object over a control.
	OnEndDock (see page 1088)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 1089)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnMouseActivate (see page 1090)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 1091)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 1093)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 1093)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 1093)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 1096)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnProgress (see page 1098)	Occurs periodically during slow operations that affect the image.
	OnStartDock (see page 1098)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 1099)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 1054)	Determines how the control aligns within its container (parent control).
	Anchors (see page 1057)	Specifies how the control is anchored to its parent.

	AutoSize (see page 1058)	Specifies whether the control sizes itself automatically to accommodate the dimensions of the image.
	Center (see page 1061)	Indicates whether the image is centered in the image control.
	Constraints (see page 1062)	Specifies the size constraints for the control.
	DragCursor (see page 1062)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 1063)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 1063)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 1065)	Controls whether the control responds to mouse, keyboard, and timer events.
	IncrementalDisplay (see page 1065)	Specifies whether successive approximations of the image should be drawn during slow operations.
	ParentShowHint (see page 1066)	Determines where a control looks to find out if its Help Hint should be shown.
	Picture (see page 1066)	Specifies the image that appears on the image control.
	PopupMenu (see page 1068)	Identifies the pop-up menu associated with the control.
	Proportional (see page 1073)	Indicates whether the image should be changed, without distortion, so that it fits the bounds of the image control.
	ShowHint (see page 1073)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Stretch (see page 1075)	Indicates whether the image should be changed so that it exactly fits the bounds of the image control.
	Transparent (see page 1077)	Specifies whether the background of the image obscures objects below the image object.
	Visible (see page 1077)	Determines whether the component appears onscreen.

3.1.34.2 TImage.Create Constructor

Creates and initializes an instance of TImage (see page 1048).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TImage(TComponent * AOwner);
```

Description

Call Create to instantiate a TImage (see page 1048) object at runtime. Images placed on forms at design time are created automatically.

AOwner is the component that is responsible for freeing the TImage (see page 1048) instance. It becomes the value of the Owner property.

See Also

Owner

3.1.34.3 TImage.Destroy Destructor

Destroys an instance of TImage (see page 1048).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TImage();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the TImage (see page 1048) reference is not nil, and only then calls Destroy.

As the control is destroyed, it frees the TPicture (see page 2812) object in the Picture (see page 1066) property.

System::TObject::Free

3.1.34.4 TImage Methods

The methods of the TImage class are listed here.

Protected Methods

	Name	Description
	CanAutoSize (see page 1051)	Indicates whether the control can resize itself automatically to accommodate its contents.
	DestRect (see page 1052)	This is DestRect, a member of class TImage.
	DoPaletteChange (see page 1052)	This is DoPaletteChange, a member of class TImage.
	GetPalette (see page 1052)	Returns the handle to a palette for use by the control.
	Paint (see page 1052)	Render control surface.
	Progress (see page 1053)	This is Progress, a member of class TImage.

3.1.34.4.1 TImage.CanAutoSize Method

Indicates whether the control can resize itself automatically to accommodate its contents.

Pascal

```
function CanAutoSize(var NewWidth: Integer; var NewHeight: Integer): Boolean; override;
```

C++

```
virtual __fastcall Boolean CanAutoSize(int NewWidth, int NewHeight);
```

Description

CanAutoSize is called automatically when the AutoSize property is true and an attempt is made to resize the control. It allows controls to implement the AutoSize property before the resize sequence that begins with the OnCanResize and OnConstrainedResize events and ends with the OnResize event.

When CanAutoSize is called, the NewWidth and NewHeight parameters indicate the proposed new dimensions of the control. CanAutoSize adjusts these values so that the control's size adjusts to its contents. If the adjustment results in values of NewWidth and NewHeight that differ from the control's current width and height, CanAutoSize returns true, indicating that the resize sequence should proceed. If, after adjustment, NewWidth and NewHeight equal Width and Height, CanAutoSize returns true, and the resize sequence is aborted.

As implemented in TControl, CanAutoSize always returns true without changing NewWidth or NewHeight. Override CanAutoSize to implement the AutoSize property for a particular control class's contents.

Height

3.1.34.4.2 TImage.DestRect Method

Pascal

```
function DestRect: TRect;
```

C++

```
__fastcall TRect DestRect();
```

Description

This is DestRect, a member of class TImage.

3.1.34.4.3 TImage.DoPaletteChange Method

Pascal

```
function DoPaletteChange: Boolean;
```

C++

```
__fastcall Boolean DoPaletteChange();
```

Description

This is DoPaletteChange, a member of class TImage.

3.1.34.4.4 TImage.GetPalette Method

Returns the handle to a palette for use by the control.

Pascal

```
function GetPalette: HPALETTE; override;
```

C++

```
virtual __fastcall HPALETTE GetPalette();
```

Description

As implemented in TControl, GetPalette returns a null handle, indicating that the control does not have a palette. Override GetPalette to implement derived objects that use a palette. Create a palette handle for the control by a call to the Windows API function CreatePalette. GetPalette should return the palette handle for the control.

Specifying the palette for a control tells the application that the control's palette needs to be realized and designates the palette to use for realization.

GetPalette is called only if the run-time video mode requires color palette support, for example, in 256-color mode.

See Also

PaletteChanged

3.1.34.4.5 TImage.Paint Method

Render control surface.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

The Paint method is called automatically when a lightweight control needs update its display area. Code in the Paint method uses the Canvas property to render the control surface.

As implemented in TGraphicControl, Paint does nothing. Specific rendering logic is provided by Paint methods in descendant control classes.

See Also

Canvas

3.1.34.4.6 TImage.Progress Method

Pascal

```
procedure Progress(Sender: TObject; Stage: TProgressStage; PercentDone: Byte; RedrawNow:
Boolean; const R: TRect; const Msg: string); dynamic;
```

C++

```
__fastcall Progress(TObject * Sender, TProgressStage Stage, Byte PercentDone, Boolean
RedrawNow, const TRect R, const UnicodeString Msg);
```

Description

This is Progress, a member of class TImage.

3.1.34.5 TImage Properties

The properties of the TImage class are listed here.

Public Properties

	Name	Description
R	Canvas (see page 1058)	Provides a drawing surface for embellishing bitmap images.

Published Properties

	Name	Description
	Align (see page 1054)	Determines how the control aligns within its container (parent control).
	Anchors (see page 1057)	Specifies how the control is anchored to its parent.
	AutoSize (see page 1058)	Specifies whether the control sizes itself automatically to accommodate the dimensions of the image.
	Center (see page 1061)	Indicates whether the image is centered in the image control.
	Constraints (see page 1062)	Specifies the size constraints for the control.
	DragCursor (see page 1062)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 1063)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 1063)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 1065)	Controls whether the control responds to mouse, keyboard, and timer events.
	IncrementalDisplay (see page 1065)	Specifies whether successive approximations of the image should be drawn during slow operations.
	ParentShowHint (see page 1066)	Determines where a control looks to find out if its Help Hint should be shown.
	Picture (see page 1066)	Specifies the image that appears on the image control.

	PopupMenu (see page 1068)	Identifies the pop-up menu associated with the control.
	Proportional (see page 1073)	Indicates whether the image should be changed, without distortion, so that it fits the bounds of the image control.
	ShowHint (see page 1073)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Stretch (see page 1075)	Indicates whether the image should be changed so that it exactly fits the bounds of the image control.
	Transparent (see page 1077)	Specifies whether the background of the image obscures objects below the image object.
	Visible (see page 1077)	Determines whether the component appears onscreen.

3.1.34.5.1 TImage.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
```

```
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}

Parent

Anchors

3.1.34.5.2 TImage.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Align

3.1.34.5.3 TImage.AutoSize Property

Specifies whether the control sizes itself automatically to accommodate the dimensions of the image.

Pascal

```
property AutoSize;
```

C++

```
__property AutoSize;
```

Description

Use AutoSize to specify whether the TImage (see page 1048) control adjusts its own dimensions to match the dimensions of the image that the Picture (see page 1066) property specifies. When AutoSize is true, the TImage (see page 1048) control forces its own height and width to match those of the picture it represents. When AutoSize is false (the default), the Center (see page 1061) and Stretch (see page 1075) properties determine how the image control deals with discrepancies between the size of the picture and the size of the image control.

3.1.34.5.4 TImage.Canvas Property

Provides a drawing surface for embellishing bitmap images.

Pascal

```
property Canvas: TCanvas;
```

C++

```
__property TCanvas Canvas;
```

Description

Canvas is the TCanvas (see page 2673) object on which the image for the TImage (see page 1048) component is drawn. The painting of the image specified in the Picture (see page 1066) property is automatic and does not require manual intercession for the picture to appear.

You can use properties and methods of TCanvas (see page 2673) to do such things as draw lines, draw images, and write text to the TImage (see page 1048) control's canvas.

Note: Canvas is only available if the Picture (see page 1066) property represents a TBitmap (see page 2628) object. Trying to read Canvas when Picture (see page 1066) represents another type of graphic image causes TImage (see page 1048) to raise an EInvalidOperation exception.

C++ Examples:

```
/*
This example creates a region and selects this region as the
clipping rectangle for the Image component's canvas. It then
sets the canvas's brush color to red and calls FillRect
using the ClipRect as the area to fill. Lastly, the ClipRect
is reset to the original value that it contained by calling
SelectClipRect with nil as the second parameter and deletes
the region.  Place a TImage object in the form.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
    HRGN MyRgn;

    MyRgn = ::CreateRectRgn(100,100,200,200);
    ::SelectClipRgn(Image1->Canvas->Handle,MyRgn);
    Image1->Canvas->Brush->Color = clRed;
    Image1->Canvas->FillRect(Image1->Canvas->ClipRect);
    Image1->Invalidate();
    ::SelectClipRgn(Image1->Canvas->Handle,NULL);
    ::DeleteObject(MyRgn);
}
/*
This example converts a specified icon to a bitmap. To run
this example, add an image, a button, and an Open dialog to
a form. Name the button ConvertIcon2Bitmap, and add the
following code as its OnClick event handler.
*/

#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::ConvertIcon2BitmapClick(TObject *Sender)
{
  OpenDialog1->DefaultExt = ".ICO";
  OpenDialog1->Filter = "icons (*.ico)|*.ICO";
  OpenDialog1->Options << ofOverwritePrompt << ofFileMustExist << ofHideReadOnly;
  if (OpenDialog1->Execute())
  {
    std::auto_ptr<TIcon> pi(new Graphics::TIcon);
    AnsiString as;
    pi->LoadFromFile(OpenDialog1->FileName);
    as = ChangeFileExt(OpenDialog1->FileName,".BMP");
    Image1->Width = pi->Width;
    Image1->Height = pi->Height;
    Image1->Canvas->Draw(0, 0, pi.get());
    Image1->Picture->SaveToFile(as);
    ShowMessage(OpenDialog1->FileName + " Saved to " + as);
  }
}
/*
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
*/
```

```
{
  TPoint APoint = Point(X, Y);
  int Index = ListBox1->ItemAtPos(APoint, True);
  TImage *myImage;
  TClass ClassRef = ListBox1->Items->Objects[Index]->ClassType();
  if (String(ClassRef->ClassName()) == "TImage")
  {
    myImage = dynamic_cast<TImage *>(ListBox1->Items->Objects[Index]);
    // make sure we are using the TControls canvas and not the from's!
    myImage->Canvas->MoveTo(myImage->ClientRect.Left, myImage->ClientRect.Top);
    myImage->Canvas->LineTo(myImage->ClientRect.Right, myImage->ClientRect.Bottom);
    myImage = NULL;
  }
}
/*
The following example paints a cross-hatched ellipse onto
Image1 which is a TImage on the form when the user clicks on
Button1.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TCanvas *pCanvas = Image1->Canvas;
  pCanvas->Brush->Color = clRed;
  pCanvas->Brush->Style = bsDiagCross;
  pCanvas->Ellipse(0, 0, Image1->Width, Image1->Height);
}
```

Delphi Examples:

```
{
This example creates a region and selects this region as the
clipping rectangle for the Image component's canvas. It then
sets the canvas's brush color to red and calls FillRect
using the ClipRect as the area to fill. Lastly, the ClipRect
is reset to the original value that it contained by calling
SelectClipRect with nil as the second parameter and deletes
the region.  Place a TImage object in the form.
}
procedure TForm1.Button1Click(Sender: TObject);
var
    MyRgn: HRGN;
begin
    MyRgn := CreateRectRgn(100,100,200,200);
    SelectClipRgn(Image1.Canvas.Handle,MyRgn);
    Image1.Canvas.Brush.Color := clRed;
    Image1.Canvas.FillRect(Image1.Canvas.ClipRect);
    Image1.Invalidate;
    SelectClipRgn(Image1.Canvas.Handle, HRGN(nil));
    DeleteObject(MyRgn);
end;
{
This example converts a specified icon to a bitmap. To run
this example, add an image, a button, and an Open dialog to
a form. Name the button ConvertIcon2Bitmap, and add the
following code as its OnClick event handler.
}
procedure TForm1.ConvertIcon2BitmapClick(Sender: TObject);
var
  s : string;
  Icon: TIcon;
begin
  OpenDialog1.DefaultExt := '.ICO';
  OpenDialog1.Filter := 'icons (*.ico)|*.ICO';
  OpenDialog1.Options := [ofOverwritePrompt, ofFileMustExist, ofHideReadOnly ];
  if OpenDialog1.Execute then
  begin
    Icon := TIcon.Create;
```

```
      try
        Icon.Loadfromfile(OpenDialog1.FileName);
        s:= ChangeFileExt(OpenDialog1.FileName,'.BMP');
        Image1.Width := Icon.Width;
        Image1.Height := Icon.Height;
        Image1.Canvas.Draw(0,0,Icon);
        Image1.Picture.SaveToFile(s);
        ShowMessage(OpenDialog1.FileName + ' Saved to ' + s);
      finally
        Icon.Free;
      end;
    end;
  end;
  {
  The following code uses ClientRect to find and draw a line
  from the top left to the bottom right of the current
  control.  Select a TControl in the ListBox list.  This
  example assumes that the current object is a descendent of
  TControl and has a public Canvas property.
  }
    if (ListBox1.Items.Objects[Index] is TImage) then
    begin
      myImage:= (ListBox1.Items.Objects[Index] as TImage);
      with myImage.ClientRect do
      begin // make sure we are using the TControl's canvas and not the form's!
        myImage.Canvas.MoveTo(Left, Top);
        myImage.Canvas.LineTo(Right, Bottom);
      end;
    myImage:= nil;
    end;
  {
  The following example paints a cross-hatched ellipse onto
  Image1 which is a TImage on the form when the user clicks on
  Button1.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  begin
    with Image1 do begin
      Canvas.Brush.Color := clRed;
      Canvas.Brush.Style := bsDiagCross;
      Canvas.Ellipse(0, 0, Image1.Width, Image1.Height);
    end;
  end;
```

3.1.34.5.5 TImage.Center Property

Indicates whether the image is centered in the image control.

Pascal

```
property Center: Boolean;
```

C++

```
__property Boolean Center;
```

Description

When the image does not fit perfectly within the image control, use Center to specify how the image is positioned. When Center

is true, the image is centered in the control. When Center is false, the upper left corner of the image is positioned at the upper left corner of the control.

The default value for Center is false.

Note: Center has no effect if the AutoSize (see page 1058) property is true or if the Stretch (see page 1075) property is true and Picture (see page 1066) does not specify an icon.

See Also

AutoSize

Picture (see page 1066)

Stretch (see page 1075)

Proportional (see page 1073)

3.1.34.5.6 TImage.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

OnCanResize

3.1.34.5.7 TImage.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

3.1.34.5.8 TImage.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

3.1.34.5.9 TImage.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
```

```
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;

3.1.34.5.10 TImage.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

3.1.34.5.11 TImage.IncrementalDisplay Property

Specifies whether successive approximations of the image should be drawn during slow operations.

Pascal

```
property IncrementalDisplay: Boolean;
```

C++

```
__property Boolean IncrementalDisplay;
```

Description

Set IncrementalDisplay to true on large compressed images that take a long time to load or on images that may be altered by a computationally slow process. When IncrementalDisplay is true, partial renderings of the image are drawn periodically during slow operations such as loading. Set IncrementalDisplay to false to wait until the entire operation is complete before drawing the image.

For some classes of graphic objects, an OnProgress (see page 1098) event occurs at various points during slow operations. If IncrementalDisplay is true, the OnProgress (see page 1098) event occurs immediately after the approximate image is drawn. If IncrementalDisplay is false, OnProgress (see page 1098) occurs but the image is not updated until the entire image has been loaded.

The default value for IncrementalDisplay is false.

See Also

OnProgress (see page 1098)

3.1.34.5.12 TImage.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

3.1.34.5.13 TImage.Picture Property

Specifies the image that appears on the image control.

Pascal

```
property Picture: TPicture;
```

C++

```
__property TPicture Picture;
```

Description

Use Picture to specify the image for the TImage (see page 1048) component. Picture is a reference to a TPicture (see page 2812) object. Use properties and methods of TPicture (see page 2812) to specify a bitmap, icon, metafile, or user-defined graphic to be displayed by the image control.

Setting Picture at design time brings up the Picture Editor, which can be used to specify the file that contains the image.

C++ Examples:

```
/*
```

```
This example uses an image, a button, and a shape component
on a form. When the user clicks the button, an image of the
form is stored in the FormImage variable and copied to the
Clipboard. The image of the form is then copied back to
the image component, producing an interesting result,
especially if the button is clicked multiple times.  Add
ExtCtrls, StdCtrls, and Clipbrd to the uses clause.
}
*/

#include <Clipbrd.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *FormImage = GetFormImage();
  try
  {
    Clipboard()->Assign(FormImage);
    Image1->Picture->Assign(Clipboard());
  }
  __finally
  {
    delete FormImage;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Shape1->Shape = stEllipse;
  Shape1->Brush->Color = clLime;
  Image1->Stretch = true;
}
/*
The following code draws the graphic in Picture1 in the
top-left corner PaintBox1.  Place a TPaintBox in the form
and a TImage in the form that contains a picture.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  PaintBox1->Canvas->Draw(0,0, Image1->Picture->Graphic);
}
```

Delphi Examples:

```
{
This example uses an image, a button, and a shape component
on a form. When the user clicks the button, an image of the
form is stored in the FormImage variable and copied to the
Clipboard. The image of the form is then copied back to
the image component, producing an interesting result,
especially if the button is clicked multiple times.  Add
ExtCtrls, StdCtrls, and Clipbrd to the uses clause.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  FormImage: TBitmap;
begin
  FormImage := GetFormImage;
  try
    Clipboard.Assign(FormImage);
    Image1.Picture.Assign(Clipboard);
  finally
    FormImage.Free;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
```

```
begin
  Shape1.Shape := stEllipse;
  Shape1.Brush.Color := clLime;
  Image1.Stretch := True;
end;
{
The following code draws the graphic in Picture1 in the
top-left corner PaintBox1.  Place a TPaintBox in the form
and a TImage in the form that contains a picture.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  PaintBox1.Canvas.Draw(0,0, Image1.Picture.Graphic);
end;
```

3.1.34.5.14 TImage.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
```

```
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)

                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
```

```
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

type

OnContextPopup

3.1.34.5.15 TImage.Proportional Property

Indicates whether the image should be changed, without distortion, so that it fits the bounds of the image control.

Pascal

```
property Proportional: Boolean;
```

C++

```
__property Boolean Proportional;
```

Description

Set Proportional to true to ensure that the image can be fully displayed in the image control without any distortion such as occurs with the Stretch (see page 1075) property. When Proportional is true, images that are too large to fit in the image control are scaled down (while maintaining the same aspect ratio) until they fit in the image control. Images that are too small are displayed normally. That is, Proportional can reduce the magnification of the image, but does not increase it.

When the image control resizes, the image resizes also.

To resize the image so that it fits exactly in the image control, even if that causes distortion, use the Stretch (see page 1075) property instead.

To resize the control to the image rather than resizing the image to the control, use the AutoSize (see page 1058) property instead.

The default value for Proportional is false.

Note: Proportional has no effect if the Picture (see page 1066) property contains an icon.

AutoSize (see page 1058)

Picture (see page 1066)

Stretch (see page 1075)

3.1.34.5.16 TImage.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
```

```
    Edit1.Hint := 'Enter your name';
    Edit1.ShowHint := True;
    with ListBox1 do
    begin
      for I := 1 to 10 do
        Items.Add('Item ' + IntToStr(I));
      Hint := 'Select an item';
      ShowHint := True;
    end;
    Application.ShowHint := True;
  end;
  {
  Note: To see an example that displays the hints of controls
  in some place other than in a Help Hint box, see the OnHint
  example.
  }
```

3.1.34.5.17 TImage.Stretch Property

Indicates whether the image should be changed so that it exactly fits the bounds of the image control.

Pascal

```
property Stretch: Boolean;
```

C++

```
__property Boolean Stretch;
```

Description

Set Stretch to true to cause the image to assume the size and shape of the image control. When the image control resizes, the image resizes also. Stretch resizes the height and width of the image independently. Thus, unlike a simple change in magnification, Stretch can distort the image if the image control is not the same shape as the image.

To resize the image without any distortion, use the Proportional (see page 1073) property instead.

To resize the control to the image rather than resizing the image to the control, use the AutoSize (see page 1058) property instead.

The default value for Stretch is false.

Note: Stretch has no effect if the Picture (see page 1066) property contains an icon.

C++ Examples:

```
/*
This example assigns a bitmap contained in an ImageList to
an Image component's Picture's Bitmap property and displays
the bitmap.  TImage Stretch will fit the bitmap to the image
size.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  ImageList1->GetBitmap(0, Image1->Picture->Bitmap);
```

```
  Image1->Stretch = True;
}
/*
This example converts a bitmap image to a jpeg file by using
the Assign method.  This example requires a button and two
images.  One image must have it's Picture property loaded
with a bitmap at design time.
*/

#include <Jpeg.hpp>
#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  //Requires "jpeg.hpp" to be included in the source file
  std::auto_ptr<TJPEGImage> jp(new TJPEGImage());
  jp->Assign(Image1->Picture->Bitmap);
  jp->SaveToFile("..\\factory.jpg");
  Image2->Stretch = True;
  Image2->Picture->LoadFromFile("..\\factory.jpg");
}
```

Delphi Examples:

```
{
This example assigns a bitmap contained in an ImageList to
an Image component's Picture's Bitmap property and displays
the bitmap.  TImage Stretch will fit the bitmap to the image
size.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   ImageList1.GetBitmap(2,Image1.Picture.Bitmap);
   Image1.Stretch := True;
end;
{
This example converts a bitmap image to a jpeg file by using
the Assign method.  This example requires a button and two
images.  One image must have it's Picture property loaded
with a bitmap at design time.
}
uses Jpeg;

procedure TForm1.Button1Click(Sender: TObject);
var
  jp: TJPEGImage;  //Requires the "jpeg" unit added to "uses" clause.
begin
  jp := TJPEGImage.Create;
  try
    with jp do
    begin
      Assign(Image1.Picture.Bitmap);
      SaveToFile('factory.jpg');
      Image2.Stretch := True;
      Image2.Picture.LoadFromFile('factory.jpg');
    end;
  finally
    jp.Free;
  end;
end;
```

3.1.34.5.18 TImage.Transparent Property

Specifies whether the background of the image obscures objects below the image object.

Pascal

```
property Transparent: Boolean;
```

C++

```
__property Boolean Transparent;
```

Description

Set Transparent to true to allow objects behind the TImage (see page 1048) object to show through the background of the image. Set Transparent to false to make the background of the image opaque. Setting Transparent sets the Transparent property of the Picture (see page 1066).

Note: Transparent has no effect unless the Picture (see page 1066) property specifies a TBitmap (see page 2628) object.

See Also

Picture (see page 1066)

Transparent (see page 2762)

Graphic (see page 2827)

3.1.34.5.19 TImage.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
```

```
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;

3.1.34.6 TImage Events

The events of the TImage class are listed here.

Published Events

	Name	Description
	OnClick (see page 1079)	Occurs when the user clicks the control.
	OnContextPopup (see page 1081)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 1082)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 1082)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 1085)	Occurs when the user drags an object over a control.
	OnEndDock (see page 1088)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 1089)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnMouseActivate (see page 1090)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 1091)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 1093)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 1093)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 1093)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 1096)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnProgress (see page 1098)	Occurs periodically during slow operations that affect the image.
	OnStartDock (see page 1098)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 1099)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

3.1.34.6.1 TImage.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check

box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.

- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
```

```
    for i := 0 to 9 do
      with TTabSheet.Create(Self) do
      begin
        PageControl := PageControl1;
        Caption := 'TabSheet' + IntToStr(i);
        with TEdit.Create(Self) do
        begin
          Parent := PageControl1.Pages[i];
          Left := Random(PageControl1.ActivePage.ClientWidth - Width);
          Top := Random(PageControl1.ActivePage.ClientHeight - Height);
        end;
      end;
      PageControl1Change(Sender);
  end;
```

3.1.34.6.2 TImage.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

AutoPopup (see page 4942)

3.1.34.6.3 TImage.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick

Responding to User Actions at Runtime

3.1.34.6.4 TImage.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
```

```
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
type
  TForm1 = class(TForm)
    Panel1: TPanel;
    Label1: TLabel;
    procedure Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
      State: TDragState; var Accept: Boolean);
```

```

3.1.34.6.5 TImage.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
```

```

3.1.34.6.7 TImage.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;

3.1.34.6.8 TImage.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

MouseCapture

3.1.34.6.9 TImage.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:

MouseCapture

3.1.34.6.10 TImage.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

3.1.34.6.11 TImage.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

3.1.34.6.12 TImage.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*

the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
```

```
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer);
begin
  StartX := X;
  StartY := Y;
end;

procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer);
begin
  Form1.Canvas.Rectangle(StartX, StartY, X, Y);
  StatusBar1.Panels[0].Text := '';
  StatusBar1.Panels[1].Text := '';
  StatusBar1.Panels[2].Text := '';
  StatusBar1.Panels[3].Text := '';
end;

procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
begin
  if ssLeft in Shift then { make sure button is down }
  begin
    if Y > StartY then
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
      end
    else
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
      end;
```

```
      if X > StartX then
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
        end
      else
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
        end;
    end;
  end;

3.1.34.6.14 TImage.OnProgress Event

Occurs periodically during slow operations that affect the image.

Pascal

```
property OnProgress: TProgressEvent;
```

C++

```
__property TProgressEvent OnProgress;
```

Description

Write an OnProgress event handler to provide the user with feedback during slow operations such as loading large compressed images.

Note: The PercentDone parameter of the event handler is only an approximation. With some image formats, the value of PercentDone may actually decrease from the value in previous events, as the graphic object discovers there is more work to do.

See Also

IncrementalDisplay (see page 1065)

OnProgress (see page 2830)

TProgressBar

3.1.34.6.15 TImage.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the

appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDockDrop

3.1.34.6.16 TImage.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

3.1.35 TLabeledEdit Class

TLabeledEdit is an edit control that has an associated label.

Class Hierarchy

Pascal

```
TLabeledEdit = class(TCustomLabeledEdit);
```

C++

```
class TLabeledEdit : public TCustomLabeledEdit;
```

File

ExtCtrls

Description

Use TLabeledEdit to add an edit control with a label to a form. TLabeledEdit works with an associated label control, which is the value of its EditLabel (see page 1115) property. The position of that label relative to the edit control is determined by the LabelPosition (see page 1118) and LabelSpacing (see page 1118) properties.

Use the Text (see page 1131) property to work with the text in the control, and the label's Caption property to work with the text in the label.

TMaskEdit (see page 4610)

3.1.35.1 TLabeledEdit Members

The following tables list the members exposed by TLabeledEdit.

Protected Methods

	Name	Description
	CMBidimodechanged (see page 792)	Responds when the BiDiMode property changes.
	CMEnabledchanged (see page 793)	Responds when the Enabled property changes.
	CMVisiblechanged (see page 793)	Responds when the Visible property changes.
	Notification (see page 793)	Responds to notifications when objects are created or destroyed.
	SetName (see page 794)	Sets the name of the control.
	SetParent (see page 795)	Sets the value of the Parent property.

Public Methods

	Name	Description
	Create (see page 791)	Creates an instance of TCustomLabeledEdit (see page 790).
	SetBounds (see page 794)	Sets the windowed control's boundary properties all at once.
	SetupInternalLabel (see page 795)	Initializes the control that implements the EditLabel (see page 796) property.

Published Events

	Name	Description
	OnChange (see page 1134)	Occurs when the text for the edit control may have changed.
	OnClick (see page 1135)	Occurs when the user clicks the control.
	OnContextPopup (see page 1137)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 1137)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 1138)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 1141)	Occurs when the user drags an object over a control.
	OnEndDock (see page 1144)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 1144)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 1145)	Occurs when a control receives the input focus.
	OnExit (see page 1148)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 1151)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 1154)	Occurs when a key is pressed.
	OnKeyUp (see page 1155)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 1157)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 1158)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 1160)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 1160)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 1161)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 1163)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 1165)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 1166)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Alignment (see page 1103)	Determines how the text is aligned within the text edit control.
	Anchors (see page 1104)	Specifies how the control is anchored to its parent.
	AutoSelect (see page 1104)	Determines whether all the text in the edit control is automatically selected when the control gets focus.
	AutoSize (see page 1105)	Determines whether the height of the edit control automatically resizes to accommodate the text.
	BevelEdges (see page 1106)	Specifies which edges of the control are beveled.
	BevelInner (see page 1106)	Specifies the cut of the inner bevel.
	BevelKind (see page 1107)	Specifies the control's bevel style.
	BevelOuter (see page 1107)	Specifies the cut of the outer bevel.
	BiDiMode (see page 1107)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 1108)	Determines whether the edit control has a single line border around the client area.
	CharCase (see page 1108)	Determines the case of the text within the edit control.
	Color (see page 1109)	Specifies the background color of the control.
	Constraints (see page 1109)	Specifies the size constraints for the control.
	Ctl3D (see page 1110)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 1110)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 1112)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 1113)	Specifies whether the control is being dragged normally or for docking.

	DragMode (see page 1113)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	EditLabel (see page 1115)	Specifies the control that implements the label.
	Enabled (see page 1115)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 1115)	Controls the attributes of text written on or in the control.
	HideSelection (see page 1116)	Determines whether the visual indication of the selected text remains when focus shifts to another control.
	ImeMode (see page 1117)	Determines the behavior of the input method editor (IME).
	ImeName (see page 1117)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	LabelPosition (see page 1118)	Specifies the position of the label relative to the edit control.
	LabelSpacing (see page 1118)	Specifies the distance, in pixels, between the label and the edit region.
	MaxLength (see page 1119)	Specifies the maximum number of characters the user can enter into the edit control.
	NumbersOnly (see page 1119)	Allows only numbers to be typed into the text edit.
	OEMConvert (see page 1120)	Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.
	ParentBiDiMode (see page 1120)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 1120)	Determines where a control looks for its color information.
	ParentCtl3D (see page 1121)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 1121)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 1121)	Determines where a control looks for its font information.
	ParentShowHint (see page 1122)	Determines where a control looks to find out if its Help Hint should be shown.
	PasswordChar (see page 1123)	Indicates the character, if any, to display in place of the actual characters typed in the control.
	PopupMenu (see page 1123)	Identifies the pop-up menu associated with the control.
	ReadOnly (see page 1128)	Determines whether the user can change the text of the edit control.
	ShowHint (see page 1128)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 1130)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 1130)	Determines if the user can tab to a control.
	Text (see page 1131)	Contains a text string associated with the control.
	TextHint (see page 1132)	A hint or message to be displayed when the Text property is empty.
	Visible (see page 1132)	Determines whether the component appears onscreen.

3.1.35.2 TLabeledEdit Properties

The properties of the TLabeledEdit class are listed here.

Published Properties

	Name	Description
	Alignment (see page 1103)	Determines how the text is aligned within the text edit control.
	Anchors (see page 1104)	Specifies how the control is anchored to its parent.
	AutoSelect (see page 1104)	Determines whether all the text in the edit control is automatically selected when the control gets focus.
	AutoSize (see page 1105)	Determines whether the height of the edit control automatically resizes to accommodate the text.
	BevelEdges (see page 1106)	Specifies which edges of the control are beveled.
	BevelInner (see page 1106)	Specifies the cut of the inner bevel.
	BevelKind (see page 1107)	Specifies the control's bevel style.
	BevelOuter (see page 1107)	Specifies the cut of the outer bevel.
	BiDiMode (see page 1107)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 1108)	Determines whether the edit control has a single line border around the client area.
	CharCase (see page 1108)	Determines the case of the text within the edit control.
	Color (see page 1109)	Specifies the background color of the control.

	Constraints (see page 1109)	Specifies the size constraints for the control.
	Ctl3D (see page 1110)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 1110)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 1112)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 1113)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 1113)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	EditLabel (see page 1115)	Specifies the control that implements the label.
	Enabled (see page 1115)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 1115)	Controls the attributes of text written on or in the control.
	HideSelection (see page 1116)	Determines whether the visual indication of the selected text remains when focus shifts to another control.
	ImeMode (see page 1117)	Determines the behavior of the input method editor (IME).
	ImeName (see page 1117)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	LabelPosition (see page 1118)	Specifies the position of the label relative to the edit control.
	LabelSpacing (see page 1118)	Specifies the distance, in pixels, between the label and the edit region.
	MaxLength (see page 1119)	Specifies the maximum number of characters the user can enter into the edit control.
	NumbersOnly (see page 1119)	Allows only numbers to be typed into the text edit.
	OEMConvert (see page 1120)	Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.
	ParentBiDiMode (see page 1120)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 1120)	Determines where a control looks for its color information.
	ParentCtl3D (see page 1121)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 1121)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 1121)	Determines where a control looks for its font information.
	ParentShowHint (see page 1122)	Determines where a control looks to find out if its Help Hint should be shown.
	PasswordChar (see page 1123)	Indicates the character, if any, to display in place of the actual characters typed in the control.
	PopupMenu (see page 1123)	Identifies the pop-up menu associated with the control.
	ReadOnly (see page 1128)	Determines whether the user can change the text of the edit control.
	ShowHint (see page 1128)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 1130)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 1130)	Determines if the user can tab to a control.
	Text (see page 1131)	Contains a text string associated with the control.
	TextHint (see page 1132)	A hint or message to be displayed when the Text property is empty.
	Visible (see page 1132)	Determines whether the component appears onscreen.

3.1.35.2.1 TLabeledEdit.Alignment Property

Determines how the text is aligned within the text edit control.

Pascal

```
property Alignment;
```

C++

```
__property Alignment;
```

Description

Use Alignment to change the way the text is formatted in the text edit control. Alignment can take one of the following values:

Value	Meaning
taLeftJustify	Align text to the left side of the control
taCenter	Center text horizontally in the control.
taRightJustify	Align text to the right side of the control.

See Also

SetAlignment

Text

Displaying and Editing Fields in an Edit Box

3.1.35.2.2 TLabeledEdit.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

3.1.35.2.3 TLabeledEdit.AutoSelect Property

Determines whether all the text in the edit control is automatically selected when the control gets focus.

Pascal

```
property AutoSelect;
```

C++

```
__property AutoSelect;
```

Description

Set AutoSelect to select all the text when the edit control gets focus. AutoSelect only applies to single-line edit controls.

Use AutoSelect when the user is more likely to replace the text in the edit control than to append to it.

See Also

SelectAll

SelLength

SelStart

SelText

SetSelTextBuf

3.1.35.2.4 TLabeledEdit.AutoSize Property

Determines whether the height of the edit control automatically resizes to accommodate the text.

Pascal

```
property AutoSize;
```

C++

```
__property AutoSize;
```

Description

Use AutoSize to make the edit control adjust its size automatically so the client area accommodates the height of the text. When AutoSize is false, the edit control has a fixed height. When AutoSize is true, the size of the control is readjusted whenever a change occurs that could affect the height of the control, such as a change to the font or border style.

Note: AutoSize only adjusts the height of the edit control. Even with AutoSize set to true, text in the edit control may appear truncated if it extends beyond the width of the control.

C++ Examples:

```
/*
This example uses an edit box and a button on a form. When
the user clicks the button, the font in the edit box
enlarges, and the edit box enlarges also to accommodate the
larger font size.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Edit1->AutoSize = true;
  Edit1->Font->Size = 20;
  Edit1->Text = "The edit box is taller now";
}
```

Delphi Examples:

```
{
{
This example uses an edit box and a button on a form. When
the user clicks the button, the font in the edit box
enlarges, and the edit box enlarges also to accommodate the
larger font size.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Edit1.AutoSize := True;
  Edit1.Font.Size := 20;
  Edit1.Text := 'The edit box is taller now';
end;
```

3.1.35.2.5 TLabeledEdit.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges;
```

C++

```
__property BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner

BevelOuter

BevelKind

3.1.35.2.6 TLabeledEdit.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner;
```

C++

```
__property BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges

BevelOuter

BevelKind

BevelWidth

BorderWidth

3.1.35.2.7 TLabeledEdit.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind;
```

C++

```
__property BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges

BevelOuter

BevelInner

BevelWidth

3.1.35.2.8 TLabeledEdit.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter;
```

C++

```
__property BevelOuter;
```

Description

Use BevelOuter to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges

BevelInner

BevelKind

BevelWidth

3.1.35.2.9 TLabeledEdit.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

3.1.35.2.10 TLabeledEdit.BorderStyle Property

Determines whether the edit control has a single line border around the client area.

Pascal

```
property BorderStyle;
```

C++

```
__property BorderStyle;
```

Description

Use BorderStyle to affect the sharpness with which the client area of the edit control stands out. BorderStyle can have a value of either bsSingle or bsNone. If BorderStyle is bsSingle, the edit control has a single-line border around the client area. If BorderStyle is bsNone, there will be no border.

3.1.35.2.11 TLabeledEdit.CharCase Property

Determines the case of the text within the edit control.

Pascal

```
property CharCase;
```

C++

```
__property CharCase;
```

Description

Use CharCase to force the contents of the edit control to assume a particular case.

When CharCase is set to ecLowerCase or ecUpperCase, the case of characters is converted as the user types them into the edit control. Changing the CharCase property to ecLowerCase or ecUpperCase changes the actual contents of the text, not just the appearance. Any case information is lost and can't be recaptured by changing CharCase to ecNormal.

Text

3.1.35.2.12 TLabeledEdit.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

ParentColor

3.1.35.2.13 TLabeledEdit.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

AutoSize

Align

Anchors

OnConstrainedResize

OnCanResize

3.1.35.2.14 TLabeledEdit.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

BorderWidth

3.1.35.2.15 TLabeledEdit.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
```

```
  This code requires a list box and three labels, each with a
  different font and color.  The DragMode property for each of
  the labels is dmAutomatic.  The user can select a label and
  drag it to a list box and drop it. When the label is dropped,
  the items in the list box assume the color and font of the
  dropped label.
  }

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    ListBox1.Items.Add('Not');
    ListBox1.Items.Add('In');
    ListBox1.Items.Add('Alphabetical');
    ListBox1.Items.Add('Order');
  end;

  // This OnDragOver event handler permits the list box to
  // accept a dropped label:

  procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TLabel;
  end;

  // This OnDragDrop event handler implements the drop behavior.

  procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
  begin
    if (Sender is TListBox) and (Source is TLabel) then
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

3.1.35.2.16 TLabeledEdit.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

3.1.35.2.17 TLabeledEdit.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

3.1.35.2.18 TLabeledEdit.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
```

```
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;

Arranging the Order of Persistent Columns

3.1.35.2.19 TLabeledEdit.EditLabel Property

Specifies the control that implements the label.

Pascal

```
property EditLabel: TBoundLabel;
```

C++

```
__property TBoundLabel EditLabel;
```

Description

Use EditLabel to work with the label that is associated with this labeled edit control. Use this label's properties to specify the caption that appears on the label, the position of the caption within the label, the font used to write that caption, and so on. At design time, expand the EditLabel property in the Object Inspector to set its properties.

See Also

LabelPosition (see page 796)

LabelSpacing (see page 796)

3.1.35.2.20 TLabeledEdit.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

3.1.35.2.21 TLabeledEdit.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

3.1.35.2.22 TLabeledEdit.HideSelection Property

Determines whether the visual indication of the selected text remains when focus shifts to another control.

Pascal

```
property HideSelection;
```

C++

```
__property HideSelection;
```

Description

Set HideSelection to false to provide visual feedback of the selected portion of the text even when the edit control does not have focus. Set HideSelection to true to show the selection only when the edit control has focus. HideSelection does not affect the actual value of the selection, only the visual indication. Always setting HideSelection to false can make forms with many edit controls look too busy.

SetSelTextBuf

3.1.35.2.23 TLabeledEdit.ImeMode Property

Determines the behavior of the input method editor (IME).

Pascal

```
property ImeMode;
```

C++

```
__property ImeMode;
```

Description

Set ImeMode to configure the way an IME processes user keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeMode allows a control to influence the type of conversion performed by the IME so that it is appropriate for the input expected by the control. For example, a control that only accepts numeric input might specify an ImeMode of imClose, as no conversion is necessary for numeric input.

Note: The value of ImeMode only takes effect when the control receives focus. To change the value of ImeMode when the control already has input focus, call the SetIme method.

ResetIme

ResetImeComposition

SetIme

SetImeCompositionWindow

3.1.35.2.24 TLabeledEdit.ImeName Property

Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

Pascal

```
property ImeName;
```

C++

```
__property ImeName;
```

Description

Set ImeName to specify which IME to use for converting keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeName must specify one of the IMEs that has been installed through the Windows control panel. The property inspector provides a drop-down list of all currently installed IMEs on the system. At runtime, applications can obtain a list of currently installed IMEs from the global Screen variable.

If ImeName specifies an unavailable IME, the IME that was active when the application started is used instead. No exception is generated.

Note: The value of ImeName only takes effect when the control receives focus. To change the value of ImeName after the control has input focus, call the SetIme method.

3.1.35.2.25 TLabeledEdit.LabelPosition Property

Specifies the position of the label relative to the edit control.

Pascal

```
property LabelPosition: TLabelPosition;
```

C++

```
__property TLabelPosition LabelPosition;
```

Description

Set LabelPosition to indicate where the label sits relative to the edit control.

See Also

EditLabel (see page 796)

LabelSpacing (see page 796)

3.1.35.2.26 TLabeledEdit.LabelSpacing Property

Specifies the distance, in pixels, between the label and the edit region.

Pascal

```
property LabelSpacing: Integer;
```

C++

```
__property int LabelSpacing;
```

Description

Set LabelSpacing to indicate the distance, in pixels, between the label and the edit control.

See Also

EditLabel (see page 796)

LabelPosition (see page 796)

3.1.35.2.27 TLabeledEdit.MaxLength Property

Specifies the maximum number of characters the user can enter into the edit control.

Pascal

```
property MaxLength;
```

C++

```
__property MaxLength;
```

Description

Use MaxLength to limit the number of characters that can be entered into the edit control. A value of 0 indicates that there is no application-defined limit on the length.

Use MaxLength to limit the length of the text in an edit control if that text will be copied into a fixed-length buffer.

Note: Setting MaxLength will not truncate the existing text, it merely prevents the user from adding more text after reaching the limit of MaxLength characters.

Note: Even when MaxLength is 0, there may be limitations imposed by the operating system on the number of characters that may be entered into an edit control.

Note: The unit of MaxLength is characters (not bytes) if the application is using themes.

3.1.35.2.28 TLabeledEdit.NumbersOnly Property

Allows only numbers to be typed into the text edit.

Pascal

```
property NumbersOnly;
```

C++

```
__property NumbersOnly;
```

Description

Use NumbersOnly to prohibit entry of non-numeric characters in the textfield. Note, however, that a user can paste non-numeric characters in the textfield even when this property is set.

3.1.35.2.29 TLabeledEdit.OEMConvert Property

Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.

Pascal

```
property OEMConvert;
```

C++

```
__property OEMConvert;
```

Description

To ensure that any characters typed in the edit control can be unambiguously converted to the OEM character set, set OEMConvert to true. This causes all characters to be converted from ANSI to OEM and then back to ANSI as they are typed. Set OEMConvert to false to avoid the overhead of this conversion when it does not matter whether the text can be unambiguously mapped to an OEM string.

OEMConvert is most useful for edit controls used to enter file names when the application does not use Unicode file names.

Text

3.1.35.2.30 TLabeledEdit.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent

BiDiMode

3.1.35.2.31 TLabeledEdit.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

3.1.35.2.32 TLabeledEdit.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

3.1.35.2.33 TLabeledEdit.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

3.1.35.2.34 TLabeledEdit.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

ParentShowHint

3.1.35.2.35 TLabeledEdit.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

3.1.35.2.36 TLabeledEdit.PasswordChar Property

Indicates the character, if any, to display in place of the actual characters typed in the control.

Pascal

```
property PasswordChar;
```

C++

```
__property PasswordChar;
```

Description

Use the PasswordChar property to create an edit control that displays a special character in place of any entered text. If PasswordChar is set to the null character (ANSI character zero), the edit control displays its text normally. If PasswordChar is any other character, the edit control displays PasswordChar in place of each character typed. PasswordChar affects the appearance of the edit control only. The value of the Text property reflects the actual characters that are typed.

3.1.35.2.37 TLabeledEdit.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
```

```
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
```

```
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");

            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
```

```
  makes the pop-up menu available to both edit boxes:
  }
  procedure TForm1.FormCreate(Sender: TObject);
  begin
    PopupMenu1.AutoPopup := True;
    Edit1.PopupMenu := PopupMenu1;
    Edit2.PopupMenu := PopupMenu1;
  end;

  {
  These are the cut, copy, and paste OnClick events for the commands
  on the pop-up menu. Double click on the pop-up menu and add three
  TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
  The names will be automatically set to "Cut1", "Copy1", and
  "Paste1".  Then double click on the OnClick events and they will
  be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
  Note: only the selected portion of the string in the edit box will
  be copied, cut or replaced.
  }
  procedure TForm1.Copy1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
     Edit1.CopyToClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.CopyToClipboard
    else
      Beep;
  end;

  procedure TForm1.Cut1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
      Edit1.CutToClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.CutToClipboard
    else
      Beep;
  end;

  procedure TForm1.Paste1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
      Edit1.PasteFromClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.PasteFromClipboard
    else
      Beep;
  end;
  {
  This example demonstrates how to add and delete menu items
  to a popup menu at runtime and assign an event handler to
  the OnClick event.  Place a TPopupMenu and three buttons on
  the form named "AddButton", "EditButton",  and
  "DestroyButton" and add OnClick events to all three buttons.
  Put the TPopupMenu in the PopupMenu property of the form.
  Place the PopupMenuItemsClick procedure in the TForm1 type
  declaration so that it can be used as the method call for
  the menu item OnClick event.
  }

OnContextPopup

3.1.35.2.38 TLabeledEdit.ReadOnly Property

Determines whether the user can change the text of the edit control.

Pascal

```
property ReadOnly;
```

C++

```
__property ReadOnly;
```

Description

To restrict the edit control to display only, set the ReadOnly property to true. Set ReadOnly to false to allow the contents of the edit control to be edited.

Setting ReadOnly to true ensures that the text is not altered, while still allowing the user to select text. The selected text can then be manipulated by the application, or copied to the Clipboard.

CopyToClipboard

GetSelTextBuf

3.1.35.2.39 TLabeledEdit.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);

  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
```

```
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

Displaying Fly-over Help

3.1.35.2.40 TLabeledEdit.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

FindNextControl

TabStop

3.1.35.2.41 TLabeledEdit.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

3.1.35.2.42 TLabeledEdit.Text Property

Contains a text string associated with the control.

Pascal

```
property Text;
```

C++

```
__property Text;
```

Description

Use the Text property to read the Text of the control or specify a new string for the Text value. By default, Text is the control name. For edit controls and memos, the Text appears within the control. For combo boxes, the Text is the content of the edit control portion of the combo box.

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
*/
#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int Size = Edit1->GetTextLen(); //Get length of string in Edit1
  Size++;                         //Add room for null character
//  Char *Buffer = new Char[Size];  //Creates Buffer dynamic variable
  std::auto_ptr<Char> Buffer(new Char[Size]);
  Edit1->GetTextBuf(Buffer.get(),Size); //Puts Edit1->Text into Buffer
  Edit2->Text = Buffer.get();
}
/*
Note: the same thing could be accomplished more simply as follows:
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Edit2->Text = Edit1->Text;
}
```

Delphi Examples:

```
{
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Buffer: PChar;
  Size: Byte;
begin
  Size := Edit1.GetTextLen;       {Get length of string in Edit1}
  Inc(Size);                      {Add room for null character}
  GetMem(Buffer, Size);           {Creates Buffer dynamic variable}
  Edit1.GetTextBuf(Buffer,Size);  {Puts Edit1.Text into Buffer}
  Edit2.Text := StrPas(Buffer);   {Converts Buffer to a Pascal-style string}
  FreeMem(Buffer, Size);{Frees memory allocated to Buffer}
end;

{
Note: the same thing could be accomplished more simply as follows:
}
procedure TForm1.Button2Click(Sender: TObject);
begin
  Edit2.Text := Edit1.Text;
end;
```

3.1.35.2.43 TLabeledEdit.TextHint Property

A hint or message to be displayed when the Text property is empty.

Pascal

```
property TextHint;
```

C++

```
__property TextHint;
```

Description

Use TextHint to cue the user on what kind of entry is expected in the text field. Runtime themes must be enabled.

3.1.35.2.44 TLabeledEdit.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;

3.1.35.3 TLabeledEdit Events

The events of the TLabeledEdit class are listed here.

Published Events

	Name	Description
	OnChange (see page 1134)	Occurs when the text for the edit control may have changed.
	OnClick (see page 1135)	Occurs when the user clicks the control.
	OnContextPopup (see page 1137)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 1137)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 1138)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 1141)	Occurs when the user drags an object over a control.
	OnEndDock (see page 1144)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 1144)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 1145)	Occurs when a control receives the input focus.
	OnExit (see page 1148)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 1151)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 1154)	Occurs when a key is pressed.
	OnKeyUp (see page 1155)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 1157)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 1158)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 1160)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 1160)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 1161)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 1163)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 1165)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 1166)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

3.1.35.3.1 TLabeledEdit.OnChange Event

Occurs when the text for the edit control may have changed.

Pascal

```
property OnChange;
```

C++

```
__property OnChange;
```

Description

Write an OnChange event handler to take specific action whenever the text for the edit control may have changed. Use the Modified property to see if a change actually occurred. The Text property of the edit control will already be updated to reflect any changes. This event provides the first opportunity to respond to modifications that the user types into the edit control.

See Also

Change

Text

3.1.35.3.2 TLabeledEdit.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
```

```
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

3.1.35.3.3 TLabeledEdit.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

3.1.35.3.4 TLabeledEdit.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

OnClick

Responding to User Actions at Runtime

3.1.35.3.5 TLabeledEdit.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/
```

```
// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}

3.1.35.3.6 TLabeledEdit.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{

3.1.35.3.8 TLabeledEdit.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
```

```
  control was successfully dropped into and accepted by a
  another control.
  */
  void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
       int Y)
  {
    if (Sender->ClassNameIs("TLabel"))
    {
      AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
      if (Target)
        S = S + "accepted!";
      else
        S = S + "rejected.";
      Status->Caption = S;
    }
  }
```

Delphi Examples:

```
  {
  This code displays a message in a label named Status. The
  message displayed depends on whether the dragged label
  control was successfully dropped into and accepted by a
  another control.
  }
  procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
  var
    S: string;
  begin
    S := (Sender as TLabel).Name + ' was dropped... and ';
    if Target <> nil then
      S := S + 'accepted!'
    else
      S := S + 'rejected!';
    Status.Caption := S;
  end;

3.1.35.3.9 TLabeledEdit.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
  property OnEnter;
```

C++

```
  __property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter

event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)

3.1.35.3.10 TLabeledEdit.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
```

```
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

procedure TForm1.MaskEdit2Exit(Sender: TObject);
var
  net1, net2, host1, host2,
  netmask1, netmask2, hostmask1, hostmask2,
  sub_net1, sub_net2, sub_host1, sub_host2: Integer;

  IP, mask: String;

begin
  // extract the net and host address from the IP
  IP := MaskEdit1.Text;
  net1 := StrToInt(TrimRight(Copy(IP, 0, 3)));
  net2 := StrToInt(TrimRight(Copy(IP, 5, 3)));
  host1 := StrToInt(TrimRight(Copy(IP, 9, 3)));
  host2 := StrToInt(TrimRight(Copy(IP, 13, 3)));
```

```
    // a range test that you cannot validate through edit masks
    if ((net1 < 0) Or (net1 > 255) Or
        (net2 < 0) Or (net2 > 255) Or
        (host1 < 0) Or (host1 > 255) Or
        (host2 < 0) Or (host2 > 255)) then
      raise EArgumentException.Create('Not a valid IP address.');

    // extract the net and host mask from the subnet mask
    mask := MaskEdit2.Text;
    netmask1 := StrToInt(TrimRight(Copy(mask, 0, 3)));
    netmask2 := StrToInt(TrimRight(Copy(mask, 5, 3)));
    hostmask1 := StrToInt(TrimRight(Copy(mask, 9, 3)));
    hostmask2 := StrToInt(TrimRight(Copy(mask, 13, 3)));

    // a range test that you cannot validate through edit masks
    if ((netmask1 < 0) Or (netmask1 > 255) Or
        (netmask2 < 0) Or (netmask2 > 255) Or
        (hostmask1 < 0) Or (hostmask1 > 255) Or
        (hostmask2 < 0) Or (hostmask2 > 255)) then
      raise EArgumentException.Create('Not a valid subnet mask.');

    // compute the subnet address using bit-wise AND
    sub_net1 := net1 And netmask1;
    sub_net2 := net2 And netmask2;
    sub_host1 := host1 And hostmask1;
    sub_host2 := host2 And hostmask2;

    // display the subnet address
    MaskEdit3.Text :=
      IntToStr(sub_net1) + '.' + IntToStr(sub_net2) + '.' +
      IntToStr(sub_host1) + '.' + IntToStr(sub_host2);
  end;
  {
  This example uses an edit box and a memo control on a form.
  When either the edit box or the memo is the active control,
  it is colored yellow. When the active control becomes
  inactive, the color of the control returns to the Windows
  system color for a window.  These event handlers could also
  be shared.
  }
  procedure TForm1.Edit1Enter(Sender: TObject);
  begin
    Edit1.Color := clYellow;
  end;

  procedure TForm1.Edit1Exit(Sender: TObject);
  begin
    Edit1.Color := clWindow;
  end;

  procedure TForm1.Memo1Enter(Sender: TObject);
  begin
    Memo1.Color := clYellow;
  end;

  procedure TForm1.Memo1Exit(Sender: TObject);
  begin
    Memo1.Color := clWindow;
  end;

3.1.35.3.11 TLabeledEdit.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown;
```

C++

```
__property OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

```
void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
/*

OnKeyPress

OnKeyUp

3.1.35.3.12 TLabeledEdit.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress;
```

C++

```
__property OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys

that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

3.1.35.3.13 TLabeledEdit.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp;
```

C++

```
__property OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).

OnKeyDown

OnKeyPress

3.1.35.3.14 TLabeledEdit.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control.

However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

MouseCapture

3.1.35.3.15 TLabeledEdit.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,

3.1.35.3.16 TLabeledEdit.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

3.1.35.3.17 TLabeledEdit.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

3.1.35.3.18 TLabeledEdit.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/

}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}
```

```
// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer);
begin
  StartX := X;
  StartY := Y;
end;

procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer);
begin
  Form1.Canvas.Rectangle(StartX, StartY, X, Y);
  StatusBar1.Panels[0].Text := '';
  StatusBar1.Panels[1].Text := '';
  StatusBar1.Panels[2].Text := '';
  StatusBar1.Panels[3].Text := '';
end;

procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
begin
  if ssLeft in Shift then { make sure button is down }
  begin
    if Y > StartY then
      begin
```

```
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
        end
      else
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
        end;
      if X > StartX then
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
        end
      else
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
        end;
    end;
  end;
```

MouseCapture

3.1.35.3.19 TLabeledEdit.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp;
```

C++

```
__property OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:

OnMouseMove

Responding to a Mouse-up Action

3.1.35.3.20 TLabeledEdit.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

DragKind

OnDragOver

OnDockDrop

3.1.35.3.21 TLabeledEdit.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

3.1.36 TLinkLabel Class

Label containing an HTML link.

Class Hierarchy

Pascal

```
TLinkLabel = class(TCustomLinkLabel);
```

C++

```
class TLinkLabel : public TCustomLinkLabel;
```

File

ExtCtrls

Description

TLinkLabel is a TCustomLinkLabel (see page 797) that can contain HTML tags, including a link. The link appears as underlined text. The OnLinkClick (see page 1202) event is triggered by clicking the link.

See Also

TCustomLinkLabel (see page 797)

OnLinkClick (see page 802)

TSysLinkEvent (see page 1555)

TSysLinkType (see page 1546)

3.1.36.1 TLinkLabel Members

The following tables list the members exposed by TLinkLabel.

Protected Methods

	Name	Description
	CreateParams (see page 799)	Initializes a window-creation parameter data structure.
	CreateWnd (see page 799)	Creates the underlying window.
	SetAutoSize (see page 800)	This is SetAutoSize, a member of class TCustomLinkLabel.
	UseThemes (see page 800)	This is UseThemes, a member of class TCustomLinkLabel.

Public Methods

	Name	Description
	Create (see page 798)	Creates an instance of TWinControl.

Public Nested Types

Name	Description
TLinkAlignment (see page 801)	This is nested type ExtCtrls.TCustomLinkLabel.TLinkAlignment.

Published Events

	Name	Description
	OnClick (see page 1191)	Occurs when the user clicks the control.

	OnContextPopup (see page 1193)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 1194)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 1194)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 1197)	Occurs when the user drags an object over a control.
	OnEndDock (see page 1200)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 1201)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnLinkClick (see page 1202)	Event for click on TCustomLinkLabel HTML link.
	OnMouseActivate (see page 1202)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 1203)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 1205)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 1205)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 1206)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 1208)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 1210)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 1211)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Alignment (see page 1169)	This is Alignment, a member of class TLinkLabel.
	Anchors (see page 1169)	Specifies how the control is anchored to its parent.
	AutoSize (see page 1170)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 1170)	Specifies which edges of the control are beveled.
	BevelInner (see page 1171)	Specifies the cut of the inner bevel.
	BevelKind (see page 1171)	Specifies the control's bevel style.
	BevelOuter (see page 1172)	Specifies the cut of the outer bevel.
	Caption (see page 1172)	Specifies a text string that identifies the control to the user.
	Color (see page 1175)	Specifies the background color of the control.
	Constraints (see page 1175)	Specifies the size constraints for the control.
	DragCursor (see page 1176)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 1176)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 1177)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 1178)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 1179)	Controls the attributes of text written on or in the control.
	ParentColor (see page 1180)	Determines where a control looks for its color information.
	ParentFont (see page 1180)	Determines where a control looks for its font information.
	ParentShowHint (see page 1181)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 1181)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 1186)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 1188)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 1188)	Determines if the user can tab to a control.
	UseVisualStyle (see page 1189)	This is UseVisualStyle, a member of class TLinkLabel.
	Visible (see page 1189)	Determines whether the component appears onscreen.

3.1.36.2 TLinkLabel Properties

The properties of the TLinkLabel class are listed here.

Published Properties

	Name	Description
	Alignment (see page 1169)	This is Alignment, a member of class TLinkLabel.
	Anchors (see page 1169)	Specifies how the control is anchored to its parent.
	AutoSize (see page 1170)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 1170)	Specifies which edges of the control are beveled.
	BevelInner (see page 1171)	Specifies the cut of the inner bevel.
	BevelKind (see page 1171)	Specifies the control's bevel style.
	BevelOuter (see page 1172)	Specifies the cut of the outer bevel.
	Caption (see page 1172)	Specifies a text string that identifies the control to the user.
	Color (see page 1175)	Specifies the background color of the control.
	Constraints (see page 1175)	Specifies the size constraints for the control.
	DragCursor (see page 1176)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 1176)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 1177)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 1178)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 1179)	Controls the attributes of text written on or in the control.
	ParentColor (see page 1180)	Determines where a control looks for its color information.
	ParentFont (see page 1180)	Determines where a control looks for its font information.
	ParentShowHint (see page 1181)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 1181)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 1186)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 1188)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 1188)	Determines if the user can tab to a control.
	UseVisualStyle (see page 1189)	This is UseVisualStyle, a member of class TLinkLabel.
	Visible (see page 1189)	Determines whether the component appears onscreen.

3.1.36.2.1 TLinkLabel.Alignment Property

Pascal

```
property Alignment: TLinkAlignment;
```

C++

```
__property TLinkAlignment Alignment;
```

Description

This is Alignment, a member of class TLinkLabel.

3.1.36.2.2 TLinkLabel.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent

Align

3.1.36.2.3 TLinkLabel.AutoSize Property

Specifies whether the control sizes itself automatically to accommodate its contents.

Pascal

```
property AutoSize: Boolean;
```

C++

```
__property Boolean AutoSize;
```

Description

Use AutoSize to specify whether the control sizes itself automatically. When AutoSize is true, the control resizes automatically when its contents change.

By default, AutoSize is false.

See Also

Constraints

CanAutoSize

3.1.36.2.4 TLinkLabel.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges;
```

C++

```
__property BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner

BevelOuter

BevelKind

3.1.36.2.5 TLinkLabel.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner;
```

C++

```
__property BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges

BevelOuter

BevelKind

BevelWidth

BorderWidth

3.1.36.2.6 TLinkLabel.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind;
```

C++

```
__property BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges

BevelOuter

BevelInner

BevelWidth

3.1.36.2.7 TLinkLabel.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter;
```

C++

```
__property BevelOuter;
```

Description

Use BevelOuter to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges

BevelInner

BevelKind

BevelWidth

3.1.36.2.8 TLinkLabel.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
```

```
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>
#include <memory>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);  // The owner (toolBar) will clean this up.
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this); // The owner (this) will clean this up.
  myToolBar->Parent = this;
//  TStringList *captions = new TStringList();
  std::auto_ptr<TStringList> captions(new TStringList());

  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions.get());
//  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}
```

Delphi Examples:

```
{
```

```
  The following code keeps the size of the label control
  constant, even though the length of the label's caption
  changes. As a result, the caption of the label is probably
  too long to display in the label when the user clicks the
  button:
  }
  procedure TForm1.Button1Click(Sender: TObject);
  begin
    Label1.AutoSize := False;
    Label1.Caption :=
      'This string is too long to be the caption of this label';
  end;
  {
  This example requires a TPageControl populated by several
  TabSheets, a TEdit and a TButton. When the button is
  clicked, the caption of the active tab changes to that of
  the TEdit.  These lines of code could also be written:
  PageControl1.ActivePage.Caption := Edit1.Text;
  This would obviate the need for a TTabSheet variable since
  PageControl1.->ActivePage is already of type TTabSheet.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    sheet: TTabSheet;
  begin
    sheet := PageControl1.ActivePage;
    sheet.Caption := Edit1.Text;
  end;
  {
  This example creates a ToolBar and adds ToolButtons to it.
  Include ComCtlrs in the uses clause.
  }
  procedure AddButtons(ToolBar: TToolBar;
    Const ButtonCaptions: array of String);
  var
    I: Integer;
  begin
    for I := 0 to High(ButtonCaptions) do
      begin
        with TToolButton.Create(ToolBar) do
        begin
          Parent := ToolBar;
          Caption := ButtonCaptions[I];
          if (ButtonCaptions[I] = '|') then
            Style := tbsSeparator
          else
            Style := tbsButton;
        end;
      end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    ToolBar1 := TToolBar.Create(Self);
    ToolBar1.Parent := Self;
    AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
    ToolBar1.ShowCaptions := True;
    ToolBar1.Height := 40;
  end;

  procedure TForm1.FormDestroy(Sender: TObject);
  var
    I: Integer;
  begin
    for I := ToolBar1.ButtonCount - 1 downto 0 do
      ToolBar1.Buttons[I].Free;
```

```
  ToolBar1.Free;
end;
```

3.1.36.2.9 TLinkLabel.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

ParentColor

3.1.36.2.10 TLinkLabel.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

OnCanResize

3.1.36.2.11 TLinkLabel.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

3.1.36.2.12 TLinkLabel.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

3.1.36.2.13 TLinkLabel.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;

Arranging the Order of Persistent Columns

3.1.36.2.14 TLinkLabel.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls

appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

3.1.36.2.15 TLinkLabel.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
```

```
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

Displaying and Editing Text in a Memo Control

3.1.36.2.16 TLinkLabel.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

3.1.36.2.17 TLinkLabel.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform

appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

ParentShowHint

3.1.36.2.18 TLinkLabel.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

3.1.36.2.19 TLinkLabel.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse

button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)

OnContextPopup

3.1.36.2.20 TLinkLabel.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine

whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin

3.1.36.2.21 TLinkLabel.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

3.1.36.2.22 TLinkLabel.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

TabOrder

3.1.36.2.23 TLinkLabel.UseVisualStyle Property

Pascal

```
property UseVisualStyle: Boolean;
```

C++

```
__property Boolean UseVisualStyle;
```

Description

This is UseVisualStyle, a member of class TLinkLabel.

3.1.36.2.24 TLinkLabel.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
```

```
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{

3.1.36.3 TLinkLabel Events

The events of the TLinkLabel class are listed here.

Published Events

	Name	Description
	OnClick (see page 1191)	Occurs when the user clicks the control.
	OnContextPopup (see page 1193)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 1194)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 1194)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 1197)	Occurs when the user drags an object over a control.
	OnEndDock (see page 1200)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 1201)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnLinkClick (see page 1202)	Event for click on TCustomLinkLabel HTML link.
	OnMouseActivate (see page 1202)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 1203)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 1205)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 1205)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 1206)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 1208)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 1210)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 1211)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

3.1.36.3.1 TLinkLabel.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check

box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.

- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
```

```
    for i := 0 to 9 do
      with TTabSheet.Create(Self) do
      begin
        PageControl := PageControl1;
        Caption := 'TabSheet' + IntToStr(i);
        with TEdit.Create(Self) do
        begin
          Parent := PageControl1.Pages[i];
          Left := Random(PageControl1.ActivePage.ClientWidth - Width);
          Top := Random(PageControl1.ActivePage.ClientHeight - Height);
        end;
      end;
      PageControl1Change(Sender);
  end;
```

3.1.36.3.2 TLinkLabel.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

3.1.36.3.3 TLinkLabel.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick

Responding to User Actions at Runtime

3.1.36.3.4 TLinkLabel.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
```

```
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,

TDragObject

3.1.36.3.5 TLinkLabel.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
```

__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;

3.1.36.3.8 TLinkLabel.OnLinkClick Event

Event for click on TCustomLinkLabel HTML link.

Pascal

```
property OnLinkClick: TSysLinkEvent;
```

C++

```
__property TSysLinkEvent OnLinkClick;
```

Description

OnLinkClick is triggered by a click on a TCustomLinkLabel's HTML link. The event identifies the link URI and link type.

3.1.36.3.9 TLinkLabel.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the

OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

3.1.36.3.10 TLinkLabel.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
```

```
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled

3.1.36.3.11 TLinkLabel.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

3.1.36.3.12 TLinkLabel.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

3.1.36.3.13 TLinkLabel.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

Responding to a Mouse-up Action

3.1.36.3.15 TLinkLabel.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDockDrop

3.1.36.3.16 TLinkLabel.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

3.1.37 TNotebook Class

TNotebook displays multiple pages, each with its own set of controls.

Class Hierarchy

Pascal

```
TNotebook = class(TCustomControl);
```

C++

```
class TNotebook : public TCustomControl;
```

File

ExtCtrls

Description

Notebook components are frequently used with tab set controls (TTabSet) to let the user select pages in the notebook by clicking a tab. TNotebook is provided for backward compatibility. New applications should use TPageControl instead.

3.1.37.1 TNotebook Members

The following tables list the members exposed by TNotebook.

Protected Methods

	Name	Description
	CreateParams (see page 1214)	Initializes a window-creation parameter data structure.
	GetChildOwner (see page 1215)	Returns the owner of a child component being read from a stream.
	ReadState (see page 1216)	Prepares the control for having its properties assigned values from a stream.
	ShowControl (see page 1216)	Ensures that a specified child control is visible.

Public Methods

	Name	Description
	Create (see page 1213)	Constructs a TNotebook (see page 1211) component.
	Destroy (see page 1214)	Destroys the TNotebook (see page 1211) component.
	GetChildren (see page 1215)	Calls a specified method for each child of the control.

Published Events

	Name	Description
	OnClick (see page 1242)	Occurs when the user clicks the control.
	OnContextPopup (see page 1244)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 1244)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 1245)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 1248)	Occurs when the user drags an object over a control.
	OnEndDock (see page 1251)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 1251)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 1252)	Occurs when a control receives the input focus.
	OnExit (see page 1255)	Occurs when the input focus shifts away from one control to another.
	OnMouseActivate (see page 1257)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 1258)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 1261)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 1261)	Occurs when the user moves the mouse outside of a control.

	OnMouseMove (see page 1261)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 1263)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnPageChanged (see page 1266)	Occurs when the user selects a new page in the notebook.
	OnStartDock (see page 1266)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 1267)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	ActivePage (see page 1217)	Determines which page displays in the notebook.
	Align (see page 1218)	Determines how the control aligns within its container (parent control).
	Anchors (see page 1221)	Specifies how the control is anchored to its parent.
	Color (see page 1222)	Specifies the background color of the control.
	Constraints (see page 1222)	Specifies the size constraints for the control.
	Ctl3D (see page 1223)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 1223)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 1225)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 1226)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 1226)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 1228)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 1228)	Controls the attributes of text written on or in the control.
	PageIndex (see page 1229)	Determines which page displays in the notebook control.
	Pages (see page 1230)	Contains the strings that identify the individual pages of the notebook control.
	ParentColor (see page 1230)	Determines where a control looks for its color information.
	ParentCtl3D (see page 1230)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 1231)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 1231)	Determines where a control looks for its font information.
	ParentShowHint (see page 1232)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 1232)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 1237)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 1239)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 1239)	Determines if the user can tab to a control.
	Visible (see page 1240)	Determines whether the component appears onscreen.

3.1.37.2 TNotebook.Create Constructor

Constructs a TNotebook (see page 1211) component.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TNotebook(TComponent * AOwner);
```

Description

Call Create to instantiate a notebook at runtime. Notebook components placed in forms at design time are created automatically.

The AOwner parameter specifies the component (usually the form) that is responsible for freeing the notebook.

3.1.37.3 TNotebook.Destroy Destructor

Destroys the TNotebook (see page 1211) component.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TNotebook();
```

Description

Do not call Destroy directly in an application. Instead, use Free, which checks that the TNotebook (see page 1211) reference is not nil before calling Destroy.

See Also

System::TObject::Free

3.1.37.4 TNotebook Methods

The methods of the TNotebook class are listed here.

Protected Methods

	Name	Description
	CreateParams (see page 1214)	Initializes a window-creation parameter data structure.
	GetChildOwner (see page 1215)	Returns the owner of a child component being read from a stream.
	ReadState (see page 1216)	Prepares the control for having its properties assigned values from a stream.
	ShowControl (see page 1216)	Ensures that a specified child control is visible.

Public Methods

	Name	Description
	GetChildren (see page 1215)	Calls a specified method for each child of the control.

3.1.37.4.1 TNotebook.CreateParams Method

Initializes a window-creation parameter data structure.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. Override CreateParams to customize the way a control creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

CreateParams fills in the parameter that is passed as the value of the Params parameter. This data structure holds information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function.

TWinControl implements CreateParams by setting all the fields of Params to generic base values. A number of the standard

controls override CreateParams to change one or more of the default values in Params.

CreateWindowHandle

CreateWnd

AddBiDiModeExStyle

3.1.37.4.2 TNotebook.GetChildOwner Method

Returns the owner of a child component being read from a stream.

Pascal

```
function GetChildOwner: TComponent; override;
```

C++

```
virtual __fastcall TComponent * GetChildOwner();
```

Description

GetChildOwner is used internally by the component streaming system. It is rarely necessary to call it directly.

In TComponent, GetChildOwner always returns nil (Delphi) or NULL (C++), indicating that the owner is the root component currently being read (usually a form or data module). The Owner of a component is responsible for destroying it.

Create

Owner

3.1.37.4.3 TNotebook.GetChildren Method

Calls a specified method for each child of the control.

Pascal

```
procedure GetChildren(Proc: TGetChildProc; Root: TComponent); override;
```

C++

```
virtual __fastcall GetChildren(TGetChildProc Proc, TComponent * Root);
```

Description

GetChildren is called by the streaming system that loads and saves components. Applications seldom need to call this routine.

GetChildren executes the callback specified by the Proc parameter for every child control listed by the Controls property that lists the Root parameter as its Owner.

Override GetChildren to limit or augment which child controls are saved with the control. When overriding GetChildren, call the procedure passed as the Proc parameter for every child control that should be saved. The Root parameter indicates the component (usually a form) that owns the control.

See Also

Controls

Owner

3.1.37.4.4 TNotebook.ReadState Method

Prepares the control for having its properties assigned values from a stream.

Pascal

```
procedure ReadState(Reader: TReader); override;
```

C++

```
virtual __fastcall ReadState(TReader Reader);
```

Description

Override ReadState to change the preparations the control makes as it readies itself to have its property values assigned from a stream. For example, a control might destroy temporary internal data structures or objects before new instances are loaded from the stream. Be sure to include a call to the inherited method when overriding ReadState.

As implemented in TWinControl, ReadState disables control alignment until all the child controls have been read from the stream, calls the inherited ReadState method, and re-enables the alignment of all the controls. The method then builds the tab order list of controls and synchronizes its visibility with that of its parent control.

Parent

ReadState

3.1.37.4.5 TNotebook.ShowControl Method

Ensures that a specified child control is visible.

Pascal

```
procedure ShowControl(AControl: TControl); override;
```

C++

```
virtual __fastcall ShowControl(TControl * AControl);
```

Description

Call ShowControl to display a child control. Specify the control you want to ensure will be visible as the value of the AControl parameter.

As implemented in TWinControl, ShowControl simply calls the ShowControl method of the control's parent. Derived objects override ShowControl to perform whatever actions are necessary to allow the indicated child object to be visible. Possible actions include scrolling the particular child object into view, or changing to the appropriate notebook page.

3.1.37.5 TNotebook Properties

The properties of the TNotebook class are listed here.

Published Properties

	Name	Description
	ActivePage (see page 1217)	Determines which page displays in the notebook.
	Align (see page 1218)	Determines how the control aligns within its container (parent control).
	Anchors (see page 1221)	Specifies how the control is anchored to its parent.
	Color (see page 1222)	Specifies the background color of the control.
	Constraints (see page 1222)	Specifies the size constraints for the control.
	Ctl3D (see page 1223)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 1223)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 1225)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 1226)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 1226)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 1228)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 1228)	Controls the attributes of text written on or in the control.
	PageIndex (see page 1229)	Determines which page displays in the notebook control.
	Pages (see page 1230)	Contains the strings that identify the individual pages of the notebook control.
	ParentColor (see page 1230)	Determines where a control looks for its color information.
	ParentCtl3D (see page 1230)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 1231)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 1231)	Determines where a control looks for its font information.
	ParentShowHint (see page 1232)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 1232)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 1237)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 1239)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 1239)	Determines if the user can tab to a control.
	Visible (see page 1240)	Determines whether the component appears onscreen.

3.1.37.5.1 TNotebook.ActivePage Property

Determines which page displays in the notebook.

Pascal

```
property ActivePage: string;
```

C++

```
__property UnicodeString ActivePage;
```

Description

ActivePage determines which page displays in the notebook. The value of ActivePage must be one of the strings contained in the Pages (see page 1230) property.

To get or set the active page by index rather than string, use the PageIndex (see page 1229) property instead.

See Also

PageIndex (see page 1229)

Pages (see page 1230)

3.1.37.5.2 TNotebook.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
```

```
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
```

```
  }
  procedure TForm1.FormCreate(Sender: TObject);
  var
    Split: TSplitter;
    Files: TFileListBox;
    Dirs: TDirectoryListBox;
  begin
    { first add a directory list box to the form }
    Dirs := TDirectoryListBox.Create(Form1);
    { line it up on the left of the form }
    Dirs.Parent := Form1;
    Dirs.Align := alLeft;
    Dirs.Width := Form1.ClientWidth div 3;
  { now add the splitter to divide the directory pane from the file pane }
    Split := TSplitter.Create(Form1);
    Split.Parent := Form1;
    { make sure the splitter is to the right of the directory list box! }
    Split.Left := Dirs.Left + Dirs.Width + 1;
    Split.Align := Dirs.Align; { give it the same alignment as the directory }
    { each pane must be at least one quarter of the form's width }
    Split.MinSize := Form1.ClientWidth div 4;
    { Finally, create the last pane - a file list box }
    Files := TFileListBox.Create(Form1);
    Files.Parent := Form1;
    Files.Align := alClient;
    Dirs.FileList := Files; { link the file list box to the directory list box }
  end;
  {
  Dynamically create a TProgressBar control and align it to
  the bottom of the form.
  }

Parent

Anchors

3.1.37.5.3 TNotebook.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

3.1.37.5.4 TNotebook.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor

3.1.37.5.5 TNotebook.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

3.1.37.5.6 TNotebook.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

3.1.37.5.7 TNotebook.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
```

```
  This code requires a list box and three labels, each with a
  different font and color.  The DragMode property for each of
  the labels is dmAutomatic.  The user can select a label and
  drag it to a list box and drop it. When the label is dropped,
  the items in the list box assume the color and font of the
  dropped label.
  }

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    ListBox1.Items.Add('Not');
    ListBox1.Items.Add('In');
    ListBox1.Items.Add('Alphabetical');
    ListBox1.Items.Add('Order');
  end;

  // This OnDragOver event handler permits the list box to
  // accept a dropped label:

  procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TLabel;
  end;

  // This OnDragDrop event handler implements the drop behavior.

  procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
  begin
    if (Sender is TListBox) and (Source is TLabel) then
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

3.1.37.5.8 TNotebook.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

3.1.37.5.9 TNotebook.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

3.1.37.5.10 TNotebook.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
```

```
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;

Arranging the Order of Persistent Columns

3.1.37.5.11 TNotebook.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

3.1.37.5.12 TNotebook.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
```

```
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;

Displaying and Editing Text in a Memo Control

3.1.37.5.13 TNotebook.PageIndex Property

Determines which page displays in the notebook control.

Pascal

```
property PageIndex: Integer;
```

C++

```
__property int PageIndex;
```

Description

The value of PageIndex determines which page displays in the notebook. Changing the PageIndex value changes the page in the control.

Each string in the Pages (see page 1230) property is automatically assigned a PageIndex value when the page is created. The first page receives a value of 0, the second has a value of 1, and so on. If you delete a string from the Pages (see page 1230) property, the PageIndex values are reassigned so that the values always begin with 0 and continue to increase without any gaps between values.

To get or set the current page using its string rather than its index, use the ActivePage (see page 1217) property instead.

See Also

ActivePage (see page 1217)

Pages (see page 1230)

3.1.37.5.14 TNotebook.Pages Property

Contains the strings that identify the individual pages of the notebook control.

Pascal

```
property Pages: TStrings;
```

C++

```
__property TStrings Pages;
```

Description

The Pages property contains the strings that identify the individual pages of the notebook control. Both these controls create a separate page for each string in the Pages property. For example, if Pages contains three strings, First, Second, and Third, the control has three separate pages.

You can access the various pages in a notebook or tabbed notebook control with either the ActivePage (see page 1217) or PageIndex (see page 1229) property.

See Also

ActivePage (see page 1217)

PageIndex (see page 1229)

3.1.37.5.15 TNotebook.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

ParentShowHint

3.1.37.5.16 TNotebook.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

3.1.37.5.17 TNotebook.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

3.1.37.5.18 TNotebook.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

Font

Parent

ParentColor

ParentShowHint

3.1.37.5.19 TNotebook.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

3.1.37.5.20 TNotebook.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
```

```
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
```

```
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
```

```
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
```

```
  "DestroyButton" and add OnClick events to all three buttons.
  Put the TPopupMenu in the PopupMenu property of the form.
  Place the PopupMenuItemsClick procedure in the TForm1 type
  declaration so that it can be used as the method call for
  the menu item OnClick event.
  }

OnContextPopup

3.1.37.5.21 TNotebook.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

3.1.37.5.22 TNotebook.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

FindNextControl

TabStop

3.1.37.5.23 TNotebook.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

TabOrder

3.1.37.5.24 TNotebook.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}

3.1.37.6 TNotebook Events

The events of the TNotebook class are listed here.

Published Events

	Name	Description
	OnClick (see page 1242)	Occurs when the user clicks the control.
	OnContextPopup (see page 1244)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 1244)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 1245)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 1248)	Occurs when the user drags an object over a control.
	OnEndDock (see page 1251)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 1251)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 1252)	Occurs when a control receives the input focus.
	OnExit (see page 1255)	Occurs when the input focus shifts away from one control to another.
	OnMouseActivate (see page 1257)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 1258)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 1261)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 1261)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 1261)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

	OnMouseUp (see page 1263)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnPageChanged (see page 1266)	Occurs when the user selects a new page in the notebook.
	OnStartDock (see page 1266)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 1267)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

3.1.37.6.1 TNotebook.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
```

```
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

3.1.37.6.2 TNotebook.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

3.1.37.6.3 TNotebook.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick

Responding to User Actions at Runtime

3.1.37.6.4 TNotebook.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{

3.1.37.6.5 TNotebook.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

3.1.37.6.7 TNotebook.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
```

```
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then

3.1.37.6.8 TNotebook.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter

event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   (dynamic_cast<TEdit *>(myActiveControl))->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    (dynamic_cast<TRichEdit *>(myActiveControl))->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.

3.1.37.6.9 TNotebook.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
```

```
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

procedure TForm1.MaskEdit2Exit(Sender: TObject);
var
  net1, net2, host1, host2,
  netmask1, netmask2, hostmask1, hostmask2,
  sub_net1, sub_net2, sub_host1, sub_host2: Integer;

  IP, mask: String;

begin
  // extract the net and host address from the IP
  IP := MaskEdit1.Text;
  net1 := StrToInt(TrimRight(Copy(IP, 0, 3)));
  net2 := StrToInt(TrimRight(Copy(IP, 5, 3)));
  host1 := StrToInt(TrimRight(Copy(IP, 9, 3)));
  host2 := StrToInt(TrimRight(Copy(IP, 13, 3)));

  // a range test that you cannot validate through edit masks
  if ((net1 < 0) Or (net1 > 255) Or
      (net2 < 0) Or (net2 > 255) Or
      (host1 < 0) Or (host1 > 255) Or
      (host2 < 0) Or (host2 > 255)) then
    raise EArgumentException.Create('Not a valid IP address.');

  // extract the net and host mask from the subnet mask
```

```
    mask := MaskEdit2.Text;
    netmask1 := StrToInt(TrimRight(Copy(mask, 0, 3)));
    netmask2 := StrToInt(TrimRight(Copy(mask, 5, 3)));
    hostmask1 := StrToInt(TrimRight(Copy(mask, 9, 3)));
    hostmask2 := StrToInt(TrimRight(Copy(mask, 13, 3)));

    // a range test that you cannot validate through edit masks
    if ((netmask1 < 0) Or (netmask1 > 255) Or
        (netmask2 < 0) Or (netmask2 > 255) Or
        (hostmask1 < 0) Or (hostmask1 > 255) Or
        (hostmask2 < 0) Or (hostmask2 > 255)) then
      raise EArgumentException.Create('Not a valid subnet mask.');

    // compute the subnet address using bit-wise AND
    sub_net1 := net1 And netmask1;
    sub_net2 := net2 And netmask2;
    sub_host1 := host1 And hostmask1;
    sub_host2 := host2 And hostmask2;

    // display the subnet address
    MaskEdit3.Text :=
      IntToStr(sub_net1) + '.' + IntToStr(sub_net2) + '.' +
      IntToStr(sub_host1) + '.' + IntToStr(sub_host2);
  end;
  {
  This example uses an edit box and a memo control on a form.
  When either the edit box or the memo is the active control,
  it is colored yellow. When the active control becomes
  inactive, the color of the control returns to the Windows
  system color for a window.  These event handlers could also
  be shared.
  }
  procedure TForm1.Edit1Enter(Sender: TObject);
  begin
    Edit1.Color := clYellow;
  end;

  procedure TForm1.Edit1Exit(Sender: TObject);
  begin
    Edit1.Color := clWindow;
  end;

  procedure TForm1.Memo1Enter(Sender: TObject);
  begin
    Memo1.Color := clYellow;
  end;

  procedure TForm1.Memo1Exit(Sender: TObject);
  begin
    Memo1.Color := clWindow;
  end;

ActiveControl (see page 2145)

3.1.37.6.10 TNotebook.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
  property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

3.1.37.6.11 TNotebook.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
```

```
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

3.1.37.6.12 TNotebook.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

3.1.37.6.13 TNotebook.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

3.1.37.6.14 TNotebook.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

MouseCapture

3.1.37.6.15 TNotebook.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp;
```

C++

```
__property OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
```

```
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer);
begin
  StartX := X;
  StartY := Y;
end;

procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer);
begin
  Form1.Canvas.Rectangle(StartX, StartY, X, Y);
  StatusBar1.Panels[0].Text := '';
  StatusBar1.Panels[1].Text := '';
  StatusBar1.Panels[2].Text := '';
  StatusBar1.Panels[3].Text := '';
end;

procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
begin
  if ssLeft in Shift then { make sure button is down }
  begin
    if Y > StartY then
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
      end
    else
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
      end;
    if X > StartX then
      begin
      StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
      StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
      end
    else
      begin
      StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
      StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
```

```
      end;
  end;
end;
```

3.1.37.6.16 TNotebook.OnPageChanged Event

Occurs when the user selects a new page in the notebook.

Pascal

```
property OnPageChanged: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnPageChanged;
```

Description

Use the OnPageChanged event when you want special processing to occur when the active page changes.

3.1.37.6.17 TNotebook.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDockDrop

3.1.37.6.18 TNotebook.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

3.1.38 TPage Class

Class Hierarchy

Pascal

```
TPage = class(TCustomControl);
```

C++

```
class TPage : public TCustomControl;
```

File

ExtCtrls

Description

This is class ExtCtrls.TPage.

3.1.38.1 TPage Members

The following tables list the members exposed by TPage.

Protected Methods

	Name	Description
	Paint (see page 1269)	Renders the image of a custom control.
	ReadState (see page 1269)	Prepares the control for having its properties assigned values from a stream.

Public Methods

	Name	Description
	Create (see page 1268)	Creates an instance of TCustomControl.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 1278)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 1278)	Occurs when an object with custom alignment is aligned.

Published Properties

	Name	Description
	Caption (see page 1270)	Specifies a text string that identifies the control to the user.
	Height (see page 1273)	Specifies the vertical size of the control in pixels.
	TabOrder (see page 1274)	Indicates the position of the control in its parent's tab order.
	Visible (see page 1274)	Determines whether the component appears onscreen.
	Width (see page 1276)	Specifies the horizontal size of the control or form in pixels.

3.1.38.2 TPage.Create Constructor

Creates an instance of TCustomControl.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TPage(TComponent * AOwner);
```

Description

Calling Create constructs and initializes an instance of TCustomControl. However, you should never attempt to instantiate a TCustomControl. This class is intended solely as a base class from which other control classes descend and you should only call Create to instantiate one of these descendants. Controls placed on forms at design time are created automatically.

After calling the inherited constructor, Create initializes the control, including the following property settings:

Initializes a TCanvas object for its Canvas property.

When overriding Create, always call the inherited Create method first, then proceed with the control's initialization. Remember to specify the override directive when overriding the Create method.

Note: If a component's constructor allocates resources or memory, also override the destructor to free those resources.

Owner

3.1.38.3 TPage Methods

The methods of the TPage class are listed here.

Protected Methods

	Name	Description
	Paint (see page 1269)	Renders the image of a custom control.
	ReadState (see page 1269)	Prepares the control for having its properties assigned values from a stream.

3.1.38.3.1 TPage.Paint Method

Renders the image of a custom control.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

The Paint method for TCustomControl does nothing other than provide the interface for a method that responds to WM_PAINT messages. Paint is called by the PaintWindow method, after that method has supplied the Canvas with the handle to a device context. When creating a custom control, always override Paint to draw the image of the control.

Tip: To determine which portions of the control's canvas need to be repainted when Paint is called, use the ClipRect property of the canvas.

Canvas

PaintWindow

GetDeviceContext

ClipRect (see page 2718)

3.1.38.3.2 TPage.ReadState Method

Prepares the control for having its properties assigned values from a stream.

Pascal

```
procedure ReadState(Reader: TReader); override;
```

C++

```
virtual __fastcall ReadState(TReader Reader);
```

Description

Override ReadState to change the preparations the control makes as it readies itself to have its property values assigned from a stream. For example, a control might destroy temporary internal data structures or objects before new instances are loaded from the stream. Be sure to include a call to the inherited method when overriding ReadState.

As implemented in TWinControl, ReadState disables control alignment until all the child controls have been read from the stream, calls the inherited ReadState method, and re-enables the alignment of all the controls. The method then builds the tab order list of controls and synchronizes its visibility with that of its parent control.

ReadState

3.1.38.4 TPage Properties

The properties of the TPage class are listed here.

Published Properties

	Name	Description
	Caption (see page 1270)	Specifies a text string that identifies the control to the user.
	Height (see page 1273)	Specifies the vertical size of the control in pixels.
	TabOrder (see page 1274)	Indicates the position of the control in its parent's tab order.
	Visible (see page 1274)	Determines whether the component appears onscreen.
	Width (see page 1276)	Specifies the horizontal size of the control or form in pixels.

3.1.38.4.1 TPage.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
```

```
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>
#include <memory>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);  // The owner (toolBar) will clean this up.
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this); // The owner (this) will clean this up.
  myToolBar->Parent = this;
//  TStringList *captions = new TStringList();
  std::auto_ptr<TStringList> captions(new TStringList());

  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions.get());
//  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}
```

Delphi Examples:

```
{
```

```
  The following code keeps the size of the label control
  constant, even though the length of the label's caption
  changes. As a result, the caption of the label is probably
  too long to display in the label when the user clicks the
  button:
  }
  procedure TForm1.Button1Click(Sender: TObject);
  begin
    Label1.AutoSize := False;
    Label1.Caption :=
      'This string is too long to be the caption of this label';
  end;
  {
  This example requires a TPageControl populated by several
  TabSheets, a TEdit and a TButton. When the button is
  clicked, the caption of the active tab changes to that of
  the TEdit.  These lines of code could also be written:
  PageControl1.ActivePage.Caption := Edit1.Text;
  This would obviate the need for a TTabSheet variable since
  PageControl1.->ActivePage is already of type TTabSheet.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    sheet: TTabSheet;
  begin
    sheet := PageControl1.ActivePage;
    sheet.Caption := Edit1.Text;
  end;
  {
  This example creates a ToolBar and adds ToolButtons to it.
  Include ComCtlrs in the uses clause.
  }
  procedure AddButtons(ToolBar: TToolBar;
    Const ButtonCaptions: array of String);
  var
    I: Integer;
  begin
    for I := 0 to High(ButtonCaptions) do
      begin
        with TToolButton.Create(ToolBar) do
        begin
          Parent := ToolBar;
          Caption := ButtonCaptions[I];
          if (ButtonCaptions[I] = '|') then
            Style := tbsSeparator
          else
            Style := tbsButton;
        end;
      end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    ToolBar1 := TToolBar.Create(Self);
    ToolBar1.Parent := Self;
    AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
    ToolBar1.ShowCaptions := True;
    ToolBar1.Height := 40;
  end;

  procedure TForm1.FormDestroy(Sender: TObject);
  var
    I: Integer;
  begin
    for I := ToolBar1.ButtonCount - 1 downto 0 do
      ToolBar1.Buttons[I].Free;
```

```
  ToolBar1.Free;
end;
```

3.1.38.4.2 TPage.Height Property

Specifies the vertical size of the control in pixels.

Pascal

```
property Height;
```

C++

```
__property Height;
```

Description

Use the Height property to read or change the height of the control.

C++ Examples:

```
/*
This example needs only a blank form.  Three Rich Edit
controls are placed vertically on the form, each contain a
line of text, and the second form has HideSelection set to
false.  Try tabbing between the three Rich Edit controls and
observe the effect on the selected text.
*/
#include <ComCtrls.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int I = 0; I <= 2; I++)
  {
    TRichEdit *pRich = new TRichEdit(this);
    pRich->Parent = this;
    pRich->Top = pRich->Height * I;
    pRich->Text = "This text will take the focus.";
    pRich->SelStart = 0;
    pRich->SelLength = pRich->Text.Length();
    if (I == 1)
      pRich->HideSelection = false;
  }
}
```

Delphi Examples:

```
{
This example needs only a blank form. Three Rich Edit
controls are placed vertically on the form, each contain a
line of text, and the second form has HideSelection set to
false.  Try tabbing between the three Rich Edit controls and
observe the effect on the selected text.
}
uses ComCtrls;

procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  for I := 0 to 2 do
    with TRichEdit.Create(Self) do
    begin
      Parent := Self;
      Top := Height * I;
      Text := 'This text will take the focus.';
      SelStart := 0;
      SelLength := Length(Text);
```

```
      if (I = 1) then
        HideSelection := False;
    end;
end;
```

ClientHeight

Width

Using TDBListBox and TDBComboBox

3.1.38.4.3 TPage.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

FindNextControl

TabStop

3.1.38.4.4 TPage.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
```

```
      begin
        PageControl := PageControl1;
        Caption := 'TabSheet' + IntToStr(i);
        with TEdit.Create(Self) do
        begin
          Parent := PageControl1.Pages[i];
          Left := Random(PageControl1.ActivePage.ClientWidth - Width);
          Top := Random(PageControl1.ActivePage.ClientHeight - Height);
        end;
      end;
      PageControl1Change(Sender);
  end;
```

3.1.38.4.5 TPage.Width Property

Specifies the horizontal size of the control or form in pixels.

Pascal

```
property Width;
```

C++

```
__property Width;
```

Description

Use the Width property to read or change the width of the control.

Note: For tab sheet controls, changing this property at runtime has no effect.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
```

```
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane – a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;

3.1.38.5 TPage Events

The events of the TPage class are listed here.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 1278)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 1278)	Occurs when an object with custom alignment is aligned.

3.1.38.5.1 TPage.OnAlignInsertBefore Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignInsertBefore;
```

C++

```
__property OnAlignInsertBefore;
```

Description

OnAlignInsertBefore occurs for each pair of child controls with an Align property of **alCustom**.

It can determine the order in which custom-aligned child controls are placed. OnAlignInsertBefore returns true if **C2** should be presented before **C1**, and false otherwise. It holds a TAlignInsertBeforeEvent type.

CustomAlignInsertBefore triggers the OnAlignInsertBefore event. If this event is defined, CustomAlignInsertBefore returns the value returned by OnAlignInsertBefore. Defining this event allows users to define the order of control alignment without overriding CustomAlignInsertBefore.

See Also

CustomAlignInsertBefore

Align

TAlignInsertBeforeEvent

3.1.38.5.2 TPage.OnAlignPosition Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignPosition;
```

C++

```
__property OnAlignPosition;
```

Description

OnAlignPosition occurs when child controls with an Align property of **alCustom** are aligned.

CustomAlignPosition triggers the OnAlignPosition event. If this event is defined, CustomAlignPosition uses the alignment parameters it obtains from OnAlignPosition. Defining this event allows users to set the alignment parameters without overriding CustomAlignPosition. It holds a TAlignPositionEvent type.

These are the parameters:

Parameter	Meaning
NewLeft | NewTop | NewWidth | NewHeight	Location and size of child control, as determined by container's size and the Anchors TControl_Anchors constraints for the control. OnAlignPosition can modify these values to reposition the control.
AlignRect	The client area in which the control is aligned. OnAlignPosition can modify this value.
AlignInfo	Alignment information in a TAlignInfo.
As implemented in TWinControl, OnAlignPosition does nothing.

3.1.39 TPaintBox Class

TPaintBox provides a canvas that applications can use for rendering an image.

Class Hierarchy

Pascal

```
TPaintBox = class(TGraphicControl);
```

C++

```
class TPaintBox : public TGraphicControl;
```

File

ExtCtrls

Description

Use TPaintBox to add custom images to a form. Unlike TImage (see page 1048), which displays an image that is stored in a bitmap, icon, or metafile, TPaintBox requires an application to draw the image directly on a canvas. Use the OnPaint (see page 1322) event handler to draw on the paint box's Canvas (see page 1286), the drawing surface of the paint box.

See Also

TCanvas (see page 2673)

TImage (see page 1048)

Graphic Controls

Paint Boxes

3.1.39.1 TPaintBox Members

The following tables list the members exposed by TPaintBox.

Protected Methods

	Name	Description
	Paint (see page 1281)	Generates an OnPaint (see page 1322) event.

Public Methods

	Name	Description
	Create (see page 1281)	Creates an instance of TPaintBox (see page 1279).

Public Properties

	Name	Description
	Canvas (see page 1286)	Provides the drawing surface used by the graphic control.

Published Events

	Name	Description
	OnClick (see page 1304)	Occurs when the user clicks the control.
	OnContextPopup (see page 1305)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 1306)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 1306)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 1309)	Occurs when the user drags an object over a control.
	OnEndDock (see page 1313)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 1313)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnMouseActivate (see page 1314)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 1315)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 1317)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 1318)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 1318)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 1320)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnPaint (see page 1322)	OnPaint occurs when the paintbox receives a Windows paint message.
	OnStartDock (see page 1324)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 1325)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 1282)	Determines how the control aligns within its container (parent control).
	Anchors (see page 1286)	Specifies how the control is anchored to its parent.
	Color (see page 1288)	Specifies the background color of the control.
	Constraints (see page 1289)	Specifies the size constraints for the control.
	DragCursor (see page 1290)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 1290)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 1290)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 1292)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 1292)	Controls the attributes of text written on or in the control.

	ParentColor (see page 1293)	Determines where a control looks for its color information.
	ParentFont (see page 1294)	Determines where a control looks for its font information.
	ParentShowHint (see page 1294)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 1295)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 1300)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Visible (see page 1301)	Determines whether the component appears onscreen.

3.1.39.2 TPaintBox.Create Constructor

Creates an instance of TPaintBox (see page 1279).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TPaintBox(TComponent * AOwner);
```

Description

Call Create to instantiate a TPaintBox (see page 1279) object at runtime. TPaintBox (see page 1279) objects added to forms at design time are created automatically.

Call Create to instantiate a TImage (see page 1048) object at runtime. Images placed on forms at design time are created automatically.

AOwner is the component that is responsible for freeing the paintbox instance. It becomes the value of the Owner property.

Owner

3.1.39.3 TPaintBox Methods

The methods of the TPaintBox class are listed here.

Protected Methods

	Name	Description
	Paint (see page 1281)	Generates an OnPaint (see page 1322) event.

3.1.39.3.1 TPaintBox.Paint Method

Generates an OnPaint (see page 1322) event.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

Paint responds to WM_PAINT (see page 5198) messages from Windows by initializing the canvas and calling the OnPaint (see page 1322) event handler if it is assigned.

See Also

OnPaint (see page 1322)

3.1.39.4 TPaintBox Properties

The properties of the TPaintBox class are listed here.

Public Properties

	Name	Description
	Canvas (see page 1286)	Provides the drawing surface used by the graphic control.

Published Properties

	Name	Description
	Align (see page 1282)	Determines how the control aligns within its container (parent control).
	Anchors (see page 1286)	Specifies how the control is anchored to its parent.
	Color (see page 1288)	Specifies the background color of the control.
	Constraints (see page 1289)	Specifies the size constraints for the control.
	DragCursor (see page 1290)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 1290)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 1290)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 1292)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 1292)	Controls the attributes of text written on or in the control.
	ParentColor (see page 1293)	Determines where a control looks for its color information.
	ParentFont (see page 1294)	Determines where a control looks for its font information.
	ParentShowHint (see page 1294)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 1295)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 1300)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Visible (see page 1301)	Determines whether the component appears onscreen.

3.1.39.4.1 TPaintBox.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
```

```
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>

Parent

Anchors

3.1.39.4.2 TPaintBox.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Align

3.1.39.4.3 TPaintBox.Canvas Property

Provides the drawing surface used by the graphic control.

Pascal

```
property Canvas;
```

C++

```
__property Canvas;
```

Description

Use the properties of the TCanvas object to draw or paint on the surface of the control.

Since a TGraphicControl instance does not have its own Windows screen object, it obtains its device context from its parent control.

C++ Examples:

```
/*
When you do custom drawing, such as shown in the code for
the Button's OnClick event handler below, this drawing will
not be persistent and will be "erased" the first time the
PaintBox component needs to repaint.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
   PaintBox1->Canvas->Brush->Color = clRed;
   PaintBox1->Canvas->FillRect(PaintBox1->Canvas->ClipRect);
```

```
   PaintBox1->Canvas->Ellipse(0,0,100,100);
}

/*
In order for the drawing to be persistent, you need to also
include an OnPaint event handler that tells the PaintBox how
to redraw itself when it needs to. In the code below, an
ellipse will be drawn everytime the PaintBox renders itself,
but the PaintBox will only paint the client area of the
control red after the Button is clicked. This client area
will only stay red until it is invalidated, but the ellipse
will persist. This behavior is different from the TImage
component, because the TImage component maintains an
internal bitmap that stores this drawing information for
you.
*/
void __fastcall TForm1::PaintBox1Paint(TObject *Sender)
{
   PaintBox1->Canvas->Brush->Color = clBlue;
   PaintBox1->Canvas->Ellipse(0,0,100,100);
}
/*
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
*/
{
  TPoint APoint = Point(X, Y);
  int Index = ListBox1->ItemAtPos(APoint, True);
  TLabel *myLabel;
  TClass ClassRef = ListBox1->Items->Objects[Index]->ClassType();
  if (String(ClassRef->ClassName()) == "TLabel")
  {
    myLabel = dynamic_cast<TLabel *>(ListBox1->Items->Objects[Index]);
    // make sure we are using the TControls canvas and not the from's!
    myLabel->Canvas->MoveTo(myLabel->ClientRect.Left, myLabel->ClientRect.Top);
    myLabel->Canvas->LineTo(myLabel->ClientRect.Right, myLabel->ClientRect.Bottom);
    myLabel = NULL;
  }
}
/*
The following code draws the graphic in Picture1 in the
top-left corner PaintBox1.  Place a TPaintBox in the form
and a TImage in the form that contains a picture.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  PaintBox1->Canvas->Draw(0,0, Image1->Picture->Graphic);
}
```

Delphi Examples:

```
{
When you do custom drawing, such as shown in the code for
the Button's OnClick event handler below, this drawing will
not be persistent and will be "erased" the first time the
PaintBox component needs to repaint.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   PaintBox1.Canvas.Brush.Color := clRed;
   PaintBox1.Canvas.FillRect(PaintBox1.Canvas.ClipRect);
   PaintBox1.Canvas.Brush.Color := clBlue;
   PaintBox1.Canvas.Ellipse(0,0,100,50);
end;
```

```
{
In order for the drawing to be persistent, you need to also
include an OnPaint event handler that tells the PaintBox how
to redraw itself when it needs to. In the code below, an
ellipse will be drawn everytime the PaintBox renders itself,
but the PaintBox will only paint the client area of the
control red after the Button is clicked. This client area
will only stay red until it is invalidated, but the ellipse
will persist. This behavior is different from the TImage
component, because the TImage component maintains an
internal bitmap that stores this drawing information for
you.
}
procedure TForm1.PaintBox1Paint(Sender: TObject);
begin
   PaintBox1.Canvas.Brush.Color := clBlue;
   PaintBox1.Canvas.Ellipse(0,0,100,50);
end;
{
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
}
  if (ListBox1.Items.Objects[Index] is TLabel) then
  begin
    myLabel:= (ListBox1.Items.Objects[Index] as TLabel);
    with myLabel.ClientRect do
    begin // make sure we are using the TControl's canvas and not the form's!
      myLabel.Canvas.MoveTo(Left, Top);
      myLabel.Canvas.LineTo(Right, Bottom);
    end;
  myLabel:= nil;
  end;
{
The following code draws the graphic in Picture1 in the
top-left corner PaintBox1.  Place a TPaintBox in the form
and a TImage in the form that contains a picture.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  PaintBox1.Canvas.Draw(0,0, Image1.Picture.Graphic);
end;
```

3.1.39.4.4 TPaintBox.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

3.1.39.4.5 TPaintBox.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

3.1.39.4.6 TPaintBox.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

3.1.39.4.7 TPaintBox.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

3.1.39.4.8 TPaintBox.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
```

```
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;

Arranging the Order of Persistent Columns

3.1.39.4.9 TPaintBox.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

3.1.39.4.10 TPaintBox.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

Displaying and Editing Text in a Memo Control

3.1.39.4.11 TPaintBox.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

3.1.39.4.12 TPaintBox.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

ParentColor

ParentShowHint

3.1.39.4.13 TPaintBox.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

3.1.39.4.14 TPaintBox.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
```

```
  "Paste1".  Then double click on the OnClick events and they will
  be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
  Note: only the selected portion of the string in the edit box will
  be copied, cut or replaced.
  */
  void __fastcall TForm1::Copy1Click(TObject *Sender)
  {
    TComponent *pComponent = PopupMenu1->PopupComponent;
    if (pComponent)
    {
      if (pComponent->ClassNameIs("TEdit"))
        (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
      else
        MessageBeep(0);
    }
    else
      MessageBeep(0);
  }

OnContextPopup

3.1.39.4.15 TPaintBox.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
```

```
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

3.1.39.4.16 TPaintBox.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;
```

```
procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin

3.1.39.5 TPaintBox Events

The events of the TPaintBox class are listed here.

Published Events

	Name	Description
	OnClick (see page 1304)	Occurs when the user clicks the control.
	OnContextPopup (see page 1305)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 1306)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 1306)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 1309)	Occurs when the user drags an object over a control.
	OnEndDock (see page 1313)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 1313)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnMouseActivate (see page 1314)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 1315)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 1317)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 1318)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 1318)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 1320)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnPaint (see page 1322)	OnPaint occurs when the paintbox receives a Windows paint message.
	OnStartDock (see page 1324)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 1325)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

3.1.39.5.1 TPaintBox.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
```

```
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;

3.1.39.5.2 TPaintBox.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

3.1.39.5.3 TPaintBox.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick

Responding to User Actions at Runtime

3.1.39.5.4 TPaintBox.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*

TDragObject

3.1.39.5.5 TPaintBox.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*

3.1.39.5.7 TPaintBox.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
```

```
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;

3.1.39.5.8 TPaintBox.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level

form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

OnMouseMove

OnMouseUp

MouseCapture

3.1.39.5.9 TPaintBox.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
```

```
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer);
begin
  StartX := X;
  StartY := Y;
end;
```

```
procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer);
begin
  Form1.Canvas.Rectangle(StartX, StartY, X, Y);
  StatusBar1.Panels[0].Text := '';
  StatusBar1.Panels[1].Text := '';
  StatusBar1.Panels[2].Text := '';
  StatusBar1.Panels[3].Text := '';
end;

procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
begin
  if ssLeft in Shift then { make sure button is down }
  begin
    if Y > StartY then
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
      end
    else
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
      end;
    if X > StartX then
      begin
      StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
      StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
      end
    else
      begin
      StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
      StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
      end;
  end;
end;

3.1.39.5.10 TPaintBox.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

3.1.39.5.11 TPaintBox.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

3.1.39.5.12 TPaintBox.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

MouseCapture

3.1.39.5.13 TPaintBox.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp;
```

C++

```
__property OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150

Responding to a Mouse-up Action

3.1.39.5.14 TPaintBox.OnPaint Event

OnPaint occurs when the paintbox receives a Windows paint message.

Pascal

```
property OnPaint: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnPaint;
```

Description

Write an OnPaint event handler to draw the image of the paint box. The OnPaint event fires when the system repaints the TPaintBox (see page 1279) control. If there is a handler for this event, its code is executed when the OnPaint event fires.

Use properties and methods of the canvas (such as LineTo, Draw, and TextOut) to programmatically construct the image that the paintbox presents on a form. This can consist of a number of operations including drawing lines, images, and shapes. A TPaintBox (see page 1279) itself has no visible manifestation, so if an OnPaint event handler is not provided or no drawing is done in the event handler, the paintbox can not be seen on the form at runtime.

C++ Examples:

```
/*
When you do custom drawing, such as shown in the code for
the Button's OnClick event handler below, this drawing will
not be persistent and will be "erased" the first time the
PaintBox component needs to repaint.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
   PaintBox1->Canvas->Brush->Color = clRed;
   PaintBox1->Canvas->FillRect(PaintBox1->Canvas->ClipRect);
   PaintBox1->Canvas->Ellipse(0,0,100,100);
}

/*
In order for the drawing to be persistent, you need to also
include an OnPaint event handler that tells the PaintBox how
to redraw itself when it needs to. In the code below, an
ellipse will be drawn everytime the PaintBox renders itself,
but the PaintBox will only paint the client area of the
control red after the Button is clicked. This client area
will only stay red until it is invalidated, but the ellipse
will persist. This behavior is different from the TImage
component, because the TImage component maintains an
internal bitmap that stores this drawing information for
you.
*/
void __fastcall TForm1::PaintBox1Paint(TObject *Sender)
{
   PaintBox1->Canvas->Brush->Color = clBlue;
   PaintBox1->Canvas->Ellipse(0,0,100,100);
}
/*
This example paints a white five-pointed star in a paintbox
control:
*/
void __fastcall TForm1::PaintBox1Paint(TObject *Sender)
{
  TPaintBox *pPB = dynamic_cast<TPaintBox *>(Sender);
  TPoint points[6];
  pPB->Canvas->Pen->Color = clWhite;
  points[0].x = 40;
  points[0].y = 10;
  points[1].x = 20;
  points[1].y = 60;
  points[2].x = 70;
  points[2].y = 30;
  points[3].x = 10;
  points[3].y = 30;
  points[4].x = 60;
  points[4].y = 60;
  points[5].x = 40;
  points[5].y = 10;
  pPB->Canvas->Polyline(points,5);
}
```

Delphi Examples:

```
{
When you do custom drawing, such as shown in the code for
```

```
  the Button's OnClick event handler below, this drawing will
  not be persistent and will be "erased" the first time the
  PaintBox component needs to repaint.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  begin
     PaintBox1.Canvas.Brush.Color := clRed;
     PaintBox1.Canvas.FillRect(PaintBox1.Canvas.ClipRect);
     PaintBox1.Canvas.Brush.Color := clBlue;
     PaintBox1.Canvas.Ellipse(0,0,100,50);
  end;
  {
  In order for the drawing to be persistent, you need to also
  include an OnPaint event handler that tells the PaintBox how
  to redraw itself when it needs to. In the code below, an
  ellipse will be drawn everytime the PaintBox renders itself,
  but the PaintBox will only paint the client area of the
  control red after the Button is clicked. This client area
  will only stay red until it is invalidated, but the ellipse
  will persist. This behavior is different from the TImage
  component, because the TImage component maintains an
  internal bitmap that stores this drawing information for
  you.
  }
  procedure TForm1.PaintBox1Paint(Sender: TObject);
  begin
     PaintBox1.Canvas.Brush.Color := clBlue;
     PaintBox1.Canvas.Ellipse(0,0,100,50);

Canvas

TCanvas (see page 2673)

3.1.39.5.15 TPaintBox.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the

appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDragOver

OnDockDrop

3.1.39.5.16 TPaintBox.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

3.1.40 TPanel Class

TPanel implements a generic panel control.

Class Hierarchy

Pascal

```
TPanel = class(TCustomPanel);
```

C++

```
class TPanel : public TCustomPanel;
```

File

ExtCtrls

Description

Use TPanel to put an empty panel on a form. Panels have properties for providing a beveled border around the control, as well as methods to help manage the placement of child controls embedded in the panel.

You can also use panels to group controls together, similar to the way you can use a group box, but with a beveled border (or no border) rather than the group box outline. Panels are typically used for groups of controls within a single form. If you intend to use the same grouping in other forms, you may want to use a frame instead.

Panels with no borders are useful as docking sites when writing applications that use drag-and-dock.

Although you can use a panel to implement a status bar or tool bar, it is recommended that you use the TToolBar and TStatusBar classes instead.

3.1.40.1 TPanel Members

The following tables list the members exposed by TPanel.

Protected Methods

	Name	Description
	AdjustClientRect (see page 804)	Adjusts the ClientRect property for the idiosyncrasies of the window.
	CanAutoSize (see page 804)	Adjusts the way the panel responds to resize attempts.
	CreateParams (see page 805)	Initializes a window-creation parameter record passed in the Params parameter.
	Paint (see page 806)	Renders the image of the panel.
	SetParentBackground (see page 806)	This is SetParentBackground, a member of class TCustomPanel.

Public Methods

	Name	Description
	Create (see page 803)	Creates and initializes an instance of TCustomPanel (see page 802).
	GetControlsAlignment (see page 805)	Returns the alignment of text in the panel.

Public Properties

	Name	Description
	DockManager (see page 1345)	Specifies the control's docking manager interface.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 1368)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 1369)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 1370)	Occurs when an attempt is made to resize the control.
	OnClick (see page 1370)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 1372)	Adjust resize constraints.
	OnContextPopup (see page 1372)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 1373)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 1373)	Occurs when another control is docked to the control.
	OnDockOver (see page 1375)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 1378)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 1381)	Occurs when the user drags an object over a control.
	OnEndDock (see page 1384)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 1384)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

	OnEnter (see page 1385)	Occurs when a control receives the input focus.
	OnExit (see page 1388)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 1390)	Returns the control's docking information.
	OnMouseActivate (see page 1393)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 1394)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 1396)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 1396)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 1396)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 1399)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnResize (see page 1401)	Occurs immediately after the control is resized.
	OnStartDock (see page 1402)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 1402)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 1403)	Occurs when the application tries to undock a control that is docked to the windowed control.

Published Properties

	Name	Description
	Align (see page 1330)	Determines how the control aligns within its container (parent control).
	Alignment (see page 1333)	Determines how the caption is aligned within the panel.
	Anchors (see page 1334)	Specifies how the control is anchored to its parent.
	AutoSize (see page 1334)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 1335)	Specifies which edges of the control are beveled.
	BevelInner (see page 1335)	Determines the style of the inner bevel of a panel.
	BevelKind (see page 1336)	Specifies the control's bevel style.
	BevelOuter (see page 1336)	Determines the style of the outer bevel of a panel.
	BevelWidth (see page 1337)	Determines the width, in pixels, of both the inner and outer bevels of a panel.
	BiDiMode (see page 1339)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 1339)	Determines the style of the line drawn around the perimeter of the panel control.
	BorderWidth (see page 1339)	Specifies the distance, in pixels, between the outer and inner bevels.
	Caption (see page 1341)	Specifies a text string that identifies the control to the user.
	Color (see page 1343)	Specifies the background color of the control.
	Constraints (see page 1344)	Specifies the size constraints for the control.
	Ctl3D (see page 1345)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DockSite (see page 1347)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 1348)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 1350)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 1350)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 1351)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 1352)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 1353)	Controls the attributes of text written on or in the control.
	FullRepaint (see page 1354)	Determines how the panel repaints itself when it is resized.
	Locked (see page 1354)	Determines whether a panel that is used as a toolbar is replaced by a toolbar supplied by an OLE server.
	Padding (see page 1354)	Specifies the padding of a control.
	ParentBackground (see page 1355)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 1355)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 1355)	Determines where a control looks for its color information.
	ParentCtl3D (see page 1356)	Determines where a component looks to determine if it should appear three dimensional.

	ParentDoubleBuffered (see page 1356)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 1356)	Determines where a control looks for its font information.
	ParentShowHint (see page 1357)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 1358)	Identifies the pop-up menu associated with the control.
	ShowCaption (see page 1363)	This is ShowCaption, a member of class TPanel.
	ShowHint (see page 1363)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 1364)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 1365)	Determines if the user can tab to a control.
	UseDockManager (see page 1365)	Specifies whether the docking manager is used in drag-and-dock operations.
	VerticalAlignment (see page 1366)	Sets the vertical position of the caption.
	Visible (see page 1366)	Determines whether the component appears onscreen.

3.1.40.2 TPanel Properties

The properties of the TPanel class are listed here.

Public Properties

	Name	Description
	DockManager (see page 1345)	Specifies the control's docking manager interface.

Published Properties

	Name	Description
	Align (see page 1330)	Determines how the control aligns within its container (parent control).
	Alignment (see page 1333)	Determines how the caption is aligned within the panel.
	Anchors (see page 1334)	Specifies how the control is anchored to its parent.
	AutoSize (see page 1334)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 1335)	Specifies which edges of the control are beveled.
	BevelInner (see page 1335)	Determines the style of the inner bevel of a panel.
	BevelKind (see page 1336)	Specifies the control's bevel style.
	BevelOuter (see page 1336)	Determines the style of the outer bevel of a panel.
	BevelWidth (see page 1337)	Determines the width, in pixels, of both the inner and outer bevels of a panel.
	BiDiMode (see page 1339)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 1339)	Determines the style of the line drawn around the perimeter of the panel control.
	BorderWidth (see page 1339)	Specifies the distance, in pixels, between the outer and inner bevels.
	Caption (see page 1341)	Specifies a text string that identifies the control to the user.
	Color (see page 1343)	Specifies the background color of the control.
	Constraints (see page 1344)	Specifies the size constraints for the control.
	Ctl3D (see page 1345)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DockSite (see page 1347)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 1348)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 1350)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 1350)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 1351)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 1352)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 1353)	Controls the attributes of text written on or in the control.
	FullRepaint (see page 1354)	Determines how the panel repaints itself when it is resized.
	Locked (see page 1354)	Determines whether a panel that is used as a toolbar is replaced by a toolbar supplied by an OLE server.
	Padding (see page 1354)	Specifies the padding of a control.

	ParentBackground (see page 1355)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 1355)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 1355)	Determines where a control looks for its color information.
	ParentCtl3D (see page 1356)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 1356)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 1356)	Determines where a control looks for its font information.
	ParentShowHint (see page 1357)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 1358)	Identifies the pop-up menu associated with the control.
	ShowCaption (see page 1363)	This is ShowCaption, a member of class TPanel.
	ShowHint (see page 1363)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 1364)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 1365)	Determines if the user can tab to a control.
	UseDockManager (see page 1365)	Specifies whether the docking manager is used in drag-and-dock operations.
	VerticalAlignment (see page 1366)	Sets the vertical position of the caption.
	Visible (see page 1366)	Determines whether the component appears onscreen.

3.1.40.2.1 TPanel.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
```

```
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
```

```
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{

Anchors

3.1.40.2.2 TPanel.Alignment Property

Determines how the caption is aligned within the panel.

Pascal

```
property Alignment: TAlignment;
```

C++

```
__property TAlignment Alignment;
```

Description

Use the Alignment property to specify if the caption of a panel appears on the left, right, or center of the panel. For example, to

use a panel as a status bar that displays the TApplication. ::Hint property as the panel's Caption property, set Alignment to taLeftJustify to place the hint text on the left side of the panel.

Note: Use the VerticalAlignment property to control the vertical position of the caption.

See Also

Hint (see page 1976)

Caption

3.1.40.2.3 TPanel.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent

Align

3.1.40.2.4 TPanel.AutoSize Property

Specifies whether the control sizes itself automatically to accommodate its contents.

Pascal

```
property AutoSize;
```

C++

```
__property AutoSize;
```

Description

Use AutoSize to specify whether the control sizes itself automatically. When AutoSize is true, the control resizes automatically when its contents change.

By default, AutoSize is false.

Constraints

CanAutoSize

3.1.40.2.5 TPanel.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges;
```

C++

```
__property BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner

BevelOuter

BevelKind

3.1.40.2.6 TPanel.BevelInner Property

Determines the style of the inner bevel of a panel.

Pascal

```
property BevelInner: TPanelBevel;
```

C++

```
__property TPanelBevel BevelInner;
```

Description

Use BevelInner to provide the panel with a three-dimensional beveled look. A panel component has two bevels, an outer bevel drawn next to the border of the control, and an inner bevel drawn inside the outer bevel, separated by the number of pixels specified in the BorderWidth property. The width of the bevels, if they are drawn, is the BevelWidth property.

C++ Examples:

```
/*
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
*/
void __fastcall TForm1::CreateStatusLineClick(TObject *Sender)
{
  Panel1->Align = alBottom;
  Panel1->BevelInner = bvLowered;
  Panel1->BevelOuter = bvRaised;
  Panel1->BorderWidth = 1;
  Panel1->BevelWidth = 1;
```

```
}
```

Delphi Examples:

```
{
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
}
procedure TForm1.CreateStatusLineClick(Sender: TObject);
begin
  with Panel1 do
  begin
    Align := alBottom;
    BevelInner := bvLowered;
    BevelOuter := bvRaised;
    BorderWidth := 1;
    BevelWidth := 1;
  end;
end;
```

See Also

BevelOuter (see page 808)

BevelWidth (see page 809)

BorderWidth (see page 811)

3.1.40.2.7 TPanel.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind;
```

C++

```
__property BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

BevelEdges

BevelOuter

BevelInner

BevelWidth

3.1.40.2.8 TPanel.BevelOuter Property

Determines the style of the outer bevel of a panel.

Pascal

```
property BevelOuter: TPanelBevel;
```

C++

```
__property TPanelBevel BevelOuter;
```

Description

Use BevelOuter to provide the panel with a three-dimensional beveled look. A panel component has two bevels, an outer bevel drawn next to the border of the control, and an inner bevel drawn inside the outer bevel, separated by the number of pixels specified in the BorderWidth property. The width of the outer bevel is specified in the BevelWidth property in pixels.

C++ Examples:

```
/*
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
*/
void __fastcall TForm1::CreateStatusLineClick(TObject *Sender)
{
  Panel1->Align = alBottom;
  Panel1->BevelInner = bvLowered;
  Panel1->BevelOuter = bvRaised;
  Panel1->BorderWidth = 1;
  Panel1->BevelWidth = 1;
}
```

Delphi Examples:

```
{
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
}
procedure TForm1.CreateStatusLineClick(Sender: TObject);
begin
  with Panel1 do
  begin
    Align := alBottom;
    BevelInner := bvLowered;
    BevelOuter := bvRaised;
    BorderWidth := 1;
    BevelWidth := 1;
  end;
end;
```

See Also

BevelInner (see page 807)

BevelWidth (see page 809)

BorderWidth (see page 811)

3.1.40.2.9 TPanel.BevelWidth Property

Determines the width, in pixels, of both the inner and outer bevels of a panel.

Pascal

```
property BevelWidth: TBevelWidth;
```

C++

```
__property TBevelWidth BevelWidth;
```

Description

Use BevelWidth to specify how wide the inner or outer bevel should be. Do not confuse BevelWidth, which is the width of the bevels, with BorderWidth, which is the space between the bevels.

If both the BevelInner and BevelOuter properties are bvNone, BevelWidth has no effect. To remove both bevels, set the BevelInner and BevelOuter properties to bvNone, rather than setting the BevelWidth to 0, as this involves less overhead when painting.

C++ Examples:

```
/*
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
*/
void __fastcall TForm1::CreateStatusLineClick(TObject *Sender)
{
  Panel1->Align = alBottom;
  Panel1->BevelInner = bvLowered;
  Panel1->BevelOuter = bvRaised;
  Panel1->BorderWidth = 1;
  Panel1->BevelWidth = 1;
}
```

Delphi Examples:

```
{
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
}
procedure TForm1.CreateStatusLineClick(Sender: TObject);
begin
  with Panel1 do
  begin
    Align := alBottom;
    BevelInner := bvLowered;
    BevelOuter := bvRaised;
    BorderWidth := 1;
    BevelWidth := 1;
  end;
end;
```

See Also

BevelInner (see page 807)

BevelOuter (see page 808)

BorderWidth (see page 811)

3.1.40.2.10 TPanel.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

3.1.40.2.11 TPanel.BorderStyle Property

Determines the style of the line drawn around the perimeter of the panel control.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Use BorderStyle to specify whether the panel has a single line drawn around it. These are the possible values:

Value	Meaning
bsNone	No visible border
bsSingle	Single-line border

Do not confuse the line drawn around the panel with the BorderWidth of the panel. The BorderWidth of the panel is the distance between the outer and inner bevels.

See Also

BorderWidth (see page 811)

3.1.40.2.12 TPanel.BorderWidth Property

Specifies the distance, in pixels, between the outer and inner bevels.

Pascal

```
property BorderWidth: TBorderWidth;
```

C++

```
__property TBorderWidth BorderWidth;
```

Description

Use BorderWidth to specify how wide the border around the panel should be. A value of 0 (zero) means no border should appear.

The border of a panel is the area between the outer and inner bevels. It is visible only if the inner bevel is raised or lowered, but affects the inset of the caption within the panel even if BevelInner is bvNone. If the Alignment property is not taCenter, the Caption will be aligned to the inner edge of the border. This edge is BorderWidth pixels in from the outer bevel if BevelInner is bvNone. It is the inner edge of the inner bevel otherwise.

Do not confuse the border of the panel with line drawn around the panel itself. The line around the panel is specified by the BorderStyle property.

C++ Examples:

```
/*
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
*/
void __fastcall TForm1::CreateStatusLineClick(TObject *Sender)
{
  Panel1->Align = alBottom;
  Panel1->BevelInner = bvLowered;
  Panel1->BevelOuter = bvRaised;
  Panel1->BorderWidth = 1;
  Panel1->BevelWidth = 1;
}
```

Delphi Examples:

```
{
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
}
procedure TForm1.CreateStatusLineClick(Sender: TObject);
begin
  with Panel1 do
  begin
    Align := alBottom;
    BevelInner := bvLowered;
    BevelOuter := bvRaised;
    BorderWidth := 1;
    BevelWidth := 1;
  end;
end;
```

See Also

Alignment (see page 807)

BevelInner (see page 807)

BevelOuter (see page 808)

BorderStyle (see page 810)

Caption

3.1.40.2.13 TPanel.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>
#include <memory>
```

```
void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);  // The owner (toolBar) will clean this up.
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this); // The owner (this) will clean this up.
  myToolBar->Parent = this;
//  TStringList *captions = new TStringList();
  std::auto_ptr<TStringList> captions(new TStringList());

  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions.get());
//  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long to be the caption of this label';
end;
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
```

```
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
        Caption := ButtonCaptions[I];
        if (ButtonCaptions[I] = '|') then
          Style := tbsSeparator
        else
          Style := tbsButton;
      end;
    end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ToolBar1 := TToolBar.Create(Self);
  ToolBar1.Parent := Self;
  AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
  ToolBar1.ShowCaptions := True;
  ToolBar1.Height := 40;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  I: Integer;
begin
  for I := ToolBar1.ButtonCount - 1 downto 0 do
    ToolBar1.Buttons[I].Free;
  ToolBar1.Free;
end;
```

3.1.40.2.14 TPanel.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
```

```
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor

3.1.40.2.15 TPanel.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

3.1.40.2.16 TPanel.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

3.1.40.2.17 TPanel.DockManager Property

Specifies the control's docking manager interface.

Pascal

```
property DockManager;
```

C++

```
__property DockManager;
```

Description

Use DockManager to specify the control's docking manager. The docking manager handles the layout of docking zones (where controls are docked) and any painting associated with docking zones.

If you set DockSite and UseDockManager to true, but do not assign a value to DockManager, the windowed control generates a default docking manager, using the global DefaultDockTreeClass variable.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
```

```
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
```

```
    if Accept then
    begin
      //Modify the DockRect to preview dock area.
      ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
      ARect.BottomRight := LeftDockPanel.ClientToScreen(
        Point(Self.ClientWidth div 3, LeftDockPanel.Height));
      Source.DockRect := ARect;
    end;
  end;

  procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
    NewTarget: TWinControl; var Allow: Boolean);
  begin
    //OnUnDock gets called BEFORE the client is undocked, in order to optionally
    //disallow the undock. DockClientCount is never 0 when called from this event.
    if (Sender as TPanel).DockClientCount = 1 then
      ShowDockPanel(Sender as TPanel, False, nil);
  end;

  procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
    DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
    var CanDock: Boolean);
  begin
    //if CanDock is true, the panel will not automatically draw the preview rect.
    CanDock := DockClient is TDockableForm;
  end;
```

See Also

DockSite

UseDockManager

DefaultDockTreeClass

3.1.40.2.18 TPanel.DockSite Property

Specifies whether the control can be the target of drag-and-dock operations.

Pascal

```
property DockSite;
```

C++

```
__property DockSite;
```

Description

Set DockSite to true to allow other controls to be docked to this windowed control.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/
void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
      TWinControl *NewTarget, bool &Allow)
{
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
```

```
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if (Client->ClassNameIs("TDockableForm"))
    dynamic_cast<TDockableForm *>(Client)->DockSite = True;
  if ((DockClientCount == 2) && (NewTarget != this))        // Self?
    PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
}
procedure TConjoinDockHost.FormUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if Client is TDockableForm then
    TDockableForm(Client).DockSite := True;
  if (DockClientCount = 2) and (NewTarget <> Self) then
    PostMessage(Self.Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
end;
```

3.1.40.2.19 TPanel.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
```

```
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
```

```
    if (Sender is TListBox) and (Source is TLabel) then
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

3.1.40.2.20 TPanel.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

3.1.40.2.21 TPanel.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

3.1.40.2.22 TPanel.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
```

```
    HT: THitTests;
  begin
    if TreeView1.Selected = nil then Exit;
    HT := TreeView1.GetHitTestInfoAt(X, Y);
    AnItem := TreeView1.GetNodeAt(X, Y);
    if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
    begin
      if (htOnItem in HT) or (htOnIcon in HT) then
        AttachMode := naAddChild
      else if htNowhere in HT then AttachMode := naAdd
      else if htOnIndent in HT then AttachMode := naInsert;
      TreeView1.Selected.MoveTo(AnItem, AttachMode);
    end;
  end;

  procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;

3.1.40.2.23 TPanel.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

3.1.40.2.24 TPanel.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

3.1.40.2.25 TPanel.FullRepaint Property

Determines how the panel repaints itself when it is resized.

Pascal

```
property FullRepaint: Boolean;
```

C++

```
__property Boolean FullRepaint;
```

Description

FullRepaint controls how the panel responds when it is resized. When FullRepaint is true, the entire panel, including the beveled border repaints when the size changes. When FullRepaint is false, only the area inside the beveled border repaints.

See Also

Invalidate

3.1.40.2.26 TPanel.Locked Property

Determines whether a panel that is used as a toolbar is replaced by a toolbar supplied by an OLE server.

Pascal

```
property Locked: Boolean;
```

C++

```
__property Boolean Locked;
```

Description

Set the Locked property to false when the panel is used as a toolbar by a TOleContainer component. Any panels aligned to a TOleContainer are assumed to be replaceable toolbars unless the Locked property is true. Prevent the panel from being replaced by an OLE server's toolbar by setting the panel's Locked property to true.

Note: An OLE application's toolbars must be in panels aligned to a side of the form (that is, their Align properties must be set to alTop, alBottom, alLeft, or alRight).

See Also

Align

TOleContainer (see page 5969)

3.1.40.2.27 TPanel.Padding Property

Specifies the padding of a control.

Pascal

```
property Padding;
```

C++

```
__property Padding;
```

Description

Use Padding to specify the padding of a control. This value is an instance of the class TPadding.

See Also

TPadding

3.1.40.2.28 TPanel.ParentBackground Property

Determines whether control uses parent's theme background.

Pascal

```
property ParentBackground;
```

C++

```
__property ParentBackground;
```

Description

If ParentBackground is true, the control uses the parent's theme background to draw its own background. ParentBackground has no effect unless XP themes are enabled.

3.1.40.2.29 TPanel.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

Parent

BiDiMode

3.1.40.2.30 TPanel.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

3.1.40.2.31 TPanel.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

3.1.40.2.32 TPanel.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

3.1.40.2.33 TPanel.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

ParentColor

ParentShowHint

3.1.40.2.34 TPanel.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

3.1.40.2.35 TPanel.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
```

```
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
```

```
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
```

```
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

OnContextPopup

3.1.40.2.36 TPanel.ShowCaption Property

Pascal

```
property ShowCaption: Boolean;
```

C++

```
__property Boolean ShowCaption;
```

Description

This is ShowCaption, a member of class TPanel.

3.1.40.2.37 TPanel.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
```

```
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

ParentShowHint

ShowHint (see page 1986)

Displaying Fly-over Help

3.1.40.2.38 TPanel.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

3.1.40.2.39 TPanel.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

TabOrder

3.1.40.2.40 TPanel.UseDockManager Property

Specifies whether the docking manager is used in drag-and-dock operations.

Pascal

```
property UseDockManager;
```

C++

```
__property UseDockManager;
```

Description

Use UseDockManager to get or set whether a docking manager is used in drag-and-dock operations.

The docking manager handles the positioning of docked controls and any painting of docking zones around those controls. If you do not use a docking manager, docked controls are aligned to the windowed control based on the closest edge to where they are released. When you do not use a docking manager, there is no region for a user to grab to automatically undock a docked control.

DockManager

3.1.40.2.41 TPanel.VerticalAlignment Property

Sets the vertical position of the caption.

Pascal

```
property VerticalAlignment: TVerticalAlignment;
```

C++

```
__property TVerticalAlignment VerticalAlignment;
```

Description

Use the VerticalAlignment property to control the position of the caption within the panel. Choose one of the following values.

Value	Description
taAlignBottom	The caption displays at the bottom of the panel.
taAlignTop	The caption displays at the top of the panel.
taVerticalCenter	The caption displays at the center of the panel.

Note: Use the Alignment property to control the horizontal position of the caption.

See Also

Caption

3.1.40.2.42 TPanel.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}
```

```
void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;

3.1.40.3 TPanel Events

The events of the TPanel class are listed here.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 1368)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 1369)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 1370)	Occurs when an attempt is made to resize the control.
	OnClick (see page 1370)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 1372)	Adjust resize constraints.
	OnContextPopup (see page 1372)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 1373)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 1373)	Occurs when another control is docked to the control.
	OnDockOver (see page 1375)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 1378)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 1381)	Occurs when the user drags an object over a control.
	OnEndDock (see page 1384)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 1384)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 1385)	Occurs when a control receives the input focus.
	OnExit (see page 1388)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 1390)	Returns the control's docking information.
	OnMouseActivate (see page 1393)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 1394)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 1396)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 1396)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 1396)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 1399)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnResize (see page 1401)	Occurs immediately after the control is resized.
	OnStartDock (see page 1402)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 1402)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 1403)	Occurs when the application tries to undock a control that is docked to the windowed control.

3.1.40.3.1 TPanel.OnAlignInsertBefore Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignInsertBefore;
```

C++

```
__property OnAlignInsertBefore;
```

Description

OnAlignInsertBefore occurs for each pair of child controls with an Align property of **alCustom**.

It can determine the order in which custom-aligned child controls are placed. OnAlignInsertBefore returns true if **C2** should be presented before **C1**, and false otherwise. It holds a TAlignInsertBeforeEvent type.

CustomAlignInsertBefore triggers the OnAlignInsertBefore event. If this event is defined, CustomAlignInsertBefore returns the value returned by OnAlignInsertBefore. Defining this event allows users to define the order of control alignment without overriding CustomAlignInsertBefore.

3.1.40.3.2 TPanel.OnAlignPosition Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignPosition;
```

C++

```
__property OnAlignPosition;
```

Description

OnAlignPosition occurs when child controls with an Align property of **alCustom** are aligned.

CustomAlignPosition triggers the OnAlignPosition event. If this event is defined, CustomAlignPosition uses the alignment parameters it obtains from OnAlignPosition. Defining this event allows users to set the alignment parameters without overriding CustomAlignPosition. It holds a TAlignPositionEvent type.

These are the parameters:

Parameter	Meaning
NewLeft | NewTop | NewWidth | NewHeight	Location and size of child control, as determined by container's size and the Anchors TControl_Anchors constraints for the control. OnAlignPosition can modify these values to reposition the control.
AlignRect	The client area in which the control is aligned. OnAlignPosition can modify this value.
AlignInfo	Alignment information in a TAlignInfo.
As implemented in TWinControl, OnAlignPosition does nothing.

3.1.40.3.3 TPanel.OnCanResize Event

Occurs when an attempt is made to resize the control.

Pascal

```
property OnCanResize;
```

C++

```
__property OnCanResize;
```

Description

Use OnCanResize to adjust the way a control is resized. If necessary, change the new width and height of the control in the OnCanResize event handler. The OnCanResize event handler also allows applications to indicate that the entire resize should be aborted.

If there is no OnCanResize event handler, or if the OnCanResize event handler indicates that the resize attempt can proceed, the OnCanResize event is followed immediately by an OnConstrainedResize event.

OnResize

3.1.40.3.4 TPanel.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
```

```
          Left := Random(PageControl1.ActivePage.ClientWidth - Width);
          Top := Random(PageControl1.ActivePage.ClientHeight - Height);
        end;

3.1.40.3.5 TPanel.OnConstrainedResize Event

Adjust resize constraints.

Pascal

```
property OnConstrainedResize;
```

C++

```
__property OnConstrainedResize;
```

Description

Use OnConstrainedResize to adjust a control's constraints when an attempt is made to resize it. Upon entry to the OnConstrainedResize event handler, the parameters of the event handler are set to the corresponding properties of the control's Constraints object. The event handler can adjust those values before they are applied to the new height and width that is being applied to the control. (The CanAutoSize method or an OnCanResize event handler may already have adjusted this new height and width).

On exit from the OnConstrainedResize event handler, the constraints are applied to the attempted new height and width. Once the constraints are applied, the control's height and width are changed. After the control's height and width change, an OnResize event occurs to allow any final adjustments or responses.

Note: The OnConstrainedResize handler is called immediately after the OnCanResize handler.

3.1.40.3.6 TPanel.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

3.1.40.3.7 TPanel.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

Responding to User Actions at Runtime

3.1.40.3.8 TPanel.OnDockDrop Event

Occurs when another control is docked to the control.

Pascal

```
property OnDockDrop;
```

C++

```
__property OnDockDrop;
```

Description

Write code in the OnDockDrop event to perform actions when another control is docked on the control.

OnDockDrop can only occur if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
```

```
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;
```

DockSite

OnDockOver

3.1.40.3.9 TPanel.OnDockOver Event

Occurs when another control is dragged over the control.

Pascal

```
property OnDockOver;
```

C++

```
__property OnDockOver;
```

Description

Write code in the OnDockOver event to indicate whether a dockable control that is dragged over the windowed control can be accepted as a dock client. OnDockOver occurs after the TDragDockObject has been initialized by an OnGetSiteInfo event.

OnDockOver occurs only if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
```

```
      ShowMessage(L"GetSiteInfo CanDock went bad!");
    }
  }
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;
```

OnDockDrop

OnGetSiteInfo

TDragDockObject

3.1.40.3.10 TPanel.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
```

```
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:

3.1.40.3.11 TPanel.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.

3.1.40.3.13 TPanel.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
```

```
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;

3.1.40.3.14 TPanel.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter

event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   (dynamic_cast<TEdit *>(myActiveControl))->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    (dynamic_cast<TRichEdit *>(myActiveControl))->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{

3.1.40.3.15 TPanel.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
```

```
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

procedure TForm1.MaskEdit2Exit(Sender: TObject);
var

OnEnter

ActiveControl (see page 2145)

3.1.40.3.16 TPanel.OnGetSiteInfo Event

Returns the control's docking information.

Pascal

```
  property OnGetSiteInfo;
```

C++

```
__property OnGetSiteInfo;
```

Description

Write code in the OnGetSiteInfo event handler to initialize a TDragDockObject with information about where a dragged object can be docked, if at all. OnGetSiteInfo occurs before the OnDockOver event.

OnGetSiteInfo occurs only if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;

3.1.40.3.17 TPanel.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

3.1.40.3.18 TPanel.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
```

```
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else

3.1.40.3.19 TPanel.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

3.1.40.3.20 TPanel.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

3.1.40.3.21 TPanel.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

Responding to a Mouse-up Action

3.1.40.3.23 TPanel.OnResize Event

Occurs immediately after the control is resized.

Pascal

```
property OnResize;
```

C++

```
__property OnResize;
```

Description

Use OnResize to make any final adjustments after a control is resized.

To modify the way a control responds when an attempt is made to resize it, use OnCanResize or OnConstrainedResize.

Note: Some controls call this event handler when the control is first created.

C++ Examples:

```
/*
The following code keeps the right edge on Button1 against
the right edge of Form1 when Form1 is resized.
*/
void __fastcall TForm1::FormResize(TObject *Sender)
{
  Button1->Left = Form1->ClientWidth - Button1->Width;
}
```

Delphi Examples:

```
{
The following code keeps the right edge on Button1 against
the right edge of Form1 when Form1 is resized.
}
procedure TForm1.FormResize(Sender: TObject);
begin
  Button1.Left := Form1.ClientWidth-Button1.Width;
end;
```

3.1.40.3.24 TPanel.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDockDrop

3.1.40.3.25 TPanel.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

3.1.40.3.26 TPanel.OnUnDock Event

Occurs when the application tries to undock a control that is docked to the windowed control.

Pascal

```
property OnUnDock;
```

C++

```
__property OnUnDock;
```

Description

Write an OnUnDock event handler to adjust the windowed control when a dock client is undocked. The OnUnDock event handler can make any necessary adjustments, or it can block the undock attempt by setting the Allow parameter to false.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/
void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
      TWinControl *NewTarget, bool &Allow)
{
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if (Client->ClassNameIs("TDockableForm"))
    dynamic_cast<TDockableForm *>(Client)->DockSite = True;
  if ((DockClientCount == 2) && (NewTarget != this))        // Self?
    PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
}
/*
```

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
}
procedure TConjoinDockHost.FormUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
```

```
    // Only 2 dock clients means the host must be destroyed and
    // the remaining window undocked to its old position and size.
    // Recall that OnUnDock gets called before the undocking
    // actually occurs.
    if Client is TDockableForm then
      TDockableForm(Client).DockSite := True;
    if (DockClientCount = 2) and (NewTarget <> Self) then
      PostMessage(Self.Handle, WM_CLOSE, 0, 0);
    UpdateCaption(Client);
  end;
  {
  The following example is taken from the docking demo. It
  shows how set permissions to dock dockable objects onto a
  docking site.
  }

  procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
    Source: TDragDockObject; X, Y: Integer);
  begin
    //OnDockDrop gets called AFTER the client has actually docked,
    //so we check for DockClientCount = 1 before making the dock panel visible.
    if (Sender as TPanel).DockClientCount = 1 then
      ShowDockPanel(Sender as TPanel, True, nil);
    (Sender as TPanel).DockManager.ResetBounds(True);
    //Make DockManager repaints it's clients.
  end;

3.1.41 TRadioGroup Class

TRadioGroup represents a group of radio buttons that function together.

Class Hierarchy

Pascal

```
TRadioGroup = class(TCustomRadioGroup);
```

C++

```
class TRadioGroup : public TCustomRadioGroup;
```

File

ExtCtrls

Description

A TRadioGroup object is a special group box that contains only radio buttons. Radio buttons that are placed directly in the same control component are said to be "grouped." When the user checks a radio button, all other radio buttons in its group become unchecked. Hence, two radio buttons on a form can be checked at the same time only if they are placed in separate containers, such as group boxes.

To add radio buttons to a TRadioGroup, edit the Items (see page 1424) property in the Object Inspector. Each string in Items (see page 1424) makes a radio button appear in the group box with the string as its caption. The value of the ItemIndex (see page 1423) property determines which radio button is currently selected.

Display the radio buttons in a single column or in multiple columns by setting the Columns (see page 1416) property.

Note: Setting the radio group's BiDiMode (see page 1413) to bdRightToLeft automatically flips its radio buttons. The FlipChildren (see page 817) method has no effect.

Group Boxes and Radio Groups

Grouping Controls

3.1.41.1 TRadioGroup Members

The following tables list the members exposed by TRadioGroup.

Protected Methods

	Name	Description
	CanModify (see page 817)	Determines whether the user can select a different radio button in the group.
	Loaded (see page 818)	Initializes the radio group after it is loaded into memory.
	ReadState (see page 819)	Prepares the control for having its properties assigned values from a stream.

Public Methods

	Name	Description
	Create (see page 816)	Creates and initializes a TCustomRadioGroup (see page 815) instance.
	Destroy (see page 816)	Destroys the TCustomRadioGroup (see page 815) instance and the radio buttons it contains.
	FlipChildren (see page 817)	Prevents the default behavior of flipping the child radio buttons.
	GetChildren (see page 818)	Prevents the streaming system from loading and saving child controls in the usual fashion.

Public Properties

	Name	Description
	Buttons (see page 819)	Access individual TRadioButton objects.

Published Events

	Name	Description
	OnClick (see page 1438)	Occurs when the user clicks the control.
	OnContextPopup (see page 1440)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDragDrop (see page 1440)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 1443)	Occurs when the user drags an object over a control.
	OnEndDock (see page 1447)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 1447)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 1448)	Occurs when a control receives the input focus.
	OnExit (see page 1451)	Occurs when the input focus shifts away from one control to another.
	OnStartDock (see page 1453)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 1454)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 1409)	Determines how the control aligns within its container (parent control).
	Anchors (see page 1412)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 1413)	Specifies the bi-directional mode for the control.
	Caption (see page 1413)	Specifies a text string that identifies the control to the user.
	Color (see page 1416)	Specifies the background color of the control.
	Columns (see page 1416)	Specifies number of columns in the radio group.
	Constraints (see page 1417)	Specifies the size constraints for the control.
	Ctl3D (see page 1417)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 1418)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 1420)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 1420)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 1420)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 1422)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 1422)	Controls the attributes of text written on or in the control.
	ItemIndex (see page 1423)	Indicates which radio button in the group is currently selected.
	Items (see page 1424)	Lists the radio buttons in the radio group.
	ParentBackground (see page 1425)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 1426)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 1426)	Determines where a control looks for its color information.
	ParentCtl3D (see page 1427)	Determines where a component looks to determine if it should appear three dimensional.

	ParentDoubleBuffered (see page 1427)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 1427)	Determines where a control looks for its font information.
	ParentShowHint (see page 1428)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 1428)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 1433)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 1435)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 1435)	Determines if the user can tab to a control.
	Visible (see page 1436)	Determines whether the component appears onscreen.
	WordWrap (see page 1437)	This is WordWrap, a member of class TRadioGroup.

3.1.41.2 TRadioGroup Properties

The properties of the TRadioGroup class are listed here.

Published Properties

	Name	Description
	Align (see page 1409)	Determines how the control aligns within its container (parent control).
	Anchors (see page 1412)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 1413)	Specifies the bi-directional mode for the control.
	Caption (see page 1413)	Specifies a text string that identifies the control to the user.
	Color (see page 1416)	Specifies the background color of the control.
	Columns (see page 1416)	Specifies number of columns in the radio group.
	Constraints (see page 1417)	Specifies the size constraints for the control.
	Ctl3D (see page 1417)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 1418)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 1420)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 1420)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 1420)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 1422)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 1422)	Controls the attributes of text written on or in the control.
	ItemIndex (see page 1423)	Indicates which radio button in the group is currently selected.
	Items (see page 1424)	Lists the radio buttons in the radio group.
	ParentBackground (see page 1425)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 1426)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 1426)	Determines where a control looks for its color information.
	ParentCtl3D (see page 1427)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 1427)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 1427)	Determines where a control looks for its font information.
	ParentShowHint (see page 1428)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 1428)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 1433)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 1435)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 1435)	Determines if the user can tab to a control.
	Visible (see page 1436)	Determines whether the component appears onscreen.
	WordWrap (see page 1437)	This is WordWrap, a member of class TRadioGroup.

3.1.41.2.1 TRadioGroup.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
```

```
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>

Parent

Anchors

3.1.41.2.2 TRadioGroup.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

3.1.41.2.3 TRadioGroup.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

Including Bi-directional Functionality in Applications

3.1.41.2.4 TRadioGroup.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
```

```
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>
#include <memory>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);  // The owner (toolBar) will clean this up.
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this); // The owner (this) will clean this up.
  myToolBar->Parent = this;
//  TStringList *captions = new TStringList();
  std::auto_ptr<TStringList> captions(new TStringList());

  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions.get());
//  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
```

```
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long to be the caption of this label';
end;
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
        Caption := ButtonCaptions[I];
        if (ButtonCaptions[I] = '|') then
          Style := tbsSeparator
        else
          Style := tbsButton;
      end;
    end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ToolBar1 := TToolBar.Create(Self);
  ToolBar1.Parent := Self;
  AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
  ToolBar1.ShowCaptions := True;
  ToolBar1.Height := 40;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  I: Integer;
begin
  for I := ToolBar1.ButtonCount - 1 downto 0 do
    ToolBar1.Buttons[I].Free;
  ToolBar1.Free;
```

```
end;
```

3.1.41.2.5 TRadioGroup.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

ParentColor

3.1.41.2.6 TRadioGroup.Columns Property

Specifies number of columns in the radio group.

Pascal

```
property Columns: Integer;
```

C++

```
__property int Columns;
```

Description

Columns determines the number of columns in the radio group if Orientation is orVertical (the default), and the number of rows if Orientation is orHorizontal. Its value can range from 1 to 16. The default value is 1, which means that the radio buttons are arranged in a single line.

3.1.41.2.7 TRadioGroup.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

OnCanResize

3.1.41.2.8 TRadioGroup.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

BevelInner

BevelOuter

BorderWidth

3.1.41.2.9 TRadioGroup.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
```

```
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

3.1.41.2.10 TRadioGroup.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

3.1.41.2.11 TRadioGroup.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

3.1.41.2.12 TRadioGroup.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;

Arranging the Order of Persistent Columns

3.1.41.2.13 TRadioGroup.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

3.1.41.2.14 TRadioGroup.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

3.1.41.2.15 TRadioGroup.ItemIndex Property

Indicates which radio button in the group is currently selected.

Pascal

```
property ItemIndex: Integer;
```

C++

```
__property int ItemIndex;
```

Description

ItemIndex holds the index of the selected radio button in the Items list. (The first button is 0.) The value of ItemIndex changes at runtime as the user selects radio buttons. If you want one of the buttons to appear selected when the application starts, assign

that button to ItemIndex at design time; otherwise, leave ItemIndex set to the default value of -1, which means that no button is selected.

C++ Examples:

```
/*
This example uses a radio group box and a scroll bar on a
form. When the user selects one of the radio buttons, the
scroll bar changes orientation accordingly.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RadioGroup1->Items->Add("Vertical");
  RadioGroup1->Items->Add("Horizontal");
  RadioGroup1->ItemIndex = 2;
}

void __fastcall TForm1::RadioGroup1Click(TObject *Sender)
{
  if (RadioGroup1->Items->Strings[RadioGroup1->ItemIndex] == "Vertical")
    ScrollBar1->Kind = sbVertical;
  else if (RadioGroup1->Items->Strings[RadioGroup1->ItemIndex] == "Horizontal")
    ScrollBar1->Kind = sbHorizontal;
}
```

Delphi Examples:

```
{
This example uses a radio group box and a scroll bar on a
form. When the user selects one of the radio buttons, the
scroll bar changes orientation accordingly.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  RadioGroup1.Items.Add('Vertical');
  RadioGroup1.Items.Add('Horizontal');
  RadioGroup1.ItemIndex := 2;
end;

procedure TForm1.RadioGroup1Click(Sender: TObject);
begin
  if RadioGroup1.Items[RadioGroup1.ItemIndex] = 'Vertical' then
    ScrollBar1.Kind := sbVertical;
  if RadioGroup1.Items[RadioGroup1.ItemIndex] = 'Horizontal' then
    ScrollBar1.Kind := sbHorizontal;
end;
```

See Also

Items (see page 821)

3.1.41.2.16 TRadioGroup.Items Property

Lists the radio buttons in the radio group.

Pascal

```
property Items: TStrings;
```

C++

```
__property TStrings Items;
```

Description

Items holds a TStrings object that lists the captions of the radio buttons in the group. In TCustomRadioGroup descendants, where this property is published, radio buttons can be added or removed by editing the Items list from the Object Inspector.

Note: A TRadioButton object is created automatically for each string in Items. You cannot directly add or remove TRadioButton objects, but you can access individual TButton objects through the Buttons property.

C++ Examples:

```
/*
This example uses a radio group box and a scroll bar on a
form. When the user selects one of the radio buttons, the
scroll bar changes orientation accordingly.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RadioGroup1->Items->Add("Vertical");
  RadioGroup1->Items->Add("Horizontal");
  RadioGroup1->ItemIndex = 2;
}

void __fastcall TForm1::RadioGroup1Click(TObject *Sender)
{
  if (RadioGroup1->Items->Strings[RadioGroup1->ItemIndex] == "Vertical")
    ScrollBar1->Kind = sbVertical;
  else if (RadioGroup1->Items->Strings[RadioGroup1->ItemIndex] == "Horizontal")
    ScrollBar1->Kind = sbHorizontal;
}
```

Delphi Examples:

```
{
This example uses a radio group box and a scroll bar on a
form. When the user selects one of the radio buttons, the
scroll bar changes orientation accordingly.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  RadioGroup1.Items.Add('Vertical');
  RadioGroup1.Items.Add('Horizontal');
  RadioGroup1.ItemIndex := 2;
end;

procedure TForm1.RadioGroup1Click(Sender: TObject);
begin
  if RadioGroup1.Items[RadioGroup1.ItemIndex] = 'Vertical' then
    ScrollBar1.Kind := sbVertical;
  if RadioGroup1.Items[RadioGroup1.ItemIndex] = 'Horizontal' then
    ScrollBar1.Kind := sbHorizontal;
end;
```

3.1.41.2.17 TRadioGroup.ParentBackground Property

Determines whether control uses parent's theme background.

Pascal

```
property ParentBackground;
```

C++

```
__property ParentBackground;
```

Description

If ParentBackground is true, the control uses the parent's theme background to draw its own background. ParentBackground has no effect unless XP themes are enabled.

3.1.41.2.18 TRadioGroup.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent

BiDiMode

3.1.41.2.19 TRadioGroup.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

3.1.41.2.20 TRadioGroup.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

3.1.41.2.21 TRadioGroup.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

3.1.41.2.22 TRadioGroup.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

See Also

Font

Parent

ParentColor

ParentShowHint

3.1.41.2.23 TRadioGroup.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

3.1.41.2.24 TRadioGroup.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
```

```
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
```

```
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

3.1.41.2.25 TRadioGroup.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
```

```
example.

3.1.41.2.26 TRadioGroup.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

FindNextControl

TabStop

3.1.41.2.27 TRadioGroup.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

3.1.41.2.28 TRadioGroup.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)

3.1.41.2.29 TRadioGroup.WordWrap Property

Pascal

```
property WordWrap: Boolean;
```

C++

```
__property Boolean WordWrap;
```

Description

This is WordWrap, a member of class TRadioGroup.

3.1.41.3 TRadioGroup Events

The events of the TRadioGroup class are listed here.

Published Events

	Name	Description
	OnClick (see page 1438)	Occurs when the user clicks the control.
	OnContextPopup (see page 1440)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDragDrop (see page 1440)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 1443)	Occurs when the user drags an object over a control.
	OnEndDock (see page 1447)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 1447)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 1448)	Occurs when a control receives the input focus.
	OnExit (see page 1451)	Occurs when the input focus shifts away from one control to another.
	OnStartDock (see page 1453)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 1454)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

3.1.41.3.1 TRadioGroup.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
```

```
    PageControl1Change(Sender);
end;
```

3.1.41.3.2 TRadioGroup.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

AutoPopup (see page 4942)

3.1.41.3.3 TRadioGroup.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
```

```
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
type
  TForm1 = class(TForm)
    Panel1: TPanel;
    Label1: TLabel;
    procedure Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
      State: TDragState; var Accept: Boolean);

3.1.41.3.4 TRadioGroup.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

3.1.41.3.7 TRadioGroup.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   (dynamic_cast<TEdit *>(myActiveControl))->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    (dynamic_cast<TRichEdit *>(myActiveControl))->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*

3.1.41.3.8 TRadioGroup.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

procedure TForm1.MaskEdit2Exit(Sender: TObject);
var
  net1, net2, host1, host2,
  netmask1, netmask2, hostmask1, hostmask2,
  sub_net1, sub_net2, sub_host1, sub_host2: Integer;

  IP, mask: String;

begin
  // extract the net and host address from the IP
  IP := MaskEdit1.Text;
  net1 := StrToInt(TrimRight(Copy(IP, 0, 3)));
  net2 := StrToInt(TrimRight(Copy(IP, 5, 3)));
  host1 := StrToInt(TrimRight(Copy(IP, 9, 3)));
  host2 := StrToInt(TrimRight(Copy(IP, 13, 3)));

  // a range test that you cannot validate through edit masks
  if ((net1 < 0) Or (net1 > 255) Or
      (net2 < 0) Or (net2 > 255) Or
      (host1 < 0) Or (host1 > 255) Or
      (host2 < 0) Or (host2 > 255)) then
    raise EArgumentException.Create('Not a valid IP address.');

  // extract the net and host mask from the subnet mask
  mask := MaskEdit2.Text;
  netmask1 := StrToInt(TrimRight(Copy(mask, 0, 3)));
  netmask2 := StrToInt(TrimRight(Copy(mask, 5, 3)));
  hostmask1 := StrToInt(TrimRight(Copy(mask, 9, 3)));
```

```
    hostmask2 := StrToInt(TrimRight(Copy(mask, 13, 3)));

    // a range test that you cannot validate through edit masks
    if ((netmask1 < 0) Or (netmask1 > 255) Or
        (netmask2 < 0) Or (netmask2 > 255) Or
        (hostmask1 < 0) Or (hostmask1 > 255) Or
        (hostmask2 < 0) Or (hostmask2 > 255)) then
      raise EArgumentException.Create('Not a valid subnet mask.');

    // compute the subnet address using bit-wise AND
    sub_net1 := net1 And netmask1;
    sub_net2 := net2 And netmask2;
    sub_host1 := host1 And hostmask1;
    sub_host2 := host2 And hostmask2;

    // display the subnet address
    MaskEdit3.Text :=
      IntToStr(sub_net1) + '.' + IntToStr(sub_net2) + '.' +
      IntToStr(sub_host1) + '.' + IntToStr(sub_host2);
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.

OnEnter

ActiveControl (see page 2145)

3.1.41.3.9 TRadioGroup.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDockDrop

3.1.41.3.10 TRadioGroup.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

3.1.42 TRowCollection Class

Controls the **Collection Editor** for rows within a grid panel.

Class Hierarchy

Pascal

```
TRowCollection = class(TCellCollection);
```

C++

```
class TRowCollection : public TCellCollection;
```

File

ExtCtrls

Description

TRowCollection controls the **Collection Editor** for rows within a grid panel.

See Also

Collection Editor

3.1.42.1 TRowCollection Members

The following tables list the members exposed by TRowCollection.

Protected Methods

	Name	Description
	GetAttr (see page 459)	Returns the name of a custom attribute that can be retrieved using the GetItemAttr method.
	GetAttrCount (see page 459)	Returns the number of custom attributes associated with items in the collection.
	GetItem (see page 460)	Returns a specified item in the collection.
	GetItemAttr (see page 1456)	Returns the value of a custom attribute assigned to one of the collection's items.
	Notify (see page 1457)	Responds when items are added to or removed from the collection.
	SetItem (see page 461)	This is SetItem, a member of class TCellCollection.
	Update (see page 461)	Updates the collection to reflect changes to its items.

Public Methods

	Name	Description
	Add (see page 1456)	Adds a row to the grid panel.
	Create (see page 1456)	This is Create, a member of class TRowCollection.
	Owner (see page 460)	Returns the Owner of the cell collection.

Public Properties

	Name	Description
	Items (see page 461)	Lists the items of the cell collection.

3.1.42.2 TRowCollection.Create Constructor

Pascal

```
constructor Create(AOwner: TPersistent);
```

C++

```
__fastcall TRowCollection(TPersistent * AOwner);
```

Description

This is Create, a member of class TRowCollection.

3.1.42.3 TRowCollection Methods

The methods of the TRowCollection class are listed here.

Protected Methods

	Name	Description
	GetItemAttr (see page 1456)	Returns the value of a custom attribute assigned to one of the collection's items.
	Notify (see page 1457)	Responds when items are added to or removed from the collection.

Public Methods

	Name	Description
	Add (see page 1456)	Adds a row to the grid panel.

3.1.42.3.1 TRowCollection.Add Method

Adds a row to the grid panel.

Pascal

```
function Add: TRowItem;
```

C++

```
__fastcall TRowItem Add();
```

Description

Use the Add method to add a row to the grid panel.

3.1.42.3.2 TRowCollection.GetItemAttr Method

Returns the value of a custom attribute assigned to one of the collection's items.

Pascal

```
function GetItemAttr(Index: Integer; ItemIndex: Integer): string; override;
```

C++

```
virtual __fastcall UnicodeString GetItemAttr(int Index, int ItemIndex);
```

Description

TCollection descendants can associate user-defined attributes with the items in the collection. Each attribute has a name and, for each item in the collection, a value that is a string. GetItemAttr returns the value of one of these attributes for a specified item in the collection.

Index identifies which attribute's value is desired. This is a value between 0 and n-1, where n is the value returned by GetAttrCount.

ItemIndex identifies the item whose attribute value is desired. This is an index into the Items property array.

As implemented in TCollection, GetItemAttr always returns an empty string, because TCollection defines no custom attributes.

See Also

GetAttr

GetAttrCount

3.1.42.3.3 TRowCollection.Notify Method

Responds when items are added to or removed from the collection.

Pascal

```
procedure Notify(Item: TCollectionItem; Action: TCollectionNotification); override;
```

C++

```
virtual __fastcall Notify(TCollectionItem Item, TCollectionNotification Action);
```

Description

Notify is called automatically when the items in the collection change.

Item is the item that was just added to or that is about to be removed from the collection.

Action indicates whether item was added, is about to be removed, or is about to be deleted:

As implemented in TCollection, Notify calls Added when Action is cnAdded and calls Deleting when Action is cnDeleting. TCollection ignores the cnExtracting action. Descendant classes can override Notify to modify this behavior.

3.1.43 TRowItem Class

Class Hierarchy

Pascal

```
TRowItem = class(TCellItem);
```

C++

```
class TRowItem : public TCellItem;
```

File

ExtCtrls

Description

This is class ExtCtrls.TRowItem.

3.1.44 TShape Class

TShape represents a geometric shape that can be drawn on a form.

Class Hierarchy

Pascal

```
TShape = class(TGraphicControl);
```

C++

```
class TShape : public TGraphicControl;
```

File

ExtCtrls

Description

Add a TShape object to a form to draw a simple geometric shape on the form. TShape introduces properties to describe the pen used to outline the shape and the brush used to fill it.

If the shape is only part of the image of a custom control, use the methods of the control's canvas instead.

Graphic Controls

Shapes

3.1.44.1 TShape Members

The following tables list the members exposed by TShape.

Protected Methods

	Name	Description
	Paint (see page 1460)	Render control surface.

Public Methods

	Name	Description
	Create (see page 1459)	Creates an instance of TShape (see page 1458).
	Destroy (see page 1460)	Destroys of an instance of TShape (see page 1458).

Published Events

	Name	Description
	OnContextPopup (see page 1474)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDragDrop (see page 1475)	Occurs when the user drops an object being dragged.

	OnDragOver (see page 1478)	Occurs when the user drags an object over a control.
	OnEndDock (see page 1481)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 1481)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnMouseActivate (see page 1482)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 1483)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 1486)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 1486)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 1486)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 1488)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 1491)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 1491)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Methods

	Name	Description
	StyleChanged (see page 1461)	This is StyleChanged, a member of class TShape.

Published Properties

	Name	Description
	Align (see page 1461)	Determines how the control aligns within its container (parent control).
	Anchors (see page 1465)	Specifies how the control is anchored to its parent.
	Brush (see page 1465)	Specifies the color and pattern used for filling the shape control.
	Constraints (see page 1466)	Specifies the size constraints for the control.
	DragCursor (see page 1466)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 1467)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 1467)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 1469)	Controls whether the control responds to mouse, keyboard, and timer events.
	ParentShowHint (see page 1469)	Determines where a control looks to find out if its Help Hint should be shown.
	Pen (see page 1470)	Specifies the pen used to outline the shape control.
	Shape (see page 1470)	Specifies the shape of the control.
	ShowHint (see page 1471)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Visible (see page 1472)	Determines whether the component appears onscreen.

3.1.44.2 TShape.Create Constructor

Creates an instance of TShape (see page 1458).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TShape(TComponent * AOwner);
```

Description

Call TShape (see page 1458) indirectly, using the new keyword, to instantiate a TShape (see page 1458) object at runtime. Shapes added to a form at design time are created automatically.

AOwner is the component, typically a form, that is responsible for freeing the shape object.

See Also

Owner

3.1.44.3 TShape.Destroy Destructor

Destroys of an instance of TShape (see page 1458).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TShape();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the object is not nil before it calls Destroy.

See Also

System::TObject::Free

3.1.44.4 TShape Methods

The methods of the TShape class are listed here.

Protected Methods

	Name	Description
	Paint (see page 1460)	Render control surface.

Published Methods

	Name	Description
	StyleChanged (see page 1461)	This is StyleChanged, a member of class TShape.

3.1.44.4.1 TShape.Paint Method

Render control surface.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

The Paint method is called automatically when a lightweight control needs update its display area. Code in the Paint method uses the Canvas property to render the control surface.

As implemented in TGraphicControl, Paint does nothing. Specific rendering logic is provided by Paint methods in descendant control classes.

See Also

Canvas

3.1.44.4.2 TShape.StyleChanged Method

Pascal

```
procedure StyleChanged(Sender: TObject);
```

C++

```
__fastcall StyleChanged(TObject * Sender);
```

Description

This is StyleChanged, a member of class TShape.

3.1.44.5 TShape Properties

The properties of the TShape class are listed here.

Published Properties

	Name	Description
	Align (see page 1461)	Determines how the control aligns within its container (parent control).
	Anchors (see page 1465)	Specifies how the control is anchored to its parent.
	Brush (see page 1465)	Specifies the color and pattern used for filling the shape control.
	Constraints (see page 1466)	Specifies the size constraints for the control.
	DragCursor (see page 1466)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 1467)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 1467)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 1469)	Controls whether the control responds to mouse, keyboard, and timer events.
	ParentShowHint (see page 1469)	Determines where a control looks to find out if its Help Hint should be shown.
	Pen (see page 1470)	Specifies the pen used to outline the shape control.
	Shape (see page 1470)	Specifies the shape of the control.
	ShowHint (see page 1471)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Visible (see page 1472)	Determines whether the component appears onscreen.

3.1.44.5.1 TShape.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
```

```
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane – a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
```

```
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
}

var
  I: Integer;

procedure TForm1.Button1Click(Sender: TObject);
var
  ProgressBar: TProgressBar;
begin
  ProgressBar := TProgressBar.Create(Self);
  with ProgressBar do
  begin
    Parent := Self;

Parent

Anchors

3.1.44.5.2 TShape.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

3.1.44.5.3 TShape.Brush Property

Specifies the color and pattern used for filling the shape control.

Pascal

```
property Brush: TBrush;
```

C++

```
__property TBrush Brush;
```

Description

Brush is a TBrush (see page 2664) object that represents the color and pattern that fill the interior of the shape. Use the properties and methods of TBrush (see page 2664) to change the color or pattern of the shape object:

```
Shape1.Brush.Color := clWhite;
Shape1->Brush->Color = clWhite;
```

Note: Setting the Brush property assigns the properties of another TBrush (see page 2664) object to the shape's brush. The shape object does not take ownership of the assigned object.

See Also

Pen (see page 1470)

TBrush (see page 2664)

3.1.44.5.4 TShape.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

AutoSize

Align

Anchors

OnConstrainedResize

OnCanResize

3.1.44.5.5 TShape.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

3.1.44.5.6 TShape.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

3.1.44.5.7 TShape.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
```

```
    else
      return;
    TreeView1->Selected->MoveTo(Item, AttachMode);
  }

  void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
        int X, int Y, TDragState State, bool &Accept)
  {
    Accept = (Source == dynamic_cast<TObject *>(TreeView1));
  }
```

Delphi Examples:

```
  {
  The following code uses GetNodeAt to add a dragged node as a
  child of the node under the mouse when it is dropped.  This
  example requires a populated TreeView.  Also, the TTreeView
  DragMode property must be set to dmAutomatic, and the TTreeView
  OnDragOver event handler must be implemented to accept the
  drop.
  }
  procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
  var
    AnItem: TTreeNode;
    AttachMode: TNodeAttachMode;
    HT: THitTests;
  begin
    if TreeView1.Selected = nil then Exit;
    HT := TreeView1.GetHitTestInfoAt(X, Y);
    AnItem := TreeView1.GetNodeAt(X, Y);
    if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
    begin
      if (htOnItem in HT) or (htOnIcon in HT) then
        AttachMode := naAddChild
      else if htNowhere in HT then AttachMode := naAdd
      else if htOnIndent in HT then AttachMode := naInsert;
      TreeView1.Selected.MoveTo(AnItem, AttachMode);
    end;
  end;

  procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);

3.1.44.5.8 TShape.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

Visible

DisableControls

EnableControls

Enabling Mouse

3.1.44.5.9 TShape.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

3.1.44.5.10 TShape.Pen Property

Specifies the pen used to outline the shape control.

Pascal

```
property Pen: TPen;
```

C++

```
__property TPen Pen;
```

Description

Read Pen to obtain the TPen (see page 2801) object that represents the color and style of the line used to outline the shape. Use the properties of Pen to change the color or style.

Pen is a TPen (see page 2801) object that represents the color and style of the line used to outline the shape. Use the properties and methods of TPen (see page 2801) to change the color or pattern of the shape object:

Shape1.Pen.Width := 1;

Shape1.Pen.Color := Red;

Shape1->Pen->Width = 1;

Shape1->Pen->Color = clRed (see page 2916);

Note: Setting the Pen property assigns the properties of another TPen (see page 2801) object to the shape's pen. The shape object does not take ownership of the assigned object.

3.1.44.5.11 TShape.Shape Property

Specifies the shape of the control.

Pascal

```
property Shape: TShapeType;
```

C++

```
__property TShapeType Shape;
```

Description

Set Shape to the geometric shape that should be drawn on the form. The Shape property has these possible values:

Value	Meaning
stCircle	The shape is a circle.
stEllipse	The shape is an ellipse.
stRectangle	The shape is a rectangle. (Default)
stRoundRect	The shape is a rectangle with rounded corners.
stRoundSquare	The shape is a square with rounded corners.
stSquare	The shape is a square.

3.1.44.5.12 TShape.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
```

```
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

3.1.44.5.13 TShape.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
```

```
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;

3.1.44.6 TShape Events

The events of the TShape class are listed here.

Published Events

	Name	Description
	OnContextPopup (see page 1474)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDragDrop (see page 1475)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 1478)	Occurs when the user drags an object over a control.
	OnEndDock (see page 1481)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 1481)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnMouseActivate (see page 1482)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 1483)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 1486)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 1486)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 1486)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 1488)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 1491)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 1491)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

3.1.44.6.1 TShape.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

AutoPopup (see page 4942)

3.1.44.6.2 TShape.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
```

```
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.

3.1.44.6.3 TShape.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
```

```

3.1.44.6.5 TShape.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
```

```
  control was successfully dropped into and accepted by a
  another control.
  */
  void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
       int Y)
  {
    if (Sender->ClassNameIs("TLabel"))
    {
      AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
      if (Target)
        S = S + "accepted!";
      else
        S = S + "rejected.";
      Status->Caption = S;
    }
  }
```

Delphi Examples:

```
  {
  This code displays a message in a label named Status. The
  message displayed depends on whether the dragged label
  control was successfully dropped into and accepted by a
  another control.
  }
  procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
  var
    S: string;
  begin
    S := (Sender as TLabel).Name + ' was dropped... and ';
    if Target <> nil then
      S := S + 'accepted!'
    else
      S := S + 'rejected!';
    Status.Caption := S;
  end;

3.1.44.6.6 TShape.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
```

```
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

3.1.44.6.7 TShape.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

3.1.44.6.8 TShape.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

3.1.44.6.9 TShape.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

3.1.44.6.10 TShape.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

MouseCapture

3.1.44.6.11 TShape.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp;
```

C++

```
__property OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

OnMouseDown

OnMouseMove

Responding to a Mouse-up Action

3.1.44.6.12 TShape.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

TDragDockObjectEx

DragKind

OnDragOver

OnDockDrop

3.1.44.6.13 TShape.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

3.1.45 TSplitter Class

TSplitter divides the client area of a form into resizable panes.

Class Hierarchy

Pascal

```
TSplitter = class(TGraphicControl);
```

C++

```
class TSplitter : public TGraphicControl;
```

File

ExtCtrls

Description

Add a splitter to a form between two aligned controls to allow users to resize the controls at runtime. The splitter sits between a control aligned to one edge of the form and the controls that fill up the rest of the client area. Give the splitter the same alignment as the control that is anchored to the edge of the form. When the user moves the splitter, it resizes the anchored control. This, in turn, changes the client area of the form, and the controls that fill up the rest of the client area resize accordingly.

Use each control on the form as a separate pane. After each pane is placed, place a splitter with the same alignment to allow that pane to be resized. The last pane to be placed on the form should be client-aligned, so that it resizes automatically to fill up the remaining space after all other panes are resized.

TForm (see page 2241)

Splitter Controls

3.1.45.1 TSplitter Members

The following tables list the members exposed by TSplitter.

Protected Methods

	Name	Description
	CanResize (see page 1496)	Determines how the splitter responds to mouse moves.
	DoCanResize (see page 1496)	Generates an OnCanResize (see page 1517) event and enforces the MinSize (see page 1511) property.
	MouseDown (see page 1497)	Dynamically locates the control that can be resized by the splitter.
	MouseMove (see page 1497)	Provides visual feedback of how the neighboring control would be resized.
	MouseUp (see page 1497)	Resizes the neighboring control when the user releases the mouse.
	Paint (see page 1498)	Draws the image of the splitter.
	RequestAlign (see page 1498)	Changes the cursor when the alignment of the splitter changes.
	StopSizing (see page 1499)	Cleans up after the splitter has resized its neighboring control.

Public Methods

	Name	Description
	Create (see page 1493)	Creates an instance of TSplitter (see page 1492).
	Destroy (see page 1495)	Frees the memory associated with the splitter.

Public Properties

	Name	Description
	Canvas (see page 1504)	Provides the drawing surface used by the graphic control.

Published Events

	Name	Description
	OnCanResize (see page 1517)	Occurs when the user tries to move the splitter with the mouse.
	OnMoved (see page 1517)	Occurs after the user has retiled the form using the splitter.
	OnPaint (see page 1520)	Occurs when the splitter needs to draw itself.

Published Properties

	Name	Description
	Align (see page 1499)	Determines how the control aligns within its container (parent control).
	AutoSnap (see page 1503)	Determines whether neighboring objects are resized to zero when the splitter is used to make them smaller than MinSize (see page 1511).
	Beveled (see page 1503)	Determines whether the splitter looks beveled along the edge that moves.
	Color (see page 1506)	Specifies the background color of the control.
	Constraints (see page 1507)	Specifies the size constraints for the control.
	Cursor (see page 1507)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	MinSize (see page 1511)	Specifies the minimum size, in pixels, of the panes on either side of the splitter.
	ParentColor (see page 1512)	Determines where a control looks for its color information.
	ResizeStyle (see page 1513)	Specifies the effect of moving the splitter.
	Visible (see page 1514)	Determines whether the component appears onscreen.
	Width (see page 1515)	Specifies the horizontal size of the control or form in pixels.

3.1.45.2 TSplitter.Create Constructor

Creates an instance of TSplitter (see page 1492).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TSplitter(TComponent * AOwner);
```

Description

Call Create to instantiate a splitter at runtime. TSplitter (see page 1492) objects placed on forms at design time are created automatically.

AOwner specifies the form whose surface the splitter divides.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
```

```
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane - a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
```

Owner

3.1.45.3 TSplitter.Destroy Destructor

Frees the memory associated with the splitter.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TSplitter();
```

Description

Do not call Destroy directly. Instead,call Free, which checks that the splitter is not nil before calling Destroy.

See Also

System::TObject::Free

3.1.45.4 TSplitter Methods

The methods of the TSplitter class are listed here.

Protected Methods

	Name	Description
	CanResize (see page 1496)	Determines how the splitter responds to mouse moves.
	DoCanResize (see page 1496)	Generates an OnCanResize (see page 1517) event and enforces the MinSize (see page 1511) property.
	MouseDown (see page 1497)	Dynamically locates the control that can be resized by the splitter.
	MouseMove (see page 1497)	Provides visual feedback of how the neighboring control would be resized.
	MouseUp (see page 1497)	Resizes the neighboring control when the user releases the mouse.
	Paint (see page 1498)	Draws the image of the splitter.
	RequestAlign (see page 1498)	Changes the cursor when the alignment of the splitter changes.
	StopSizing (see page 1499)	Cleans up after the splitter has resized its neighboring control.

3.1.45.4.1 TSplitter.CanResize Method

Determines how the splitter responds to mouse moves.

Pascal

```
function CanResize(var NewSize: Integer): Boolean; virtual; reintroduce;
```

C++

```
virtual __fastcall Boolean CanResize(int NewSize);
```

Description

CanResize is called by the DoCanResize (see page 1496) method to generate an OnCanResize (see page 1517) event. The NewSize parameter indicates the size the associated control will have if the splitter is allowed to perform the resize. CanResize returns a boolean value that indicates whether the value specified by NewSize should be applied by redrawing the line (when ResizeStyle (see page 1513) is rsLine) or resizing the associated control (when ResizeStyle (see page 1513) is rsUpdate);

Unless an OnCanResize (see page 1517) event handler sets the value of NewSize and the return value, CanResize returns true without changing the NewSize parameter.

Note: CanResize is not called if the value of ResizeStyle (see page 1513) is rsNone when the user presses the mouse button.

See Also

OnCanResize (see page 1517)

ResizeStyle (see page 1513)

DoCanResize (see page 1496)

3.1.45.4.2 TSplitter.DoCanResize Method

Generates an OnCanResize (see page 1517) event and enforces the MinSize (see page 1511) property.

Pascal

```
function DoCanResize(var NewSize: Integer): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean DoCanResize(int NewSize);
```

Description

DoCanResize is called automatically when the user moves the mouse after pressing the mouse button on the splitter. The NewSize parameter indicates the size the associated control will have if the splitter is allowed to perform the resize. DoCanResize returns a boolean value that indicates whether the value specified by NewSize should be applied by redrawing the line (when ResizeStyle (see page 1513) is rsLine) or resizing the associated control (when ResizeStyle (see page 1513) is rsUpdate).

DoCanResize calls CanResize (see page 1496) to generate an OnCanResize (see page 1517) event. If, after calling the event handler, NewSize is less than the value of MinSize (see page 1511), NewSize is changed to zero.

Note: DoCanResize is not called if the value of ResizeStyle (see page 1513) is rsNone when the user presses the mouse button.

3.1.45.4.3 TSplitter.MouseDown Method

Dynamically locates the control that can be resized by the splitter.

Pascal

```
procedure MouseDown(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer);
override;
```

C++

```
virtual __fastcall MouseDown(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

After calling the parent class's method, MouseDown locates the control that it is about to resize. Because this control is located dynamically, an application can delete or add aligned controls beside a splitter at runtime and the splitter will resize whichever control is currently beside it.

See Also

MouseDown

MouseMove (see page 1497)

MouseUp (see page 1497)

3.1.45.4.4 TSplitter.MouseMove Method

Provides visual feedback of how the neighboring control would be resized.

Pascal

```
procedure MouseMove(Shift: TShiftState; X: Integer; Y: Integer); override;
```

C++

```
virtual __fastcall MouseMove(TShiftState Shift, int X, int Y);
```

Description

After calling the inherited method, MouseMove computes the new boundaries of the neighboring control and draws a line where the new edge would be. The control is not actually resized until the mouse is released.

See Also

OnCanResize (see page 1517)

ResizeStyle (see page 1513)

CanResize (see page 1496)

MinSize (see page 1511)

MouseMove

MouseDown (see page 1497)

MouseUp (see page 1497)

3.1.45.4.5 TSplitter.MouseUp Method

Resizes the neighboring control when the user releases the mouse.

Pascal

```
procedure MouseUp(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer); override;
```

C++

```
virtual __fastcall MouseUp(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

After calling the inherited method, MouseUp resizes the neighboring control that was located when the mouse went down. After the control is resized, MouseUp generates an OnMoved (see page 1517) event.

See Also

MouseUp

MouseDown (see page 1497)

MouseMove (see page 1497)

3.1.45.4.6 TSplitter.Paint Method

Draws the image of the splitter.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

The Paint method is called automatically when the splitter receives WM_PAINT (see page 5198) messages from its Parent. Paint draws the background color of the splitter, and if Beveled (see page 1503) is true, draws a bevel along the movable edges. After drawing the background and bevel, Paint generates an OnPaint (see page 1520) event.

See Also

Beveled (see page 1503)

Color

Parent

OnPaint (see page 1520)

3.1.45.4.7 TSplitter.RequestAlign Method

Changes the cursor when the alignment of the splitter changes.

Pascal

```
procedure RequestAlign; override;
```

C++

```
virtual __fastcall RequestAlign();
```

Description

RequestAlign changes the cursor from crHSplit to crVSplit when the Align (see page 1499) property changes to alBottom or alTop. It changes the cursor from crVSplit to crHSplit when the Align (see page 1499) property changes to any other value.

If the Cursor (see page 1507) property is not crHSplit or crVSplit, RequestAlign has no effect.

Override RequestAlign to suppress the automatic cursor change or to implement a different association between alignment and the splitter's cursor.

See Also

Align

Cursor

3.1.45.4.8 TSplitter.StopSizing Method

Cleans up after the splitter has resized its neighboring control.

Pascal

```
procedure StopSizing; dynamic;
```

C++

```
__fastcall StopSizing();
```

Description

This protected procedure is called when the user releases the mouse or hits the Escape key while using the splitter to resize a control. StopSizing makes sure that the resize line is no longer visible and generates an OnMoved (see page 1517) event.

See Also

OnMoved (see page 1517)

3.1.45.5 TSplitter Properties

The properties of the TSplitter class are listed here.

Public Properties

	Name	Description
	Canvas (see page 1504)	Provides the drawing surface used by the graphic control.

Published Properties

	Name	Description
	Align (see page 1499)	Determines how the control aligns within its container (parent control).
	AutoSnap (see page 1503)	Determines whether neighboring objects are resized to zero when the splitter is used to make them smaller than MinSize (see page 1511).
	Beveled (see page 1503)	Determines whether the splitter looks beveled along the edge that moves.
	Color (see page 1506)	Specifies the background color of the control.
	Constraints (see page 1507)	Specifies the size constraints for the control.
	Cursor (see page 1507)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	MinSize (see page 1511)	Specifies the minimum size, in pixels, of the panes on either side of the splitter.
	ParentColor (see page 1512)	Determines where a control looks for its color information.
	ResizeStyle (see page 1513)	Specifies the effect of moving the splitter.
	Visible (see page 1514)	Determines whether the component appears onscreen.
	Width (see page 1515)	Specifies the horizontal size of the control or form in pixels.

3.1.45.5.1 TSplitter.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;
```

```
  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
```

```
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane - a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
}

var
  I: Integer;

procedure TForm1.Button1Click(Sender: TObject);
var
  ProgressBar: TProgressBar;
begin
  ProgressBar := TProgressBar.Create(Self);
  with ProgressBar do
  begin
    Parent := Self;
    Align := alBottom;
  end;
end;
{
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
}
var
  PageControl1: TPageControl;
  pts: array[0..3] of TTabSheet;
const
  TabTitles: array[0..3] of ShortString = ('Customer', 'Orders', 'Items', 'Parts' );

procedure TForm1.FormCreate(Sender: TObject);
const
  colorpalette: Array[0..11] of TColor = (
    clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia, clTeal,
    clNavy, clMaroon, clLime, clOlive, clPurple);
var
  i: Integer;
begin
  PageControl1 := TPageControl.Create(Self);
  PageControl1.Parent := Self;
  PageControl1.Align := alClient;
  for i := Low(TabTitles) to High(TabTitles) do
  begin
    pts[i]:= TTabSheet.Create(PageControl1);
    with pts[i] do
```

```
      begin
        PageControl := PageControl1;
        Name := 'ts' + TabTitles[i];
        Caption := TabTitles[i];
        Brush.Color := colorPalette[i];
     end;
    end;
  end;

  procedure TForm1.FormDestroy(Sender: TObject);
  var
    i: Integer;
  begin
    for i := Low(TabTitles) to High(TabTitles) do
    begin
      pts[i].Free;
    end;
    PageControl1.Free;
  end;
```

See Also

Parent

Anchors

3.1.45.5.2 TSplitter.AutoSnap Property

Determines whether neighboring objects are resized to zero when the splitter is used to make them smaller than MinSize (see page 1511).

Pascal

```
property AutoSnap: Boolean;
```

C++

```
__property Boolean AutoSnap;
```

Description

Set AutoSnap to false to prevent the splitter from resizing neighboring objects to zero when the user tries to make them smaller than MinSize (see page 1511). When AutoSnap is false, such resize attempts are simply blocked, leaving the neighboring object with a size of MinSize (see page 1511). The default value of AutoSnap is true.

See Also

MinSize (see page 1511)

3.1.45.5.3 TSplitter.Beveled Property

Determines whether the splitter looks beveled along the edge that moves.

Pascal

```
property Beveled: Boolean;
```

C++

```
__property Boolean Beveled;
```

Description

Set Beveled to false to remove the beveled edges from the splitter. Set Beveled to true to give the edge a 3D beveled look.

The bevel on a splitter runs in a single direction only: along the edges the user moves to resize neighboring objects. Thus, if the

Align (see page 1499) property is alLeft or alRight, the vertical edges of the splitter are beveled. If the Align (see page 1499) property is alTop or alBottom, the horizontal edges of the splitter are beveled. The default value of Beveled is false.

See Also

Align

3.1.45.5.4 TSplitter.Canvas Property

Provides the drawing surface used by the graphic control.

Pascal

```
property Canvas;
```

C++

```
__property Canvas;
```

Description

Use the properties of the TCanvas object to draw or paint on the surface of the control.

Since a TGraphicControl instance does not have its own Windows screen object, it obtains its device context from its parent control.

C++ Examples:

```
/*
When you do custom drawing, such as shown in the code for
the Button's OnClick event handler below, this drawing will
not be persistent and will be "erased" the first time the
PaintBox component needs to repaint.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
   PaintBox1->Canvas->Brush->Color = clRed;
   PaintBox1->Canvas->FillRect(PaintBox1->Canvas->ClipRect);
   PaintBox1->Canvas->Ellipse(0,0,100,100);
}

/*
In order for the drawing to be persistent, you need to also
include an OnPaint event handler that tells the PaintBox how
to redraw itself when it needs to. In the code below, an
ellipse will be drawn everytime the PaintBox renders itself,
but the PaintBox will only paint the client area of the
control red after the Button is clicked. This client area
will only stay red until it is invalidated, but the ellipse
will persist. This behavior is different from the TImage
component, because the TImage component maintains an
internal bitmap that stores this drawing information for
you.
*/
void __fastcall TForm1::PaintBox1Paint(TObject *Sender)
{
   PaintBox1->Canvas->Brush->Color = clBlue;
   PaintBox1->Canvas->Ellipse(0,0,100,100);
}
/*
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
*/
```

```
{
  TPoint APoint = Point(X, Y);
  int Index = ListBox1->ItemAtPos(APoint, True);
  TLabel *myLabel;
  TClass ClassRef = ListBox1->Items->Objects[Index]->ClassType();
  if (String(ClassRef->ClassName()) == "TLabel")
  {
    myLabel = dynamic_cast<TLabel *>(ListBox1->Items->Objects[Index]);
    // make sure we are using the TControls canvas and not the from's!
    myLabel->Canvas->MoveTo(myLabel->ClientRect.Left, myLabel->ClientRect.Top);
    myLabel->Canvas->LineTo(myLabel->ClientRect.Right, myLabel->ClientRect.Bottom);
    myLabel = NULL;
  }
}
/*
The following code draws the graphic in Picture1 in the
top-left corner PaintBox1.  Place a TPaintBox in the form
and a TImage in the form that contains a picture.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  PaintBox1->Canvas->Draw(0,0, Image1->Picture->Graphic);
}
```

Delphi Examples:

```
{
When you do custom drawing, such as shown in the code for
the Button's OnClick event handler below, this drawing will
not be persistent and will be "erased" the first time the
PaintBox component needs to repaint.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   PaintBox1.Canvas.Brush.Color := clRed;
   PaintBox1.Canvas.FillRect(PaintBox1.Canvas.ClipRect);
   PaintBox1.Canvas.Brush.Color := clBlue;
   PaintBox1.Canvas.Ellipse(0,0,100,50);
end;
{
In order for the drawing to be persistent, you need to also
include an OnPaint event handler that tells the PaintBox how
to redraw itself when it needs to. In the code below, an
ellipse will be drawn everytime the PaintBox renders itself,
but the PaintBox will only paint the client area of the
control red after the Button is clicked. This client area
will only stay red until it is invalidated, but the ellipse
will persist. This behavior is different from the TImage
component, because the TImage component maintains an
internal bitmap that stores this drawing information for
you.
}
procedure TForm1.PaintBox1Paint(Sender: TObject);
begin
   PaintBox1.Canvas.Brush.Color := clBlue;
   PaintBox1.Canvas.Ellipse(0,0,100,50);
end;
{
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
}
  if (ListBox1.Items.Objects[Index] is TLabel) then
  begin
    myLabel:= (ListBox1.Items.Objects[Index] as TLabel);
```

```
    with myLabel.ClientRect do
    begin // make sure we are using the TControl's canvas and not the form's!
      myLabel.Canvas.MoveTo(Left, Top);
      myLabel.Canvas.LineTo(Right, Bottom);
    end;
  myLabel:= nil;
  end;
{
The following code draws the graphic in Picture1 in the
top-left corner PaintBox1.  Place a TPaintBox in the form
and a TImage in the form that contains a picture.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  PaintBox1.Canvas.Draw(0,0, Image1.Picture.Graphic);
end;
```

3.1.45.5.5 TSplitter.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
```

```
end;
```

See Also

ParentColor

3.1.45.5.6 TSplitter.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

AutoSize

Align

Anchors

OnConstrainedResize

OnCanResize

3.1.45.5.7 TSplitter.Cursor Property

Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.

Pascal

```
property Cursor;
```

C++

```
__property Cursor;
```

Description

Change the value of Cursor to provide feedback to the user when the mouse pointer enters the control. The value of Cursor is the index of the cursor in the list of cursors maintained by the global variable, Screen. In addition to the built-in cursors provided by TScreen, applications can add custom cursors to the list.

C++ Examples:

```
/*
```

```
  This example uses a splitter and two image controls to
  create a "slide show" effect.  The example displays an image
  (the current "slide"), which can be hidden behind a screen
  that looks like a venetian blind. When the blind is pulled
  down to completely cover the current slide, the slide changes
  to a different image.  When the blind is raised, the new
  image appears.
  To prepare this example, follow these steps:
  1. Place an image control on the form.
  Set the picture property to a bitmap of a venetian blind,
  Set the Stretch property to True.
  Set the Align property to alTop.
  2. Add a splitter control to the form.
  Set the Align property to alTop.
  Set the Cursor property to crVSplit.
  Set the OnMoved event handler to the code that appears below.
  Set the MinSize property to 1.
  3. Add a second image control to the form.
  Set the Align property to alClient.
  Set the Stretch property to True.
  4. Select the form and add the OnCreate and OnDestroy event
     handlers that appear below.
  5. Add the global variables below to the unit.
  */
  int CurImage;
  Graphics::TBitmap *BMPs[5];

3.1.45.5.8 TSplitter.MinSize Property

Specifies the minimum size, in pixels, of the panes on either side of the splitter.

Pascal

```
property MinSize: NaturalNumber;
```

C++

```
__property NaturalNumber MinSize;
```

Description

Set MinSize to provide a minimum size the splitter must leave when resizing its neighboring control. For example, if the Align (see page 1499) property is alLeft or alRight, the splitter cannot resize the regions to its left or right any smaller than MinSize pixels. If the Align (see page 1499) property is alTop or alBottom, the splitter cannot resize the regions above or below it any smaller than MinSize pixels. The default value of MinSize is 30.

Note: Always set MinSize to a value less than half the client width of its parent. When MinSize is half the client width of the splitter's parent, the splitter cannot move because to do so would be to resize one of the panes less than MinSize pixels.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);
```

```
  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
```

Delphi Examples:

```
{

Align

3.1.45.5.9 TSplitter.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

3.1.45.5.10 TSplitter.ResizeStyle Property

Specifies the effect of moving the splitter.

Pascal

```
property ResizeStyle: TResizeStyle;
```

C++

```
__property TResizeStyle ResizeStyle;
```

Description

Use ResizeStyle to determine what happens when the user moves the splitter with the mouse.

ResizeStyle can have one of the values in the following table:

Value	Meaning
rsNone	Moving the splitter with the mouse has no effect.
rsLine	A line is drawn indicating the new position of the splitter that would result if the user released the mouse at the current position. The splitter does not actually move and no controls are resized.
rsUpdate	The control against which the splitter is aligned is resized based on the current mouse position, and the splitter is moved to that position.
rsPattern	A pattern is drawn indicating the new position of the splitter that would result if the user released the mouse at the current position. The splitter does not actually move and no controls are resized. This is the default value for ResizeStyle.

OnCanResize (see page 1517)

OnMoved (see page 1517)

3.1.45.5.11 TSplitter.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;
```

```
procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;

3.1.45.5.12 TSplitter.Width Property

Specifies the horizontal size of the control or form in pixels.

Pascal

```
property Width;
```

C++

```
__property Width;
```

Description

Use the Width property to read or change the width of the control.

Note: For tab sheet controls, changing this property at runtime has no effect.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses

3.1.45.6 TSplitter Events

The events of the TSplitter class are listed here.

Published Events

	Name	Description
	OnCanResize (see page 1517)	Occurs when the user tries to move the splitter with the mouse.
	OnMoved (see page 1517)	Occurs after the user has retiled the form using the splitter.
	OnPaint (see page 1520)	Occurs when the splitter needs to draw itself.

3.1.45.6.1 TSplitter.OnCanResize Event

Occurs when the user tries to move the splitter with the mouse.

Pascal

```
property OnCanResize: TCanResizeEvent;
```

C++

```
__property TCanResizeEvent OnCanResize;
```

Description

Write an OnCanResize event handler to conditionally prevent the user from resizing neighboring components using the splitter.

The NewSize parameter indicates the size the associated control will have if the splitter is allowed to perform the resize. This value can be changed if the attempted resize can be partially allowed. The Accept parameter indicates whether the resize should be permitted at all. Set Accept to false to disallow any movement of the splitter.

See Also

OnMoved (see page 1517)

ResizeStyle (see page 1513)

3.1.45.6.2 TSplitter.OnMoved Event

Occurs after the user has retiled the form using the splitter.

Pascal

```
property OnMoved: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMoved;
```

Description

Write an OnMoved event handler to take specific action when the user finishes dragging the edge of the neighboring control using the splitter. For example, after resizing a control on the edge of the form, use an OnMoved event handler to update the layout of the new client area of the form. Use the ClientRect property of the form to determine the new size remaining.

C++ Examples:

```
/*
This example uses a splitter and two image controls to
create a "slide show" effect.  The example displays an image
(the current "slide"), which can be hidden behind a screen
that looks like a venetian blind. When the blind is pulled
down to completely cover the current slide, the slide changes
to a different image.  When the blind is raised, the new
image appears.
To prepare this example, follow these steps:
1. Place an image control on the form.
Set the picture property to a bitmap of a venetian blind,
Set the Stretch property to True.
Set the Align property to alTop.
2. Add a splitter control to the form.
Set the Align property to alTop.
Set the Cursor property to crVSplit.
Set the OnMoved event handler to the code that appears below.
Set the MinSize property to 1.
3. Add a second image control to the form.
Set the Align property to alClient.
Set the Stretch property to True.
4. Select the form and add the OnCreate and OnDestroy event
   handlers that appear below.
5. Add the global variables below to the unit.
*/

ClientRect

3.1.45.6.3 TSplitter.OnPaint Event

Occurs when the splitter needs to draw itself.

Pascal

```
property OnPaint: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnPaint;
```

Description

Write an OnPaint event handler to customize the appearance of the splitter. For example, use an OnPaint event handler to give a splitter the appearance of the splitters that appear in cool bar objects. Use the Canvas (see page 1504) property as a drawing surface for painting the splitter. Use the ClientRect property to determine the coordinates of the canvas on which to paint the splitter.

When a splitter object receives a WM_PAINT (see page 5198) message, it paints its background before generating the OnPaint event. If the Beveled (see page 1503) property is true, the beveled appearance will also be added before the OnPaint event. Most applications set Beveled (see page 1503) to false when using the OnPaint event to customize the appearance of the splitter.

Canvas

Beveled (see page 1503)

3.1.46 TTimer Class

TTimer encapsulates the Windows API timer functions.

Class Hierarchy

Pascal

```
[RootDesignerSerializerAttribute('', '', False)]
TTimer = class(TComponent);
```

C++

```
[RootDesignerSerializerAttribute('', '', False)]
class TTimer : public TComponent;
```

File

ExtCtrls

Description

TTimer is used to simplify calling the Windows API timer functions SetTimer and KillTimer, and to simplify processing the WM_TIMER (see page 5215) messages. Use one timer component for each timer in the application.

The execution of the timer occurs through its OnTimer (see page 1527) event. TTimer has an Interval (see page 1525) property that determines how often the timer's OnTimer (see page 1527) event occurs. Interval (see page 1525) corresponds to the parameter for the Windows API SetTimer function.

Warning: Caution:Limitations on the total number of timers system-wide are system dependent.

3.1.46.1 TTimer Members

The following tables list the members exposed by TTimer.

Protected Methods

	Name	Description
	Timer (see page 1522)	This is Timer, a member of class TTimer.

Public Methods

	Name	Description
	Create (see page 1521)	Instantiates a timer object.
	Destroy (see page 1522)	Disposes of a timer object.

Published Events

	Name	Description
	OnTimer (see page 1527)	Occurs when a specified amount of time, determined by the Interval (see page 1525) property, has passed.

Published Properties

	Name	Description
	Enabled (see page 1523)	Controls whether the timer generates OnTimer (see page 1527) events periodically.
	Interval (see page 1525)	Determines the amount of time, in milliseconds, that passes before the timer component initiates another OnTimer (see page 1527) event.

3.1.46.2 TTimer.Create Constructor

Instantiates a timer object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TTimer(TComponent * AOwner);
```

Description

Call Create to instantiate a timer at runtime. Timers added to forms or data modules at design time are created automatically.

AOwner specifies the component, typically a form or data module, that is responsible for freeing the timer.

See Also

Owner

3.1.46.3 TTimer.Destroy Destructor

Disposes of a timer object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TTimer();
```

Description

Do not call Destroy directly in an application. Instead, an application should call Free. Free verifies that the timer is not nil before it calls Destroy.

Destroy deactivates the timer by setting Enabled (see page 1523) to False before freeing the resources required by the timer.

See Also

Create (see page 1521)

3.1.46.4 TTimer Methods

The methods of the TTimer class are listed here.

Protected Methods

	Name	Description
	Timer (see page 1522)	This is Timer, a member of class TTimer.

3.1.46.4.1 TTimer.Timer Method

Pascal

```
procedure Timer; dynamic;
```

C++

```
__fastcall Timer();
```

Description

This is Timer, a member of class TTimer.

3.1.46.5 TTimer Properties

The properties of the TTimer class are listed here.

Published Properties

	Name	Description
	Enabled (see page 1523)	Controls whether the timer generates OnTimer (see page 1527) events periodically.

	Interval (see page 1525)	Determines the amount of time, in milliseconds, that passes before the timer component initiates another OnTimer (see page 1527) event.

3.1.46.5.1 TTimer.Enabled Property

Controls whether the timer generates OnTimer (see page 1527) events periodically.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to enable or disable the timer. If Enabled is true, the timer responds normally. If Enabled is false, the timer does not generate OnTimer (see page 1527) events. The default is true.

C++ Examples:

```
/*
This example uses a timer on a form. When the application
runs and the user minimizes the application, the timer
starts and the application returns to its normal size when
an OnTimer event occurs.  The timer then shuts down until
the next time the form is minimized.  Be sure to declare the
AppStartTimer method as a public method of TForm1.  Place a
TTimer object in the form and enter Timer1Timer in the OnTimer
event.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnMinimize = AppStartTimer;
  Timer1->Interval = 1000;
}

void __fastcall TForm1::AppStartTimer(TObject *Sender)
{
  Timer1->Enabled = true;
}

//---------------------------------------------------------------------------
void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  Application->Restore();
  Timer1->Enabled = false;
}
/*
This code ejects the CD from the CD-ROM player and shuts
down the media player after 10 seconds. For the code to run
correctly, you must have your CD audio device installed
correctly, and the device must have software-ejecting
capabilities.
*/

Word TimeOver;

void __fastcall TForm1::FormClick(TObject *Sender)
{
  MediaPlayer1->DeviceType = dtCDAudio;
  MediaPlayer1->Open();
  MediaPlayer1->Play();
  Timer1->Enabled = true;
  TimeOver = 0;
```

```
}

void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  if (TimeOver == 10)
  {
    MediaPlayer1->Eject();
    MediaPlayer1->Close();
    // disable the timer, as we are done
    Timer1->Enabled = false;
  }
  else
    TimeOver++;
}
```

Delphi Examples:

```
{
This example uses a timer on a form. When the application
runs and the user minimizes the application, the timer
starts and the application returns to its normal size when
an OnTimer event occurs.  The timer then shuts down until
the next time the form is minimized.  Be sure to declare the
AppStartTimer method as a public method of TForm1.  Place a
TTimer object in the form and enter Timer1Timer in the OnTimer
event.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnMinimize := AppStartTimer;
end;

procedure TForm1.AppStartTimer(Sender: TObject);
begin
  Timer1.Enabled := True;
end;

procedure TForm1.Timer1Timer(Sender: TObject);
begin
  Application.Restore;
  Timer1.Enabled := False;
end;
{
This code ejects the CD from the CD-ROM player and shuts
down the media player after 10 seconds. For the code to run
correctly, you must have your CD audio device installed
correctly, and the device must have software-ejecting
capabilities.
}
var
  TimerOver: Word;

procedure TForm1.FormClick(Sender: TObject);
begin
  MediaPlayer1.DeviceType := dtCDAudio;
  MediaPlayer1.Open;
  MediaPlayer1.Play;
end;

procedure TForm1.Timer1Timer(Sender: TObject);
begin
  if TimeOver = 10 then
  begin
    MediaPlayer1.Eject;
    MediaPlayer1.Close;
    { disable the timer, as we are done }
    Timer1.Enabled := False;
```

```
    end
    else
      if (MediaPlayer1.Mode = mpOpen) then
       Inc(TimeOver);
end;
```

See Also

OnTimer (see page 1527)

3.1.46.5.2 TTimer.Interval Property

Determines the amount of time, in milliseconds, that passes before the timer component initiates another OnTimer (see page 1527) event.

Pascal

```
property Interval: Cardinal;
```

C++

```
__property unsigned Interval;
```

Description

Interval determines how frequently the OnTimer (see page 1527) event occurs. Each time the specified interval passes, the OnTimer (see page 1527) event occurs.

Use Interval to specify any cardinal value as the interval between OnTimer (see page 1527) events. The default value is 1000 (one second).

Note: A 0 value is valid, however the timer will not call an OnTimer (see page 1527) event for a value of 0.

C++ Examples:

```
/*
Place a TTimer object in the form and enter Timer1Timer in
the OnTimer event.  Place other controls in the form and
change the active control at runtime.  The following event
handler responds to timer events by moving the active control
one pixel to the right every 100 miliseconds:
*/
void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  Timer1->Interval = 100;
  if (ActiveControl)
    ActiveControl->Left = ActiveControl->Left + 1;
}
/*
This code uses a button, a timer and a maskedit on a
form. When the user clicks the button, the form
disappears for the period of time specified in the
Interval property of the timer control, then the form
reappears:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Timer1->Interval = StrToInt(MaskEdit1->Text);
  Timer1->Enabled = true;
  Hide();
}

void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
```

```
  Visible = true;
  Timer1->Enabled = false;
}
/*
This example uses a timer on a form. When the application
runs and the user minimizes the application, the timer
starts and the application returns to its normal size when
an OnTimer event occurs.  The timer then shuts down until
the next time the form is minimized.  Be sure to declare the
AppStartTimer method as a public method of TForm1.  Place a
TTimer object in the form and enter Timer1Timer in the OnTimer
event.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnMinimize = AppStartTimer;
  Timer1->Interval = 1000;
}

void __fastcall TForm1::AppStartTimer(TObject *Sender)
{
  Timer1->Enabled = true;
}

//---------------------------------------------------------------------------
void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  Application->Restore();
  Timer1->Enabled = false;
}
```

Delphi Examples:

```
{
Place a TTimer object in the form and enter Timer1Timer in
the OnTimer event.  Place other controls in the form and
change the active control at runtime.  The following event
handler responds to timer events by moving the active control
one pixel to the right every 100 miliseconds:
}
procedure TForm1.Timer1Timer(Sender: TObject);
begin
  Timer1.Interval := 100;
  if ActiveControl <> nil then
    ActiveControl.Left := ActiveControl.Left + 1;
end;
{
This code uses a button, a timer and a maskedit on a
form. When the user clicks the button, the form
disappears for the period of time specified in the
Interval property of the timer control, then the form
reappears:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Timer1.Interval := StrtoInt(MaskEdit1.Text);
  Timer1.Enabled := True;
  Hide;
end;

procedure TForm1.Timer1Timer(Sender: TObject);
begin
  Visible := True;
  Timer1.Enabled := False;
end;
{
This example uses a timer on a form. When the application
```

```
runs and the user minimizes the application, the timer
starts and the application returns to its normal size when
an OnTimer event occurs.  The timer then shuts down until
the next time the form is minimized.  Be sure to declare the
AppStartTimer method as a public method of TForm1.  Place a
TTimer object in the form and enter Timer1Timer in the OnTimer
event.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnMinimize := AppStartTimer;
end;

procedure TForm1.AppStartTimer(Sender: TObject);
begin
  Timer1.Enabled := True;
end;

procedure TForm1.Timer1Timer(Sender: TObject);
begin
  Application.Restore;
  Timer1.Enabled := False;
end;
```

OnTimer (see page 1527)

3.1.46.6 TTimer Events

The events of the TTimer class are listed here.

Published Events

	Name	Description
	OnTimer (see page 1527)	Occurs when a specified amount of time, determined by the Interval (see page 1525) property, has passed.

3.1.46.6.1 TTimer.OnTimer Event

Occurs when a specified amount of time, determined by the Interval (see page 1525) property, has passed.

Pascal

```
property OnTimer: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnTimer;
```

Description

Write an OnTimer event handler to execute an action at regular intervals.

The Interval (see page 1525) property of a timer determines how frequently the OnTimer event occurs. Each time the specified interval passes, the OnTimer event occurs.

C++ Examples:

```
/*
Place a TTimer object in the form and enter Timer1Timer in
the OnTimer event.  Place other controls in the form and
change the active control at runtime.  The following event
handler responds to timer events by moving the active control
one pixel to the right every 100 miliseconds:
```

```
*/
void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  Timer1->Interval = 100;
  if (ActiveControl)
    ActiveControl->Left = ActiveControl->Left + 1;
}
```

Delphi Examples:

```
{
Place a TTimer object in the form and enter Timer1Timer in
the OnTimer event.  Place other controls in the form and
change the active control at runtime.  The following event
handler responds to timer events by moving the active control
one pixel to the right every 100 miliseconds:
}
procedure TForm1.Timer1Timer(Sender: TObject);
begin
  Timer1.Interval := 100;
  if ActiveControl <> nil then
    ActiveControl.Left := ActiveControl.Left + 1;
end;
```

Interval (see page 1525)

3.1.47 TTrayIcon Class

Creates an icon in the system tray next to the clock.

Class Hierarchy

Pascal

```
TTrayIcon = class(TCustomTrayIcon);
```

C++

```
class TTrayIcon : public TCustomTrayIcon;
```

File

ExtCtrls

Description

Use the TTrayIcon component to create an icon in the system tray next to the clock. TTrayIcon has events for mouse clicks, properties for menus and animation of the icon, and methods for showing balloon hints.

3.1.47.1 TTrayIcon Members

The following tables list the members exposed by TTrayIcon.

Protected Methods

	Name	Description
	DoOnAnimate (see page 825)	This is DoOnAnimate, a member of class TCustomTrayIcon.
	GetAnimateInterval (see page 825)	This is GetAnimateInterval, a member of class TCustomTrayIcon.

	GetBalloonTimeout (see page 825)	This is GetBalloonTimeout, a member of class TCustomTrayIcon.
V	Notification (see page 826)	Forwards notification messages to all owned components.
	SetAnimate (see page 827)	This is SetAnimate, a member of class TCustomTrayIcon.
	SetAnimateInterval (see page 827)	This is SetAnimateInterval, a member of class TCustomTrayIcon.
	SetBalloonHint (see page 827)	This is SetBalloonHint, a member of class TCustomTrayIcon.
	SetBalloonTimeout (see page 827)	This is SetBalloonTimeout, a member of class TCustomTrayIcon.
	SetBalloonTitle (see page 828)	This is SetBalloonTitle, a member of class TCustomTrayIcon.
	SetHint (see page 828)	This is SetHint, a member of class TCustomTrayIcon.
	SetIcon (see page 828)	This is SetIcon, a member of class TCustomTrayIcon.
V	SetIconIndex (see page 828)	This is SetIconIndex, a member of class TCustomTrayIcon.
	SetIconList (see page 829)	This is SetIconList, a member of class TCustomTrayIcon.
V	SetVisible (see page 829)	This is SetVisible, a member of class TCustomTrayIcon.
V	WindowProc (see page 829)	This is WindowProc, a member of class TCustomTrayIcon.

Protected Properties

	Name	Description
R	Data (see page 832)	This is Data, a member of class TCustomTrayIcon.

Public Methods

	Name	Description
V	Create (see page 824)	Creates and initializes a TCustomTrayIcon (see page 822) instance.
V	Destroy (see page 824)	Frees the memory associated with the TCustomTrayIcon (see page 822) object.
	Refresh (see page 826)	This is the overview for the Refresh method overload.
	SetDefaultIcon (see page 828)	Sets the tray icon to the default application icon.
V	ShowBalloonHint (see page 829)	Displays the balloon hint.

Published Events

	Name	Description
	OnAnimate (see page 1533)	Occurs each time the icon changes when the tray icon is animating.
	OnBalloonClick (see page 1534)	This is OnBalloonClick, a member of class TTrayIcon.
	OnClick (see page 1534)	Occurs when the user clicks the tray icon.
	OnDblClick (see page 1534)	Occurs when the user double clicks the tray icon.
	OnMouseDown (see page 1534)	Occurs when the user presses a mouse button while the mouse pointer is over a control.
	OnMouseMove (see page 1535)	Occurs when the user moves the mouse pointer while the mouse pointer is over the tray icon.
	OnMouseUp (see page 1535)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Published Properties

	Name	Description
	Animate (see page 1530)	Specifies whether the icon in the system tray is static or animated.
	AnimateInterval (see page 1530)	Controls the length of time between image changes for the tray icon image.
	BalloonFlags (see page 1530)	Specifies an icon for the balloon hint.
	BalloonHint (see page 1531)	Specifies the text within a balloon hint.
	BalloonTimeout (see page 1531)	Specifies the length of time that the balloon displays.
	BalloonTitle (see page 1531)	Specifies the text that appears as the balloon title.
	Hint (see page 1532)	Specifies the text that appears when the user moves the mouse over the control.
	Icon (see page 1532)	Specifies the default icon shown in the system tray.
	IconIndex (see page 1532)	This is an index into the Icons image list which is the icon currently being displayed in the system tray.
	Icons (see page 1532)	Specifies the list of images to be displayed for the icon in the system tray.
	PopupMenu (see page 1533)	Identifies the pop-up menu associated with the tray icon.
	Visible (see page 1533)	Determines whether the icon appears in the system tray.

3.1.47.2 TTrayIcon Properties

The properties of the TTrayIcon class are listed here.

Published Properties

	Name	Description
	Animate (see page 1530)	Specifies whether the icon in the system tray is static or animated.
	AnimateInterval (see page 1530)	Controls the length of time between image changes for the tray icon image.
	BalloonFlags (see page 1530)	Specifies an icon for the balloon hint.
	BalloonHint (see page 1531)	Specifies the text within a balloon hint.
	BalloonTimeout (see page 1531)	Specifies the length of time that the balloon displays.
	BalloonTitle (see page 1531)	Specifies the text that appears as the balloon title.
	Hint (see page 1532)	Specifies the text that appears when the user moves the mouse over the control.
	Icon (see page 1532)	Specifies the default icon shown in the system tray.
	IconIndex (see page 1532)	This is an index into the Icons image list which is the icon currently being displayed in the system tray.
	Icons (see page 1532)	Specifies the list of images to be displayed for the icon in the system tray.
	PopupMenu (see page 1533)	Identifies the pop-up menu associated with the tray icon.
	Visible (see page 1533)	Determines whether the icon appears in the system tray.

3.1.47.2.1 TTrayIcon.Animate Property

Specifies whether the icon in the system tray is static or animated.

Pascal

```
property Animate: Boolean;
```

C++

```
__property Boolean Animate;
```

Description

When set to True, the icon shown in the system tray displays, in sequence, the images in the image list specified by the Icons property. The images change only if the specified image list contains images. The images change on a rotating basis by the interval set by the AnimateInterval property. When set to False the animation stops.

3.1.47.2.2 TTrayIcon.AnimateInterval Property

Controls the length of time between image changes for the tray icon image.

Pascal

```
property AnimateInterval: Cardinal;
```

C++

```
__property unsigned AnimateInterval;
```

Description

Use AnimateInterval to specify the length of time between image changes in the tray icon. The default interval is 1000 ms (1 second).

3.1.47.2.3 TTrayIcon.BalloonFlags Property

Specifies an icon for the balloon hint.

Pascal

```
property BalloonFlags: TBalloonFlags;
```

C++

```
__property TBalloonFlags BalloonFlags;
```

Description

The following values specify an icon to be displayed in the balloon hint:

- bfNone
- bfInfo
- bfWarning
- bfError

3.1.47.2.4 TTrayIcon.BalloonHint Property

Specifies the text within a balloon hint.

Pascal

```
property BalloonHint: string;
```

C++

```
__property UnicodeString BalloonHint;
```

Description

Use BalloonHint to specify the text string that appears when a balloon hint is shown.

3.1.47.2.5 TTrayIcon.BalloonTimeout Property

Specifies the length of time that the balloon displays.

Pascal

```
property BalloonTimeout: Integer;
```

C++

```
__property int BalloonTimeout;
```

Description

Use BalloonTimeout to set the length of time that a balloon displays. By default, this value is set to 3000 ms (3 seconds).

3.1.47.2.6 TTrayIcon.BalloonTitle Property

Specifies the text that appears as the balloon title.

Pascal

```
property BalloonTitle: string;
```

C++

```
__property UnicodeString BalloonTitle;
```

Description

Specifies the text that appears as the balloon title.

3.1.47.2.7 TTrayIcon.Hint Property

Specifies the text that appears when the user moves the mouse over the control.

Pascal

```
property Hint: string;
```

C++

```
__property UnicodeString Hint;
```

Description

Specifies the text that appears when the user moves the mouse over the control.

3.1.47.2.8 TTrayIcon.Icon Property

Specifies the default icon shown in the system tray.

Pascal

```
property Icon: TIcon;
```

C++

```
__property TIcon Icon;
```

Description

Use the Icon property to set the default icon to be shown in the system tray. If you do not specify a value, the application icon is used.

3.1.47.2.9 TTrayIcon.IconIndex Property

This is an index into the Icons image list which is the icon currently being displayed in the system tray.

Pascal

```
property IconIndex: Integer;
```

C++

```
__property int IconIndex;
```

Description

This is an index into the Icons image list which is the icon currently being displayed in the system tray.

3.1.47.2.10 TTrayIcon.Icons Property

Specifies the list of images to be displayed for the icon in the system tray.

Pascal

```
property Icons: TImageList;
```

C++

```
__property TImageList Icons;
```

Description

Use this property to specify the list of images used for the icon in the system tray. These images are displayed when the Animate property is set to True.

3.1.47.2.11 TTrayIcon.PopupMenu Property

Identifies the pop-up menu associated with the tray icon.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Use PopupMenuOn to specify when the menu is displayed.

3.1.47.2.12 TTrayIcon.Visible Property

Determines whether the icon appears in the system tray.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Determines whether the icon appears in the system tray.

3.1.47.3 TTrayIcon Events

The events of the TTrayIcon class are listed here.

Published Events

	Name	Description
	OnAnimate (see page 1533)	Occurs each time the icon changes when the tray icon is animating.
	OnBalloonClick (see page 1534)	This is OnBalloonClick, a member of class TTrayIcon.
	OnClick (see page 1534)	Occurs when the user clicks the tray icon.
	OnDblClick (see page 1534)	Occurs when the user double clicks the tray icon.
	OnMouseDown (see page 1534)	Occurs when the user presses a mouse button while the mouse pointer is over a control.
	OnMouseMove (see page 1535)	Occurs when the user moves the mouse pointer while the mouse pointer is over the tray icon.
	OnMouseUp (see page 1535)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

3.1.47.3.1 TTrayIcon.OnAnimate Event

Occurs each time the icon changes when the tray icon is animating.

Pascal

```
property OnAnimate: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnAnimate;
```

Description

Occurs each time the icon changes when the tray icon is animating.

3.1.47.3.2 TTrayIcon.OnBalloonClick Event

Pascal

```
property OnBalloonClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnBalloonClick;
```

Description

This is OnBalloonClick, a member of class TTrayIcon.

3.1.47.3.3 TTrayIcon.OnClick Event

Occurs when the user clicks the tray icon.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Occurs when the user clicks the tray icon.

3.1.47.3.4 TTrayIcon.OnDblClick Event

Occurs when the user double clicks the tray icon.

Pascal

```
property OnDblClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDblClick;
```

Description

Occurs when the user double clicks the tray icon.

3.1.47.3.5 TTrayIcon.OnMouseDown Event

Occurs when the user presses a mouse button while the mouse pointer is over a control.

Pascal

```
property OnMouseDown: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseDown;
```

Description

Occurs when the user presses a mouse button while the mouse pointer is over a control.

3.1.47.3.6 TTrayIcon.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over the tray icon.

Pascal

```
property OnMouseMove: TMouseMoveEvent;
```

C++

```
__property TMouseMoveEvent OnMouseMove;
```

Description

Occurs when the user moves the mouse pointer while the mouse pointer is over the tray icon.

3.1.47.3.7 TTrayIcon.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseUp;
```

Description

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

3.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	Frame3D (see page 1536)	Draws a three dimensional frame on a canvas.
	NotebookHandlesNeeded (see page 1537)	This is function ExtCtrls.NotebookHandlesNeeded.

3.2.1 ExtCtrls.Frame3D Function

Draws a three dimensional frame on a canvas.

Pascal

```
procedure Frame3D(Canvas: TCanvas; var Rect: TRect; TopColor: TColor; BottomColor: TColor;
Width: Integer);
```

C++

```
Frame3D(TCanvas Canvas, TRect Rect, TColor TopColor, TColor BottomColor, int Width);
```

File

ExtCtrls

Description

Use Frame3D to create three-dimensional effects when drawing directly on a canvas.

The Canvas parameter is the canvas to draw on.

The Rect parameter specifies the position on the canvas where the three-dimensional rectangle should appear. It returns the dimensions of the rectangle that lies inside the frame.

The TopColor and BottomColor parameters indicate the colors that appear on the left and top or the right and bottom of the rectangle respectively.

The Width parameter specifies the width of the frame.

To create a raised effect, the TopColor should be a light color and the BottomColor should be a shadow color. To create a depressed effect, the TopColor should be the shadow color and the BottomColor should be the light color. To create a beveled effect, draw a frame immediately inside another frame with the colors reversed.

3.2.2 ExtCtrls.NotebookHandlesNeeded Function

Pascal

```
procedure NotebookHandlesNeeded(Notebook: TNotebook);
```

C++

```
NotebookHandlesNeeded(TNotebook Notebook);
```

File

ExtCtrls

Description

This is function ExtCtrls.NotebookHandlesNeeded.

3.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TBalloonFlags (see page 1538)	A type specified when showing a balloon hint that puts one of the default icons on the balloon message.
	TBandDrawingStyle (see page 1539)	This is record ExtCtrls.TBandDrawingStyle.
	TBandPaintOption (see page 1539)	TBandPaintOption and TBandPaintOptions (see page 1549) specify which parts of a band are painted.
	TBevelShape (see page 1540)	TBevelShape determines the overall shape of a bevel control.
	TBevelStyle (see page 1541)	TBevelStyle indicates whether a bevel appears raised or lowered.
	TColorBoxStyles (see page 1541)	This is record ExtCtrls.TColorBoxStyles.
	TCornerEdge (see page 1542)	The size of the cornering for the edge of the bands in a TControlBar (see page 590).
	TExpandStyle (see page 1542)	Specifies how a grid panel expands.
	TFlowStyle (see page 1543)	This is record ExtCtrls.TFlowStyle.
	TLabelPosition (see page 1543)	TLabelPosition specifies the position of the label in a labeled edit control.
	TResizeStyle (see page 1544)	This is record ExtCtrls.TResizeStyle.
	TShapeType (see page 1544)	TShapeType determines the shape of a TShape (see page 1458) control.
	TSizeStyle (see page 1545)	This is record ExtCtrls.TSizeStyle.
	TSysLinkType (see page 1546)	TSysLinkType describes an HTML link type.

3.3.1 ExtCtrls.TBalloonFlags Enumeration

A type specified when showing a balloon hint that puts one of the default icons on the balloon message.

Pascal

```
TBalloonFlags = (
  bfNone = NIIF_NONE,
  bfInfo = NIIF_INFO,
  bfWarning = NIIF_WARNING,
  bfError = NIIF_ERROR
);
```

C++

```
enum TBalloonFlags {
  bfNone = NIIF_NONE,
  bfInfo = NIIF_INFO,
  bfWarning = NIIF_WARNING,
  bfError = NIIF_ERROR
};
```

File

ExtCtrls

Description

You can set TBalloonFlags to one of the following values:

- bfNone

- bfInfo
- bfWarning
- bfError

3.3.2 ExtCtrls.TBandDrawingStyle Enumeration

Pascal

```
TBandDrawingStyle = (
  dsNormal,
  dsGradient
);
```

C++

```
enum TBandDrawingStyle {
  dsNormal,
  dsGradient
};
```

File

ExtCtrls

Description

This is record ExtCtrls.TBandDrawingStyle.

3.3.3 ExtCtrls.TBandPaintOption Enumeration

TBandPaintOption and TBandPaintOptions (see page 1549) specify which parts of a band are painted.

Pascal

```
TBandPaintOption = (
  bpoGrabber,
  bpoFrame,
  bpoGradient,
  bpoRoundRect
);
```

C++

```
enum TBandPaintOption {
  bpoGrabber,
  bpoFrame,
  bpoGradient,
  bpoRoundRect
};
```

File

ExtCtrls

Description

TBandPaintOptions (see page 1549) has one or more of the following values:

Value	Meaning
bpoGrabber	The grabber is painted.
bpoFrame	The frame is painted.
bpoGradient	The gradient is painted.
bpoRoundRect	The round rectangle is painted.

3.3.4 ExtCtrls.TBevelShape Enumeration

TBevelShape determines the overall shape of a bevel control.

Pascal

```
TBevelShape = (
  bsBox,
  bsFrame,
  bsTopLine,
  bsBottomLine,
  bsLeftLine,
  bsRightLine,
  bsSpacer
);
```

C++

```
enum TBevelShape {
  bsBox,
  bsFrame,
  bsTopLine,
  bsBottomLine,
  bsLeftLine,
  bsRightLine,
  bsSpacer
};
```

File

ExtCtrls

Description

These are the possible values of the TBevelShape type:

Value	Meaning
bsBox	The entire client area appears raised or lowered.
bsFrame	The client area is outlined by a raised or lowered frame.
bsTopLine	The bevel displays a line at the top of the client area.
bsBottomLine	The bevel displays a line at the bottom of the client area.
bsLeftLine	The bevel displays a line at the left side of the client area.
bsRightLine	The bevel displays a line at the right side of the client area.
bsSpacer	The bevel is an empty space.

3.3.5 ExtCtrls.TBevelStyle Enumeration

TBevelStyle indicates whether a bevel appears raised or lowered.

Pascal

```
TBevelStyle = (
  bsLowered,
  bsRaised
);
```

C++

```
enum TBevelStyle {
  bsLowered,
  bsRaised
};
```

File

ExtCtrls

Description

These are the possible values of the TBevelStyle type:

Value	Meaning
bsLowered	The bevel is lowered.
bsRaised	The bevel is raised.

3.3.6 ExtCtrls.TColorBoxStyles Enumeration

Pascal

```
TColorBoxStyles = (
  cbStandardColors,
  cbExtendedColors,
  cbSystemColors,
  cbIncludeNone,
  cbIncludeDefault,
  cbCustomColor,
  cbPrettyNames,
  cbCustomColors
);
```

C++

```
enum TColorBoxStyles {
  cbStandardColors,
  cbExtendedColors,
  cbSystemColors,
  cbIncludeNone,
  cbIncludeDefault,
  cbCustomColor,
  cbPrettyNames,
  cbCustomColors
};
```

File

ExtCtrls

Description

This is record ExtCtrls.TColorBoxStyles.

3.3.7 ExtCtrls.TCornerEdge Enumeration

The size of the cornering for the edge of the bands in a TControlBar (see page 590).

Pascal

```
TCornerEdge = (
  ceNone,
  ceSmall,
  ceMedium,
  ceLarge
);
```

C++

```
enum TCornerEdge {
  ceNone,
  ceSmall,
  ceMedium,
  ceLarge
};
```

File

ExtCtrls

Description

This type contains the size of the cornering for the edge of the bands in a TControlBar (see page 590).

3.3.8 ExtCtrls.TExpandStyle Enumeration

Specifies how a grid panel expands.

Pascal

```
TExpandStyle = (
  emAddRows,
  emAddColumns,
  emFixedSize
);
```

C++

```
enum TExpandStyle {
  emAddRows,
  emAddColumns,
  emFixedSize
};
```

File

ExtCtrls

Description

Use TExpandStyle to specify whether a grid panel adds rows or columns when new controls are added.

3.3.9 ExtCtrls.TFlowStyle Enumeration

Pascal

```
TFlowStyle = (
  fsLeftRightTopBottom,
  fsRightLeftTopBottom,
  fsLeftRightBottomTop,
  fsRightLeftBottomTop,
  fsTopBottomLeftRight,
  fsBottomTopLeftRight,
  fsTopBottomRightLeft,
  fsBottomTopRightLeft
);
```

C++

```
enum TFlowStyle {
  fsLeftRightTopBottom,
  fsRightLeftTopBottom,
  fsLeftRightBottomTop,
  fsRightLeftBottomTop,
  fsTopBottomLeftRight,
  fsBottomTopLeftRight,
  fsTopBottomRightLeft,
  fsBottomTopRightLeft
};
```

File

ExtCtrls

Description

This is record ExtCtrls.TFlowStyle.

3.3.10 ExtCtrls.TLabelPosition Enumeration

TLabelPosition specifies the position of the label in a labeled edit control.

Pascal

```
TLabelPosition = (
  lpAbove,
  lpBelow,
  lpLeft,
  lpRight
);
```

C++

```
enum TLabelPosition {
  lpAbove,
  lpBelow,
  lpLeft,
  lpRight
```

```
};
```

File

ExtCtrls

Description

The following are possible values of TLabelPosition:

Value	Meaning
lpAbove	The label appears above the edit control.
lpBelow	The label appears below the edit control.
lpLeft	The label appears to the left of the edit control.
lpRight	The label appears to the right of the edit control.

3.3.11 ExtCtrls.TResizeStyle Enumeration

Pascal

```
TResizeStyle = (
  rsNone,
  rsLine,
  rsUpdate,
  rsPattern
);
```

C++

```
enum TResizeStyle {
  rsNone,
  rsLine,
  rsUpdate,
  rsPattern
};
```

File

ExtCtrls

Description

This is record ExtCtrls.TResizeStyle.

3.3.12 ExtCtrls.TShapeType Enumeration

TShapeType determines the shape of a TShape (see page 1458) control.

Pascal

```
TShapeType = (
  stRectangle,
  stSquare,
  stRoundRect,
  stRoundSquare,
  stEllipse,
  stCircle
```

```
);
```

C++

```
enum TShapeType {
  stRectangle,
  stSquare,
  stRoundRect,
  stRoundSquare,
  stEllipse,
  stCircle
};
```

File

ExtCtrls

Description

These are the possible values of the TShapeType type:

Value	Meaning
stCircle	The shape is a circle.
stEllipse	The shape is an ellipse.
stRectangle	The shape is a rectangle. (Default)
stRoundRect	The shape is a rectangle with rounded corners.
stRoundSquare	The shape is a square with rounded corners.
stSquare	The shape is a square.

3.3.13 ExtCtrls.TSizeStyle Enumeration

Pascal

```
TSizeStyle = (
  ssAbsolute,
  ssPercent,
  ssAuto
);
```

C++

```
enum TSizeStyle {
  ssAbsolute,
  ssPercent,
  ssAuto
};
```

File

ExtCtrls

Description

This is record ExtCtrls.TSizeStyle.

3.3.14 ExtCtrls.TSysLinkType Enumeration

TSysLinkType describes an HTML link type.

Pascal

```
TSysLinkType = (
  sltURL,
  sltID
);
```

C++

```
enum TSysLinkType {
  sltURL,
  sltID
};
```

File

ExtCtrls

Description

TSysLinkType is used in HTML link click events to identify the link type. These are the possible values of the TSysLinkType type:

Value	Meaning
sltURL	HREF link
sltID	ID

See Also

TCustomLinkLabel (see page 797)

OnLinkClick (see page 802)

TSysLinkEvent (see page 1555)

3.4 Types

The following table lists types in this documentation.

Types

Name	Description
NaturalNumber (see page 1547)	This is type ExtCtrls.NaturalNumber.
TBandDragEvent (see page 1548)	This is type ExtCtrls.TBandDragEvent.
TBandInfoEvent (see page 1548)	This is type ExtCtrls.TBandInfoEvent.
TBandMoveEvent (see page 1548)	This is type ExtCtrls.TBandMoveEvent.
TBandPaintEvent (see page 1549)	This is type ExtCtrls.TBandPaintEvent.
TBandPaintOptions (see page 1549)	This is type ExtCtrls.TBandPaintOptions.
TBeginBandMoveEvent (see page 1549)	This is type ExtCtrls.TBeginBandMoveEvent.
TCanResizeEvent (see page 1550)	This is type ExtCtrls.TCanResizeEvent.
TCategoryPanelClass (see page 1550)	This is type ExtCtrls.TCategoryPanelClass.
TCategoryPanelSurfaceClass (see page 1550)	This is type ExtCtrls.TCategoryPanelSurfaceClass.
TCellSpan (see page 1551)	This is type ExtCtrls.TCellSpan.
TColorBoxStyle (see page 1551)	TColorBoxStyle and TColorBoxStyles (see page 1541) specify how a color box control displays its selections.
TEditButtonClass (see page 1552)	This is type ExtCtrls.TEditButtonClass.
TEndBandMoveEvent (see page 1552)	This is type ExtCtrls.TEndBandMoveEvent.
TGetColorsEvent (see page 1552)	This is type ExtCtrls.TGetColorsEvent.
TLBGetColorsEvent (see page 1553)	This is type ExtCtrls.TLBGetColorsEvent.
TPanelBevel (see page 1553)	TPanelBevel specifies a bevel's cut.
TRowSize (see page 1554)	This is type ExtCtrls.TRowSize.
TSectionEvent (see page 1554)	TSectionEvent is the type of event handlers that respond when a section of a THeader (see page 1021) control is resized.
TSplitterCanResizeEvent (see page 1554)	This is type ExtCtrls.TSplitterCanResizeEvent.
TSysLinkEvent (see page 1555)	Event routine for click on TCustomLinkLabel (see page 797) HTML link.

3.4.1 ExtCtrls.NaturalNumber Type

Pascal

```
NaturalNumber = 1..High(Integer);
```

C++

```
1..High(Integer) NaturalNumber;
```

File

ExtCtrls

Description

This is type ExtCtrls.NaturalNumber.

3.4.2 ExtCtrls.TBandDragEvent Type

Pascal

```
TBandDragEvent = procedure (Sender: TObject; Control: TControl; var Drag: Boolean) of object;
```

C++

```
(Sender: TObject; Control: TControl; var Drag: Boolean) ( TBandDragEvent)();
```

File

ExtCtrls

Description

This is type ExtCtrls.TBandDragEvent.

3.4.3 ExtCtrls.TBandInfoEvent Type

Pascal

```
TBandInfoEvent = procedure (Sender: TObject; Control: TControl; var Insets: TRect; var
PreferredSize, RowCount: Integer) of object;
```

C++

```
(Sender: TObject; Control: TControl; var Insets: TRect; var PreferredSize, RowCount: Integer)
( TBandInfoEvent)();
```

File

ExtCtrls

Description

This is type ExtCtrls.TBandInfoEvent.

3.4.4 ExtCtrls.TBandMoveEvent Type

Pascal

```
TBandMoveEvent = procedure (Sender: TObject; Control: TControl; var ARect: TRect) of object;
```

C++

```
(Sender: TObject; Control: TControl; var ARect: TRect) ( TBandMoveEvent)();
```

File

ExtCtrls

Description

This is type ExtCtrls.TBandMoveEvent.

3.4.5 ExtCtrls.TBandPaintEvent Type

Pascal

```
TBandPaintEvent = procedure (Sender: TObject; Control: TControl; Canvas: TCanvas; var ARect:
TRect; var Options: TBandPaintOptions) of object;
```

C++

```
(Sender: TObject; Control: TControl; Canvas: TCanvas; var ARect: TRect; var Options:
TBandPaintOptions) ( TBandPaintEvent)();
```

File

ExtCtrls

Description

This is type ExtCtrls.TBandPaintEvent.

3.4.6 ExtCtrls.TBandPaintOptions Type

Pascal

```
TBandPaintOptions = set of TBandPaintOption;
```

C++

```
TBandPaintOption TBandPaintOptions;
```

File

ExtCtrls

Description

This is type ExtCtrls.TBandPaintOptions.

3.4.7 ExtCtrls.TBeginBandMoveEvent Type

Pascal

```
TBeginBandMoveEvent = procedure (Sender: TObject; Control: TControl; var AllowMove: Boolean)
of object;
```

C++

```
(Sender: TObject; Control: TControl; var AllowMove: Boolean) ( TBeginBandMoveEvent)();
```

File

ExtCtrls

Description

This is type ExtCtrls.TBeginBandMoveEvent.

3.4.8 ExtCtrls.TCanResizeEvent Type

Pascal

```
TCanResizeEvent = TSplitterCanResizeEvent;
```

C++

```
TSplitterCanResizeEvent TCanResizeEvent;
```

File

ExtCtrls

Description

This is type ExtCtrls.TCanResizeEvent.

3.4.9 ExtCtrls.TCategoryPanelClass Type

Pascal

```
TCategoryPanelClass = class of TCustomCategoryPanel;
```

C++

```
TCustomCategoryPanel TCategoryPanelClass;
```

File

ExtCtrls

Description

This is type ExtCtrls.TCategoryPanelClass.

3.4.10 ExtCtrls.TCategoryPanelSurfaceClass Type

Pascal

```
TCategoryPanelSurfaceClass = class of TCategoryPanelSurface;
```

C++

```
TCategoryPanelSurface TCategoryPanelSurfaceClass;
```

File

ExtCtrls

Description

This is type ExtCtrls.TCategoryPanelSurfaceClass.

3.4.11 ExtCtrls.TCellSpan Type

Pascal

```
TCellSpan = 1..MaxInt;
```

C++

```
1..MaxInt TCellSpan;
```

File

ExtCtrls

Description

This is type ExtCtrls.TCellSpan.

3.4.12 ExtCtrls.TColorBoxStyle Type

TColorBoxStyle and TColorBoxStyles (see page 1541) specify how a color box control displays its selections.

Pascal

```
TColorBoxStyle = set of TColorBoxStyles;
```

C++

```
TColorBoxStyles TColorBoxStyle;
```

File

ExtCtrls

Description

TColorBoxStyle is a set of TColorBoxStyles (see page 1541) values. The possible values of TColorBoxStyles (see page 1541) are

Style	Meaning when included
cbStandardColors	The color box lists the first 16 color constants from the Graphics (see page 2619) unit. These are the constants such as clRed (see page 2916) or clBlack (see page 2899), that represent fixed RGB values.
cbExtendedColors	The color box includes clMoneyGreen (see page 2913), clSkyBlue (see page 2917), clCream (see page 2902), and clMedGray (see page 2911).
cbSystemColors	The color box includes the symbolic color constants that reflect the values specified in the Windows control panel.
cbIncludeNone	The color box includes clNone (see page 2914). This option only has an effect if Style includes cbSystemColors.
cbIncludeDefault	The color box includes clNone (see page 2914). This option only has an effect if Style includes cbSystemColors.
cbCustomColor	The first entry in the color box represents a custom color. When the user selects the Custom entry, the color box displays the Color selection dialog, where the user can specify a custom color.
cbPrettyNames	The color box lists the names as words rather than as the color constant strings. (for example 'Black' rather than 'clBlack (see page 2899)').

3.4.13 ExtCtrls.TEditButtonClass Type

Pascal

```
TEditButtonClass = class of TEditButton;
```

C++

```
TEditButton TEditButtonClass;
```

File

ExtCtrls

Description

This is type ExtCtrls.TEditButtonClass.

3.4.14 ExtCtrls.TEndBandMoveEvent Type

Pascal

```
TEndBandMoveEvent = procedure (Sender: TObject; Control: TControl) of object;
```

C++

```
(Sender: TObject; Control: TControl) ( TEndBandMoveEvent)();
```

File

ExtCtrls

Description

This is type ExtCtrls.TEndBandMoveEvent.

3.4.15 ExtCtrls.TGetColorsEvent Type

Pascal

```
TGetColorsEvent = procedure (Sender: TCustomColorBox; Items: TStrings) of object;
```

C++

```
(Sender: TCustomColorBox; Items: TStrings) ( TGetColorsEvent)();
```

File

ExtCtrls

Description

This is type ExtCtrls.TGetColorsEvent.

3.4.16 ExtCtrls.TLBGetColorsEvent Type

Pascal

```
TLBGetColorsEvent = procedure (Sender: TCustomColorListBox; Items: TStrings) of object;
```

C++

```
(Sender: TCustomColorListBox; Items: TStrings) ( TLBGetColorsEvent)();
```

File

ExtCtrls

Description

This is type ExtCtrls.TLBGetColorsEvent.

3.4.17 ExtCtrls.TPanelBevel Type

TPanelBevel specifies a bevel's cut.

Pascal

```
TPanelBevel = TBevelCut;
```

C++

```
TBevelCut TPanelBevel;
```

File

ExtCtrls

Description

TPanelBevel can have one of the following values:

Value	Meaning
bvNone	The bevel does not exist.
bvLowered	The bevel appears lowered.
bvRaised	The bevel appears raised.
bvSpace	The bevel appears as a space if its kind is not bkTile. Otherwise, the bevel appears raised.

See Also

TWinControl

TWinControl

3.4.18 ExtCtrls.TRowSize Type

Pascal

```
TRowSize = 1..MaxInt;
```

C++

```
1..MaxInt TRowSize;
```

File

ExtCtrls

Description

This is type ExtCtrls.TRowSize.

3.4.19 ExtCtrls.TSectionEvent Type

TSectionEvent is the type of event handlers that respond when a section of a THeader (see page 1021) control is resized.

Pascal

```
TSectionEvent = procedure (Sender: TObject; ASection, AWidth: Integer) of object;
```

C++

```
(Sender: TObject; ASection, AWidth: Integer) ( TSectionEvent)();
```

File

ExtCtrls

Description

Sender is the header control.

ASection is the index of the section that was resized.

AWidth is the width of the section.

3.4.20 ExtCtrls.TSplitterCanResizeEvent Type

Pascal

```
TSplitterCanResizeEvent = procedure (Sender: TObject; var NewSize: Integer; var Accept:
Boolean) of object;
```

C++

```
(Sender: TObject; var NewSize: Integer; var Accept: Boolean) ( TSplitterCanResizeEvent)();
```

File

ExtCtrls

Description

This is type ExtCtrls.TSplitterCanResizeEvent.

3.4.21 ExtCtrls.TSysLinkEvent Type

Event routine for click on TCustomLinkLabel (see page 797) HTML link.

Pascal

```
TSysLinkEvent = procedure (Sender: TObject; const Link: string; LinkType: TSysLinkType) of object;
```

C++

```
(Sender: TObject; const Link: string; LinkType: TSysLinkType) ( TSysLinkEvent)();
```

File

ExtCtrls

Description

TSysLinkEvent is a click event routine for a TCustomLinkLabel (see page 797) HTML link. It identifies the link URI and link type.

See Also

TCustomLinkLabel (see page 797)

OnLinkClick (see page 802)

TSysLinkType (see page 1546)

3.5 Constants

The following table lists constants in this documentation.

Constants

Name	Description
DefaultCategoryPanelHeight (see page 1556)	This is constant ExtCtrls.DefaultCategoryPanelHeight.
NoColorSelected (see page 1556)	This is constant ExtCtrls.NoColorSelected.
WM_SYSTEM_TRAY_MESSAGE (see page 1556)	This is constant ExtCtrls.WM_SYSTEM_TRAY_MESSAGE.

3.5.1 ExtCtrls.DefaultCategoryPanelHeight Constant

Pascal

```
DefaultCategoryPanelHeight = 200;
```

C++

```
DefaultCategoryPanelHeight = 200;
```

File

ExtCtrls

Description

This is constant ExtCtrls.DefaultCategoryPanelHeight.

3.5.2 ExtCtrls.NoColorSelected Constant

Pascal

```
NoColorSelected = TColor($FF000000);
```

C++

```
NoColorSelected = TColor($FF000000);
```

File

ExtCtrls

Description

This is constant ExtCtrls.NoColorSelected.

3.5.3 ExtCtrls.WM_SYSTEM_TRAY_MESSAGE Constant

Pascal

```
WM_SYSTEM_TRAY_MESSAGE = WM_USER + 1;
```

C++

```
WM_SYSTEM_TRAY_MESSAGE = WM_USER + 1;
```

File

ExtCtrls

Description

This is constant ExtCtrls.WM_SYSTEM_TRAY_MESSAGE.

4 ExtDlgs Namespace

This is namespace ExtDlgs.

Topics

Name	Description
Classes (see page 1560)	The following table lists classes in this documentation.
Functions (see page 1585)	The following table lists functions in this documentation.
Constants (see page 1586)	The following table lists constants in this documentation.

Classes

	Name	Description
	TOpenPictureDialog (see page 1560)	TOpenPictureDialog displays a graphics-file selection dialog.
	TOpenTextFileDialog (see page 1570)	This is class ExtDlgs.TOpenTextFileDialog.
	TSavePictureDialog (see page 1577)	TSavePictureDialog displays a "Save As" dialog for saving graphics files.
	TSaveTextFileDialog (see page 1580)	This is class ExtDlgs.TSaveTextFileDialog.

Constants

Name	Description
DefaultEncodingNames (see page 1586)	This is constant ExtDlgs.DefaultEncodingNames.

Functions

	Name	Description
	StandardEncodingFromName (see page 1585)	This is function ExtDlgs.StandardEncodingFromName.

4.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TOpenPictureDialog (see page 1560)	TOpenPictureDialog displays a graphics-file selection dialog.
	TOpenTextFileDialog (see page 1570)	This is class ExtDlgs.TOpenTextFileDialog.
	TSavePictureDialog (see page 1577)	TSavePictureDialog displays a "Save As" dialog for saving graphics files.
	TSaveTextFileDialog (see page 1580)	This is class ExtDlgs.TSaveTextFileDialog.

4.1.1 TOpenPictureDialog Class

TOpenPictureDialog displays a graphics-file selection dialog.

Class Hierarchy

Pascal

```
TOpenPictureDialog = class(TOpenDialog);
```

C++

```
class TOpenPictureDialog : public TOpenDialog;
```

File

ExtDlgs

Description

TOpenPictureDialog displays a modal Windows dialog box for selecting and opening graphics files. This component is just like TOpenDialog, except that it includes a rectangular preview region. If the selected image can be read by TPicture (see page 2812), it is displayed in the preview region; supported file types include bitmap (.BMP), icon (.ICO), Windows metafile (.WMF), and enhanced Windows metafile (.EMF). If the selected image cannot be displayed, "(None)" appears in the preview region.

If the user selects a file of an unrecognized type, TPicture (see page 2812) raises an EInvalidGraphic (see page 2627) exception.

Delphi Examples:

```
{
This example uses an image, two buttons, an open picture dialog
and a save picture dialog on a form. Clicking on the Open/Save button
executes the open/save picture dialog.
An exception is raised when trying to open a file that
does not exist, or when trying to overwrite a file using the
save dialog.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  { execute an open picture dialog }
  if OpenPictureDialog1.Execute then
    { first check if file exists }
```

```
    if FileExists(OpenPictureDialog1.FileName) then
      { if it exists, load the data into the image component }
      Image1.Picture.LoadFromFile(OpenPictureDialog1.FileName)
    else
      { otherwise raise an exception }
      raise Exception.Create('File does not exist.');
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  { execute a save picture dialog }
  if SavePictureDialog1.Execute then
    { first check if file exists }
    if FileExists(SavePictureDialog1.FileName) then
      { if it exists, raise an exception }
      raise Exception.Create('File already exists. Cannot overwrite.')
    else
      { otherwise, save the image data into the file }
      Image1.Picture.SaveToFile(SavePictureDialog1.FileName);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Image1.Canvas.Refresh;
end;
```

4.1.1.1 TOpenPictureDialog Members

The following tables list the members exposed by TOpenPictureDialog.

Protected Methods

	Name	Description
V	DoClose (see page 1562)	Generates an OnClose event.
V	DoSelectionChange (see page 1563)	This is DoSelectionChange, a member of class TOpenPictureDialog.
V	DoShow (see page 1563)	Generates an OnShow event.
V	PreviewClick (see page 1565)	This is PreviewClick, a member of class TOpenPictureDialog.

Protected Properties

	Name	Description
R	ImageCtrl (see page 1569)	This is ImageCtrl, a member of class TOpenPictureDialog.
R	PictureLabel (see page 1570)	This is PictureLabel, a member of class TOpenPictureDialog.

Public Methods

	Name	Description
V	Create (see page 1562)	Creates and initializes a TOpenPictureDialog (see page 1560) instance.
V	Execute (see page 1564)	Displays the file-selection dialog.

Published Properties

	Name	Description
	Filter (see page 1566)	Determines the file masks (filters) available in the dialog.

4.1.1.2 TOpenPictureDialog.Create Constructor

Creates and initializes a TOpenPictureDialog (see page 1560) instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TOpenPictureDialog(TComponent * AOwner);
```

Description

The Create method generates a TOpenPictureDialog (see page 1560) instance, but the dialog does not appear at runtime until the Execute (see page 1564) method is called. Create initializes the Filter (see page 1566) property by defining a filter for each file type that TPicture (see page 2812) supports.

Execute (see page 1564)

Filter

TPicture (see page 2812)

4.1.1.3 TOpenPictureDialog Methods

The methods of the TOpenPictureDialog class are listed here.

Protected Methods

	Name	Description
	DoClose (see page 1562)	Generates an OnClose event.
	DoSelectionChange (see page 1563)	This is DoSelectionChange, a member of class TOpenPictureDialog.
	DoShow (see page 1563)	Generates an OnShow event.
	PreviewClick (see page 1565)	This is PreviewClick, a member of class TOpenPictureDialog.

Public Methods

	Name	Description
	Execute (see page 1564)	Displays the file-selection dialog.

4.1.1.3.1 TOpenPictureDialog.DoClose Method

Generates an OnClose event.

Pascal

```
procedure DoClose; override;
```

C++

```
virtual __fastcall DoClose();
```

Description

DoClose is called automatically when the user closes the dialog. Override this method to provide additional processing other

than calling the OnClose event handler. For example, to perform shutdown operations that use protected methods of the dialog class, override DoClose rather than writing an OnClose event handler (which can access only public methods).

See Also

OnClose

4.1.1.3.2 TOpenPictureDialog.DoSelectionChange Method

Pascal

```
procedure DoSelectionChange; override;
```

C++

```
virtual __fastcall DoSelectionChange();
```

Description

This is DoSelectionChange, a member of class TOpenPictureDialog.

4.1.1.3.3 TOpenPictureDialog.DoShow Method

Generates an OnShow event.

Pascal

```
procedure DoShow; override;
```

C++

```
virtual __fastcall DoShow();
```

Description

DoShow is called automatically when the dialog is first displayed. Override this method to provide additional processing other than calling the OnShow event handler. For example, to perform initializations that use protected methods of the dialog class, override DoShow rather than writing an OnShow event handler (which can access only public methods).

C++ Examples:

```
/*
The following example is taken from TOpenPictureDialog. It
calculates the preview rectangle based on the difference
between the client area of the dialog and the static area of
the standard controls.
*/

#include <ExtDlgs.hpp>

class MyOpenPictureDialog : public TOpenPictureDialog
{
private:    // User declarations
    TPanel *FPicturePanel;  // can't use the private versions in TOpenPictureDialog
    TLabel *FPictureLabel;
    TSpeedButton *FPreviewButton;
    TPanel *FPaintPanel;
    TImage *FImageCtrl;
    AnsiString FSavedFilename;
protected:  // User declarations
    DYNAMIC void __fastcall DoShow(void);
public:     // User declarations
    __fastcall MyOpenPictureDialog(TComponent* Owner);
    virtual bool __fastcall  Execute(HWND ParentWnd){ return TOpenDialog::Execute(ParentWnd); }
};
```

```
__fastcall MyOpenPictureDialog::MyOpenPictureDialog(TComponent* Owner)
    : TOpenPictureDialog(Owner)
{
}

#include <memory>       //for STL auto_ptr class

void __fastcall MyOpenPictureDialog::DoShow(void)
{
//  RECT *PreviewRect = new RECT();
  std::auto_ptr<RECT> PreviewRect(new RECT());
  TRect StaticRect;
  FPicturePanel = new TPanel(this); // the owner will clean this up
  FPictureLabel = new TLabel(this); // the owner will clean this up
  FPreviewButton = new TSpeedButton(this); // the owner will clean this up
  FPaintPanel = new TPanel(this); // the owner will clean this up
  FImageCtrl = new TImage(this); // the owner will clean this up
  // Set preview area to entire dialog
  GetClientRect(Handle, PreviewRect.get());
  StaticRect = GetStaticRect();
  // Move preview area to right of static area
  PreviewRect->left = StaticRect.Left + (StaticRect.Right - StaticRect.Left);
  PreviewRect->top += 4;
  FPicturePanel->BoundsRect.Left = PreviewRect->left;
  FPicturePanel->BoundsRect.Right = PreviewRect->right;
  FPicturePanel->BoundsRect.Top = PreviewRect->top;
  FPicturePanel->BoundsRect.Bottom = PreviewRect->bottom;

  FPreviewButton->Left = FPaintPanel->BoundsRect.Right - FPreviewButton->Width - 2;
  FImageCtrl->Picture = NULL;
  FSavedFilename = "";
  FPaintPanel->Caption = "";
  FPicturePanel->ParentWindow = Handle;
//  TOpenDialog::DoShow();   // the above code is equivalent to the inherited version
}

TForm1 *Form1;
MyOpenPictureDialog *OpenPictureDialog1;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (OpenPictureDialog1->Execute(GetParentHandle()))
      Image1->Picture->LoadFromFile(OpenPictureDialog1->FileName);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  OpenPictureDialog1 =  new MyOpenPictureDialog(Form1); // the owner will clean this up
}
```

See Also

OnShow

4.1.1.3.4 TOpenPictureDialog.Execute Method

Displays the file-selection dialog.

Pascal

```
function Execute(ParentWnd: HWND): Boolean; override;
```

C++

```
virtual __fastcall Boolean Execute(HWND ParentWnd);
```

Description

Execute opens the file-selection dialog, returning true when the user selects a file and clicks Open. If the user clicks Cancel, Execute returns false.

Delphi Examples:

```
{
This example uses an image, two buttons, an open picture dialog
and a save picture dialog on a form. Clicking on the Open/Save button
executes the open/save picture dialog.
An exception is raised when trying to open a file that
does not exist, or when trying to overwrite a file using the
save dialog.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  { execute an open picture dialog }
  if OpenPictureDialog1.Execute then
    { first check if file exists }
    if FileExists(OpenPictureDialog1.FileName) then
      { if it exists, load the data into the image component }
      Image1.Picture.LoadFromFile(OpenPictureDialog1.FileName)
    else
      { otherwise raise an exception }
      raise Exception.Create('File does not exist.');
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  { execute a save picture dialog }
  if SavePictureDialog1.Execute then
    { first check if file exists }
    if FileExists(SavePictureDialog1.FileName) then
      { if it exists, raise an exception }
      raise Exception.Create('File already exists. Cannot overwrite.')
    else
      { otherwise, save the image data into the file }
      Image1.Picture.SaveToFile(SavePictureDialog1.FileName);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Image1.Canvas.Refresh;
end;
```

4.1.1.3.5 TOpenPictureDialog.PreviewClick Method

Pascal

```
procedure PreviewClick(Sender: TObject); virtual;
```

C++

```
virtual __fastcall PreviewClick(TObject * Sender);
```

Description

This is PreviewClick, a member of class TOpenPictureDialog.

4.1.1.4 TOpenPictureDialog Properties

The properties of the TOpenPictureDialog class are listed here.

Protected Properties

	Name	Description
	ImageCtrl (see page 1569)	This is ImageCtrl, a member of class TOpenPictureDialog.
	PictureLabel (see page 1570)	This is PictureLabel, a member of class TOpenPictureDialog.

Published Properties

	Name	Description
	Filter (see page 1566)	Determines the file masks (filters) available in the dialog.

4.1.1.4.1 TOpenPictureDialog.Filter Property

Determines the file masks (filters) available in the dialog.

Pascal

```
property Filter;
```

C++

```
__property Filter;
```

Description

The file-selection dialog includes a drop-down list of file types under the edit box. When the user picks a file type from the list, only files of the selected type are displayed in the dialog.

To configure file masks at design time, click on the ellipsis marks (...) to the right of the Filter property in the Object Inspector. This opens the Filter editor. In the left column of the Filter editor, under Filter Name, type a brief description of each file type that will be available at runtime. In the right column, under Filter, type the file mask corresponding to each description. For example, the description "Text files" might appear to the left of the mask "*.txt", and the description "Pascal source files" might appear to the left of the mask "*.pas". Since the description appears in the drop-down list at runtime, it is often helpful to show the mask explicitly in the description (for example, "Text files (*.txt)").

To create file masks in program code, assign a value to the Filter property that consists of a description and a mask separated by a vertical bar (pipe) character. Do not include spaces around the vertical bar. For example,

```
OpenDialog1.Filter := 'Text files (*.txt)|*.TXT';
OpenDialog1->Filter = "Text files (*.txt)|*.TXT";
```

Multiple filters should be separated by vertical bars. For example,

```
OpenDialog1.Filter := 'Text files (*.txt)|*.TXT|Pascal files (*.pas)|*.PAS';
OpenDialog1->Filter = "Text files (*.txt)|*.TXT|Pascal files (*.pas)|*.PAS";
```

To include multiple masks in a single filter, separate the masks with semicolons. This works both in the Object Inspector and in program code. For example,

```
OpenDialog1.Filter := 'Pascal files|*.PAS;*.DPK;*.DPR';
OpenDialog1->Filter = "Pascal files|*.PAS;*.DPK;*.DPR";
```

If no value is assigned to Filter, the dialog displays all file types.

C++ Examples:

```
/*
This code displays a Save Picture dialog box with the
TBitmap default extension that is added automatically to
files that are given no extension. Confirm that the
bitmap file has been saved under the filename and path
specified.
*/
#include <memory>       //for STL auto_ptr class
```

```
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  AnsiString NewFileName, OldFileName;
  SavePictureDialog1->DefaultExt = GraphicExtension(__classid(Graphics::TBitmap));
  SavePictureDialog1->Filter = GraphicFilter(__classid(Graphics::TBitmap));
  OldFileName = "factory.bmp";
  if (SavePictureDialog1->Execute())
  {
    NewFileName = SavePictureDialog1->FileName;
    std::auto_ptr<TFileStream> OldFile(new TFileStream(OldFileName, (fmOpenRead |
fmShareDenyWrite)));
    std::auto_ptr<TFileStream> NewFile(new TFileStream(NewFileName, (fmCreate |
fmShareDenyRead)));
    NewFile->CopyFrom(OldFile.get(), OldFile->Size);
  };
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Image1->Picture->LoadFromFile("../factory.bmp");
}
/*
The following code allows the user to use a dialog box to
redefine the icon for the application at run time. When the
user clicks Button1, OpenDialog1 executes and the user
specifies an icon filename. The Icon is then assigned to the
application.  At runtime, click Button1 to select the icon,
then minimize the application to see the icon.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  OpenPictureDialog1->DefaultExt = GraphicExtension(__classid(TIcon));
  OpenPictureDialog1->FileName = GraphicFileMask(__classid(TIcon));
  OpenPictureDialog1->Filter = GraphicFilter(__classid(TIcon));
  OpenPictureDialog1->Options.Clear();
  OpenPictureDialog1->Options << ofFileMustExist << ofHideReadOnly << ofNoChangeDir;
  while (true)
  {
    if (OpenPictureDialog1->Execute())
    {
      if (!OpenPictureDialog1->Options.Contains(ofExtensionDifferent))
      {
        Application->Icon->LoadFromFile(OpenPictureDialog1->FileName);
        break;
      }
      else // reset Options to remove ofExtensionDifferent
      {
        OpenPictureDialog1->Options.Clear();
        OpenPictureDialog1->Options << ofFileMustExist << ofHideReadOnly << ofNoChangeDir;
      }
    }
    else // user cancelled
      break;
  }
}
```

Delphi Examples:

```
{
This code displays a Save Picture dialog box with the
TBitmap default extension that is added automatically to
files that are given no extension. Confirm that the
bitmap file has been saved under the filename and path
specified.
}
procedure TForm1.Button1Click(Sender: TObject);
var NewFileName, OldFileName: string;
```

```
    NewFile, OldFile: TFileStream;
begin
  SavePictureDialog1.DefaultExt := GraphicExtension(TBitmap);
  SavePictureDialog1.Filter := GraphicFilter(TBitmap);
  OldFileName := 'factory.bmp';
  if SavePictureDialog1.Execute then
  begin
    NewFileName := SavePictureDialog1.FileName;
    OldFile := TFileStream.Create(
      OldFileName, fmOpenRead or fmShareDenyWrite);
    try
      NewFile := TFileStream.Create(
        NewFileName, fmCreate or fmShareDenyRead);
      try
        NewFile.CopyFrom(OldFile, OldFile.Size);
      finally
        FreeAndNil(NewFile);
      end;
    finally
      FreeAndNil(OldFile);
    end;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Image1.Picture.LoadFromFile('factory.bmp');
end;
{
The following code allows the user to use a dialog box to
redefine the icon for the application at run time. When the
user clicks Button1, OpenDialog1 executes and the user
specifies an icon filename. The Icon is then assigned to the
application.  At runtime, click Button1 to select the icon,
then minimize the application to see the icon.
}
procedure TForm1.Button1Click(Sender: TObject);
var
Done: Boolean;
filenamestring : String;
begin
  OpenPictureDialog1.DefaultExt := GraphicExtension(TIcon);
  filenamestring := GraphicFileMask(TIcon);
  OpenPictureDialog1.FileName := filenamestring;
  OpenPictureDialog1.Filter := GraphicFilter(TIcon);
  OpenPictureDialog1.Options := [ ofFileMustExist, ofHideReadOnly, ofNoChangeDir ];
  Done := False;
  while not Done do
  begin
  if OpenPictureDialog1.Execute then
    begin
    if not (ofExtensionDifferent in OpenPictureDialog1.Options) then
      begin
      Application.Icon.LoadFromFile(OpenPictureDialog1.FileName);
      Done := True;
      end
    else
//      OpenPictureDialog1.Options := OpenPictureDialog1.Options - ofExtensionDifferent;
    end
  else { User cancelled }
    Done := True;
  end;
end;
{
This example uses a memo box, two buttons, an open dialog
and a save dialog on a form. When the application runs,
```

```
  the open dialog and save dialog filters are initialized,
  so to open and save *.txt files or files with any extension.
  Clicking on the Open/Save button executes the open/save dialog.
  An exception is raised when trying to open a file that
  does not exist, or when trying to overwrite a file using the
  save dialog.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  begin
    { execute an open file dialog }
    if OpenDialog1.Execute then
      { first check if file exists }
      if FileExists(OpenDialog1.FileName) then
        { if it exists, load the data into the memo box }
        Memo1.Lines.LoadFromFile(OpenDialog1.FileName)
      else
        { otherwise raise an exception }
        raise Exception.Create('File does not exist.');
  end;

  procedure TForm1.Button2Click(Sender: TObject);
  begin
    { execute a save file dialog }
    if SaveDialog1.Execute then
      { first check if file exists }
      if FileExists(SaveDialog1.FileName) then
        { if it exists, raise an exception }
        raise Exception.Create('File already exists. Cannot overwrite.')
      else
        { otherwise, save the memo box lines into the file }
        Memo1.Lines.SaveToFile(SaveDialog1.FileName);
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    {
    initialize the dialog filters to open/save *.txt files
    and also files with arbitrary extension
    }
    OpenDialog1.Filter := 'Text files (*.txt)|*.TXT|Any file (*.*)|*.*';
    SaveDialog1.Filter := 'Text files (*.txt)|*.TXT|Any file (*.*)|*.*';
  end;
```

4.1.1.4.2 TOpenPictureDialog.ImageCtrl Property

Pascal

```
property ImageCtrl: TImage;
```

C++

```
__property TImage ImageCtrl;
```

Description

This is ImageCtrl, a member of class TOpenPictureDialog.

4.1.1.4.3 TOpenPictureDialog.PictureLabel Property

Pascal

```
property PictureLabel: TLabel;
```

C++

```
__property TLabel PictureLabel;
```

Description

This is PictureLabel, a member of class TOpenPictureDialog.

4.1.2 TOpenTextFileDialog Class

Class Hierarchy

Pascal

```
TOpenTextFileDialog = class(TOpenDialog);
```

C++

```
class TOpenTextFileDialog : public TOpenDialog;
```

File

ExtDlgs

Description

This is class ExtDlgs.TOpenTextFileDialog.

4.1.2.1 TOpenTextFileDialog Members

The following tables list the members exposed by TOpenTextFileDialog.

Protected Methods

	Name	Description
	DoClose (see page 1572)	Generates an OnClose event.
	DoShow (see page 1572)	Generates an OnShow event.

Public Methods

	Name	Description
	Create (see page 1571)	Creates and initializes a TOpenDialog instance.
	Destroy (see page 1571)	Destroys the TOpenDialog and frees its memory.
	Execute (see page 1573)	Displays the file-selection dialog.

Published Properties

	Name	Description
	EncodingIndex (see page 1576)	This is EncodingIndex, a member of class TOpenTextFileDialog.
	Encodings (see page 1576)	This is Encodings, a member of class TOpenTextFileDialog.

4.1.2.2 TOpenTextFileDialog.Create Constructor

Creates and initializes a TOpenDialog instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TOpenTextFileDialog(TComponent * AOwner);
```

Description

Create generates a TOpenDialog instance, but the new dialog does not appear on the form at runtime until the Execute method is called.

AOwner is the component that is responsible for freeing the TOpenDialog instance. It becomes the value of the Owner property.

See Also

Execute

Owner

Destroy

4.1.2.3 TOpenTextFileDialog.Destroy Destructor

Destroys the TOpenDialog and frees its memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TOpenTextFileDialog();
```

Description

Do not call Destroy directly in an application. Call Free instead. Free verifies that the TOpenDialog reference is not nil before calling Destroy.

Create

4.1.2.4 TOpenTextFileDialog Methods

The methods of the TOpenTextFileDialog class are listed here.

Protected Methods

	Name	Description
	DoClose (see page 1572)	Generates an OnClose event.
	DoShow (see page 1572)	Generates an OnShow event.

Public Methods

	Name	Description
	Execute (see page 1573)	Displays the file-selection dialog.

4.1.2.4.1 TOpenTextFileDialog.DoClose Method

Generates an OnClose event.

Pascal

```
procedure DoClose; override;
```

C++

```
virtual __fastcall DoClose();
```

Description

DoClose is called automatically when the user closes the dialog. Override this method to provide additional processing other than calling the OnClose event handler. For example, to perform shutdown operations that use protected methods of the dialog class, override DoClose rather than writing an OnClose event handler (which can access only public methods).

See Also

OnClose

4.1.2.4.2 TOpenTextFileDialog.DoShow Method

Generates an OnShow event.

Pascal

```
procedure DoShow; override;
```

C++

```
virtual __fastcall DoShow();
```

Description

DoShow is called automatically when the dialog is first displayed. Override this method to provide additional processing other than calling the OnShow event handler. For example, to perform initializations that use protected methods of the dialog class, override DoShow rather than writing an OnShow event handler (which can access only public methods).

C++ Examples:

```
/*
The following example is taken from TOpenPictureDialog. It
calculates the preview rectangle based on the difference
between the client area of the dialog and the static area of
the standard controls.

OnShow

4.1.2.4.3 TOpenTextFileDialog.Execute Method

Displays the file-selection dialog.

Pascal

```
function Execute(ParentWnd: HWND): Boolean; override;
```

C++

```
virtual __fastcall Boolean Execute(HWND ParentWnd);
```

Description

Execute opens the file-selection dialog, returning true when the user selects a file and clicks Open. If the user clicks Cancel, Execute returns false.

```
if OpenDialog1.Execute then
  Memo1.Lines.LoadFromFile(OpenDialog1.FileName)
else
  Memo1.Lines.Clear;
if (OpenDialog1->Execute())
  Memo1->Lines->LoadFromFile(OpenDialog1->FileName);
else
  Memo1->Clear();
```

C++ Examples:

```
/*
The following code allows the user to use a dialog box to
redefine the icon for the application at run time. When the
user clicks Button1, OpenDialog1 executes and the user
specifies an icon filename. The Icon is then assigned to the
application.  At runtime, click Button1 to select the icon,
then minimize the application to see the icon.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  OpenPictureDialog1->DefaultExt = GraphicExtension(__classid(TIcon));
  OpenPictureDialog1->FileName = GraphicFileMask(__classid(TIcon));
  OpenPictureDialog1->Filter = GraphicFilter(__classid(TIcon));
  OpenPictureDialog1->Options.Clear();
  OpenPictureDialog1->Options << ofFileMustExist << ofHideReadOnly << ofNoChangeDir;
  while (true)
  {
    if (OpenPictureDialog1->Execute())
    {
      if (!OpenPictureDialog1->Options.Contains(ofExtensionDifferent))
      {
        Application->Icon->LoadFromFile(OpenPictureDialog1->FileName);
        break;
      }
      else // reset Options to remove ofExtensionDifferent
      {
        OpenPictureDialog1->Options.Clear();

      }
    }
    else // user cancelled
      break;
  }
}
```

Delphi Examples:

```
{
The following code allows the user to use a dialog box to
redefine the icon for the application at run time. When the
user clicks Button1, OpenDialog1 executes and the user
specifies an icon filename. The Icon is then assigned to the
application.  At runtime, click Button1 to select the icon,
then minimize the application to see the icon.
```

```
}
procedure TForm1.Button1Click(Sender: TObject);
var
Done: Boolean;
filenamestring : String;
begin
  OpenPictureDialog1.DefaultExt := GraphicExtension(TIcon);
  filenamestring := GraphicFileMask(TIcon);
  OpenPictureDialog1.FileName := filenamestring;
  OpenPictureDialog1.Filter := GraphicFilter(TIcon);
  OpenPictureDialog1.Options := [ ofFileMustExist, ofHideReadOnly, ofNoChangeDir ];
  Done := False;
  while not Done do
  begin
  if OpenPictureDialog1.Execute then
    begin
    if not (ofExtensionDifferent in OpenPictureDialog1.Options) then
      begin
      Application.Icon.LoadFromFile(OpenPictureDialog1.FileName);
      Done := True;
      end
    else
//      OpenPictureDialog1.Options := OpenPictureDialog1.Options - ofExtensionDifferent;
    end
  else { User cancelled }
    Done := True;
  end;
end;
{
Use a TOpenDialog to select a file.  Place the first line of
the file into a TEdit.  Click on the text edit to open the
open dialog box.
}
procedure TForm1.Edit1Click(Sender: TObject);
var
  F: TextFile;
  S: string;
begin
  if OpenDialog1.Execute then            { Display Open dialog box }
  begin
    AssignFile(F, OpenDialog1.FileName); { File selected in dialog }
    Reset(F);
    Readln(F, S);                        { Read first line of file }
    Edit1.Text := S;                     { Put string in a TEdit control }
    CloseFile(F);
  end;
end;
{
This example uses a memo box, two buttons, an open dialog
and a save dialog on a form. When the application runs,
the open dialog and save dialog filters are initialized,
so to open and save *.txt files or files with any extension.
Clicking on the Open/Save button executes the open/save dialog.
An exception is raised when trying to open a file that
does not exist, or when trying to overwrite a file using the
save dialog.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  { execute an open file dialog }
  if OpenDialog1.Execute then
    { first check if file exists }
    if FileExists(OpenDialog1.FileName) then
      { if it exists, load the data into the memo box }
      Memo1.Lines.LoadFromFile(OpenDialog1.FileName)
    else
```

```
      { otherwise raise an exception }
      raise Exception.Create('File does not exist.');
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  { execute a save file dialog }
  if SaveDialog1.Execute then
    { first check if file exists }
    if FileExists(SaveDialog1.FileName) then
      { if it exists, raise an exception }
      raise Exception.Create('File already exists. Cannot overwrite.')
    else
      { otherwise, save the memo box lines into the file }
      Memo1.Lines.SaveToFile(SaveDialog1.FileName);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  {
  initialize the dialog filters to open/save *.txt files
  and also files with arbitrary extension
  }
  OpenDialog1.Filter := 'Text files (*.txt)|*.TXT|Any file (*.*)|*.*';
  SaveDialog1.Filter := 'Text files (*.txt)|*.TXT|Any file (*.*)|*.*';
end;

4.1.2.5 TOpenTextFileDialog Properties

The properties of the TOpenTextFileDialog class are listed here.

Published Properties

	Name	Description
	EncodingIndex (see page 1576)	This is EncodingIndex, a member of class TOpenTextFileDialog.
	Encodings (see page 1576)	This is Encodings, a member of class TOpenTextFileDialog.

4.1.2.5.1 TOpenTextFileDialog.EncodingIndex Property

Pascal

```
property EncodingIndex: Integer;
```

C++

```
__property int EncodingIndex;
```

Description

This is EncodingIndex, a member of class TOpenTextFileDialog.

4.1.2.5.2 TOpenTextFileDialog.Encodings Property

Pascal

```
property Encodings: TStrings;
```

C++

```
__property TStrings Encodings;
```

Description

This is Encodings, a member of class TOpenTextFileDialog.

4.1.3 TSavePictureDialog Class

TSavePictureDialog displays a "Save As" dialog for saving graphics files.

Class Hierarchy

Pascal

```
TSavePictureDialog = class(TOpenPictureDialog);
```

C++

```
class TSavePictureDialog : public TOpenPictureDialog;
```

File

ExtDlgs

Description

TSavePictureDialog displays a modal Windows dialog box for selecting file names and saving graphics files. This component is just like TSaveDialog, except that it includes a rectangular preview region. If the selected image can be read by TPicture (see page 2812), it is displayed in the preview region; supported file types include bitmap (.BMP), icon (.ICO), Windows metafile (.WMF), and enhanced Windows metafile (.EMF). If the selected image cannot be displayed, "(None)" appears in the preview region.

Delphi Examples:

```
{
This example uses an image, two buttons, an open picture dialog
and a save picture dialog on a form. Clicking on the Open/Save button
executes the open/save picture dialog.
An exception is raised when trying to open a file that
does not exist, or when trying to overwrite a file using the
save dialog.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  { execute an open picture dialog }
  if OpenPictureDialog1.Execute then
    { first check if file exists }
    if FileExists(OpenPictureDialog1.FileName) then
      { if it exists, load the data into the image component }
      Image1.Picture.LoadFromFile(OpenPictureDialog1.FileName)
    else
      { otherwise raise an exception }
      raise Exception.Create('File does not exist.');
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  { execute a save picture dialog }
  if SavePictureDialog1.Execute then
```

```
    { first check if file exists }
    if FileExists(SavePictureDialog1.FileName) then
      { if it exists, raise an exception }
      raise Exception.Create('File already exists. Cannot overwrite.')
    else
      { otherwise, save the image data into the file }
      Image1.Picture.SaveToFile(SavePictureDialog1.FileName);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Image1.Canvas.Refresh;
end;
```

4.1.3.1 TSavePictureDialog Members

The following tables list the members exposed by TSavePictureDialog.

Protected Methods

	Name	Description
	DoClose (see page 1562)	Generates an OnClose event.
	DoSelectionChange (see page 1563)	This is DoSelectionChange, a member of class TOpenPictureDialog.
	DoShow (see page 1563)	Generates an OnShow event.
	PreviewClick (see page 1565)	This is PreviewClick, a member of class TOpenPictureDialog.

Protected Properties

	Name	Description
	ImageCtrl (see page 1569)	This is ImageCtrl, a member of class TOpenPictureDialog.
	PictureLabel (see page 1570)	This is PictureLabel, a member of class TOpenPictureDialog.

Public Methods

	Name	Description
	Create (see page 1562)	Creates and initializes a TOpenPictureDialog (see page 1560) instance.
	Execute (see page 1579)	This is the overview for the Execute method overload.

Published Properties

	Name	Description
	Filter (see page 1566)	Determines the file masks (filters) available in the dialog.

4.1.3.2 TSavePictureDialog Methods

The methods of the TSavePictureDialog class are listed here.

Public Methods

	Name	Description
	Execute (see page 1579)	This is the overview for the Execute method overload.

4.1.3.2.1 Execute Method

This is the overview for the Execute method overload.

Overload List

	Name	Description
	TSavePictureDialog.Execute () (see page 1579)	Displays the Save As dialog box.
	TSavePictureDialog.Execute (HWND) (see page 1579)	Displays the Save As dialog box.

4.1.3.2.1.1 TSavePictureDialog.Execute Method ()

Displays the Save As dialog box.

Pascal

```
function Execute: Boolean; override;
function Execute(ParentWnd: HWND): Boolean; override;
```

C++

```
virtual __fastcall Boolean Execute();
virtual __fastcall Boolean Execute(HWND ParentWnd);
```

Description

Execute opens the Save As dialog, returning true when the user selects a file name and clicks Save.

Delphi Examples:

```
{
This example uses an image, two buttons, an open picture dialog
and a save picture dialog on a form. Clicking on the Open/Save button
executes the open/save picture dialog.
An exception is raised when trying to open a file that
does not exist, or when trying to overwrite a file using the
save dialog.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  { execute an open picture dialog }
  if OpenPictureDialog1.Execute then
    { first check if file exists }
    if FileExists(OpenPictureDialog1.FileName) then
      { if it exists, load the data into the image component }
      Image1.Picture.LoadFromFile(OpenPictureDialog1.FileName)
    else
      { otherwise raise an exception }
      raise Exception.Create('File does not exist.');
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  { execute a save picture dialog }
  if SavePictureDialog1.Execute then
    { first check if file exists }
    if FileExists(SavePictureDialog1.FileName) then
      { if it exists, raise an exception }
      raise Exception.Create('File already exists. Cannot overwrite.')
    else
      { otherwise, save the image data into the file }
      Image1.Picture.SaveToFile(SavePictureDialog1.FileName);
```

```
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Image1.Canvas.Refresh;
end;
```

4.1.4 TSaveTextFileDialog Class

Class Hierarchy

Pascal

```
TSaveTextFileDialog = class(TOpenTextFileDialog);
```

C++

```
class TSaveTextFileDialog : public TOpenTextFileDialog;
```

File

ExtDlgs

Description

This is class ExtDlgs.TSaveTextFileDialog.

4.1.4.1 TSaveTextFileDialog Members

The following tables list the members exposed by TSaveTextFileDialog.

Protected Methods

	Name	Description
	DoClose (see page 1572)	Generates an OnClose event.
	DoShow (see page 1572)	Generates an OnShow event.

Public Methods

	Name	Description
	Create (see page 1571)	Creates and initializes a TOpenDialog instance.
	Destroy (see page 1571)	Destroys the TOpenDialog and frees its memory.
	Execute (see page 1581)	This is the overview for the Execute method overload.

Published Properties

	Name	Description
	EncodingIndex (see page 1576)	This is EncodingIndex, a member of class TOpenTextFileDialog.
	Encodings (see page 1576)	This is Encodings, a member of class TOpenTextFileDialog.

4.1.4.2 TSaveTextFileDialog Methods

The methods of the TSaveTextFileDialog class are listed here.

Public Methods

	Name	Description
	Execute (see page 1581)	This is the overview for the Execute method overload.

4.1.4.2.1 Execute Method

This is the overview for the Execute method overload.

Overload List

	Name	Description
	TSaveTextFileDialog.Execute () (see page 1581)	Displays the dialog box.
	TSaveTextFileDialog.Execute (HWND) (see page 1581)	Displays the file-selection dialog.

4.1.4.2.1.1 TSaveTextFileDialog.Execute Method ()

Displays the dialog box.

Pascal

```
function Execute: Boolean; override;
```

C++

```
virtual __fastcall Boolean Execute();
```

Description

TCommonDialog introduces the abstract Execute method, which descendant classes use to open the dialog instance at runtime. Generally, Execute returns true when the user makes a selection and clicks OK, and returns false when the user closes the dialog without making a selection.

See Also

TaskModalDialog

4.1.4.2.1.2 TSaveTextFileDialog.Execute Method (HWND)

Displays the file-selection dialog.

Pascal

```
function Execute(ParentWnd: HWND): Boolean; override;
```

C++

```
virtual __fastcall Boolean Execute(HWND ParentWnd);
```

Description

Execute opens the file-selection dialog, returning true when the user selects a file and clicks Open. If the user clicks Cancel, Execute returns false.

```
if OpenDialog1.Execute then
  Memo1.Lines.LoadFromFile(OpenDialog1.FileName)
else
  Memo1.Lines.Clear;
if (OpenDialog1->Execute())
  Memo1->Lines->LoadFromFile(OpenDialog1->FileName);
else
  Memo1->Clear();
```

C++ Examples:

```
/*
```

```
  The following code allows the user to use a dialog box to
  redefine the icon for the application at run time. When the
  user clicks Button1, OpenDialog1 executes and the user
  specifies an icon filename. The Icon is then assigned to the
  application.  At runtime, click Button1 to select the icon,
  then minimize the application to see the icon.
  */
  void __fastcall TForm1::Button1Click(TObject *Sender)
  {
    OpenPictureDialog1->DefaultExt = GraphicExtension(__classid(TIcon));
    OpenPictureDialog1->FileName = GraphicFileMask(__classid(TIcon));
    OpenPictureDialog1->Filter = GraphicFilter(__classid(TIcon));
    OpenPictureDialog1->Options.Clear();
    OpenPictureDialog1->Options << ofFileMustExist << ofHideReadOnly << ofNoChangeDir;
    while (true)
    {
      if (OpenPictureDialog1->Execute())
      {
        if (!OpenPictureDialog1->Options.Contains(ofExtensionDifferent))
        {
          Application->Icon->LoadFromFile(OpenPictureDialog1->FileName);
          break;
        }
        else // reset Options to remove ofExtensionDifferent
        {
          OpenPictureDialog1->Options.Clear();
          OpenPictureDialog1->Options << ofFileMustExist << ofHideReadOnly << ofNoChangeDir;
        }
      }
      else // user cancelled
        break;
    }
  }
```

Delphi Examples:

```
{
The following code allows the user to use a dialog box to
redefine the icon for the application at run time. When the
user clicks Button1, OpenDialog1 executes and the user
specifies an icon filename. The Icon is then assigned to the
application.  At runtime, click Button1 to select the icon,
then minimize the application to see the icon.
}
procedure TForm1.Button1Click(Sender: TObject);
var
Done: Boolean;
filenamestring : String;
begin
  OpenPictureDialog1.DefaultExt := GraphicExtension(TIcon);
  filenamestring := GraphicFileMask(TIcon);
  OpenPictureDialog1.FileName := filenamestring;
  OpenPictureDialog1.Filter := GraphicFilter(TIcon);
  OpenPictureDialog1.Options := [ ofFileMustExist, ofHideReadOnly, ofNoChangeDir ];
  Done := False;
  while not Done do
  begin
  if OpenPictureDialog1.Execute then

4.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	StandardEncodingFromName (see page 1585)	This is function ExtDlgs.StandardEncodingFromName.

4.2.1 ExtDlgs.StandardEncodingFromName Function

Pascal

```
function StandardEncodingFromName(const Name: string): TEncoding;
```

C++

```
TEncoding StandardEncodingFromName(const UnicodeString Name);
```

File

ExtDlgs

Description

This is function ExtDlgs.StandardEncodingFromName.

4.3 Constants

The following table lists constants in this documentation.

Constants

Name	Description
DefaultEncodingNames (see page 1586)	This is constant ExtDlgs.DefaultEncodingNames.

4.3.1 ExtDlgs.DefaultEncodingNames Constant

Pascal

```
DefaultEncodingNames: array[0..5] of string = (SANSIEncoding, SASCIIEncoding,
SUnicodeEncoding, SBigEndianEncoding, SUTF8Encoding, SUTF7Encoding);
```

C++

```
array[0..5] of string DefaultEncodingNames = (SANSIEncoding, SASCIIEncoding, SUnicodeEncoding,
SBigEndianEncoding, SUTF8Encoding, SUTF7Encoding);
```

File

ExtDlgs

Description

This is constant ExtDlgs.DefaultEncodingNames.

5 FileCtrl Namespace

This is namespace FileCtrl.

Topics

Name	Description
Classes (see page 1589)	The following table lists classes in this documentation.
Functions (see page 1879)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 1883)	The following table lists structs, records, enums in this documentation.
Types (see page 1887)	The following table lists types in this documentation.
Constants (see page 1889)	The following table lists constants in this documentation.

Classes

	Name	Description
	TDirectoryListBox (see page 1589)	TDirectoryListBox represents a list box control that is aware of the directory structure of the current drive.
	TDriveComboBox (see page 1668)	TDriveComboBox implements a specialized combo box that displays all the drives available when the application runs.
	TFileListBox (see page 1734)	TFileListBox is a specialized list box that lists all the files in a specified directory.
	TFilterComboBox (see page 1813)	TFilterComboBox is a specialized combo box that presents the user with a choice of file filters.

Constants

Name	Description
WNTYPE_DRIVE (see page 1889)	This is constant FileCtrl.WNTYPE_DRIVE.

Functions

	Name	Description
	DirectoryExists (see page 1879)	Determines whether a specified directory exists.
	ForceDirectories (see page 1879)	Creates a new directory, including the creation of parent directories as needed.
	MinimizeName (see page 1880)	Shortens a fully qualified path name so that it can be drawn with a specified length limit.
	ProcessPath (see page 1881)	Parses a file name into its constituent parts.
	SelectDirectory (see page 1881)	Brings up a dialog to allow the user to enter a directory name.
	SelectDirectory (see page 1881)	Brings up a dialog to allow the user to enter a directory name.

Structs, Records, Enums

	Name	Description
	TDriveType (see page 1883)	This is record FileCtrl.TDriveType.
	TFileAttr (see page 1883)	TFileAttr and TFileType (see page 1887) determine which files a file list box displays.
	TSelectDirExtOpt (see page 1884)	This is record FileCtrl.TSelectDirExtOpt.
	TSelectDirOpt (see page 1885)	TSelectDirOpt and TSelectDirOpts (see page 1888) determine how a directory selection dialog responds when the user enters a nonexistent directory.
	TTextCase (see page 1886)	TTextCase indicates the case of the volume name or drive letter that appears in a dialog box.

Types

Name	Description
TFileType (see page 1887)	TFileType describes possible combinations of file attributes.
TSelectDirExtOpts (see page 1887)	This is type FileCtrl.TSelectDirExtOpts.
TSelectDirOpts (see page 1888)	This is type FileCtrl.TSelectDirOpts.

5.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TDirectoryListBox (see page 1589)	TDirectoryListBox represents a list box control that is aware of the directory structure of the current drive.
	TDriveComboBox (see page 1668)	TDriveComboBox implements a specialized combo box that displays all the drives available when the application runs.
	TFileListBox (see page 1734)	TFileListBox is a specialized list box that lists all the files in a specified directory.
	TFilterComboBox (see page 1813)	TFilterComboBox is a specialized combo box that presents the user with a choice of file filters.

5.1.1 TDirectoryListBox Class

TDirectoryListBox represents a list box control that is aware of the directory structure of the current drive.

Class Hierarchy

Pascal

```
[SecurityPermission(SecurityAction.Demand, Unrestricted=True)]
TDirectoryListBox = class(TCustomListBox);
```

C++

```
[SecurityPermission(SecurityAction.Demand, Unrestricted=True)]
class TDirectoryListBox : public TCustomListBox;
```

File

FileCtrl

Description

TDirectoryListBox implements the generic behavior introduced in TCustomListBox. TDirectoryListBox publishes many of the properties inherited from TCustomListBox and introduces new behavior to let the user change directories or drives.

C++ Examples:

```
/*
This example uses a file list box, a directory list box, and
a label on a form. When the user uses the directory list box
to change directories, a message appears and the color of
the form changes if the file AUTOEXEC.BAT is in the new
directory. The code is written in the OnChange event of the
directory list box:
*/
void __fastcall TForm1::DirectoryListBox1Change(TObject *Sender)
{
  FileListBox1->Directory = DirectoryListBox1->Directory;
  if (FileListBox1->Items->IndexOf("AUTOEXEC.BAT") > -1)
  {
    Color = clYellow;
    Label1->Caption = "You are in the root directory!";
```

```
  }
}
```

Delphi Examples:

```
{
This example uses a file list box, a directory list box, and
a label on a form. When the user uses the directory list box
to change directories, a message appears and the color of
the form changes if the file AUTOEXEC.BAT is in the new
directory. The code is written in the OnChange event of the
directory list box:
}
procedure TForm1.DirectoryListBox1Change(Sender: TObject);
begin
  FileListBox1.Directory := DirectoryListBox1.Directory;
  if FileListBox1.Items.IndexOf('AUTOEXEC.BAT') > -1 then
  begin
    Color := clYellow;
    Label1.Caption := 'You are in the root directory!';
  end
  else
  begin
    Color := clBtnFace;
    Label1.Caption := '';
  end;
end;
```

5.1.1.1 TDirectoryListBox Members

The following tables list the members exposed by TDirectoryListBox.

Protected Fields

	Name	Description
	ClosedBMP (see page 1593)	This is ClosedBMP, a member of class TDirectoryListBox.
	CurrentBMP (see page 1593)	This is CurrentBMP, a member of class TDirectoryListBox.
	FDirectory (see page 1594)	This is FDirectory, a member of class TDirectoryListBox.
	FOnChange (see page 1594)	This is FOnChange, a member of class TDirectoryListBox.
	OpenedBMP (see page 1594)	This is OpenedBMP, a member of class TDirectoryListBox.

Protected Methods

	Name	Description
	BuildList (see page 1595)	This is BuildList, a member of class TDirectoryListBox.
	Change (see page 1595)	This is Change, a member of class TDirectoryListBox.
	CreateWnd (see page 1595)	Creates a Windows control corresponding to the list box component.
	DblClick (see page 1596)	OnDblClick event dispatcher.
	DrawItem (see page 1597)	Generates an OnDrawItem event.
	KeyPress (see page 1598)	Responds when the user presses a key.
	Notification (see page 1598)	Responds to notifications that components are being created or destroyed.
	ReadBitmaps (see page 1599)	This is ReadBitmaps, a member of class TDirectoryListBox.
	ReadDirectoryNames (see page 1599)	This is ReadDirectoryNames, a member of class TDirectoryListBox.

Public Methods

	Name	Description
	Create (see page 1592)	Creates and initializes a directory list box.
	Destroy (see page 1593)	Disposes of an instance of a directory list box.
	DisplayCase (see page 1596)	Preserves or converts the case of the string passed to it.
	FileCompareText (see page 1597)	Compares two strings, taking into account the case-sensitivity of the file system.
	GetItemPath (see page 1597)	This is GetItemPath, a member of class TDirectoryListBox.
	OpenCurrent (see page 1598)	Opens the selected directory.
	Update (see page 1600)	Refreshes the directory list.

Public Properties

	Name	Description
	CaseSensitive (see page 1608)	Indicates whether the system supports case-sensitive directory information.
	Directory (see page 1611)	Determines the current directory for the directory list box control.
	Drive (see page 1617)	Determines the drive for which the list box displays the directory structure.
	PreserveCase (see page 1631)	Indicates whether the file system preserves the case of file names when writing to disk.

Published Events

	Name	Description
	OnChange (see page 1636)	Occurs when the user selects a new directory with the mouse or keyboard when the user moves the selection bar and presses enter.
	OnClick (see page 1638)	Occurs when the user clicks the control.
	OnContextPopup (see page 1639)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 1640)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 1640)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 1643)	Occurs when the user drags an object over a control.
	OnEndDrag (see page 1647)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 1648)	Occurs when a control receives the input focus.
	OnExit (see page 1650)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 1653)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 1657)	Occurs when a key is pressed.
	OnKeyUp (see page 1658)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 1659)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 1660)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 1663)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 1663)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 1663)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 1665)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDrag (see page 1668)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 1602)	Determines how the control aligns within its container (parent control).
	Anchors (see page 1605)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 1606)	Determines whether the user can give focus to items by typing in the list.
	BevelEdges (see page 1606)	Specifies which edges of the control are beveled.
	BevelInner (see page 1606)	Specifies the cut of the inner bevel.
	BevelKind (see page 1607)	Specifies the control's bevel style.

	BevelOuter (see page 1607)	Specifies the cut of the outer bevel.
	Color (see page 1608)	Specifies the background color of the control.
	Columns (see page 1609)	Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.
	Constraints (see page 1610)	Specifies the size constraints for the control.
	Ctl3D (see page 1610)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DirLabel (see page 1612)	Provides a simple way to display the current directory as the caption of a label control.
	DoubleBuffered (see page 1613)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 1615)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragMode (see page 1615)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 1618)	Controls whether the control responds to mouse, keyboard, and timer events.
	FileList (see page 1618)	Provides a simple way to connect a directory list box with a file list box.
	Font (see page 1621)	Controls the attributes of text written on or in the control.
	ImeMode (see page 1622)	Determines the behavior of the input method editor (IME).
	ImeName (see page 1622)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IntegralHeight (see page 1623)	Determines whether the list box displays the partial items.
	ItemHeight (see page 1623)	Specifies the height in pixels of an item in an owner-draw list box.
	ParentColor (see page 1624)	Determines where a control looks for its color information.
	ParentCtl3D (see page 1624)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 1625)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 1625)	Determines where a control looks for its font information.
	ParentShowHint (see page 1625)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 1626)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 1631)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 1633)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 1633)	Determines if the user can tab to a control.
	Visible (see page 1634)	Determines whether the component appears onscreen.

5.1.1.2 TDirectoryListBox.Create Constructor

Creates and initializes a directory list box.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TDirectoryListBox(TComponent * AOwner);
```

Description

Call Create to instantiate a directory list box at runtime. For directory list boxes created at design time, Create is called automatically.

See Also

Create

Sorted

Style

ParentWindow

5.1.1.3 TDirectoryListBox.Destroy Destructor

Disposes of an instance of a directory list box.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDirectoryListBox();
```

Description

Do not call Destroy directly in an application. Call Free instead. Free checks that the list box reference is not nil before it calls Destroy.

Destroy frees the bitmaps used for the Open, Close and Current folders, and then calls the inherited Destroy method.

See Also

Destroy

5.1.1.4 TDirectoryListBox Fields

The fields of the TDirectoryListBox class are listed here.

Protected Fields

	Name	Description
	ClosedBMP (see page 1593)	This is ClosedBMP, a member of class TDirectoryListBox.
	CurrentBMP (see page 1593)	This is CurrentBMP, a member of class TDirectoryListBox.
	FDirectory (see page 1594)	This is FDirectory, a member of class TDirectoryListBox.
	FOnChange (see page 1594)	This is FOnChange, a member of class TDirectoryListBox.
	OpenedBMP (see page 1594)	This is OpenedBMP, a member of class TDirectoryListBox.

5.1.1.4.1 TDirectoryListBox.ClosedBMP Field

Pascal

```
ClosedBMP: TBitmap;
```

C++

```
TBitmap ClosedBMP;
```

Description

This is ClosedBMP, a member of class TDirectoryListBox.

5.1.1.4.2 TDirectoryListBox.CurrentBMP Field

Pascal

```
CurrentBMP: TBitmap;
```

C++

```
TBitmap CurrentBMP;
```

Description

This is CurrentBMP, a member of class TDirectoryListBox.

5.1.1.4.3 TDirectoryListBox.FDirectory Field

Pascal

```
FDirectory: string;
```

C++

```
UnicodeString FDirectory;
```

Description

This is FDirectory, a member of class TDirectoryListBox.

5.1.1.4.4 TDirectoryListBox.FOnChange Field

Pascal

```
FOnChange: TNotifyEvent;
```

C++

```
TNotifyEvent FOnChange;
```

Description

This is FOnChange, a member of class TDirectoryListBox.

5.1.1.4.5 TDirectoryListBox.OpenedBMP Field

Pascal

```
OpenedBMP: TBitmap;
```

C++

```
TBitmap OpenedBMP;
```

Description

This is OpenedBMP, a member of class TDirectoryListBox.

5.1.1.5 TDirectoryListBox Methods

The methods of the TDirectoryListBox class are listed here.

Protected Methods

	Name	Description
	BuildList (see page 1595)	This is BuildList, a member of class TDirectoryListBox.
	Change (see page 1595)	This is Change, a member of class TDirectoryListBox.
	CreateWnd (see page 1595)	Creates a Windows control corresponding to the list box component.
	DblClick (see page 1596)	OnDblClick event dispatcher.
	DrawItem (see page 1597)	Generates an OnDrawItem event.
	KeyPress (see page 1598)	Responds when the user presses a key.
	Notification (see page 1598)	Responds to notifications that components are being created or destroyed.
	ReadBitmaps (see page 1599)	This is ReadBitmaps, a member of class TDirectoryListBox.

	ReadDirectoryNames (see page 1599)	This is ReadDirectoryNames, a member of class TDirectoryListBox.

Public Methods

	Name	Description
	DisplayCase (see page 1596)	Preserves or converts the case of the string passed to it.
	FileCompareText (see page 1597)	Compares two strings, taking into account the case-sensitivity of the file system.
	GetItemPath (see page 1597)	This is GetItemPath, a member of class TDirectoryListBox.
	OpenCurrent (see page 1598)	Opens the selected directory.
	Update (see page 1600)	Refreshes the directory list.

5.1.1.5.1 TDirectoryListBox.BuildList Method

Pascal

```
procedure BuildList; virtual;
```

C++

```
virtual __fastcall BuildList();
```

Description

This is BuildList, a member of class TDirectoryListBox.

5.1.1.5.2 TDirectoryListBox.Change Method

Pascal

```
procedure Change; virtual;
```

C++

```
virtual __fastcall Change();
```

Description

This is Change, a member of class TDirectoryListBox.

5.1.1.5.3 TDirectoryListBox.CreateWnd Method

Creates a Windows control corresponding to the list box component.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the list box must be displayed. CreateWnd calls the inherited CreateWnd method, which calls

CreateParams to initialize the window-creation parameters.

CreateWindowHandle to create the window handle for the control.

CreateWnd additionally sets up the list box position, tabs, items, and columns.

See Also

Columns

CreateHandle

CreateParams

CreateWindowHandle

CreateWnd

ItemIndex

Items

TabWidth

TopIndex

5.1.1.5.4 TDirectoryListBox.DblClick Method

OnDblClick event dispatcher.

Pascal

```
procedure DblClick; override;
```

C++

```
virtual __fastcall DblClick();
```

Description

DblClick calls any event handler attached to the OnDblClick event. Override DblClick to provide other responses in addition to the inherited event-handler call when the user double-clicks the control.

The DblClick method is triggered by left mouse-button double-click message (WM_LBUTTONDBLCLK) from Windows.

See Also

Click

OnDblClick

5.1.1.5.5 TDirectoryListBox.DisplayCase Method

Preserves or converts the case of the string passed to it.

Pascal

```
function DisplayCase(const S: String): String;
```

C++

```
__fastcall UnicodeString DisplayCase(const UnicodeString S);
```

Description

DisplayCase converts S to all-lower-case (using the currently installed language driver) if neither PreserveCase (see page 1631) nor CaseSensitive (see page 1608) is true. Otherwise, it returns S unmodified.

See Also

CaseSensitive (see page 1608)

PreserveCase (see page 1631)

5.1.1.5.6 TDirectoryListBox.DrawItem Method

Generates an OnDrawItem event.

Pascal

```
procedure DrawItem(Index: Integer; Rect: TRect; State: TOwnerDrawState); override;
```

C++

```
virtual __fastcall DrawItem(int Index, TRect Rect, TOwnerDrawState State);
```

Description

DrawItem is called whenever a visual aspect of an owner-draw list box changes. The list box calls DrawItem for each visible item in its list, passing the index of the item in the Index parameter.

By default, the DrawItem method for a list box calls any event handler attached to the component's OnDrawItem event. If there is no handler attached, DrawItem fills the rectangle passed in Rect and draws any text associated with the indexed item. The default drawing ignores the State parameter, although State is passed along to attached event handlers.

See Also

ItemHeight

MeasureItem

OnDrawItem

OnMeasureItem

Style

5.1.1.5.7 TDirectoryListBox.FileCompareText Method

Compares two strings, taking into account the case-sensitivity of the file system.

Pascal

```
function FileCompareText(const A: String; const B: String): Integer;
```

C++

```
__fastcall int FileCompareText(const UnicodeString A, const UnicodeString B);
```

Description

If CaseSensitive (see page 1608) is false, FileCompareText compares the strings passed to it case-insensitively. Otherwise, it uses AnsiCompareStr to compare the strings.

See Also

AnsiCompareStr

CaseSensitive (see page 1608)

5.1.1.5.8 TDirectoryListBox.GetItemPath Method

Pascal

```
function GetItemPath(Index: Integer): string;
```

C++

```
__fastcall UnicodeString GetItemPath(int Index);
```

Description

This is GetItemPath, a member of class TDirectoryListBox.

5.1.1.5.9 TDirectoryListBox.KeyPress Method

Responds when the user presses a key.

Pascal

```
procedure KeyPress(var Key: Char); override;
```

C++

```
virtual __fastcall KeyPress(Char Key);
```

Description

KeyPress is called automatically when the list box receives a key-press message (WM_CHAR). It generates an OnKeyPress event, and then, if the AutoComplete property is true, updates ItemIndex to reflect the next character that the user typed.

The Key parameter is the character represented by the key that is pressed, not a Windows virtual key code.

See Also

OnKeyPress

5.1.1.5.10 TDirectoryListBox.Notification Method

Responds to notifications that components are being created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification allows TControl to update its PopupMenu property when the pop-up menu it refers to is destroyed.

Override the Notification method to respond to notifications that other components are about to be destroyed or have just been created. Use the Notification method to update controls that rely on other objects. Remove references to objects that are going away so that the control does not refer to objects that have been destroyed. For example, data-aware objects override the Notification method to update themselves when their data source is removed. Some objects respond to notifications that other objects of a specific type are being created. For example, the session component sets the Session property of new data-aware controls to itself when the AutoSessionName property is true.

By default, components pass along the notification to their owned components, if any.

See Also

PopupMenu

Notification

5.1.1.5.11 TDirectoryListBox.OpenCurrent Method

Opens the selected directory.

Pascal

```
procedure OpenCurrent;
```

C++

```
__fastcall OpenCurrent();
```

Description

OpenCurrent opens the directory selected in the directory list box, as if the user had double-clicked the directory.

C++ Examples:

```
/*
This example uses a directory list box, a button, and a
label on a form. When the user selects a directory in the
directory list box and clicks the button, the selected
directory opens, and the path of the second directory
displayed in the list box appears as the caption of the
label.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  DirectoryListBox1->OpenCurrent();
  Label1->Caption = DirectoryListBox1->GetItemPath(1);
}
```

Delphi Examples:

```
{
This example uses a directory list box, a button, and a
label on a form. When the user selects a directory in the
directory list box and clicks the button, the selected
directory opens, and the path of the second directory
displayed in the list box appears as the caption of the
label.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  DirectoryListBox1.OpenCurrent;
  Label1.Caption := DirectoryListBox1.GetItemPath(1);
end;
```

5.1.1.5.12 TDirectoryListBox.ReadBitmaps Method

Pascal

```
procedure ReadBitmaps; virtual;
```

C++

```
virtual __fastcall ReadBitmaps();
```

Description

This is ReadBitmaps, a member of class TDirectoryListBox.

5.1.1.5.13 TDirectoryListBox.ReadDirectoryNames Method

Pascal

```
function ReadDirectoryNames(const ParentDirectory: string; DirectoryList: TStringList):
Integer;
```

C++

```
__fastcall int ReadDirectoryNames(const UnicodeString ParentDirectory, TStringList
```

```
DirectoryList);
```

Description

This is ReadDirectoryNames, a member of class TDirectoryListBox.

5.1.1.5.14 TDirectoryListBox.Update Method

Refreshes the directory list.

Pascal

```
procedure Update; reintroduce;
```

C++

```
__fastcall Update();
```

Description

Call Update to refresh the directory list after new directories have been created or existing directories deleted.

C++ Examples:

```
/*
The following sample code sets the directory of
DirectoryListBox1 to c:\\WINDOWS when the form is created.
When Button1 is pressed, a subdirectory called
c:\\WINDOWS\\mytemp is added, but note that it is not updated
in DirectoryListBox1 until Button2 is pressed and Update is
called.
Note: A EInOutError will occur if you add a directory that
already exists.  Also, you must add the new directory to
your current directory to see the magic happen.  Also,
capitalization matters in C++ and the file spearators must
be "\\".
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  ForceDirectories(Edit1->Text);
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  DirectoryListBox1->Update();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  DirectoryListBox1->Directory = "c:\\WINDOWS";
}
```

Delphi Examples:

```
{
The following sample code sets the directory of
DirectoryListBox1 to C:\WINDOWS when the form is created.
When Button1 is pressed, a subdirectory called
mytemp is added to C:\WINDOWS, but note that it is not
updated in DirectoryListBox1 until Button2 is pressed
and Update is called.
Note: A EInOutError will occur if you add a directory that
already exists.  Also, you must add the new directory to
your current path to see the magic happen.
}

procedure TForm1.Button1Click(Sender: TObject);
begin
```

```
  MkDir(Edit1.Text);
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  DirectoryListBox1.Update;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  DirectoryListBox1.Directory := 'c:\WINDOWS';
end;
```

5.1.1.6 TDirectoryListBox Properties

The properties of the TDirectoryListBox class are listed here.

Public Properties

	Name	Description
R	CaseSensitive (see page 1608)	Indicates whether the system supports case-sensitive directory information.
	Directory (see page 1611)	Determines the current directory for the directory list box control.
	Drive (see page 1617)	Determines the drive for which the list box displays the directory structure.
R	PreserveCase (see page 1631)	Indicates whether the file system preserves the case of file names when writing to disk.

Published Properties

	Name	Description
	Align (see page 1602)	Determines how the control aligns within its container (parent control).
	Anchors (see page 1605)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 1606)	Determines whether the user can give focus to items by typing in the list.
	BevelEdges (see page 1606)	Specifies which edges of the control are beveled.
	BevelInner (see page 1606)	Specifies the cut of the inner bevel.
	BevelKind (see page 1607)	Specifies the control's bevel style.
	BevelOuter (see page 1607)	Specifies the cut of the outer bevel.
	Color (see page 1608)	Specifies the background color of the control.
	Columns (see page 1609)	Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.
	Constraints (see page 1610)	Specifies the size constraints for the control.
	Ctl3D (see page 1610)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DirLabel (see page 1612)	Provides a simple way to display the current directory as the caption of a label control.
	DoubleBuffered (see page 1613)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 1615)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragMode (see page 1615)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 1618)	Controls whether the control responds to mouse, keyboard, and timer events.
	FileList (see page 1618)	Provides a simple way to connect a directory list box with a file list box.
	Font (see page 1621)	Controls the attributes of text written on or in the control.
	ImeMode (see page 1622)	Determines the behavior of the input method editor (IME).
	ImeName (see page 1622)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IntegralHeight (see page 1623)	Determines whether the list box displays the partial items.
	ItemHeight (see page 1623)	Specifies the height in pixels of an item in an owner-draw list box.
	ParentColor (see page 1624)	Determines where a control looks for its color information.
	ParentCtl3D (see page 1624)	Determines where a component looks to determine if it should appear three dimensional.

	ParentDoubleBuffered (see page 1625)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 1625)	Determines where a control looks for its font information.
	ParentShowHint (see page 1625)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 1626)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 1631)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 1633)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 1633)	Determines if the user can tab to a control.
	Visible (see page 1634)	Determines whether the component appears onscreen.

5.1.1.6.1 TDirectoryListBox.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
```

```
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*

        pts[i]->Brush->Color = colorPalette[i];
  }
```

```
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane - a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;

Parent

Anchors

5.1.1.6.2 TDirectoryListBox.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

5.1.1.6.3 TDirectoryListBox.AutoComplete Property

Determines whether the user can give focus to items by typing in the list.

Pascal

```
property AutoComplete;
```

C++

```
__property AutoComplete;
```

Description

Use AutoComplete to specify whether the list box automatically updates the ItemIndex property in response to user keystrokes. When AutoComplete is true, the item with focus changes to the first item that begins with the sequence of characters that the user typed. As the user types more characters, ItemIndex may change to a later item because the string to match becomes longer.

ItemIndex

5.1.1.6.4 TDirectoryListBox.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges;
```

C++

```
__property BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner

BevelOuter

BevelKind

5.1.1.6.5 TDirectoryListBox.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner;
```

C++

```
__property BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges

BevelOuter

BevelKind

BevelWidth

BorderWidth

5.1.1.6.6 TDirectoryListBox.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind;
```

C++

```
__property BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges

BevelOuter

BevelInner

BevelWidth

5.1.1.6.7 TDirectoryListBox.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter;
```

C++

```
__property BevelOuter;
```

Description

Use BevelOuter to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges

BevelInner

BevelKind

BevelWidth

5.1.1.6.8 TDirectoryListBox.CaseSensitive Property

Indicates whether the system supports case-sensitive directory information.

Pascal

```
property CaseSensitive: Boolean;
```

C++

```
__property Boolean CaseSensitive;
```

Description

Read CaseSensitive to ascertain whether the current file system supports case-sensitive file names. CaseSensitive returns true if it does and false if it does not.

See Also

DisplayCase (see page 1596)

FileCompareText (see page 1597)

PreserveCase (see page 1631)

5.1.1.6.9 TDirectoryListBox.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
```

```
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

ParentColor

5.1.1.6.10 TDirectoryListBox.Columns Property

Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.

Pascal

```
property Columns;
```

C++

```
__property Columns;
```

Description

Use Columns to specify the number of columns, in a multi-column list box, that are visible without having to use the horizontal scroll bar.

Multi-column list boxes have a horizontal scroll bar that allows users to view multiple columns as they wrap. The default value for Columns is 0, meaning that the list box is not multi-column. That is, users can scroll only vertically and the list of items will not wrap.

For Columns values greater than 0, multiple columns accommodate the items as they wrap beyond the bottom of the list box. The Columns property specifies the number of columns that are visible without having to horizontally scroll the list box.

The width of each column depends upon both the Width property and the number of Columns.

See Also

ItemHeight

Width

5.1.1.6.11 TDirectoryListBox.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

OnCanResize

5.1.1.6.12 TDirectoryListBox.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

BevelOuter

BorderWidth

5.1.1.6.13 TDirectoryListBox.Directory Property

Determines the current directory for the directory list box control.

Pascal

```
property Directory: string;
```

C++

```
__property UnicodeString Directory;
```

Description

The directory list box displays the value of the Directory property as the current directory in the list box. The example shows how a directory list box and a file list box can work together through their Directory properties.

If the form contains a file list box, you can set the FileList (see page 1618) property to have the file list box automatically display the files from the directory specified by the Directory property.

C++ Examples:

```
/*
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
*/
void __fastcall TForm1::DriveComboBox1Change(TObject *Sender)
{
  DirectoryListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Directory = DirectoryListBox1->Directory;
}

void __fastcall TForm1::DirectoryListBox1Change(TObject *Sender)
{
  FileListBox1->Directory = DirectoryListBox1->Directory;
}
```

Delphi Examples:

```
{
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
}
procedure TForm1.DirectoryListBox1Change(Sender: TObject);
begin
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;
```

```
procedure TForm1.DriveComboBox1Change(Sender: TObject);
begin
  DirectoryListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;
```

DirLabel (see page 1612)

Drive (see page 1617)

FileList (see page 1618)

5.1.1.6.14 TDirectoryListBox.DirLabel Property

Provides a simple way to display the current directory as the caption of a label control.

Pascal

```
property DirLabel: TLabel;
```

C++

```
__property TLabel DirLabel;
```

Description

Use DirLabel to specify a label. When the current directory changes in the directory list box, the change is reflected in the caption of the label.

C++ Examples:

```
/*
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  FileListBox1->FileEdit = Edit1;
  FilterComboBox1->FileList = FileListBox1;
  DirectoryListBox1->FileList = FileListBox1;
  DirectoryListBox1->DirLabel = Label1;
  DriveComboBox1->DirList = DirectoryListBox1;
  Button1->Default = true;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FileListBox1->ApplyFilePath(Edit1->Text);
}
```

Delphi Examples:

```
{
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
}
procedure TForm1.Button1Click(Sender: TObject);
```

```
begin
  FileListBox1.ApplyFilePath(Edit1.Text);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  FileListBox1.FileEdit := Edit1;
  FilterComboBox1.FileList := FileListBox1;
  DirectoryListBox1.FileList := FileListBox1;
  DirectoryListBox1.DirLabel := Label1;
  DriveComboBox1.DirList := DirectoryListBox1;
  Button1.Default := True;
end;
```

FileEdit (see page 1763)

FileList (see page 1618)

5.1.1.6.15 TDirectoryListBox.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
```

```
    Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
```

```
    end;
  end;
end;

5.1.1.6.16 TDirectoryListBox.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

5.1.1.6.17 TDirectoryListBox.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
```

```
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}

Arranging the Order of Persistent Columns

5.1.1.6.18 TDirectoryListBox.Drive Property

Determines the drive for which the list box displays the directory structure.

Pascal

```
property Drive: Char;
```

C++

```
__property Char Drive;
```

Description

When the value of Drive changes, the Directory (see page 1611) value changes to the current directory on the specified drive.

C++ Examples:

```
/*
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
*/
void __fastcall TForm1::DriveComboBox1Change(TObject *Sender)
{
  DirectoryListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Directory = DirectoryListBox1->Directory;
}

void __fastcall TForm1::DirectoryListBox1Change(TObject *Sender)
{
  FileListBox1->Directory = DirectoryListBox1->Directory;
}
```

Delphi Examples:

```
{
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
}
procedure TForm1.DirectoryListBox1Change(Sender: TObject);
begin
  FileListBox1.Directory := DirectoryListBox1.Directory;
```

```
end;

procedure TForm1.DriveComboBox1Change(Sender: TObject);
begin
  DirectoryListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;

5.1.1.6.19 TDirectoryListBox.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

5.1.1.6.20 TDirectoryListBox.FileList Property

Provides a simple way to connect a directory list box with a file list box.

Pascal

```
property FileList: TFileListBox;
```

C++

```
__property TFileListBox FileList;
```

Description

Use FileList to specify a file list box in which to display the files of the current directory.

C++ Examples:

```
/*
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
```

```
and enters a path or filename in the edit box and presses
the button, all the controls update:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  FileListBox1->FileEdit = Edit1;
  FilterComboBox1->FileList = FileListBox1;
  DirectoryListBox1->FileList = FileListBox1;
  DirectoryListBox1->DirLabel = Label1;
  DriveComboBox1->DirList = DirectoryListBox1;
  Button1->Default = true;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FileListBox1->ApplyFilePath(Edit1->Text);
}
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
```

Delphi Examples:

```
{
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  FileListBox1.ApplyFilePath(Edit1.Text);
```

```
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    FileListBox1.FileEdit := Edit1;
    FilterComboBox1.FileList := FileListBox1;
    DirectoryListBox1.FileList := FileListBox1;
    DirectoryListBox1.DirLabel := Label1;
    DriveComboBox1.DirList := DirectoryListBox1;
    Button1.Default := True;
  end;
  {
  This example shows how to use a splitter to divide a form
  into resizable panes.  All objects on the form are created
  dynamically in the OnCreate event handler of the form. To
  run this example, add ExtCtrls and FileCtrl to the uses
  clause of the form's implementation section.
  Note that when creating a splitter dynamically at runtime,
  it is important to set its position to the appropriate side
  of the control it will resize.
  }
  procedure TForm1.FormCreate(Sender: TObject);
  var
    Split: TSplitter;
    Files: TFileListBox;
    Dirs: TDirectoryListBox;
  begin
    { first add a directory list box to the form }
    Dirs := TDirectoryListBox.Create(Form1);
    { line it up on the left of the form }
    Dirs.Parent := Form1;
    Dirs.Align := alLeft;
    Dirs.Width := Form1.ClientWidth div 3;
  { now add the splitter to divide the directory pane from the file pane }
    Split := TSplitter.Create(Form1);
    Split.Parent := Form1;
    { make sure the splitter is to the right of the directory list box! }
    Split.Left := Dirs.Left + Dirs.Width + 1;
    Split.Align := Dirs.Align; { give it the same alignment as the directory }
    { each pane must be at least one quarter of the form's width }
    Split.MinSize := Form1.ClientWidth div 4;
    { Finally, create the last pane - a file list box }
    Files := TFileListBox.Create(Form1);
    Files.Parent := Form1;
    Files.Align := alClient;
    Dirs.FileList := Files; { link the file list box to the directory list box }
  end;
```

5.1.1.6.21 TDirectoryListBox.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;

Displaying and Editing Text in a Memo Control

5.1.1.6.22 TDirectoryListBox.ImeMode Property

Determines the behavior of the input method editor (IME).

Pascal

```
property ImeMode;
```

C++

```
__property ImeMode;
```

Description

Set ImeMode to configure the way an IME processes user keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeMode allows a control to influence the type of conversion performed by the IME so that it is appropriate for the input expected by the control. For example, a control that only accepts numeric input might specify an ImeMode of imClose, as no conversion is necessary for numeric input.

Note: The value of ImeMode only takes effect when the control receives focus. To change the value of ImeMode when the control already has input focus, call the SetIme method.

ImeName

ResetIme

ResetImeComposition

SetIme

SetImeCompositionWindow

5.1.1.6.23 TDirectoryListBox.ImeName Property

Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

Pascal

```
property ImeName;
```

C++

```
__property ImeName;
```

Description

Set ImeName to specify which IME to use for converting keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeName must specify one of the IMEs that has been installed through the Windows control panel. The property inspector provides a drop-down list of all currently installed IMEs on the system. At runtime, applications can obtain a list of currently installed IMEs from the global Screen variable.

If ImeName specifies an unavailable IME, the IME that was active when the application started is used instead. No exception is generated.

Note: The value of ImeName only takes effect when the control receives focus. To change the value of ImeName after the control has input focus, call the SetIme method.

5.1.1.6.24 TDirectoryListBox.IntegralHeight Property

Determines whether the list box displays the partial items.

Pascal

```
property IntegralHeight;
```

C++

```
__property IntegralHeight;
```

Description

IntegralHeight controls the height of the list box itself.

When IntegralHeight is true, and the Style property is lsOwnerDrawFixed, the list box height will always be a multiple of the ItemHeight property value. In this case, items will never be partially displayed.

If IntegralHeight is false, the list box height can be set to any value, but the last item may not be fully displayed.

If the Style property value of the list box is lbOwnerDrawVariable, setting the IntegralHeight property to true has no effect.

ItemHeight

Items

Style

Using TDBListBox and TDBComboBox

5.1.1.6.25 TDirectoryListBox.ItemHeight Property

Specifies the height in pixels of an item in an owner-draw list box.

Pascal

```
property ItemHeight;
```

C++

```
__property ItemHeight;
```

Description

Use ItemHeight to control the height of an item in a list box when the Style property is lbOwnerDrawFixed. The ItemHeight property can also affect the height of the list box itself. When the IntegralHeight property is true, the height of the list box is always an increment of the ItemHeight value.

If the Style property is lbStandard or lbOwnerDrawVariable, the value of ItemHeight is ignored.

5.1.1.6.26 TDirectoryListBox.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

ParentShowHint

5.1.1.6.27 TDirectoryListBox.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

5.1.1.6.28 TDirectoryListBox.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

5.1.1.6.29 TDirectoryListBox.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

ParentColor

ParentShowHint

5.1.1.6.30 TDirectoryListBox.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

5.1.1.6.31 TDirectoryListBox.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
```

```
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
```

```
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
```

```
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{

5.1.1.6.32 TDirectoryListBox.PreserveCase Property

Indicates whether the file system preserves the case of file names when writing to disk.

Pascal

```
property PreserveCase: Boolean;
```

C++

```
__property Boolean PreserveCase;
```

Description

Read PreserveCase to ascertain whether the current file system preserves the case of file names. PreserveCase returns true if it does and false if it does not.

See Also

CaseSensitive (see page 1608)

DisplayCase (see page 1596)

5.1.1.6.33 TDirectoryListBox.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
```

```
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

Displaying Fly-over Help

5.1.1.6.34 TDirectoryListBox.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

5.1.1.6.35 TDirectoryListBox.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

TabOrder

5.1.1.6.36 TDirectoryListBox.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
```

```
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin

5.1.1.7 TDirectoryListBox Events

The events of the TDirectoryListBox class are listed here.

Published Events

	Name	Description
	OnChange (see page 1636)	Occurs when the user selects a new directory with the mouse or keyboard when the user moves the selection bar and presses enter.
	OnClick (see page 1638)	Occurs when the user clicks the control.

	OnContextPopup (see page 1639)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 1640)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 1640)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 1643)	Occurs when the user drags an object over a control.
	OnEndDrag (see page 1647)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 1648)	Occurs when a control receives the input focus.
	OnExit (see page 1650)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 1653)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 1657)	Occurs when a key is pressed.
	OnKeyUp (see page 1658)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 1659)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 1660)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 1663)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 1663)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 1663)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 1665)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDrag (see page 1668)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

5.1.1.7.1 TDirectoryListBox.OnChange Event

Occurs when the user selects a new directory with the mouse or keyboard when the user moves the selection bar and presses enter.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write an OnChange event handler to perform an action whenever a new directory is selected.

C++ Examples:

```
/*
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
*/
void __fastcall TForm1::DriveComboBox1Change(TObject *Sender)
{
  DirectoryListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Directory = DirectoryListBox1->Directory;
}

void __fastcall TForm1::DirectoryListBox1Change(TObject *Sender)
```

```
{
  FileListBox1->Directory = DirectoryListBox1->Directory;
}
/*
This example uses a file list box, a directory list box, and
a label on a form. When the user uses the directory list box
to change directories, a message appears and the color of
the form changes if the file AUTOEXEC.BAT is in the new
directory. The code is written in the OnChange event of the
directory list box:
*/
void __fastcall TForm1::DirectoryListBox1Change(TObject *Sender)
{
  FileListBox1->Directory = DirectoryListBox1->Directory;
  if (FileListBox1->Items->IndexOf("AUTOEXEC.BAT") > -1)
  {
    Color = clYellow;
    Label1->Caption = "You are in the root directory!";
  }
}
```

Delphi Examples:

```
{
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
}
procedure TForm1.DirectoryListBox1Change(Sender: TObject);
begin
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;

procedure TForm1.DriveComboBox1Change(Sender: TObject);
begin
  DirectoryListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;
{
This example uses a file list box, a directory list box, and
a label on a form. When the user uses the directory list box
to change directories, a message appears and the color of
the form changes if the file AUTOEXEC.BAT is in the new
directory. The code is written in the OnChange event of the
directory list box:
}
procedure TForm1.DirectoryListBox1Change(Sender: TObject);
begin
  FileListBox1.Directory := DirectoryListBox1.Directory;
  if FileListBox1.Items.IndexOf('AUTOEXEC.BAT') > -1 then
  begin
    Color := clYellow;
    Label1.Caption := 'You are in the root directory!';
  end
  else
  begin
    Color := clBtnFace;
    Label1.Caption := '';
  end;
end;
```

5.1.1.7.2 TDirectoryListBox.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
```

```
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

5.1.1.7.3 TDirectoryListBox.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

5.1.1.7.4 TDirectoryListBox.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick

Responding to User Actions at Runtime

5.1.1.7.5 TDirectoryListBox.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
```

```
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}

5.1.1.7.6 TDirectoryListBox.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
```

```
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
type
  TForm1 = class(TForm)
    Panel1: TPanel;
    Label1: TLabel;
    procedure Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
      State: TDragState; var Accept: Boolean);
    procedure FormDragOver(Sender, Source: TObject; X, Y: Integer;
      State: TDragState; var Accept: Boolean);
    procedure FormDragDrop(Sender, Source: TObject; X, Y: Integer);

OnStartDock

5.1.1.7.7 TDirectoryListBox.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;

5.1.1.7.8 TDirectoryListBox.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/

5.1.1.7.9 TDirectoryListBox.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK

button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
```

```
    initialize the mask of each maskedit box
    according to IP address coding conventions
    }
    MaskEdit1.EditMask := '!099.099.099.099;1; ';
    MaskEdit2.EditMask := '!099.099.099.099;1; ';
    MaskEdit3.EditMask := '!099.099.099.099;1; ';

    MaskEdit2.OnExit := MaskEdit2Exit;
  end;

  procedure TForm1.MaskEdit2Exit(Sender: TObject);
  var
    net1, net2, host1, host2,
    netmask1, netmask2, hostmask1, hostmask2,

OnEnter

ActiveControl (see page 2145)

5.1.1.7.10 TDirectoryListBox.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown;
```

C++

```
__property OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).

OnKeyPress

OnKeyUp

5.1.1.7.11 TDirectoryListBox.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress;
```

C++

```
__property OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

5.1.1.7.12 TDirectoryListBox.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp;
```

C++

```
__property OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
end;

procedure TForm1.FormKeyDown(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := clAqua;
    if (ComboBox1.Text = 'KeyDown') then
      ComboBox1.Text := 'KeyDown2'
    else
      ComboBox1.Text := 'KeyDown';
    WriteLn(ComboBox1.Text);
  end;
end;

procedure TForm1.FormKeyUp(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := FormColor;
    if (ComboBox1.Text = 'KeyUp') then
      ComboBox1.Text := 'KeyUp2'
    else
      ComboBox1.Text := 'KeyUp';
    WriteLn(ComboBox1.Text);
  end;
end;

OnKeyPress

5.1.1.7.13 TDirectoryListBox.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

5.1.1.7.14 TDirectoryListBox.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse

button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }

5.1.1.7.15 TDirectoryListBox.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

5.1.1.7.16 TDirectoryListBox.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

5.1.1.7.17 TDirectoryListBox.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

Responding to a Mouse-up Action

5.1.1.7.19 TDirectoryListBox.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

5.1.2 TDriveComboBox Class

TDriveComboBox implements a specialized combo box that displays all the drives available when the application runs.

Class Hierarchy

Pascal

```
[SecurityPermission(SecurityAction.Demand, Unrestricted=True)]
TDriveComboBox = class(TCustomComboBox);
```

C++

```
[SecurityPermission(SecurityAction.Demand, Unrestricted=True)]
class TDriveComboBox : public TCustomComboBox;
```

File

FileCtrl

Description

Add TDriveComboBox to a form to allow users to select a drive. Use TDriveComboBox along with TFileListBox (see page 1734), TFilterComboBox (see page 1813), and TDirectoryListBox (see page 1589) to add full file selection capabilities to a form.

To add a standard Windows 95 file open or save dialog to an application, use TOpenDialog or TSaveDialog instead.

See Also

TDirectoryListBox (see page 1589)

TFileListBox (see page 1734)

TFilterComboBox (see page 1813)

TOpenDialog

TSaveDialog

5.1.2.1 TDriveComboBox Members

The following tables list the members exposed by TDriveComboBox.

Protected Fields

	Name	Description
	CDROMBMP (see page 1672)	This is CDROMBMP, a member of class TDriveComboBox.
	FixedBMP (see page 1672)	This is FixedBMP, a member of class TDriveComboBox.
	FloppyBMP (see page 1672)	This is FloppyBMP, a member of class TDriveComboBox.
	NetworkBMP (see page 1672)	This is NetworkBMP, a member of class TDriveComboBox.
	RAMBMP (see page 1673)	This is RAMBMP, a member of class TDriveComboBox.

Protected Methods

	Name	Description
	BuildList (see page 1673)	This is BuildList, a member of class TDriveComboBox.
	Click (see page 1673)	Respond to user click.
	CreateWnd (see page 1674)	Creates the Windows control that represents the combo box.
	DrawItem (see page 1674)	Generates an OnDrawItem event.
	Notification (see page 1675)	Responds to notifications that components are being created or destroyed.

Public Methods

	Name	Description
	Create (see page 1671)	Creates and initializes an instance of TDriveComboBox (see page 1668).
	Destroy (see page 1671)	Destroys an instance of TDriveComboBox (see page 1668).

Public Properties

	Name	Description
	Drive (see page 1690)	Indicates the currently selected drive displayed in the edit portion of the combo box.
	Text (see page 1704)	Contains a text string associated with the control.

Published Events

	Name	Description
	OnChange (see page 1708)	Occurs when the user changes the text displayed in the edit region.
	OnClick (see page 1710)	Occurs when the user clicks the control.
	OnContextPopup (see page 1712)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 1712)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 1713)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 1716)	Occurs when the user drags an object over a control.
	OnDropDown (see page 1719)	Occurs when the user opens the drop-down list.
	OnEndDrag (see page 1720)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 1721)	Occurs when a control receives the input focus.
	OnExit (see page 1724)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 1727)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 1730)	Occurs when a key is pressed.
	OnKeyUp (see page 1731)	Occurs when the user releases a key that has been pressed.
	OnMouseEnter (see page 1733)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 1733)	Occurs when the user moves the mouse outside of a control.
	OnStartDrag (see page 1734)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 1676)	Determines how the control aligns within its container (parent control).
	Anchors (see page 1680)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 1680)	Positions to matching list items as you type.
	AutoDropDown (see page 1681)	Specifies whether the drop-down list drops down automatically in response to user keystrokes.
	BevelEdges (see page 1682)	Specifies which edges of the control are beveled.
	BevelInner (see page 1682)	Specifies the cut of the inner bevel.
	BevelKind (see page 1683)	Specifies the control's bevel style.
	BevelOuter (see page 1683)	Specifies the cut of the outer bevel.
	Color (see page 1684)	Specifies the background color of the control.
	Constraints (see page 1684)	Specifies the size constraints for the control.
	Ctl3D (see page 1685)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DirList (see page 1685)	Connects the drive combo box to a directory list box.
	DoubleBuffered (see page 1687)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 1688)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragMode (see page 1689)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 1692)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 1692)	Controls the attributes of text written on or in the control.
	ImeMode (see page 1693)	Determines the behavior of the input method editor (IME).
	ImeName (see page 1694)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	ParentColor (see page 1694)	Determines where a control looks for its color information.

	ParentCtl3D (see page 1695)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 1695)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 1695)	Determines where a control looks for its font information.
	ParentShowHint (see page 1696)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 1696)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 1701)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 1703)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 1704)	Determines if the user can tab to a control.
	TextCase (see page 1705)	Determines if the volume name in the Text (see page 1704) property appears in uppercase or lowercase.
	Visible (see page 1706)	Determines whether the component appears onscreen.

5.1.2.2 TDriveComboBox.Create Constructor

Creates and initializes an instance of TDriveComboBox (see page 1668).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TDriveComboBox(TComponent * AOwner);
```

Description

Call Create to create a TDriveComboBox (see page 1668) object at runtime. Drive (see page 1690) combo boxes placed on a form at design time are created automatically.

After allocating the memory for the combo box, Create fills the combo box with all the drives on the system, and initializes the Drive (see page 1690) property to the current drive.

See Also

Drive (see page 1690)

Create

5.1.2.3 TDriveComboBox.Destroy Destructor

Destroys an instance of TDriveComboBox (see page 1668).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDriveComboBox();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free checks that the drive combo box reference is not nil, and only then calls Destroy.

See Also

System::TObject::Free

5.1.2.4 TDriveComboBox Fields

The fields of the TDriveComboBox class are listed here.

Protected Fields

	Name	Description
	CDROMBMP (see page 1672)	This is CDROMBMP, a member of class TDriveComboBox.
	FixedBMP (see page 1672)	This is FixedBMP, a member of class TDriveComboBox.
	FloppyBMP (see page 1672)	This is FloppyBMP, a member of class TDriveComboBox.
	NetworkBMP (see page 1672)	This is NetworkBMP, a member of class TDriveComboBox.
	RAMBMP (see page 1673)	This is RAMBMP, a member of class TDriveComboBox.

5.1.2.4.1 TDriveComboBox.CDROMBMP Field

Pascal

```
CDROMBMP: TBitmap;
```

C++

```
TBitmap CDROMBMP;
```

Description

This is CDROMBMP, a member of class TDriveComboBox.

5.1.2.4.2 TDriveComboBox.FixedBMP Field

Pascal

```
FixedBMP: TBitmap;
```

C++

```
TBitmap FixedBMP;
```

Description

This is FixedBMP, a member of class TDriveComboBox.

5.1.2.4.3 TDriveComboBox.FloppyBMP Field

Pascal

```
FloppyBMP: TBitmap;
```

C++

```
TBitmap FloppyBMP;
```

Description

This is FloppyBMP, a member of class TDriveComboBox.

5.1.2.4.4 TDriveComboBox.NetworkBMP Field

Pascal

```
NetworkBMP: TBitmap;
```

C++

```
TBitmap NetworkBMP;
```

Description

This is NetworkBMP, a member of class TDriveComboBox.

5.1.2.4.5 TDriveComboBox.RAMBMP Field

Pascal

```
RAMBMP: TBitmap;
```

C++

```
TBitmap RAMBMP;
```

Description

This is RAMBMP, a member of class TDriveComboBox.

5.1.2.5 TDriveComboBox Methods

The methods of the TDriveComboBox class are listed here.

Protected Methods

	Name	Description
	BuildList (see page 1673)	This is BuildList, a member of class TDriveComboBox.
	Click (see page 1673)	Respond to user click.
	CreateWnd (see page 1674)	Creates the Windows control that represents the combo box.
	DrawItem (see page 1674)	Generates an OnDrawItem event.
	Notification (see page 1675)	Responds to notifications that components are being created or destroyed.

5.1.2.5.1 TDriveComboBox.BuildList Method

Pascal

```
procedure BuildList; virtual;
```

C++

```
virtual __fastcall BuildList();
```

Description

This is BuildList, a member of class TDriveComboBox.

5.1.2.5.2 TDriveComboBox.Click Method

Respond to user click.

Pascal

```
procedure Click; override;
```

C++

```
virtual __fastcall Click();
```

Description

Click is called automatically when the user left-clicks the control. Component or application code can call Click to simulate a user mouse click. This is often done in menu actions and hotkey handlers.

As implemented in TControl, Click queries whether the OnClick event handler exists and is different from the OnExecute handler for the control's Action. If this is true, the OnClick event handler is called. If this is false, and the Action OnExecute event handler exists, the Action's Execute method is called. Override Click to provide additional behavior.

See Also

Action

OnExecute

Execute

DblClick

OnClick

5.1.2.5.3 TDriveComboBox.CreateWnd Method

Creates the Windows control that represents the combo box.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

The CreateHandle method calls CreateWnd to handle the particulars of creating the combo box window. TCustomCombo overrides the inherited method to ensure that the newly-created window and the TCustomCombo properties correctly reflect each other.

The Windows control for the combo box can be temporarily destroyed and recreated in order to set properties that require changing the window creation parameters. Thus, CreateWnd may be called more than once during the lifetime of the TCustomCombo instance.

See Also

CreateHandle

5.1.2.5.4 TDriveComboBox.DrawItem Method

Generates an OnDrawItem event.

Pascal

```
procedure DrawItem(Index: Integer; Rect: TRect; State: TOwnerDrawState); override;
```

C++

```
virtual __fastcall DrawItem(int Index, TRect Rect, TOwnerDrawState State);
```

Description

When Style is csOwnerDrawFixed or csOwnerDrawVariable, DrawItem is called whenever an item in the list needs to be drawn. If an OnDrawItem event handler is assigned, DrawItem generates an OnDrawItem event, passing the Index, Rect, and State parameters to the event handler. Otherwise, OnDrawItem fills the rectangle passed in Rect and draws any text associated with

the indexed item, ignoring the State parameter.

Override DrawItem to provide class-specific drawing code for the items in the list.

See Also

OnDrawItem

Style

5.1.2.5.5 TDriveComboBox.Notification Method

Responds to notifications that components are being created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification allows TControl to update its PopupMenu property when the pop-up menu it refers to is destroyed.

Override the Notification method to respond to notifications that other components are about to be destroyed or have just been created. Use the Notification method to update controls that rely on other objects. Remove references to objects that are going away so that the control does not refer to objects that have been destroyed. For example, data-aware objects override the Notification method to update themselves when their data source is removed. Some objects respond to notifications that other objects of a specific type are being created. For example, the session component sets the Session property of new data-aware controls to itself when the AutoSessionName property is true.

By default, components pass along the notification to their owned components, if any.

Notification

5.1.2.6 TDriveComboBox Properties

The properties of the TDriveComboBox class are listed here.

Public Properties

	Name	Description
	Drive (see page 1690)	Indicates the currently selected drive displayed in the edit portion of the combo box.
	Text (see page 1704)	Contains a text string associated with the control.

Published Properties

	Name	Description
	Align (see page 1676)	Determines how the control aligns within its container (parent control).
	Anchors (see page 1680)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 1680)	Positions to matching list items as you type.
	AutoDropDown (see page 1681)	Specifies whether the drop-down list drops down automatically in response to user keystrokes.
	BevelEdges (see page 1682)	Specifies which edges of the control are beveled.
	BevelInner (see page 1682)	Specifies the cut of the inner bevel.

	BevelKind (see page 1683)	Specifies the control's bevel style.
	BevelOuter (see page 1683)	Specifies the cut of the outer bevel.
	Color (see page 1684)	Specifies the background color of the control.
	Constraints (see page 1684)	Specifies the size constraints for the control.
	Ctl3D (see page 1685)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DirList (see page 1685)	Connects the drive combo box to a directory list box.
	DoubleBuffered (see page 1687)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 1688)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragMode (see page 1689)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 1692)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 1692)	Controls the attributes of text written on or in the control.
	ImeMode (see page 1693)	Determines the behavior of the input method editor (IME).
	ImeName (see page 1694)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	ParentColor (see page 1694)	Determines where a control looks for its color information.
	ParentCtl3D (see page 1695)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 1695)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 1695)	Determines where a control looks for its font information.
	ParentShowHint (see page 1696)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 1696)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 1701)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 1703)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 1704)	Determines if the user can tab to a control.
	TextCase (see page 1705)	Determines if the volume name in the Text (see page 1704) property appears in uppercase or lowercase.
	Visible (see page 1706)	Determines whether the component appears onscreen.

5.1.2.6.1 TDriveComboBox.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the

edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
```

```
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane - a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
```

```
  }

Parent

Anchors

5.1.2.6.2 TDriveComboBox.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

5.1.2.6.3 TDriveComboBox.AutoComplete Property

Positions to matching list items as you type.

Pascal

```
property AutoComplete;
```

C++

```
__property AutoComplete;
```

Description

AutoComplete will position to matching list values as you type, saving you keystrokes.

As you type, the ItemIndex property is updated with the list entry that matches the characters you have entered. As you type, different list entries may match, and ItemIndex changes accordingly.

There is a delay of AutoCompleteDelay milliseconds between the characters typed and the autocomplete operation.

C++ Examples:

```
/*
This is a very simple example showing how to create a comboBox, add to
it some choices, selecting a default value and getting the selected
value.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
//comboBox initialize
```

```
comb = new TComboBox(this);
comb->Parent = this;

//visual options
comb->Align = TAlign::alLeft;
comb->DoubleBuffered = true;
comb->AutoComplete = true;

//adding items to the combo box
comb->AddItem("firstChoice",NULL);
comb->AddItem("secondChoice",NULL);
comb->AddItem("thirdChoice",NULL);

//setting the default value
comb->ItemIndex = 1;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Button1Click(TObject *Sender)
{
MessageDlg("Selected text: " + comb->Text,
            mtInformation, TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This is a very simple example showing how to create a comboBox, add to
it some choices, selecting a default value and getting the selected
value.
}
procedure TForm3.Button1Click(Sender: TObject);
begin
  MessageDlg('Selected text: ' + comb.Text, mtInformation,
            mbYesNo, 0);
end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  //initialize the combo box
  comb := TComboBox.Create(Self);
  comb.Parent := Self;

  //visual options
  comb.Align := alLeft;
  comb.DoubleBuffered := true;
  comb.AutoComplete := true;

  //adding items to the combo box
  comb.AddItem('firstChoice', nil);
  comb.AddItem('secondChoice', nil);
  comb.AddItem('thirdChoice', nil);

  //setting the default value
  comb.ItemIndex := 1;
end;
```

AutoCompleteDelay

5.1.2.6.4 TDriveComboBox.AutoDropDown Property

Specifies whether the drop-down list drops down automatically in response to user keystrokes.

Pascal

```
property AutoDropDown;
```

C++

```
__property AutoDropDown;
```

Description

When AutoDropDown is true, the combo box automatically drops down its list when the user starts typing a string while the combo box has focus.

When AutoDropDown is false, the user must explicitly use the drop-down button to drop down the combo box list.

See Also

autocomplete

OnDropDown

DroppedDown

5.1.2.6.5 TDriveComboBox.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges;
```

C++

```
__property BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner

BevelOuter

BevelKind

5.1.2.6.6 TDriveComboBox.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner;
```

C++

```
__property BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges

BevelOuter

BevelKind

BevelWidth

BorderWidth

5.1.2.6.7 TDriveComboBox.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind;
```

C++

```
__property BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

BevelEdges

BevelOuter

BevelInner

BevelWidth

5.1.2.6.8 TDriveComboBox.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter;
```

C++

```
__property BevelOuter;
```

Description

Use BevelOuter to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges

BevelInner

BevelKind

BevelWidth

5.1.2.6.9 TDriveComboBox.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor

5.1.2.6.10 TDriveComboBox.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

AutoSize

Align

Anchors

OnConstrainedResize

OnCanResize

5.1.2.6.11 TDriveComboBox.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

ParentCtl3D

BevelKind

BevelInner

BevelOuter

BorderWidth

5.1.2.6.12 TDriveComboBox.DirList Property

Connects the drive combo box to a directory list box.

Pascal

```
property DirList: TDirectoryListBox;
```

C++

```
__property TDirectoryListBox DirList;
```

Description

Set DirList to a directory list box control that should update when the user changes the drive. When a new drive is selected in the drive combo box, the specified directory list box updates to display the directory structure and the current directory on the new drive.

Note: If the form contains a file list box as well, it can be updated automatically using the FileList property of the directory list box object.

C++ Examples:

```
/*
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  FileListBox1->FileEdit = Edit1;
  FilterComboBox1->FileList = FileListBox1;
  DirectoryListBox1->FileList = FileListBox1;
  DirectoryListBox1->DirLabel = Label1;
  DriveComboBox1->DirList = DirectoryListBox1;
  Button1->Default = true;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FileListBox1->ApplyFilePath(Edit1->Text);
}
```

Delphi Examples:

```
{
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  FileListBox1.ApplyFilePath(Edit1.Text);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  FileListBox1.FileEdit := Edit1;
  FilterComboBox1.FileList := FileListBox1;
  DirectoryListBox1.FileList := FileListBox1;
  DirectoryListBox1.DirLabel := Label1;
  DriveComboBox1.DirList := DirectoryListBox1;
  Button1.Default := True;
end;
```

TDirectoryListBox (see page 1589)

TFileListBox (see page 1734)

5.1.2.6.13 TDriveComboBox.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}
```

```
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

5.1.2.6.14 TDriveComboBox.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

5.1.2.6.15 TDriveComboBox.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}
```

```
void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);

Arranging the Order of Persistent Columns

5.1.2.6.16 TDriveComboBox.Drive Property

Indicates the currently selected drive displayed in the edit portion of the combo box.

Pascal

```
property Drive: Char;
```

C++

```
__property Char Drive;
```

Description

Set Drive to initialize the combo box to a particular drive. Read Drive to obtain the drive that was selected by the user.

When the user uses the drive combo box to select a new drive, the selected drive becomes the value of the Drive property. The value of the Text (see page 1704) property also changes to the new volume name when the Drive property value changes.

C++ Examples:

```
/*
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
*/
void __fastcall TForm1::DriveComboBox1Change(TObject *Sender)
{
  DirectoryListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Directory = DirectoryListBox1->Directory;
}

void __fastcall TForm1::DirectoryListBox1Change(TObject *Sender)
{
  FileListBox1->Directory = DirectoryListBox1->Directory;
}
```

Delphi Examples:

```
{
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
}
procedure TForm1.DirectoryListBox1Change(Sender: TObject);
begin
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;

procedure TForm1.DriveComboBox1Change(Sender: TObject);
begin
  DirectoryListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;
```

5.1.2.6.17 TDriveComboBox.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

5.1.2.6.18 TDriveComboBox.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

Displaying and Editing Text in a Memo Control

5.1.2.6.19 TDriveComboBox.ImeMode Property

Determines the behavior of the input method editor (IME).

Pascal

```
property ImeMode;
```

C++

```
__property ImeMode;
```

Description

Set ImeMode to configure the way an IME processes user keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeMode allows a control to influence the type of conversion performed by the IME so that it is appropriate for the input expected by the control. For example, a control that only accepts numeric input might specify an ImeMode of imClose, as no conversion is necessary for numeric input.

Note: The value of ImeMode only takes effect when the control receives focus. To change the value of ImeMode when the control already has input focus, call the SetIme method.

ImeName

ResetIme

ResetImeComposition

SetIme

SetImeCompositionWindow

5.1.2.6.20 TDriveComboBox.ImeName Property

Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

Pascal

```
property ImeName;
```

C++

```
__property ImeName;
```

Description

Set ImeName to specify which IME to use for converting keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeName must specify one of the IMEs that has been installed through the Windows control panel. The property inspector provides a drop-down list of all currently installed IMEs on the system. At runtime, applications can obtain a list of currently installed IMEs from the global Screen variable.

If ImeName specifies an unavailable IME, the IME that was active when the application started is used instead. No exception is generated.

Note: The value of ImeName only takes effect when the control receives focus. To change the value of ImeName after the control has input focus, call the SetIme method.

5.1.2.6.21 TDriveComboBox.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

5.1.2.6.22 TDriveComboBox.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

5.1.2.6.23 TDriveComboBox.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

5.1.2.6.24 TDriveComboBox.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own

Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

See Also

Font

Parent

ParentColor

ParentShowHint

5.1.2.6.25 TDriveComboBox.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

5.1.2.6.26 TDriveComboBox.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
```

```
    else
      Beep;
  end;

  procedure TForm1.Paste1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
      Edit1.PasteFromClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.PasteFromClipboard
    else
      Beep;
  end;
  {

OnContextPopup

5.1.2.6.27 TDriveComboBox.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
```

```
    begin
      for I := 1 to 10 do
        Items.Add('Item ' + IntToStr(I));
      Hint := 'Select an item';
      ShowHint := True;
    end;
    Application.ShowHint := True;
  end;
  {
  Note: To see an example that displays the hints of controls
  in some place other than in a Help Hint box, see the OnHint
  example.
  }

Displaying Fly-over Help

5.1.2.6.28 TDriveComboBox.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

5.1.2.6.29 TDriveComboBox.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

5.1.2.6.30 TDriveComboBox.Text Property

Contains a text string associated with the control.

Pascal

```
property Text;
```

C++

```
__property Text;
```

Description

Use the Text property to read the Text of the control or specify a new string for the Text value. By default, Text is the control name. For edit controls and memos, the Text appears within the control. For combo boxes, the Text is the content of the edit control portion of the combo box.

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
*/
#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int Size = Edit1->GetTextLen(); //Get length of string in Edit1
  Size++;                       //Add room for null character
//  Char *Buffer = new Char[Size];  //Creates Buffer dynamic variable
  std::auto_ptr<Char> Buffer(new Char[Size]);
  Edit1->GetTextBuf(Buffer.get(),Size); //Puts Edit1->Text into Buffer
  Edit2->Text = Buffer.get();
```

```
}
/*
Note: the same thing could be accomplished more simply as follows:
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Edit2->Text = Edit1->Text;
}
```

Delphi Examples:

```
{
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Buffer: PChar;
  Size: Byte;
begin
  Size := Edit1.GetTextLen;       {Get length of string in Edit1}
  Inc(Size);                      {Add room for null character}
  GetMem(Buffer, Size);           {Creates Buffer dynamic variable}
  Edit1.GetTextBuf(Buffer,Size);  {Puts Edit1.Text into Buffer}
  Edit2.Text := StrPas(Buffer);   {Converts Buffer to a Pascal-style string}
  FreeMem(Buffer, Size);{Frees memory allocated to Buffer}
end;

{
Note: the same thing could be accomplished more simply as follows:
}
procedure TForm1.Button2Click(Sender: TObject);
begin
  Edit2.Text := Edit1.Text;
end;
```

Caption

Lines

5.1.2.6.31 TDriveComboBox.TextCase Property

Determines if the volume name in the Text (see page 1704) property appears in uppercase or lowercase.

Pascal

```
property TextCase: TTextCase;
```

C++

```
__property TTextCase TextCase;
```

Description

Set TextCase to the case that should be used to represent the drive letter that is the value of the Text (see page 1704) property.

Note: Changes made to the TextCase property at design time don't appear until the application runs.

See Also

Drive (see page 1690)

Text

5.1.2.6.32 TDriveComboBox.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;
```

```

5.1.2.7 TDriveComboBox Events

The events of the TDriveComboBox class are listed here.

Published Events

	Name	Description
	OnChange (see page 1708)	Occurs when the user changes the text displayed in the edit region.
	OnClick (see page 1710)	Occurs when the user clicks the control.
	OnContextPopup (see page 1712)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 1712)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 1713)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 1716)	Occurs when the user drags an object over a control.
	OnDropDown (see page 1719)	Occurs when the user opens the drop-down list.
	OnEndDrag (see page 1720)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 1721)	Occurs when a control receives the input focus.
	OnExit (see page 1724)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 1727)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 1730)	Occurs when a key is pressed.
	OnKeyUp (see page 1731)	Occurs when the user releases a key that has been pressed.
	OnMouseEnter (see page 1733)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 1733)	Occurs when the user moves the mouse outside of a control.
	OnStartDrag (see page 1734)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

5.1.2.7.1 TDriveComboBox.OnChange Event

Occurs when the user changes the text displayed in the edit region.

Pascal

```
property OnChange;
```

C++

```
__property OnChange;
```

Description

Write an OnChange event handler to take specific action immediately after the user edits the text in the edit region or selects an item from the list. The Text property gives the new value in the edit region.

Note: OnChange only occurs in response to user actions. Changing the Text property programmatically does not trigger an OnChange event.

C++ Examples:

```
/*
This example requires a TPageControl already on the form.
Also, you must add pages to the TPageControl by right
clicking and selecting New Page.
The example code will allow the user to select the
ActivePage property through selection of a ComboBox item.
During the form create, the Combo Box control is loaded with
the names of each of the tabs, as well as the instance
pointers to the corresponding tab.  When the user selects
the Combo Box item, the associated TTabSheet object
contained in the Combo Box Objects array is used to set the
ActivePage property.  Select the Lines property of the
TRichEdit to enter a string.  Select the string before
justifying.
*/
void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  TComboBox *pCB = dynamic_cast<TComboBox *>(Sender);
  if (pCB)
    PageControl1->ActivePage = dynamic_cast<TTabSheet *>(pCB->Items->Objects[pCB->ItemIndex]);
}

    clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
    clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};
  for (int i = 0; i < PageControl1->PageCount; i++)
  {
    PageControl1->Pages[i]->Brush->Color = colorPalette[i];
    ComboBox1->Items->AddObject(PageControl1->Pages[i]->Name, PageControl1->Pages[i]);
  }
  ComboBox1->ItemIndex = 0;
  PageControl1->ActivePage = dynamic_cast<TTabSheet
*>(ComboBox1->Items->Objects[ComboBox1->ItemIndex]);
}
/*
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
```

```
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
*/
void __fastcall TForm1::DriveComboBox1Change(TObject *Sender)
{
  DirectoryListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Directory = DirectoryListBox1->Directory;
}

void __fastcall TForm1::DirectoryListBox1Change(TObject *Sender)
{
  FileListBox1->Directory = DirectoryListBox1->Directory;
}
```

Delphi Examples:

```
{
This example requires a TPageControl already on the form.
Also, you must add pages to the TPageControl by right
clicking and selecting New Page.
The example code will allow the user to select the
ActivePage property through selection of a ComboBox item.
During the form create, the Combo Box control is loaded with
the names of each of the tabs, as well as the instance
pointers to the corresponding tab.  When the user selects
the Combo Box item, the associated TTabSheet object
contained in the Combo Box Objects array is used to set the
ActivePage property.  Select the Lines property of the
TRichEdit to enter a string.  Select the string before
justifying.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
const
  colorarray : Array[0..4] of TColor = (
    clYellow, clGreen, clBlue, clLime, clFuchsia);
begin
  for i := 0 to PageControl1.PageCount - 1 do
    begin
    PageControl1.Pages[i].Brush.Color := colorarray[i];
    ComboBox1.Items.AddObject(PageControl1.Pages[i].Name,
      PageControl1.Pages[i]);
    end;
  ComboBox1.ItemIndex := 0;
  PageControl1.ActivePage := TTabSheet(ComboBox1.Items.Objects[ComboBox1.ItemIndex]);
end;

procedure TForm1.ComboBox1Change(Sender: TObject);
begin
  if (Sender is TComboBox) then
    with (Sender as TComboBox) do
      PageControl1.ActivePage := TTabSheet(Items.Objects[ItemIndex]);
end;
{
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
```

```
}
procedure TForm1.DirectoryListBox1Change(Sender: TObject);
begin
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;

procedure TForm1.DriveComboBox1Change(Sender: TObject);
begin
  DirectoryListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;
```

OnCloseUp

5.1.2.7.2 TDriveComboBox.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
```

```
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin

5.1.2.7.3 TDriveComboBox.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

OnClick

Responding to User Actions at Runtime

5.1.2.7.5 TDriveComboBox.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

5.1.2.7.6 TDriveComboBox.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/

5.1.2.7.7 TDriveComboBox.OnDropDown Event

Occurs when the user opens the drop-down list.

Pascal

```
property OnDropDown;
```

C++

```
__property OnDropDown;
```

Description

Write an OnDropDown event handler to implement special processing that needs to occur only when the drop-down list is activated.

C++ Examples:

```
/*
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
*/
#include "Unit2.h"
#include "Unit3.h"

void __fastcall TForm1::ComboBox1DropDown(TObject *Sender)
{
  ComboBox1->Items->BeginUpdate(); // prevent repaints until done
  ComboBox1->Items->Clear(); // empty the list of any old values
  for (int i = 0; i < Screen->CustomFormCount; i++)
  {
    if ((reinterpret_cast<TForm1 *>(Screen->CustomForms[i]))->Visible)
      ComboBox1->Items->Add(Screen->CustomForms[i]->Caption);  // add form names
  }
  ComboBox1->Items->EndUpdate(); //reenable painting
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ComboBox1->Sorted = True; // make sure the form names are sorted
}

void __fastcall TForm1::Button1Click(TObject *Sender)
```

```
{
  Form2->Show();
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Form3->Show();
}
```

Delphi Examples:

```
{
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
}
procedure TForm1.ComboBox1DropDown(Sender: TObject);
var
  I: Integer;
begin
  with ComboBox1 do
  begin
    Items.BeginUpdate; { prevent repaints until done }
    Items.Clear; { empty the list of any old values }
    for I := 0 to Screen.CustomFormCount - 1 do
    begin
      if (Screen.CustomForms[I].Visible) then
        Items.Add(Screen.CustomForms[I].Caption); { add form name }
    end;
    Items.EndUpdate; {reenable painting }
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ComboBox1.Sorted := True; { make sure the form names are sorted }
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Form2.Show;
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  Form3.Show;
end;
```

DroppedDown

OnCloseUp

5.1.2.7.8 TDriveComboBox.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;

DragKind

5.1.2.7.9 TDriveComboBox.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   (dynamic_cast<TEdit *>(myActiveControl))->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    (dynamic_cast<TRichEdit *>(myActiveControl))->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
```

```
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
```

```
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

5.1.2.7.10 TDriveComboBox.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
```

```
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

procedure TForm1.MaskEdit2Exit(Sender: TObject);
var
  net1, net2, host1, host2,
  netmask1, netmask2, hostmask1, hostmask2,
  sub_net1, sub_net2, sub_host1, sub_host2: Integer;

  IP, mask: String;
```

```
begin
  // extract the net and host address from the IP
  IP := MaskEdit1.Text;
  net1 := StrToInt(TrimRight(Copy(IP, 0, 3)));
  net2 := StrToInt(TrimRight(Copy(IP, 5, 3)));
  host1 := StrToInt(TrimRight(Copy(IP, 9, 3)));
  host2 := StrToInt(TrimRight(Copy(IP, 13, 3)));

  // a range test that you cannot validate through edit masks
  if ((net1 < 0) Or (net1 > 255) Or
      (net2 < 0) Or (net2 > 255) Or
      (host1 < 0) Or (host1 > 255) Or
      (host2 < 0) Or (host2 > 255)) then
    raise EArgumentException.Create('Not a valid IP address.');

  // extract the net and host mask from the subnet mask
  mask := MaskEdit2.Text;
  netmask1 := StrToInt(TrimRight(Copy(mask, 0, 3)));
  netmask2 := StrToInt(TrimRight(Copy(mask, 5, 3)));
  hostmask1 := StrToInt(TrimRight(Copy(mask, 9, 3)));
  hostmask2 := StrToInt(TrimRight(Copy(mask, 13, 3)));

  // a range test that you cannot validate through edit masks
  if ((netmask1 < 0) Or (netmask1 > 255) Or
      (netmask2 < 0) Or (netmask2 > 255) Or
      (hostmask1 < 0) Or (hostmask1 > 255) Or
      (hostmask2 < 0) Or (hostmask2 > 255)) then
    raise EArgumentException.Create('Not a valid subnet mask.');

  // compute the subnet address using bit-wise AND
  sub_net1 := net1 And netmask1;
  sub_net2 := net2 And netmask2;
  sub_host1 := host1 And hostmask1;
  sub_host2 := host2 And hostmask2;

  // display the subnet address
  MaskEdit3.Text :=
    IntToStr(sub_net1) + '.' + IntToStr(sub_net2) + '.' +
    IntToStr(sub_host1) + '.' + IntToStr(sub_host2);
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.

OnEnter

ActiveControl (see page 2145)

5.1.2.7.11 TDriveComboBox.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown;
```

C++

```
__property OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,

OnKeyPress

OnKeyUp

5.1.2.7.12 TDriveComboBox.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress;
```

C++

```
__property OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII

character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

OnKeyDown

OnKeyPress

5.1.2.7.14 TDriveComboBox.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

5.1.2.7.15 TDriveComboBox.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

5.1.2.7.16 TDriveComboBox.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

5.1.3 TFileListBox Class

TFileListBox is a specialized list box that lists all the files in a specified directory.

Class Hierarchy

Pascal

```
[SecurityPermission(SecurityAction.Demand, Unrestricted=True)]
TFileListBox = class(TCustomListBox);
```

C++

```
[SecurityPermission(SecurityAction.Demand, Unrestricted=True)]
class TFileListBox : public TCustomListBox;
```

File

FileCtrl

Description

Add TFileListBox to a form to allow users to select a file. Use TFileListBox along with TDriveComboBox (see page 1668), TFilterComboBox (see page 1813), and TDirectoryListBox (see page 1589) to add full file selection capabilities to a form.

Note: To add a standard Windows file open or save dialog to an application, use TOpenDialog or TSaveDialog instead.

C++ Examples:

```
/*
This example uses a file list box, a directory list box, and
a label on a form. When the user uses the directory list box
to change directories, a message appears and the color of
the form changes if the file AUTOEXEC.BAT is in the new
directory. The code is written in the OnChange event of the
directory list box:
*/
void __fastcall TForm1::DirectoryListBox1Change(TObject *Sender)
{
  FileListBox1->Directory = DirectoryListBox1->Directory;
  if (FileListBox1->Items->IndexOf("AUTOEXEC.BAT") > -1)
  {
    Color = clYellow;
    Label1->Caption = "You are in the root directory!";
  }
}
```

Delphi Examples:

```
{
This example uses a file list box, a directory list box, and
a label on a form. When the user uses the directory list box
to change directories, a message appears and the color of
the form changes if the file AUTOEXEC.BAT is in the new
directory. The code is written in the OnChange event of the
directory list box:
}
procedure TForm1.DirectoryListBox1Change(Sender: TObject);
begin
  FileListBox1.Directory := DirectoryListBox1.Directory;
  if FileListBox1.Items.IndexOf('AUTOEXEC.BAT') > -1 then
  begin
    Color := clYellow;
    Label1.Caption := 'You are in the root directory!';
  end
  else
  begin
    Color := clBtnFace;
    Label1.Caption := '';
  end;
end;
```

5.1.3.1 TFileListBox Members

The following tables list the members exposed by TFileListBox.

Protected Fields

	Name	Description
	DirBMP (see page 1739)	This is DirBMP, a member of class TFileListBox.
	ExeBMP (see page 1739)	This is ExeBMP, a member of class TFileListBox.
	FDirectory (see page 1739)	This is FDirectory, a member of class TFileListBox.
	FDirList (see page 1740)	This is FDirList, a member of class TFileListBox.
	FFileEdit (see page 1740)	This is FFileEdit, a member of class TFileListBox.
	FFileType (see page 1740)	This is FFileType, a member of class TFileListBox.
	FFilterCombo (see page 1740)	This is FFilterCombo, a member of class TFileListBox.
	FLastSel (see page 1741)	This is FLastSel, a member of class TFileListBox.
	FMask (see page 1741)	This is FMask, a member of class TFileListBox.
	FOnChange (see page 1741)	This is FOnChange, a member of class TFileListBox.
	FShowGlyphs (see page 1741)	This is FShowGlyphs, a member of class TFileListBox.
	UnknownBMP (see page 1741)	This is UnknownBMP, a member of class TFileListBox.

Protected Methods

	Name	Description
	Change (see page 1743)	This is Change, a member of class TFileListBox.
	Click (see page 1744)	Respond to user click.
	CreateWnd (see page 1744)	Creates a Windows control corresponding to the list box component.
	DrawItem (see page 1745)	Generates an OnDrawItem event.
	GetFilePath (see page 1745)	This is GetFilePath, a member of class TFileListBox.
	Notification (see page 1745)	Responds to notifications that components are being created or destroyed.
	ReadBitmaps (see page 1746)	This is ReadBitmaps, a member of class TFileListBox.
	ReadFileNames (see page 1746)	This is ReadFileNames, a member of class TFileListBox.

Public Methods

	Name	Description
	ApplyFilePath (see page 1742)	Updates the file list box to represent a fully qualified file name.
	Create (see page 1738)	Creates an instance of TFileListBox (see page 1734).
	Destroy (see page 1738)	Destroys an instance of TFileListBox (see page 1734).
	Update (see page 1746)	Refreshes the directory list for the file list box.

Public Properties

	Name	Description
	Directory (see page 1756)	Specifies the directory that contains all the files listed in the file list box.
	Drive (see page 1761)	Specifies the drive which contains the files listed in the list box.
	FileName (see page 1764)	Indicates the name of the selected file in the list box, including the path name.

Published Events

	Name	Description
	OnChange (see page 1782)	Occurs immediately after the user changes the selected file in the list.
	OnClick (see page 1782)	Occurs when the user clicks the control.
	OnContextPopup (see page 1784)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

	OnDblClick (see page 1785)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 1785)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 1788)	Occurs when the user drags an object over a control.
	OnEndDrag (see page 1791)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 1792)	Occurs when a control receives the input focus.
	OnExit (see page 1795)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 1797)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 1801)	Occurs when a key is pressed.
	OnKeyUp (see page 1802)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 1804)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 1805)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 1807)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 1807)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 1808)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 1810)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDrag (see page 1812)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 1748)	Determines how the control aligns within its container (parent control).
	Anchors (see page 1751)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 1752)	Determines whether the user can give focus to items by typing in the list.
	BevelEdges (see page 1752)	Specifies which edges of the control are beveled.
	BevelInner (see page 1753)	Specifies the cut of the inner bevel.
	BevelKind (see page 1753)	Specifies the control's bevel style.
	BevelOuter (see page 1754)	Specifies the cut of the outer bevel.
	Color (see page 1754)	Specifies the background color of the control.
	Constraints (see page 1755)	Specifies the size constraints for the control.
	Ctl3D (see page 1755)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 1757)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 1759)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragMode (see page 1759)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 1762)	Controls whether the control responds to mouse, keyboard, and timer events.
	ExtendedSelect (see page 1762)	Determines if the user can select a sequential range of items in the list box.
	FileEdit (see page 1763)	Links the directory list box to an edit control that displays the currently selected file.
	FileType (see page 1764)	Determines which files are displayed in the file list box based on the attributes of the files.
	Font (see page 1765)	Controls the attributes of text written on or in the control.
	ImeMode (see page 1766)	Determines the behavior of the input method editor (IME).
	ImeName (see page 1767)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IntegralHeight (see page 1767)	Determines whether the list box displays the partial items.
	ItemHeight (see page 1768)	Specifies the height in pixels of an item in an owner-draw list box.
	Mask (see page 1768)	Limits which files are displayed in the file list box.
	MultiSelect (see page 1769)	Specifies whether the user can select more than one item.
	ParentColor (see page 1770)	Determines where a control looks for its color information.
	ParentCtl3D (see page 1770)	Determines where a component looks to determine if it should appear three dimensional.

	ParentDoubleBuffered (see page 1771)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 1771)	Determines where a control looks for its font information.
	ParentShowHint (see page 1771)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 1772)	Identifies the pop-up menu associated with the control.
	ShowGlyphs (see page 1777)	Determines whether glyphs (bitmaps) appear next to the file names listed in the file list box.
	ShowHint (see page 1777)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 1779)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 1779)	Determines if the user can tab to a control.
	Visible (see page 1780)	Determines whether the component appears onscreen.

5.1.3.2 TFileListBox.Create Constructor

Creates an instance of TFileListBox (see page 1734).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TFileListBox(TComponent * AOwner);
```

Description

Call Create to create a TFileListBox (see page 1734) object at runtime. File list boxes placed on a form at design time are created automatically.

See Also

Directory (see page 1756)

Drive (see page 1761)

FileType (see page 1764)

Mask (see page 1768)

5.1.3.3 TFileListBox.Destroy Destructor

Destroys an instance of TFileListBox (see page 1734).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TFileListBox();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free checks that the file list box reference is not nil, and only then calls Destroy.

See Also

System::TObject::Free

5.1.3.4 TFileListBox Fields

The fields of the TFileListBox class are listed here.

Protected Fields

	Name	Description
	DirBMP (see page 1739)	This is DirBMP, a member of class TFileListBox.
	ExeBMP (see page 1739)	This is ExeBMP, a member of class TFileListBox.
	FDirectory (see page 1739)	This is FDirectory, a member of class TFileListBox.
	FDirList (see page 1740)	This is FDirList, a member of class TFileListBox.
	FFileEdit (see page 1740)	This is FFileEdit, a member of class TFileListBox.
	FFileType (see page 1740)	This is FFileType, a member of class TFileListBox.
	FFilterCombo (see page 1740)	This is FFilterCombo, a member of class TFileListBox.
	FLastSel (see page 1741)	This is FLastSel, a member of class TFileListBox.
	FMask (see page 1741)	This is FMask, a member of class TFileListBox.
	FOnChange (see page 1741)	This is FOnChange, a member of class TFileListBox.
	FShowGlyphs (see page 1741)	This is FShowGlyphs, a member of class TFileListBox.
	UnknownBMP (see page 1741)	This is UnknownBMP, a member of class TFileListBox.

5.1.3.4.1 TFileListBox.DirBMP Field

Pascal

```
DirBMP: TBitmap;
```

C++

```
TBitmap DirBMP;
```

Description

This is DirBMP, a member of class TFileListBox.

5.1.3.4.2 TFileListBox.ExeBMP Field

Pascal

```
ExeBMP: TBitmap;
```

C++

```
TBitmap ExeBMP;
```

Description

This is ExeBMP, a member of class TFileListBox.

5.1.3.4.3 TFileListBox.FDirectory Field

Pascal

```
FDirectory: string;
```

C++

```
UnicodeString FDirectory;
```

Description

This is FDirectory, a member of class TFileListBox.

5.1.3.4.4 TFileListBox.FDirList Field

Pascal

```
FDirList: TDirectoryListBox;
```

C++

```
TDirectoryListBox FDirList;
```

Description

This is FDirList, a member of class TFileListBox.

5.1.3.4.5 TFileListBox.FFileEdit Field

Pascal

```
FFileEdit: TEdit;
```

C++

```
TEdit FFileEdit;
```

Description

This is FFileEdit, a member of class TFileListBox.

5.1.3.4.6 TFileListBox.FFileType Field

Pascal

```
FFileType: TFileType;
```

C++

```
TFileType FFileType;
```

Description

This is FFileType, a member of class TFileListBox.

5.1.3.4.7 TFileListBox.FFilterCombo Field

Pascal

```
FFilterCombo: TFilterComboBox;
```

C++

```
TFilterComboBox FFilterCombo;
```

Description

This is FFilterCombo, a member of class TFileListBox.

5.1.3.4.8 TFileListBox.FLastSel Field

Pascal

```
FLastSel: Integer;
```

C++

```
int FLastSel;
```

Description

This is FLastSel, a member of class TFileListBox.

5.1.3.4.9 TFileListBox.FMask Field

Pascal

```
FMask: string;
```

C++

```
UnicodeString FMask;
```

Description

This is FMask, a member of class TFileListBox.

5.1.3.4.10 TFileListBox.FOnChange Field

Pascal

```
FOnChange: TNotifyEvent;
```

C++

```
TNotifyEvent FOnChange;
```

Description

This is FOnChange, a member of class TFileListBox.

5.1.3.4.11 TFileListBox.FShowGlyphs Field

Pascal

```
FShowGlyphs: Boolean;
```

C++

```
Boolean FShowGlyphs;
```

Description

This is FShowGlyphs, a member of class TFileListBox.

5.1.3.4.12 TFileListBox.UnknownBMP Field

Pascal

```
UnknownBMP: TBitmap;
```

C++

```
TBitmap UnknownBMP;
```

Description

This is UnknownBMP, a member of class TFileListBox.

5.1.3.5 TFileListBox Methods

The methods of the TFileListBox class are listed here.

Protected Methods

	Name	Description
	Change (see page 1743)	This is Change, a member of class TFileListBox.
	Click (see page 1744)	Respond to user click.
	CreateWnd (see page 1744)	Creates a Windows control corresponding to the list box component.
	DrawItem (see page 1745)	Generates an OnDrawItem event.
	GetFilePath (see page 1745)	This is GetFilePath, a member of class TFileListBox.
	Notification (see page 1745)	Responds to notifications that components are being created or destroyed.
	ReadBitmaps (see page 1746)	This is ReadBitmaps, a member of class TFileListBox.
	ReadFileNames (see page 1746)	This is ReadFileNames, a member of class TFileListBox.

Public Methods

	Name	Description
	ApplyFilePath (see page 1742)	Updates the file list box to represent a fully qualified file name.
	Update (see page 1746)	Refreshes the directory list for the file list box.

5.1.3.5.1 TFileListBox.ApplyFilePath Method

Updates the file list box to represent a fully qualified file name.

Pascal

```
procedure ApplyFilePath(const EditText: string); virtual;
```

C++

```
virtual __fastcall ApplyFilePath(const UnicodeString EditText);
```

Description

Call ApplyFilePath to change the Directory (see page 1756), Drive (see page 1761), FileName (see page 1764), and Mask (see page 1768) properties so that they match the values implied by the EditText parameter. For example, if an edit control is linked to the file list box using the FileEdit (see page 1763) property, call ApplyFilePath from the OnChange (see page 1782) event handler of the edit control to update the file list box whenever the user types a value in the edit control.

ApplyFilePath updates the Mask (see page 1768) property only if the EditText parameter includes wildcards. If the form contains a TDirectoryListBox (see page 1589) object that specifies this file list box object in its FileList property, the Directory (see page 1756) and Drive (see page 1761) properties of the directory list box object are updated as well. If the form also includes a TDriveComboBox (see page 1668) object that specifies the directory list box in its DirList property, the Drive (see page 1761) property of the drive combo box will also be updated. However, the Mask (see page 1768) property of any TFilterComboBox (see page 1813) will not be updated.

C++ Examples:

```
/*
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
```

```
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  FileListBox1->FileEdit = Edit1;
  FilterComboBox1->FileList = FileListBox1;
  DirectoryListBox1->FileList = FileListBox1;
  DirectoryListBox1->DirLabel = Label1;
  DriveComboBox1->DirList = DirectoryListBox1;
  Button1->Default = true;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FileListBox1->ApplyFilePath(Edit1->Text);
}
```

Delphi Examples:

```
{
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  FileListBox1.ApplyFilePath(Edit1.Text);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  FileListBox1.FileEdit := Edit1;
  FilterComboBox1.FileList := FileListBox1;
  DirectoryListBox1.FileList := FileListBox1;
  DirectoryListBox1.DirLabel := Label1;
  DriveComboBox1.DirList := DirectoryListBox1;
  Button1.Default := True;
end;
```

See Also

Directory (see page 1756)

Drive (see page 1761)

FileEdit (see page 1763)

FileName (see page 1764)

Mask (see page 1768)

TDirectoryListBox (see page 1589)

TDriveComboBox (see page 1668)

TFilterComboBox (see page 1813)

5.1.3.5.2 TFileListBox.Change Method

Pascal

```
procedure Change; virtual;
```

C++

```
virtual __fastcall Change();
```

Description

This is Change, a member of class TFileListBox.

5.1.3.5.3 TFileListBox.Click Method

Respond to user click.

Pascal

```
procedure Click; override;
```

C++

```
virtual __fastcall Click();
```

Description

Click is called automatically when the user left-clicks the control. Component or application code can call Click to simulate a user mouse click. This is often done in menu actions and hotkey handlers.

As implemented in TControl, Click queries whether the OnClick event handler exists and is different from the OnExecute handler for the control's Action. If this is true, the OnClick event handler is called. If this is false, and the Action OnExecute event handler exists, the Action's Execute method is called. Override Click to provide additional behavior.

See Also

Action

OnExecute

Execute

DblClick

OnClick

5.1.3.5.4 TFileListBox.CreateWnd Method

Creates a Windows control corresponding to the list box component.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the list box must be displayed. CreateWnd calls the inherited CreateWnd method, which calls

CreateParams to initialize the window-creation parameters.

CreateWindowHandle to create the window handle for the control.

CreateWnd additionally sets up the list box position, tabs, items, and columns.

See Also

Columns

CreateHandle

CreateParams

CreateWindowHandle

CreateWnd

ItemIndex

Items

TabWidth

TopIndex

5.1.3.5.5 TFileListBox.DrawItem Method

Generates an OnDrawItem event.

Pascal

```
procedure DrawItem(Index: Integer; Rect: TRect; State: TOwnerDrawState); override;
```

C++

```
virtual __fastcall DrawItem(int Index, TRect Rect, TOwnerDrawState State);
```

Description

DrawItem is called whenever a visual aspect of an owner-draw list box changes. The list box calls DrawItem for each visible item in its list, passing the index of the item in the Index parameter.

By default, the DrawItem method for a list box calls any event handler attached to the component's OnDrawItem event. If there is no handler attached, DrawItem fills the rectangle passed in Rect and draws any text associated with the indexed item. The default drawing ignores the State parameter, although State is passed along to attached event handlers.

5.1.3.5.6 TFileListBox.GetFilePath Method

Pascal

```
function GetFilePath: string; virtual;
```

C++

```
virtual __fastcall UnicodeString GetFilePath();
```

Description

This is GetFilePath, a member of class TFileListBox.

5.1.3.5.7 TFileListBox.Notification Method

Responds to notifications that components are being created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification allows TControl to update its PopupMenu property when the pop-up menu it refers to is destroyed.

Override the Notification method to respond to notifications that other components are about to be destroyed or have just been created. Use the Notification method to update controls that rely on other objects. Remove references to objects that are going away so that the control does not refer to objects that have been destroyed. For example, data-aware objects override the Notification method to update themselves when their data source is removed. Some objects respond to notifications that other objects of a specific type are being created. For example, the session component sets the Session property of new data-aware controls to itself when the AutoSessionName property is true.

By default, components pass along the notification to their owned components, if any.

PopupMenu

Notification

5.1.3.5.8 TFileListBox.ReadBitmaps Method

Pascal

```
procedure ReadBitmaps; virtual;
```

C++

```
virtual __fastcall ReadBitmaps();
```

Description

This is ReadBitmaps, a member of class TFileListBox.

5.1.3.5.9 TFileListBox.ReadFileNames Method

Pascal

```
procedure ReadFileNames; virtual;
```

C++

```
virtual __fastcall ReadFileNames();
```

Description

This is ReadFileNames, a member of class TFileListBox.

5.1.3.5.10 TFileListBox.Update Method

Refreshes the directory list for the file list box.

Pascal

```
procedure Update; reintroduce;
```

C++

```
__fastcall Update();
```

Description

Call Update whenever the files listed by the file list box may be out of date. For example, if an application creates, renames, or deletes files, calling Update will ensure that those changes are reflected in the file list box.

The list box is updated automatically when the Drive (see page 1761), Directory (see page 1756), FileType (see page 1764), or Mask (see page 1768) property is changed.

See Also

Directory (see page 1756)

Drive (see page 1761)

FileType (see page 1764)

Mask (see page 1768)

5.1.3.6 TFileListBox Properties

The properties of the TFileListBox class are listed here.

Public Properties

	Name	Description
	Directory (see page 1756)	Specifies the directory that contains all the files listed in the file list box.
	Drive (see page 1761)	Specifies the drive which contains the files listed in the list box.
	FileName (see page 1764)	Indicates the name of the selected file in the list box, including the path name.

Published Properties

	Name	Description
	Align (see page 1748)	Determines how the control aligns within its container (parent control).
	Anchors (see page 1751)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 1752)	Determines whether the user can give focus to items by typing in the list.
	BevelEdges (see page 1752)	Specifies which edges of the control are beveled.
	BevelInner (see page 1753)	Specifies the cut of the inner bevel.
	BevelKind (see page 1753)	Specifies the control's bevel style.
	BevelOuter (see page 1754)	Specifies the cut of the outer bevel.
	Color (see page 1754)	Specifies the background color of the control.
	Constraints (see page 1755)	Specifies the size constraints for the control.
	Ctl3D (see page 1755)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 1757)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 1759)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragMode (see page 1759)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 1762)	Controls whether the control responds to mouse, keyboard, and timer events.
	ExtendedSelect (see page 1762)	Determines if the user can select a sequential range of items in the list box.
	FileEdit (see page 1763)	Links the directory list box to an edit control that displays the currently selected file.
	FileType (see page 1764)	Determines which files are displayed in the file list box based on the attributes of the files.
	Font (see page 1765)	Controls the attributes of text written on or in the control.
	ImeMode (see page 1766)	Determines the behavior of the input method editor (IME).

	ImeName (see page 1767)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IntegralHeight (see page 1767)	Determines whether the list box displays the partial items.
	ItemHeight (see page 1768)	Specifies the height in pixels of an item in an owner-draw list box.
	Mask (see page 1768)	Limits which files are displayed in the file list box.
	MultiSelect (see page 1769)	Specifies whether the user can select more than one item.
	ParentColor (see page 1770)	Determines where a control looks for its color information.
	ParentCtl3D (see page 1770)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 1771)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 1771)	Determines where a control looks for its font information.
	ParentShowHint (see page 1771)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 1772)	Identifies the pop-up menu associated with the control.
	ShowGlyphs (see page 1777)	Determines whether glyphs (bitmaps) appear next to the file names listed in the file list box.
	ShowHint (see page 1777)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 1779)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 1779)	Determines if the user can tab to a control.
	Visible (see page 1780)	Determines whether the component appears onscreen.

5.1.3.6.1 TFileListBox.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
```

```
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
```

```
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}

Parent

Anchors

5.1.3.6.2 TFileListBox.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

5.1.3.6.3 TFileListBox.AutoComplete Property

Determines whether the user can give focus to items by typing in the list.

Pascal

```
property AutoComplete;
```

C++

```
__property AutoComplete;
```

Description

Use AutoComplete to specify whether the list box automatically updates the ItemIndex property in response to user keystrokes. When AutoComplete is true, the item with focus changes to the first item that begins with the sequence of characters that the user typed. As the user types more characters, ItemIndex may change to a later item because the string to match becomes longer.

ItemIndex

5.1.3.6.4 TFileListBox.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges;
```

C++

```
__property BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner

BevelOuter

BevelKind

5.1.3.6.5 TFileListBox.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner;
```

C++

```
__property BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges

BevelOuter

BevelKind

BevelWidth

BorderWidth

5.1.3.6.6 TFileListBox.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind;
```

C++

```
__property BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges

BevelOuter

5.1.3.6.7 TFileListBox.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter;
```

C++

```
__property BevelOuter;
```

Description

Use BevelOuter to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges

BevelInner

BevelKind

BevelWidth

5.1.3.6.8 TFileListBox.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
```

```
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor

5.1.3.6.9 TFileListBox.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

5.1.3.6.10 TFileListBox.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

BorderWidth

5.1.3.6.11 TFileListBox.Directory Property

Specifies the directory that contains all the files listed in the file list box.

Pascal

```
property Directory: string;
```

C++

```
__property UnicodeString Directory;
```

Description

Set Directory to update the file list box so that it displays the files in a new directory. If the form includes a TDirectoryListBox (see page 1589) object, set the FileList property of the directory list box to have the Directory property updated automatically when the user selects a new directory.

C++ Examples:

```
/*
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
*/
void __fastcall TForm1::DriveComboBox1Change(TObject *Sender)
{
  DirectoryListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Directory = DirectoryListBox1->Directory;
}

void __fastcall TForm1::DirectoryListBox1Change(TObject *Sender)
{
  FileListBox1->Directory = DirectoryListBox1->Directory;
}
```

Delphi Examples:

```
{
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
}
procedure TForm1.DirectoryListBox1Change(Sender: TObject);
begin
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;

procedure TForm1.DriveComboBox1Change(Sender: TObject);
begin
  DirectoryListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Directory := DirectoryListBox1.Directory;
end;
```

5.1.3.6.12 TFileListBox.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/
```

```
// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
```

```
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

5.1.3.6.13 TFileListBox.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

5.1.3.6.14 TFileListBox.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
```

```
  OnDragOver event handler must be implemented to accept the
  drop.
  */
  void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
        int X, int Y)
  {
    if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
      return;
    THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
    TNodeAttachMode AttachMode;
    TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
    if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
      AttachMode = naAddChild;
    else if (HT.Contains(htNowhere))
      AttachMode = naAdd;
    else if (HT.Contains(htOnIndent))
      AttachMode = naInsert;
    else
      return;
    TreeView1->Selected->MoveTo(Item, AttachMode);
  }

  void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
        int X, int Y, TDragState State, bool &Accept)
  {
    Accept = (Source == dynamic_cast<TObject *>(TreeView1));
  }
```

Delphi Examples:

```
  {
  The following code uses GetNodeAt to add a dragged node as a
  child of the node under the mouse when it is dropped.  This
  example requires a populated TreeView.  Also, the TTreeView
  DragMode property must be set to dmAutomatic, and the TTreeView
  OnDragOver event handler must be implemented to accept the
  drop.
  }
  procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
  var
    AnItem: TTreeNode;
    AttachMode: TNodeAttachMode;
    HT: THitTests;
  begin
    if TreeView1.Selected = nil then Exit;
    HT := TreeView1.GetHitTestInfoAt(X, Y);
    AnItem := TreeView1.GetNodeAt(X, Y);
    if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
    begin
      if (htOnItem in HT) or (htOnIcon in HT) then
        AttachMode := naAddChild
      else if htNowhere in HT then AttachMode := naAdd
      else if htOnIndent in HT then AttachMode := naInsert;
      TreeView1.Selected.MoveTo(AnItem, AttachMode);
    end;
  end;

  procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);

Arranging the Order of Persistent Columns

5.1.3.6.15 TFileListBox.Drive Property

Specifies the drive which contains the files listed in the list box.

Pascal

```
property Drive: char;
```

C++

```
__property char Drive;
```

Description

Set the value of Drive to the drive that contains the files that the list box should display. When the value of Drive changes, the Directory (see page 1756) value also changes to the current directory on the specified drive.

If the form includes a TDirectoryListBox (see page 1589) object, set the FileList property of the directory list box to have the Drive property updated automatically when the Drive property of the directory list box changes.

C++ Examples:

```
/*
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
and the OnChange event handler for the directory list box.
When the user changes the drive using the combo box, the
directory list box and file list box will update to reflect
the new drive and the current directory on that drive.  When
the user double clicks on a directory in the file list box
will update to reflect the new directory.
*/
void __fastcall TForm1::DriveComboBox1Change(TObject *Sender)
{
  DirectoryListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Drive = DriveComboBox1->Drive;
  FileListBox1->Directory = DirectoryListBox1->Directory;
}

void __fastcall TForm1::DirectoryListBox1Change(TObject *Sender)
{
  FileListBox1->Directory = DirectoryListBox1->Directory;
}
```

Delphi Examples:

```
{
The following example assumes that a drive combo box, a file
list box, and a directory list box are on a form. Add this
code as the OnChange event handler for the drive combo box
```

```
  and the OnChange event handler for the directory list box.
  When the user changes the drive using the combo box, the
  directory list box and file list box will update to reflect
  the new drive and the current directory on that drive.  When
  the user double clicks on a directory in the file list box
  will update to reflect the new directory.
  }
  procedure TForm1.DirectoryListBox1Change(Sender: TObject);
  begin
    FileListBox1.Directory := DirectoryListBox1.Directory;
  end;

  procedure TForm1.DriveComboBox1Change(Sender: TObject);
  begin
    DirectoryListBox1.Drive := DriveComboBox1.Drive;
    FileListBox1.Drive := DriveComboBox1.Drive;
    FileListBox1.Directory := DirectoryListBox1.Directory;
  end;
```

5.1.3.6.16 TFileListBox.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

Visible

DisableControls

EnableControls

Enabling Mouse

5.1.3.6.17 TFileListBox.ExtendedSelect Property

Determines if the user can select a sequential range of items in the list box.

Pascal

```
property ExtendedSelect;
```

C++

```
__property ExtendedSelect;
```

Description

ExtendedSelect works with the MultiSelect property. If ExtendedSelect is true and MultiSelect is true, the user can select an item then hold down the Shift key and select another and all the items in between the two selected items also become selected.

If the user doesn't hold down the Shift or Ctrl key while selecting a second item, the first selected item becomes unselected— in other words, the user must use the Ctrl key to select multiple noncontiguous items, or the Shift key to select a range of items.

If ExtendedSelect is false and MultiSelect is true, the user can select multiple items without using the Shift or Ctrl key, but they can't select a range of items in one operation.

If MultiSelect is false, the setting of ExtendedSelect has no effect as the user will not be able to select more than one item at a time in the list box.

See Also

MultiSelect

5.1.3.6.18 TFileListBox.FileEdit Property

Links the directory list box to an edit control that displays the currently selected file.

Pascal

```
property FileEdit: TEdit;
```

C++

```
__property TEdit FileEdit;
```

Description

Set FileEdit to an edit control that displays the selected file from the file list box, as is commonly done in Open and Save dialog boxes. If no file is selected in the file list box, the text of the edit control is the current value of the file list box's Mask (see page 1768) property.

Note: If the user changes the text of the edit control, the results are not automatically reflected in the file list box. Use the ApplyFilePath (see page 1742) method to update the file list box when the edit control's text changes.

C++ Examples:

```
/*
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  FileListBox1->FileEdit = Edit1;
  FilterComboBox1->FileList = FileListBox1;
  DirectoryListBox1->FileList = FileListBox1;
  DirectoryListBox1->DirLabel = Label1;
  DriveComboBox1->DirList = DirectoryListBox1;
  Button1->Default = true;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FileListBox1->ApplyFilePath(Edit1->Text);
}
```

Delphi Examples:

```
{
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  FileListBox1.ApplyFilePath(Edit1.Text);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  FileListBox1.FileEdit := Edit1;
  FilterComboBox1.FileList := FileListBox1;
  DirectoryListBox1.FileList := FileListBox1;
  DirectoryListBox1.DirLabel := Label1;
  DriveComboBox1.DirList := DirectoryListBox1;
  Button1.Default := True;
end;
```

ApplyFilePath (see page 1742)

FileName (see page 1764)

Mask (see page 1768)

5.1.3.6.19 TFileListBox.FileName Property

Indicates the name of the selected file in the list box, including the path name.

Pascal

```
property FileName: string;
```

C++

```
__property UnicodeString FileName;
```

Description

Set FileName to initialize the file list box to a particular file. Read FileName to obtain the name of the file the user selected.

If the FileEdit (see page 1763) property is set, the linked edit control displays the value of FileName whenever the FileName property changes.

See Also

FileEdit (see page 1763)

FileType (see page 1764)

5.1.3.6.20 TFileListBox.FileType Property

Determines which files are displayed in the file list box based on the attributes of the files.

Pascal

```
property FileType: TFileType;
```

C++

```
__property TFileType FileType;
```

Description

Set FileType to the type of files the list box should display. FileType can specify more than one type of file. For example, if the value of FileType is a set containing the values ftReadOnly and ftHidden, files that have either the read-only or the hidden attributes are displayed in the list box.

To set the FileType property using the Object Inspector, click the FileType property to see the attribute values. Then set each value to True or False true or false to specify whether it is included in the FileType set.

Note: The files that are listed can also be limited by the form of their names. To restrict the files to particular names, use the Mask (see page 1768) property or include a TFilterComboBox (see page 1813) on the form.

See Also

Mask (see page 1768)

TFilterComboBox (see page 1813)

5.1.3.6.21 TFileListBox.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
```

```
  the memo or Rich Edit control font is set to the
  corresponding font name in the combo box.
  }
  procedure TForm1.FormCreate(Sender: TObject);
  var
    i : Integer;
  begin
    for i := 0 to Screen.Fonts.Count - 1 do
     ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
  //  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
    RichEdit1.Lines.Text := 'How is it to be you?';
  end;

  procedure TForm1.ComboBox1Click(Sender: TObject);
  begin
    RichEdit1.Font.Name := ComboBox1.Text;
  end;
```

Displaying and Editing Text in a Memo Control

5.1.3.6.22 TFileListBox.ImeMode Property

Determines the behavior of the input method editor (IME).

Pascal

```
property ImeMode;
```

C++

```
__property ImeMode;
```

Description

Set ImeMode to configure the way an IME processes user keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeMode allows a control to influence the type of conversion performed by the IME so that it is appropriate for the input expected by the control. For example, a control that only accepts numeric input might specify an ImeMode of imClose, as no conversion is necessary for numeric input.

Note: The value of ImeMode only takes effect when the control receives focus. To change the value of ImeMode when the control already has input focus, call the SetIme method.

See Also

ImeName

ResetIme

ResetImeComposition

SetIme

SetImeCompositionWindow

5.1.3.6.23 TFileListBox.ImeName Property

Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

Pascal

```
property ImeName;
```

C++

```
__property ImeName;
```

Description

Set ImeName to specify which IME to use for converting keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeName must specify one of the IMEs that has been installed through the Windows control panel. The property inspector provides a drop-down list of all currently installed IMEs on the system. At runtime, applications can obtain a list of currently installed IMEs from the global Screen variable.

If ImeName specifies an unavailable IME, the IME that was active when the application started is used instead. No exception is generated.

Note: The value of ImeName only takes effect when the control receives focus. To change the value of ImeName after the control has input focus, call the SetIme method.

5.1.3.6.24 TFileListBox.IntegralHeight Property

Determines whether the list box displays the partial items.

Pascal

```
property IntegralHeight;
```

C++

```
__property IntegralHeight;
```

Description

IntegralHeight controls the height of the list box itself.

When IntegralHeight is true, and the Style property is lsOwnerDrawFixed, the list box height will always be a multiple of the ItemHeight property value. In this case, items will never be partially displayed.

If IntegralHeight is false, the list box height can be set to any value, but the last item may not be fully displayed.

If the Style property value of the list box is lbOwnerDrawVariable, setting the IntegralHeight property to true has no effect.

See Also

ItemHeight

Items

Style

Using TDBListBox and TDBComboBox

5.1.3.6.25 TFileListBox.ItemHeight Property

Specifies the height in pixels of an item in an owner-draw list box.

Pascal

```
property ItemHeight;
```

C++

```
__property ItemHeight;
```

Description

Use ItemHeight to control the height of an item in a list box when the Style property is lbOwnerDrawFixed. The ItemHeight property can also affect the height of the list box itself. When the IntegralHeight property is true, the height of the list box is always an increment of the ItemHeight value.

If the Style property is lbStandard or lbOwnerDrawVariable, the value of ItemHeight is ignored.

OnDrawItem

OnMeasureItem

Style

Using TDBListBox and TDBComboBox

5.1.3.6.26 TFileListBox.Mask Property

Limits which files are displayed in the file list box.

Pascal

```
property Mask: string;
```

C++

```
__property UnicodeString Mask;
```

Description

Set Mask to a regular expression to limit the list box to files that match the mask. The value of the mask is a file name that may include wildcards. The asterisk (*) is a wildcard which matches any number of arbitrary characters. The question mark (?) is a wildcard which matches a single arbitrary character. The file mask *.* displays all files, which is the default value.

To specify multiple file masks, separate the file mask specifications with semicolons. For example, *.DLL;*.EXE.

If the form includes a TFilterComboBox (see page 1813) object, set the FileList property of the filter combo box to have the Mask property updated automatically when the Mask property of the filter combo box changes.

C++ Examples:

```
/*
This example uses a filter combo box and a file list box on
a form. When the user selects a filter in the filter combo
box, the file list box displays only files which match the
selected mask:
*/
void __fastcall TForm1::FilterComboBox1Change(TObject *Sender)
{
  FileListBox1->Mask = FilterComboBox1->Mask;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  FilterComboBox1->Filter = "All files (*.*)|*.*| Executable files (*.exe)|*.exe";
}
```

Delphi Examples:

```
{
This example uses a filter combo box and a file list box on
a form. When the user selects a filter in the filter combo
box, the file list box displays only files which match the
selected mask:
}
procedure TForm1.FilterComboBox1Change(Sender: TObject);
begin
  FileListBox1.Mask := FilterComboBox1.Mask;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  FilterComboBox1.Filter := 'All files (*.*)|*.*| Pascal files (*.pas)|*.pas';
end;
```

5.1.3.6.27 TFileListBox.MultiSelect Property

Specifies whether the user can select more than one item.

Pascal

```
property MultiSelect;
```

C++

```
__property MultiSelect;
```

Description

Use MultiSelect to specify whether the user can select more than one item. When MultiSelect is true, the user can select multiple items in the control, and the SelCount property indicates the number of selected items. When MultiSelect is false, the user can

only select one item, which is indicated by the ItemIndex property.

Note: To implement the MultiSelect property in a TCustomMultiSelectListControl descendant, override the protected SetMultiSelect method.

See Also

SelCount

ItemIndex

5.1.3.6.28 TFileListBox.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

ParentShowHint

5.1.3.6.29 TFileListBox.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

5.1.3.6.30 TFileListBox.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

5.1.3.6.31 TFileListBox.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

Font

Parent

ParentColor

ParentShowHint

5.1.3.6.32 TFileListBox.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

5.1.3.6.33 TFileListBox.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
```

```
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
```

```
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
```

```
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

OnContextPopup

5.1.3.6.34 TFileListBox.ShowGlyphs Property

Determines whether glyphs (bitmaps) appear next to the file names listed in the file list box.

Pascal

```
property ShowGlyphs: Boolean;
```

C++

```
__property Boolean ShowGlyphs;
```

Description

Set ShowGlyphs to true to display icons next to the files in the list that indicate the file type. Set ShowGlyphs to false to list only the file names.

5.1.3.6.35 TFileListBox.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

5.1.3.6.36 TFileListBox.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

5.1.3.6.37 TFileListBox.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

TabOrder

5.1.3.6.38 TFileListBox.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
```

```
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);

5.1.3.7 TFileListBox Events

The events of the TFileListBox class are listed here.

Published Events

	Name	Description
	OnChange (see page 1782)	Occurs immediately after the user changes the selected file in the list.
	OnClick (see page 1782)	Occurs when the user clicks the control.
	OnContextPopup (see page 1784)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 1785)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 1785)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 1788)	Occurs when the user drags an object over a control.
	OnEndDrag (see page 1791)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 1792)	Occurs when a control receives the input focus.
	OnExit (see page 1795)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 1797)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 1801)	Occurs when a key is pressed.
	OnKeyUp (see page 1802)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 1804)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

	OnMouseDown (see page 1805)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 1807)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 1807)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 1808)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 1810)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDrag (see page 1812)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

5.1.3.7.1 TFileListBox.OnChange Event

Occurs immediately after the user changes the selected file in the list.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write an OnChange event handler to take specific action when the FileName (see page 1764) property changes. If the FileEdit (see page 1763) property has been set, the edit control is updated before the OnChange event.

See Also

FileEdit (see page 1763)

FileName (see page 1764)

5.1.3.7.2 TFileListBox.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.

- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
```

```
        PageControl := PageControl1;
        Caption := 'TabSheet' + IntToStr(i);
        with TEdit.Create(Self) do
        begin
          Parent := PageControl1.Pages[i];
          Left := Random(PageControl1.ActivePage.ClientWidth - Width);
          Top := Random(PageControl1.ActivePage.ClientHeight - Height);
        end;
      end;
      PageControl1Change(Sender);
  end;
```

5.1.3.7.3 TFileListBox.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

AutoPopup (see page 4942)

5.1.3.7.4 TFileListBox.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick

Responding to User Actions at Runtime

5.1.3.7.5 TFileListBox.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
```

```
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{

TDragObject

5.1.3.7.6 TFileListBox.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
```

```
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");

5.1.3.7.7 TFileListBox.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
```

```
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;

5.1.3.7.8 TFileListBox.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/

5.1.3.7.9 TFileListBox.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

procedure TForm1.MaskEdit2Exit(Sender: TObject);
var
  net1, net2, host1, host2,
  netmask1, netmask2, hostmask1, hostmask2,
  sub_net1, sub_net2, sub_host1, sub_host2: Integer;

  net2 := StrToInt(TrimRight(Copy(IP, 5, 3)));
  host1 := StrToInt(TrimRight(Copy(IP, 9, 3)));
  host2 := StrToInt(TrimRight(Copy(IP, 13, 3)));

  // a range test that you cannot validate through edit masks
  if ((net1 < 0) Or (net1 > 255) Or
      (net2 < 0) Or (net2 > 255) Or
      (host1 < 0) Or (host1 > 255) Or
      (host2 < 0) Or (host2 > 255)) then
    raise EArgumentException.Create('Not a valid IP address.');

  // extract the net and host mask from the subnet mask
  mask := MaskEdit2.Text;
  netmask1 := StrToInt(TrimRight(Copy(mask, 0, 3)));
  netmask2 := StrToInt(TrimRight(Copy(mask, 5, 3)));
  hostmask1 := StrToInt(TrimRight(Copy(mask, 9, 3)));
```

```
    hostmask2 := StrToInt(TrimRight(Copy(mask, 13, 3)));

    // a range test that you cannot validate through edit masks
    if ((netmask1 < 0) Or (netmask1 > 255) Or
        (netmask2 < 0) Or (netmask2 > 255) Or
        (hostmask1 < 0) Or (hostmask1 > 255) Or
        (hostmask2 < 0) Or (hostmask2 > 255)) then
      raise EArgumentException.Create('Not a valid subnet mask.');

    // compute the subnet address using bit-wise AND
    sub_net1 := net1 And netmask1;
    sub_net2 := net2 And netmask2;
    sub_host1 := host1 And hostmask1;
    sub_host2 := host2 And hostmask2;

    // display the subnet address
    MaskEdit3.Text :=
      IntToStr(sub_net1) + '.' + IntToStr(sub_net2) + '.' +
      IntToStr(sub_host1) + '.' + IntToStr(sub_host2);
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin

OnEnter

ActiveControl (see page 2145)

5.1.3.7.10 TFileListBox.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown;
```

C++

```
__property OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/

OnKeyPress

OnKeyUp

5.1.3.7.11 TFileListBox.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress;
```

C++

```
__property OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

5.1.3.7.12 TFileListBox.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp;
```

C++

```
__property OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/
```

```
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
end;

procedure TForm1.FormKeyDown(
  Sender: TObject; var Key: Word; Shift: TShiftState);

OnKeyPress

5.1.3.7.13 TFileListBox.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events.

This information is applicable to both VCL Win32 and VCL.NET.

5.1.3.7.14 TFileListBox.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
```

```
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {

5.1.3.7.15 TFileListBox.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

5.1.3.7.16 TFileListBox.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

5.1.3.7.17 TFileListBox.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse

OnMouseMove

Responding to a Mouse-up Action

5.1.3.7.19 TFileListBox.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

5.1.4 TFilterComboBox Class

TFilterComboBox is a specialized combo box that presents the user with a choice of file filters.

Class Hierarchy

Pascal

```
[SecurityPermission(SecurityAction.Demand, Unrestricted=True)]
TFilterComboBox = class(TCustomComboBox);
```

C++

```
[SecurityPermission(SecurityAction.Demand, Unrestricted=True)]
class TFilterComboBox : public TCustomComboBox;
```

File

FileCtrl

Description

Add a filter combo box to a form that includes a file selection control to provide a set of predefined file filters. Use TFilterComboBox along with TDriveComboBox (see page 1668), TDirectoryListBox (see page 1589), and TFileListBox (see page 1734) to add full file selection capabilities to a form.

To add a standard Win32 file open or save dialog to an application, use TOpenDialog or TSaveDialog instead.

See Also

TDirectoryListBox (see page 1589)

TDriveComboBox (see page 1668)

TFileListBox (see page 1734)

5.1.4.1 TFilterComboBox Members

The following tables list the members exposed by TFilterComboBox.

Protected Methods

	Name	Description
	BuildList (see page 1816)	This is BuildList, a member of class TFilterComboBox.
V	Change (see page 1816)	Generates an OnChange event.
V	Click (see page 1816)	Respond to user click.
V	CreateWnd (see page 1817)	Creates the Windows control that represents the combo box.

	Notification (see page 1817)	Responds to notifications that components are being created or destroyed.

Public Methods

	Name	Description
	Create (see page 1815)	Creates and initializes an instance of TFilterComboBox (see page 1813).
	Destroy (see page 1815)	Destroys an instance of TFilterComboBox (see page 1813).

Public Properties

	Name	Description
	Mask (see page 1837)	Specifies the mask associated with the string selected in the filter combo box.
	Text (see page 1848)	Contains a text string associated with the control.

Published Events

	Name	Description
	OnChange (see page 1851)	Occurs when the user changes the text displayed in the edit region.
	OnClick (see page 1853)	Occurs when the user clicks the control.
	OnContextPopup (see page 1855)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 1856)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 1856)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 1859)	Occurs when the user drags an object over a control.
	OnDropDown (see page 1862)	Occurs when the user opens the drop-down list.
	OnEndDrag (see page 1864)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 1865)	Occurs when a control receives the input focus.
	OnExit (see page 1867)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 1870)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 1874)	Occurs when a key is pressed.
	OnKeyUp (see page 1875)	Occurs when the user releases a key that has been pressed.
	OnMouseEnter (see page 1876)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 1877)	Occurs when the user moves the mouse outside of a control.
	OnStartDrag (see page 1877)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 1819)	Determines how the control aligns within its container (parent control).
	Anchors (see page 1822)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 1823)	Positions to matching list items as you type.
	AutoDropDown (see page 1824)	Specifies whether the drop-down list drops down automatically in response to user keystrokes.
	BevelEdges (see page 1825)	Specifies which edges of the control are beveled.
	BevelInner (see page 1825)	Specifies the cut of the inner bevel.
	BevelKind (see page 1825)	Specifies the control's bevel style.
	BevelOuter (see page 1826)	Specifies the cut of the outer bevel.
	Color (see page 1826)	Specifies the background color of the control.
	Constraints (see page 1827)	Specifies the size constraints for the control.
	Ctl3D (see page 1828)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 1828)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 1830)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragMode (see page 1830)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 1832)	Controls whether the control responds to mouse, keyboard, and timer events.
	FileList (see page 1832)	Links the filter combo box to a file list box control.

	Filter (see page 1833)	Contains all the file masks displayed in the filter combo box.
	Font (see page 1835)	Controls the attributes of text written on or in the control.
	ImeMode (see page 1836)	Determines the behavior of the input method editor (IME).
	ImeName (see page 1836)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	ParentColor (see page 1838)	Determines where a control looks for its color information.
	ParentCtl3D (see page 1839)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 1839)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 1839)	Determines where a control looks for its font information.
	ParentShowHint (see page 1840)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 1840)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 1845)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 1847)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 1847)	Determines if the user can tab to a control.
	Visible (see page 1849)	Determines whether the component appears onscreen.

5.1.4.2 TFilterComboBox.Create Constructor

Creates and initializes an instance of TFilterComboBox (see page 1813).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TFilterComboBox(TComponent * AOwner);
```

Description

Call Create to create a TFilterComboBox (see page 1813) objectat runtime. Filter (see page 1833) combo boxes placed on a form at design time are created automatically.

See Also

Mask (see page 1837)

Style

Create

5.1.4.3 TFilterComboBox.Destroy Destructor

Destroys an instance of TFilterComboBox (see page 1813).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TFilterComboBox();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free checks that the filter combo box is not nil, and only then calls Destroy.

System::TObject::Free

5.1.4.4 TFilterComboBox Methods

The methods of the TFilterComboBox class are listed here.

Protected Methods

	Name	Description
	BuildList (see page 1816)	This is BuildList, a member of class TFilterComboBox.
V	Change (see page 1816)	Generates an OnChange event.
V	Click (see page 1816)	Respond to user click.
V	CreateWnd (see page 1817)	Creates the Windows control that represents the combo box.
V	Notification (see page 1817)	Responds to notifications that components are being created or destroyed.

5.1.4.4.1 TFilterComboBox.BuildList Method

Pascal

```
procedure BuildList;
```

C++

```
__fastcall BuildList();
```

Description

This is BuildList, a member of class TFilterComboBox.

5.1.4.4.2 TFilterComboBox.Change Method

Generates an OnChange event.

Pascal

```
procedure Change; override;
```

C++

```
virtual __fastcall Change();
```

Description

Change is called automatically in response to notifications that the text has changed. It responds by generating an OnChange event. Override this method to add additional processing when the text changes, or to block the OnChange event.

See Also

OnChange

Changed

5.1.4.4.3 TFilterComboBox.Click Method

Respond to user click.

Pascal

```
procedure Click; override;
```

C++

```
virtual __fastcall Click();
```

Description

Click is called automatically when the user left-clicks the control. Component or application code can call Click to simulate a user mouse click. This is often done in menu actions and hotkey handlers.

As implemented in TControl, Click queries whether the OnClick event handler exists and is different from the OnExecute handler for the control's Action. If this is true, the OnClick event handler is called. If this is false, and the Action OnExecute event handler exists, the Action's Execute method is called. Override Click to provide additional behavior.

See Also

Action

OnExecute

Execute

DblClick

OnClick

5.1.4.4.4 TFilterComboBox.CreateWnd Method

Creates the Windows control that represents the combo box.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

The CreateHandle method calls CreateWnd to handle the particulars of creating the combo box window. TCustomCombo overrides the inherited method to ensure that the newly-created window and the TCustomCombo properties correctly reflect each other.

The Windows control for the combo box can be temporarily destroyed and recreated in order to set properties that require changing the window creation parameters. Thus, CreateWnd may be called more than once during the lifetime of the TCustomCombo instance.

See Also

CreateHandle

5.1.4.4.5 TFilterComboBox.Notification Method

Responds to notifications that components are being created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification allows TControl to update its PopupMenu property when the pop-up menu it refers to is destroyed.

Override the Notification method to respond to notifications that other components are about to be destroyed or have just been created. Use the Notification method to update controls that rely on other objects. Remove references to objects that are going away so that the control does not refer to objects that have been destroyed. For example, data-aware objects override the Notification method to update themselves when their data source is removed. Some objects respond to notifications that other objects of a specific type are being created. For example, the session component sets the Session property of new data-aware controls to itself when the AutoSessionName property is true.

By default, components pass along the notification to their owned components, if any.

Notification

5.1.4.5 TFilterComboBox Properties

The properties of the TFilterComboBox class are listed here.

Public Properties

	Name	Description
	Mask (see page 1837)	Specifies the mask associated with the string selected in the filter combo box.
	Text (see page 1848)	Contains a text string associated with the control.

Published Properties

	Name	Description
	Align (see page 1819)	Determines how the control aligns within its container (parent control).
	Anchors (see page 1822)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 1823)	Positions to matching list items as you type.
	AutoDropDown (see page 1824)	Specifies whether the drop-down list drops down automatically in response to user keystrokes.
	BevelEdges (see page 1825)	Specifies which edges of the control are beveled.
	BevelInner (see page 1825)	Specifies the cut of the inner bevel.
	BevelKind (see page 1825)	Specifies the control's bevel style.
	BevelOuter (see page 1826)	Specifies the cut of the outer bevel.
	Color (see page 1826)	Specifies the background color of the control.
	Constraints (see page 1827)	Specifies the size constraints for the control.
	Ctl3D (see page 1828)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 1828)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 1830)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragMode (see page 1830)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 1832)	Controls whether the control responds to mouse, keyboard, and timer events.
	FileList (see page 1832)	Links the filter combo box to a file list box control.
	Filter (see page 1833)	Contains all the file masks displayed in the filter combo box.
	Font (see page 1835)	Controls the attributes of text written on or in the control.
	ImeMode (see page 1836)	Determines the behavior of the input method editor (IME).
	ImeName (see page 1836)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	ParentColor (see page 1838)	Determines where a control looks for its color information.

	ParentCtl3D (see page 1839)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 1839)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 1839)	Determines where a control looks for its font information.
	ParentShowHint (see page 1840)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 1840)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 1845)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 1847)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 1847)	Determines if the user can tab to a control.
	Visible (see page 1849)	Determines whether the component appears onscreen.

5.1.4.5.1 TFilterComboBox.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
```

```
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
```

```
        pts[i]->Brush->Color = colorPalette[i];
    }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane - a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
}

Parent

Anchors

5.1.4.5.2 TFilterComboBox.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at

design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

5.1.4.5.3 TFilterComboBox.AutoComplete Property

Positions to matching list items as you type.

Pascal

```
property AutoComplete;
```

C++

```
__property AutoComplete;
```

Description

AutoComplete will position to matching list values as you type, saving you keystrokes.

As you type, the ItemIndex property is updated with the list entry that matches the characters you have entered. As you type, different list entries may match, and ItemIndex changes accordingly.

There is a delay of AutoCompleteDelay milliseconds between the characters typed and the autocomplete operation.

C++ Examples:

```
/*
This is a very simple example showing how to create a comboBox, add to
it some choices, selecting a default value and getting the selected
value.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
//comboBox initialize
comb = new TComboBox(this);
comb->Parent = this;

//visual options
comb->Align = TAlign::alLeft;
comb->DoubleBuffered = true;
comb->AutoComplete = true;

//adding items to the combo box
comb->AddItem("firstChoice",NULL);
comb->AddItem("secondChoice",NULL);
comb->AddItem("thirdChoice",NULL);

//setting the default value
comb->ItemIndex = 1;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Button1Click(TObject *Sender)
{
MessageDlg("Selected text: " + comb->Text,
            mtInformation, TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This is a very simple example showing how to create a comboBox, add to
it some choices, selecting a default value and getting the selected
value.
}
procedure TForm3.Button1Click(Sender: TObject);
begin
  MessageDlg('Selected text: ' + comb.Text, mtInformation,
            mbYesNo, 0);
end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  //initialize the combo box
  comb := TComboBox.Create(Self);
  comb.Parent := Self;

  //visual options
  comb.Align := alLeft;
  comb.DoubleBuffered := true;
  comb.AutoComplete := true;

  //adding items to the combo box
  comb.AddItem('firstChoice', nil);
  comb.AddItem('secondChoice', nil);
  comb.AddItem('thirdChoice', nil);

  //setting the default value
  comb.ItemIndex := 1;
end;
```

See Also

AutoCompleteDelay

5.1.4.5.4 TFilterComboBox.AutoDropDown Property

Specifies whether the drop-down list drops down automatically in response to user keystrokes.

Pascal

```
property AutoDropDown;
```

C++

```
__property AutoDropDown;
```

Description

When AutoDropDown is true, the combo box automatically drops down its list when the user starts typing a string while the combo box has focus.

When AutoDropDown is false, the user must explicitly use the drop-down button to drop down the combo box list.

autocomplete

OnDropDown

DroppedDown

5.1.4.5.5 TFilterComboBox.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges;
```

C++

```
__property BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner

BevelKind

5.1.4.5.6 TFilterComboBox.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner;
```

C++

```
__property BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges

BevelKind

BevelWidth

BorderWidth

5.1.4.5.7 TFilterComboBox.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind;
```

C++

```
__property BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

5.1.4.5.8 TFilterComboBox.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter;
```

C++

```
__property BevelOuter;
```

Description

Use BevelOuter to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

BevelEdges

BevelInner

BevelKind

BevelWidth

5.1.4.5.9 TFilterComboBox.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically

set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor

5.1.4.5.10 TFilterComboBox.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

OnCanResize

5.1.4.5.11 TFilterComboBox.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

See Also

BorderWidth

5.1.4.5.12 TFilterComboBox.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:
```

```
procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

5.1.4.5.13 TFilterComboBox.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

5.1.4.5.14 TFilterComboBox.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
```

```
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TTreeView;

5.1.4.5.15 TFilterComboBox.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

5.1.4.5.16 TFilterComboBox.FileList Property

Links the filter combo box to a file list box control.

Pascal

```
property FileList: TFileListBox;
```

C++

```
__property TFileListBox FileList;
```

Description

If the form includes a TFileListBox (see page 1734) object to display a list of files to choose from, set FileList to allow the filter combo box to limit which files are displayed in the list box. Once the two controls are connected, whenever a new filter is selected using a filter combo box, the file list box displays the files that match the selected filter.

C++ Examples:

```
/*
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  FileListBox1->FileEdit = Edit1;
  FilterComboBox1->FileList = FileListBox1;
  DirectoryListBox1->FileList = FileListBox1;
  DirectoryListBox1->DirLabel = Label1;
  DriveComboBox1->DirList = DirectoryListBox1;
  Button1->Default = true;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FileListBox1->ApplyFilePath(Edit1->Text);
}
```

Delphi Examples:

```
{
This example uses a file list box, a directory list box, a
filter combo box, a drive combo box, a label, an edit box,
and a button on a form. When the user runs the application
and enters a path or filename in the edit box and presses
the button, all the controls update:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  FileListBox1.ApplyFilePath(Edit1.Text);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  FileListBox1.FileEdit := Edit1;
  FilterComboBox1.FileList := FileListBox1;
  DirectoryListBox1.FileList := FileListBox1;
  DirectoryListBox1.DirLabel := Label1;
  DriveComboBox1.DirList := DirectoryListBox1;
  Button1.Default := True;
end;
```

See Also

Mask (see page 1837)

5.1.4.5.17 TFilterComboBox.Filter Property

Contains all the file masks displayed in the filter combo box.

Pascal

```
property Filter: string;
```

C++

```
__property UnicodeString Filter;
```

Description

Set the Filter property to specify the names that appear in the filter combo box, along with the masks associated with each name. Each mask is a file name that may include wildcards. The asterisk (*) is a wildcard which matches any number of arbitrary characters. The question mark (?) is a wildcard which matches a single arbitrary character. When the application runs, the file filter the user selects in the filter combo box becomes the value of the Mask (see page 1837) property.

To create the value of Filter for a single file type, follow these steps:

1Type some meaningful text to indicate the type of file.

2Type a | character (vertical bar).

3Type the file filter.

Don't put in any spaces around the | character in the string.

Here's an example:

```
FilterComboBox1.Filter := 'Text files|*.TXT';
FilterComboBox1->Filter = "Text files|*.TXT";
```

If Filter is set to this string, the string "Text (see page 1848) files" appears in the filter combo box. When the user selects "Text (see page 1848) files", the mask is set to "*.TXT".

To specify multiple file filters, extend the value of Filter, separating each file name/mask combination with a | character. Filter can specify an any number of file filters, as long as the string is less than 255 characters.

Here's an example of two file filters that could be specified as the value of the Filter property:

```
'Text files (*.TXT)|*.TXT|Pascal files (*.PAS)|*.PAS'
"Text files (*.TXT)|*.TXT|C++ files (*.CPP)|*.CPP"
```

The previous example includes the file filters in parentheses in the text parts. This isn't required, but it's a common convention that helps users understand what to expect when they select a file filter.

The mask portion can include multiple file specifiers if they are separated with semicolons:

```
'All files|*.TXT;*.PAS;*.WB1'
"All files|*.TXT;*.CPP;*.RC"
```

C++ Examples:

```
/*
This example uses a filter combo box and a file list box on
a form. When the user selects a filter in the filter combo
box, the file list box displays only files which match the
selected mask:
*/
void __fastcall TForm1::FilterComboBox1Change(TObject *Sender)
{
  FileListBox1->Mask = FilterComboBox1->Mask;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  FilterComboBox1->Filter = "All files (*.*)|*.*| Executable files (*.exe)|*.exe";
}
```

Delphi Examples:

```
{
This example uses a filter combo box and a file list box on
a form. When the user selects a filter in the filter combo
box, the file list box displays only files which match the
selected mask:
}
procedure TForm1.FilterComboBox1Change(Sender: TObject);
begin
  FileListBox1.Mask := FilterComboBox1.Mask;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  FilterComboBox1.Filter := 'All files (*.*)|*.*| Pascal files (*.pas)|*.pas';
end;
```

Mask (see page 1837)

5.1.4.5.18 TFilterComboBox.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
```

```
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

5.1.4.5.19 TFilterComboBox.ImeMode Property

Determines the behavior of the input method editor (IME).

Pascal

```
property ImeMode;
```

C++

```
__property ImeMode;
```

Description

Set ImeMode to configure the way an IME processes user keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeMode allows a control to influence the type of conversion performed by the IME so that it is appropriate for the input expected by the control. For example, a control that only accepts numeric input might specify an ImeMode of imClose, as no conversion is necessary for numeric input.

Note: The value of ImeMode only takes effect when the control receives focus. To change the value of ImeMode when the control already has input focus, call the SetIme method.

ImeName

ResetIme

ResetImeComposition

SetIme

SetImeCompositionWindow

5.1.4.5.20 TFilterComboBox.ImeName Property

Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

Pascal

```
property ImeName;
```

C++

```
__property ImeName;
```

Description

Set ImeName to specify which IME to use for converting keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeName must specify one of the IMEs that has been installed through the Windows control panel. The property inspector provides a drop-down list of all currently installed IMEs on the system. At runtime, applications can obtain a list of currently installed IMEs from the global Screen variable.

If ImeName specifies an unavailable IME, the IME that was active when the application started is used instead. No exception is generated.

Note: The value of ImeName only takes effect when the control receives focus. To change the value of ImeName after the control has input focus, call the SetIme method.

DefaultIme (see page 2462)

Imes (see page 2472)

5.1.4.5.21 TFilterComboBox.Mask Property

Specifies the mask associated with the string selected in the filter combo box.

Pascal

```
property Mask: string;
```

C++

```
__property UnicodeString Mask;
```

Description

Read Mask to obtain the mask that was selected by the user.

When the user uses the filter combo box to select a new filter, the mask associated with the selected file type becomes the value of the Mask property. If a file list box is linked to the filter combo box with the FileList (see page 1832) property, the file list will update when the value of Mask changes.

C++ Examples:

```
/*
This example uses a filter combo box and a file list box on
a form. When the user selects a filter in the filter combo
box, the file list box displays only files which match the
selected mask:
*/
void __fastcall TForm1::FilterComboBox1Change(TObject *Sender)
{
```

```
  FileListBox1->Mask = FilterComboBox1->Mask;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  FilterComboBox1->Filter = "All files (*.*)|*.*| Executable files (*.exe)|*.exe";
}
```

Delphi Examples:

```
{
This example uses a filter combo box and a file list box on
a form. When the user selects a filter in the filter combo
box, the file list box displays only files which match the
selected mask:
}
procedure TForm1.FilterComboBox1Change(Sender: TObject);
begin
  FileListBox1.Mask := FilterComboBox1.Mask;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  FilterComboBox1.Filter := 'All files (*.*)|*.*| Pascal files (*.pas)|*.pas';
end;
```

FileList (see page 1832)

Filter (see page 1833)

Mask (see page 1768)

5.1.4.5.22 TFilterComboBox.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

5.1.4.5.23 TFilterComboBox.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

5.1.4.5.24 TFilterComboBox.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

5.1.4.5.25 TFilterComboBox.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

Parent

ParentColor

ParentShowHint

5.1.4.5.26 TFilterComboBox.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

5.1.4.5.27 TFilterComboBox.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
```

```
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.

        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
```

```
  This example demonstrates how to add and delete menu items
  to a popup menu at runtime and assign an event handler to
  the OnClick event.  Place a TPopupMenu and three buttons on
  the form named "AddButton", "EditButton",  and
  "DestroyButton" and add OnClick events to all three buttons.
  Put the TPopupMenu in the PopupMenu property of the form.
  Place the PopupMenuItemsClick procedure in the TForm1 type
  declaration so that it can be used as the method call for
  the menu item OnClick event.
  }

OnContextPopup

5.1.4.5.28 TFilterComboBox.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;

Displaying Fly-over Help

5.1.4.5.29 TFilterComboBox.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

FindNextControl

TabStop

5.1.4.5.30 TFilterComboBox.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

5.1.4.5.31 TFilterComboBox.Text Property

Contains a text string associated with the control.

Pascal

```
property Text;
```

C++

```
__property Text;
```

Description

Use the Text property to read the Text of the control or specify a new string for the Text value. By default, Text is the control name. For edit controls and memos, the Text appears within the control. For combo boxes, the Text is the content of the edit control portion of the combo box.

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
*/
#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int Size = Edit1->GetTextLen(); //Get length of string in Edit1
  Size++;                         //Add room for null character
//  Char *Buffer = new Char[Size];  //Creates Buffer dynamic variable
  std::auto_ptr<Char> Buffer(new Char[Size]);
  Edit1->GetTextBuf(Buffer.get(),Size); //Puts Edit1->Text into Buffer
  Edit2->Text = Buffer.get();
}
/*
Note: the same thing could be accomplished more simply as follows:
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Edit2->Text = Edit1->Text;
}
```

Delphi Examples:

```
{
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Buffer: PChar;
  Size: Byte;
```

```
begin
  Size := Edit1.GetTextLen;       {Get length of string in Edit1}
  Inc(Size);                      {Add room for null character}
  GetMem(Buffer, Size);           {Creates Buffer dynamic variable}
  Edit1.GetTextBuf(Buffer,Size);  {Puts Edit1.Text into Buffer}
  Edit2.Text := StrPas(Buffer);   {Converts Buffer to a Pascal-style string}
  FreeMem(Buffer, Size);{Frees memory allocated to Buffer}
end;

{
Note: the same thing could be accomplished more simply as follows:
}
procedure TForm1.Button2Click(Sender: TObject);
begin
  Edit2.Text := Edit1.Text;
end;
```

Lines

5.1.4.5.32 TFilterComboBox.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
```

```
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;

5.1.4.6 TFilterComboBox Events

The events of the TFilterComboBox class are listed here.

Published Events

	Name	Description
	OnChange (see page 1851)	Occurs when the user changes the text displayed in the edit region.

	OnClick (see page 1853)	Occurs when the user clicks the control.
	OnContextPopup (see page 1855)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 1856)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 1856)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 1859)	Occurs when the user drags an object over a control.
	OnDropDown (see page 1862)	Occurs when the user opens the drop-down list.
	OnEndDrag (see page 1864)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 1865)	Occurs when a control receives the input focus.
	OnExit (see page 1867)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 1870)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 1874)	Occurs when a key is pressed.
	OnKeyUp (see page 1875)	Occurs when the user releases a key that has been pressed.
	OnMouseEnter (see page 1876)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 1877)	Occurs when the user moves the mouse outside of a control.
	OnStartDrag (see page 1877)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

5.1.4.6.1 TFilterComboBox.OnChange Event

Occurs when the user changes the text displayed in the edit region.

Pascal

```
property OnChange;
```

C++

```
__property OnChange;
```

Description

Write an OnChange event handler to take specific action immediately after the user edits the text in the edit region or selects an item from the list. The Text property gives the new value in the edit region.

Note: OnChange only occurs in response to user actions. Changing the Text property programmatically does not trigger an OnChange event.

C++ Examples:

```
/*
This example requires a TPageControl already on the form.
Also, you must add pages to the TPageControl by right
clicking and selecting New Page.
The example code will allow the user to select the
ActivePage property through selection of a ComboBox item.
During the form create, the Combo Box control is loaded with
the names of each of the tabs, as well as the instance
pointers to the corresponding tab.  When the user selects
the Combo Box item, the associated TTabSheet object
contained in the Combo Box Objects array is used to set the
ActivePage property.  Select the Lines property of the
TRichEdit to enter a string.  Select the string before
justifying.
*/

  procedure TForm1.ComboBox1Change(Sender: TObject);
  begin
    if (Sender is TComboBox) then
      with (Sender as TComboBox) do
        PageControl1.ActivePage := TTabSheet(Items.Objects[ItemIndex]);
  end;
  {
  The following example assumes that a drive combo box, a file
  list box, and a directory list box are on a form. Add this
  code as the OnChange event handler for the drive combo box
  and the OnChange event handler for the directory list box.
  When the user changes the drive using the combo box, the
  directory list box and file list box will update to reflect
  the new drive and the current directory on that drive.  When
  the user double clicks on a directory in the file list box
  will update to reflect the new directory.
  }
  procedure TForm1.DirectoryListBox1Change(Sender: TObject);
  begin
    FileListBox1.Directory := DirectoryListBox1.Directory;
  end;

  procedure TForm1.DriveComboBox1Change(Sender: TObject);
  begin
    DirectoryListBox1.Drive := DriveComboBox1.Drive;
    FileListBox1.Drive := DriveComboBox1.Drive;
    FileListBox1.Directory := DirectoryListBox1.Directory;
  end;
```

OnCloseUp

5.1.4.6.2 TFilterComboBox.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).

- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
```

```
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;

5.1.4.6.3 TFilterComboBox.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple

times for each context menu invocation.

OnClick

Responding to User Actions at Runtime

5.1.4.6.5 TFilterComboBox.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
```

```
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

TDragObject

5.1.4.6.6 TFilterComboBox.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
```

```
Note: Set the label's DragMode property to dmAutomatic.

5.1.4.6.7 TFilterComboBox.OnDropDown Event

Occurs when the user opens the drop-down list.

Pascal

```
property OnDropDown;
```

C++

```
__property OnDropDown;
```

Description

Write an OnDropDown event handler to implement special processing that needs to occur only when the drop-down list is activated.

C++ Examples:

```
/*
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
*/
```

```
#include "Unit2.h"
#include "Unit3.h"

void __fastcall TForm1::ComboBox1DropDown(TObject *Sender)
{
  ComboBox1->Items->BeginUpdate(); // prevent repaints until done
  ComboBox1->Items->Clear(); // empty the list of any old values
  for (int i = 0; i < Screen->CustomFormCount; i++)
  {
    if ((reinterpret_cast<TForm1 *>(Screen->CustomForms[i]))->Visible)
      ComboBox1->Items->Add(Screen->CustomForms[i]->Caption);  // add form names
  }
  ComboBox1->Items->EndUpdate(); //reenable painting
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ComboBox1->Sorted = True; // make sure the form names are sorted
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Form2->Show();
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Form3->Show();
}
```

Delphi Examples:

```
{
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
}
procedure TForm1.ComboBox1DropDown(Sender: TObject);
var
  I: Integer;
begin
  with ComboBox1 do
  begin
    Items.BeginUpdate; { prevent repaints until done }
    Items.Clear; { empty the list of any old values }
    for I := 0 to Screen.CustomFormCount - 1 do
    begin
      if (Screen.CustomForms[I].Visible) then
        Items.Add(Screen.CustomForms[I].Caption); { add form name }
    end;
    Items.EndUpdate; {reenable painting }
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ComboBox1.Sorted := True; { make sure the form names are sorted }
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Form2.Show;
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
```

```
  Form3.Show;
end;
```

DroppedDown

OnCloseUp

5.1.4.6.8 TFilterComboBox.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;

OnDragDrop

OnDragOver

OnStartDrag

DragKind

5.1.4.6.9 TFilterComboBox.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
```

```
    (dynamic_cast<TEdit *>(myActiveControl))->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    (dynamic_cast<TRichEdit *>(myActiveControl))->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
```

```
    else if myActiveControl is TRichEdit then
      with myActiveControl as TRichEdit do
        SelAttributes.Assign(TFontDialog(Sender).Font)
    else
      Beep;
  end;
  {
  This example uses an edit box and a memo control on a form.
  When either the edit box or the memo is the active control,
  it is colored yellow. When the active control becomes
  inactive, the color of the control returns to the Windows
  system color for a window.  These event handlers could also
  be shared.
  }
  procedure TForm1.Edit1Enter(Sender: TObject);
  begin
    Edit1.Color := clYellow;
  end;

  procedure TForm1.Edit1Exit(Sender: TObject);
  begin
    Edit1.Color := clWindow;
  end;

  procedure TForm1.Memo1Enter(Sender: TObject);
  begin
    Memo1.Color := clYellow;
  end;

  procedure TForm1.Memo1Exit(Sender: TObject);
  begin
    Memo1.Color := clWindow;
  end;
```

5.1.4.6.10 TFilterComboBox.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
```

```
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

procedure TForm1.MaskEdit2Exit(Sender: TObject);
var
  net1, net2, host1, host2,
  netmask1, netmask2, hostmask1, hostmask2,
  sub_net1, sub_net2, sub_host1, sub_host2: Integer;

OnEnter

ActiveControl (see page 2145)

5.1.4.6.11 TFilterComboBox.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown;
```

C++

```
__property OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not

generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/

KeyPreview (see page 2167)

OnKeyPress

OnKeyUp

5.1.4.6.12 TFilterComboBox.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress;
```

C++

```
__property OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

OnKeyDown

OnKeyPress

5.1.4.6.14 TFilterComboBox.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

5.1.4.6.15 TFilterComboBox.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

5.1.4.6.16 TFilterComboBox.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

5.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	DirectoryExists (see page 1879)	Determines whether a specified directory exists.
	ForceDirectories (see page 1879)	Creates a new directory, including the creation of parent directories as needed.
	MinimizeName (see page 1880)	Shortens a fully qualified path name so that it can be drawn with a specified length limit.
	ProcessPath (see page 1881)	Parses a file name into its constituent parts.
	SelectDirectory (see page 1881)	Brings up a dialog to allow the user to enter a directory name.
	SelectDirectory (see page 1881)	Brings up a dialog to allow the user to enter a directory name.

5.2.1 FileCtrl.DirectoryExists Function

Determines whether a specified directory exists.

Pascal

```
function DirectoryExists(const Name: string): Boolean;
```

C++

```
Boolean DirectoryExists(const UnicodeString Name);
```

File

FileCtrl

Description

Call DirectoryExists to determine whether the directory specified by the Name parameter exists. If the directory exists, the function returns true. If the directory does not exist, the function returns false.

If a full path name is entered, DirectoryExists searches for the directory along the designated path. Otherwise, the Name parameter is interpreted as a relative path name from the current directory.

Note: The FileCtrl (see page 1587) unit (Windows only) also contains a DirectoryExists function. However, the FileCtrl (see page 1587) version is deprecated, and the SysUtils version preferred, even if the code does not need to be cross-platform.

See Also

ForceDirectories

SelectDirectory

FileExists

5.2.2 FileCtrl.ForceDirectories Function

Creates a new directory, including the creation of parent directories as needed.

Pascal

```
function ForceDirectories(const Dir: string): Boolean;
```

C++

```
Boolean ForceDirectories(const UnicodeString Dir);
```

File

FileCtrl

Description

ForceDirectories creates a new directory as specified in Dir, which must be a fully-qualified path name. If the directories given in the path do not yet exist, ForceDirectories attempts to create them.

ForceDirectories returns true if it successfully creates all necessary directories, false if it could not create a needed directory.

Warning: Important:Do not call ForceDirectories with an empty string. Doing so causes ForceDirectories to raise an exception.

Note: The FileCtrl (see page 1587) unit (Windows only) also contains a ForceDirectories function. However, the FileCtrl (see page 1587) version is deprecated, and the SysUtils version preferred, even if the code does not need to be cross-platform.

5.2.3 FileCtrl.MinimizeName Function

Shortens a fully qualified path name so that it can be drawn with a specified length limit.

Pascal

```
function MinimizeName(const Filename: TFileName; Canvas: TCanvas; MaxLen: Integer): TFileName;
```

C++

```
TFileName MinimizeName(const TFileName Filename, TCanvas Canvas, int MaxLen);
```

File

FileCtrl

Description

Use MinimizeName to obtain a version of a file name and path that can be drawn on a limited size drawing surface. MinimizeName replaces directories in the path portion of the file name with dots until the resulting name fits the specified number of pixels in length.

MinimizeName returns the shortened name.

Filename is the fully qualified path name that (possibly) needs to be shortened.

Canvas is the drawing surface on which the resulting name is to be rendered. It is used to determine font metrics.

MaxLen is the length, in pixels, available for drawing the file name on the canvas.

AdjustLineBreaks

WrapText

5.2.4 FileCtrl.ProcessPath Function

Parses a file name into its constituent parts.

Pascal

```
procedure ProcessPath(const EditText: string; var Drive: Char; var DirPart: string; var
FilePart: string);
```

C++

```
ProcessPath(const UnicodeString EditText, Char Drive, UnicodeString DirPart, UnicodeString
FilePart);
```

File

FileCtrl

Description

Call ProcessPath to parse a file name into its drive, path, and file name.

Pass the full file name that should be parsed as the EditText parameter. EditText must refer to an existing file or directory name.

ProcessPath returns the indicated drive, directory, and file name as the Drive, DirPart, and FilePart parameters.

ExtractFilePath

5.2.5 FileCtrl.SelectDirectory Function

Brings up a dialog to allow the user to enter a directory name.

Pascal

```
function SelectDirectory(var Directory: string; Options: TSelectDirOpts; HelpCtx: Longint):
Boolean; overload;
function SelectDirectory(const Caption: string; const Root: WideString; var Directory: string;
Options: TSelectDirExtOpts = [sdNewUI]; Parent: TWinControl = nil): Boolean; overload;
```

C++

```
Boolean SelectDirectory(UnicodeString Directory, TSelectDirOpts Options, Longint HelpCtx);
Boolean SelectDirectory(const UnicodeString Caption, const BSTR Root, UnicodeString Directory,
TSelectDirExtOpts Options = [sdNewUI], TWinControl * Parent = nil);
```

File

FileCtrl

Description

Call SelectDirectory to let the user enter a directory name.

Use the first syntax to call the Select Directory dialog box. The directory passed to the function with the Directory parameter appears as the currently selected directory when the dialog box appears. The name of the directory the user selects becomes the value of Directory when the function returns.

The HelpCtx parameter is the help context ID number.

Use the second syntax to display the Windows directory browser. The Caption parameter specifies a caption for the dialog. The Root parameter specifies the root directory from which to browse. The selected directory is returned as the Directory parameter. When using this syntax, SelectDirectory does not change the value of the current directory.

Warning: You can't use the same variable for the Root parameter and the Directory parameter.

The Options parameter is a set of values. If Options is the empty set, the user can only select a directory that already exists. No edit box is provided for the user to enter a new directory name. If Options is not empty, the included values determine how the dialog responds when the user types a nonexistent directory name.

With either syntax, SelectDirectory returns true if the user selected a directory and chose OK, and false if the user chose Cancel or closed the dialog box without selecting a directory.

DirectoryExists (see page 1879)

ForceDirectories (see page 1879)

5.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TDriveType (see page 1883)	This is record FileCtrl.TDriveType.
	TFileAttr (see page 1883)	TFileAttr and TFileType (see page 1887) determine which files a file list box displays.
	TSelectDirExtOpt (see page 1884)	This is record FileCtrl.TSelectDirExtOpt.
	TSelectDirOpt (see page 1885)	TSelectDirOpt and TSelectDirOpts (see page 1888) determine how a directory selection dialog responds when the user enters a nonexistent directory.
	TTextCase (see page 1886)	TTextCase indicates the case of the volume name or drive letter that appears in a dialog box.

5.3.1 FileCtrl.TDriveType Enumeration

Pascal

```
TDriveType = (
  dtUnknown,
  dtNoDrive,
  dtFloppy,
  dtFixed,
  dtNetwork,
  dtCDROM,
  dtRAM
);
```

C++

```
enum TDriveType {
  dtUnknown,
  dtNoDrive,
  dtFloppy,
  dtFixed,
  dtNetwork,
  dtCDROM,
  dtRAM
};
```

File

FileCtrl

Description

This is record FileCtrl.TDriveType.

5.3.2 FileCtrl.TFileAttr Enumeration

TFileAttr and TFileType (see page 1887) determine which files a file list box displays.

Pascal

```
TFileAttr = (
  ftReadOnly,
  ftHidden,
  ftSystem,
  ftVolumeID,
  ftDirectory,
  ftArchive,
  ftNormal
);
```

C++

```
enum TFileAttr {
  ftReadOnly,
  ftHidden,
  ftSystem,
  ftVolumeID,
  ftDirectory,
  ftArchive,
  ftNormal
};
```

File

FileCtrl

Description

TFileType (see page 1887) is a set of TFileAttr values. These are the possible TFileAttr values:

Value	Meaning
ftReadOnly	The list box displays files with the read-only attribute.
ftHidden	The list box displays files with the hidden attribute.
ftSystem	The list box displays system files.
ftVolumeID	The list box displays the volume name.
ftDirectory	The list box displays directories.
ftArchive	The list box displays files with archive attribute.
ftNormal	The list box displays files with no special attributes.

See Also

SelectDirectory

5.3.3 FileCtrl.TSelectDirExtOpt Enumeration

Pascal

```
TSelectDirExtOpt = (
  sdNewFolder,
  sdShowEdit,
  sdShowShares,
  sdNewUI,
  sdShowFiles,
  sdValidateDir
);
```

C++

```
enum TSelectDirExtOpt {
  sdNewFolder,
  sdShowEdit,
  sdShowShares,
  sdNewUI,
  sdShowFiles,
  sdValidateDir
};
```

File

FileCtrl

Description

This is record FileCtrl.TSelectDirExtOpt.

5.3.4 FileCtrl.TSelectDirOpt Enumeration

TSelectDirOpt and TSelectDirOpts (see page 1888) determine how a directory selection dialog responds when the user enters a nonexistent directory.

Pascal

```
TSelectDirOpt = (
  sdAllowCreate,
  sdPerformCreate,
  sdPrompt
);
```

C++

```
enum TSelectDirOpt {
  sdAllowCreate,
  sdPerformCreate,
  sdPrompt
};
```

File

FileCtrl

Description

These are the possible values that can be added to the set of options:

Value	Meaning
sdAllowCreate	An edit box allows the user to type in the name of a directory that does not exist. This option does not create a directory: the application must read the name of the selected directory and create it if desired.
sdPerformCreate	Used only in combination with sdAllowCreate. If the user enters a directory name that does not exist, the directory selection dialog creates it.
sdPrompt	Used only in combination with sdAllowCreate. Displays a message box that informs the user when the entered directory does not exist and asks if the directory should be created. If the user chooses OK, the directory is created if the option set includes sdPerformCreate. If the option set does not include sdPerformCreate, the directory is not created: the application must read the directory name and create it.

See Also

SelectDirectory

5.3.5 FileCtrl.TTextCase Enumeration

TTextCase indicates the case of the volume name or drive letter that appears in a dialog box.

Pascal

```
TTextCase = (
  tcLowerCase,
  tcUpperCase
);
```

C++

```
enum TTextCase {
  tcLowerCase,
  tcUpperCase
};
```

File

FileCtrl

Description

TTextCase can have one of the following values:

Value	Meaning
tcLowerCase	The volume name is displayed in lowercase letters.
tcUpperCase	The volume name is displayed in uppercase letters.

5.4 Types

The following table lists types in this documentation.

Types

Name	Description
TFileType (see page 1887)	TFileType describes possible combinations of file attributes.
TSelectDirExtOpts (see page 1887)	This is type FileCtrl.TSelectDirExtOpts.
TSelectDirOpts (see page 1888)	This is type FileCtrl.TSelectDirOpts.

5.4.1 FileCtrl.TFileType Type

TFileType describes possible combinations of file attributes.

Pascal

```
TFileType = set of TFileAttr;
```

C++

```
TFileAttr TFileType;
```

File

FileCtrl

Description

TFileType describes possible combinations of file attributes.

See Also

TFileListView

5.4.2 FileCtrl.TSelectDirExtOpts Type

Pascal

```
TSelectDirExtOpts = set of TSelectDirExtOpt;
```

C++

```
TSelectDirExtOpt TSelectDirExtOpts;
```

File

FileCtrl

Description

This is type FileCtrl.TSelectDirExtOpts.

5.4.3 FileCtrl.TSelectDirOpts Type

Pascal

```
TSelectDirOpts = set of TSelectDirOpt;
```

C++

```
TSelectDirOpt TSelectDirOpts;
```

File

FileCtrl

Description

This is type FileCtrl.TSelectDirOpts.

5.5 Constants

The following table lists constants in this documentation.

Constants

Name	Description
WNTYPE_DRIVE (see page 1889)	This is constant FileCtrl.WNTYPE_DRIVE.

5.5.1 FileCtrl.WNTYPE_DRIVE Constant

Pascal

```
WNTYPE_DRIVE = 1;
```

C++

```
WNTYPE_DRIVE = 1;
```

File

FileCtrl

Description

This is constant FileCtrl.WNTYPE_DRIVE.

6 FMTBcd Namespace

This is namespace FMTBcd.

Topics

Name	Description
Classes (see page 1894)	The following table lists classes in this documentation.
Functions (see page 1896)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 1913)	The following table lists structs, records, enums in this documentation.
Types (see page 1914)	The following table lists types in this documentation.
Constants (see page 1915)	The following table lists constants in this documentation.

Classes

	Name	Description
	EBcdException (see page 1894)	EBcdException is the exception class for errors that occur when working with BCD values.
	EBcdOverflowException (see page 1894)	EBcdOverflowException is the exception class for errors that occur when a Variant can't create a BCD value due to the requested precision and number of decimals.

Constants

Name	Description
_DefaultDecimals (see page 1915)	This is constant FMTBcd._DefaultDecimals.
_NoDecimal (see page 1915)	This is constant FMTBcd._NoDecimal.
DefaultFMTBcdScale (see page 1916)	This is constant FMTBcd.DefaultFMTBcdScale.
MaxBcdPrecision (see page 1916)	This is constant FMTBcd.MaxBcdPrecision.
MaxBcdScale (see page 1916)	This is constant FMTBcd.MaxBcdScale.
MaxFMTBcdDigits (see page 1917)	This is constant FMTBcd.MaxFMTBcdDigits.
MaxFMTBcdFractionSize (see page 1917)	This is constant FMTBcd.MaxFMTBcdFractionSize.
MaxStringDigits (see page 1917)	This is constant FMTBcd.MaxStringDigits.
NullBcd (see page 1918)	Represents a NULL TBcd (see page 1913) value.
SizeOfFraction (see page 1918)	This is constant FMTBcd.SizeOfFraction.
SizeOfTBCD (see page 1918)	This is constant FMTBcd.SizeOfTBCD.

Functions

	Name	Description
	BcdAdd (see page 1897)	Adds two TBcd (see page 1913) values.
	BcdCompare (see page 1897)	Compares two TBcd (see page 1913) values.

	BcdDivide (see page 1898)	Divides one BCD value by another.
	BcdDivide (see page 1898)	Divides one BCD value by another.
	BcdDivide (see page 1898)	Divides one BCD value by another.
	BcdDivide (see page 1898)	Divides one BCD value by another.
	BcdFromBytes (see page 1899)	This is function FMTBcd.BcdFromBytes.
	BcdMultiply (see page 1899)	Multiplies two BCD values.
	BcdMultiply (see page 1899)	Multiplies two BCD values.
	BcdMultiply (see page 1899)	Multiplies two BCD values.
	BcdMultiply (see page 1899)	Multiplies two BCD values.
	BcdPrecision (see page 1900)	Returns the precision of a binary-coded decimal (BCD) value.
	BcdScale (see page 1900)	Returns the number of decimal places for a binary-coded decimal (BCD) value.
	BcdSubtract (see page 1901)	Subtracts one BCD value from another.
	BcdToBytes (see page 1901)	This is function FMTBcd.BcdToBytes.
	BCDToCurr (see page 1901)	Converts a binary-coded decimal value (BCD) to the corresponding Currency value.
	BcdToDouble (see page 1902)	Converts a binary-coded decimal value (BCD) to the corresponding double precision floating point value.
	BcdToInteger (see page 1902)	Converts a binary-coded decimal value (BCD) to an integer.
	BcdToStr (see page 1903)	Returns a string representation of a binary-coded decimal (BCD) value.
	BcdToStrF (see page 1903)	Returns a string representation of a binary-coded decimal (BCD) value that reflects specified formatting.
	CurrToBCD (see page 1904)	Converts a Currency value to the corresponding binary-coded decimal (BCD) value.
	DoubleToBcd (see page 1905)	Converts a double precision floating point value to the corresponding binary-coded decimal (BCD) value.
	DoubleToBcd (see page 1905)	Converts a double precision floating point value to the corresponding binary-coded decimal (BCD) value.
	FormatBcd (see page 1905)	Returns a string representation of a binary-coded decimal (BCD) value that reflects specified formatting.
	IntegerToBcd (see page 1906)	Converts an integer value to the corresponding binary-coded decimal (BCD) value.
	IsBcdNegative (see page 1906)	Indicates whether a binary-coded decimal (BCD) value is less than 0.
	NormalizeBcd (see page 1907)	Converts a BCD value into another BCD value with a specified precision and number of decimals.
	OldBCDToCurr (see page 1907)	This is function FMTBcd.OldBCDToCurr.
	OldCurrToBCD (see page 1908)	This is function FMTBcd.OldCurrToBCD.
	RoundAt (see page 1908)	This is function FMTBcd.RoundAt.
	StrToBcd (see page 1908)	Converts a string to the corresponding binary-coded decimal (BCD) value.
	TryStrToBcd (see page 1909)	Converts a string to the corresponding binary-coded decimal (BCD) value.
	VarFMTBcd (see page 1910)	Returns the TVarType constant that identifies the internal type of a Variant as a TBcd (see page 1913) value.
	VarFMTBcdCreate (see page 1910)	Creates a new Variant that stores its value internally as a TBcd (see page 1913) value.
	VarFMTBcdCreate (see page 1910)	Creates a new Variant that stores its value internally as a TBcd (see page 1913) value.
	VarFMTBcdCreate (see page 1910)	Creates a new Variant that stores its value internally as a TBcd (see page 1913) value.
	VarFMTBcdCreate (see page 1910)	Creates a new Variant that stores its value internally as a TBcd (see page 1913) value.
	VarFMTBcdCreate (see page 1910)	Creates a new Variant that stores its value internally as a TBcd (see page 1913) value.
	VarIsFMTBcd (see page 1911)	Indicates whether a specified Variant represents a TBcd (see page 1913) value.
	VarToBcd (see page 1911)	Converts a Variant into a TBcd (see page 1913) type.

Structs, Records, Enums

	Name	Description
	TBcd (see page 1913)	TBcd stores a binary coded decimal value.

Types

Name	Description
PBcd (see page 1914)	This is type FMTBcd.PBcd.
TNibbleArray (see page 1914)	This is type FMTBcd.TNibbleArray.

6.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EBcdException (see page 1894)	EBcdException is the exception class for errors that occur when working with BCD values.
	EBcdOverflowException (see page 1894)	EBcdOverflowException is the exception class for errors that occur when a Variant can't create a BCD value due to the requested precision and number of decimals.

6.1.1 EBcdException Class

EBcdException is the exception class for errors that occur when working with BCD values.

Class Hierarchy

Pascal

```
EBcdException = class(Exception);
```

C++

```
class EBcdException : public Exception;
```

File

FMTBcd

Description

EBcdException is raised when

An attempt to convert a Variant or string to a BCD value is unsuccessful.

An application tries to create a Variant that represents a BCD value, starting with a value that can't be successfully converted.

An application tries to divide by a BCD type whose value is 0.

See Also

VarFMTBcdCreate (see page 1910)

TBcd (see page 1913)

StrToBCD

BCDDivide

6.1.2 EBcdOverflowException Class

EBcdOverflowException is the exception class for errors that occur when a Variant can't create a BCD value due to the

requested precision and number of decimals.

Class Hierarchy

Pascal

```
EBcdOverflowException = class(EBcdException);
```

C++

```
class EBcdOverflowException : public EBcdException;
```

File

FMTBcd

Description

EBcdOverflowException is raised when

A call to VarFMTBcdCreate (see page 1910) tries to create a BCD value with a precision and number of decimals that can't be supported.

An application tries to cast a Variant to a BCD value but it can't be expressed using the default precision and number of decimals.

See Also

VarFMTBcdCreate (see page 1910)

TBcd (see page 1913)

6.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	BcdAdd (see page 1897)	Adds two TBcd (see page 1913) values.
	BcdCompare (see page 1897)	Compares two TBcd (see page 1913) values.
	BcdDivide (see page 1898)	Divides one BCD value by another.
	BcdDivide (see page 1898)	Divides one BCD value by another.
	BcdDivide (see page 1898)	Divides one BCD value by another.
	BcdDivide (see page 1898)	Divides one BCD value by another.
	BcdFromBytes (see page 1899)	This is function FMTBcd.BcdFromBytes.
	BcdMultiply (see page 1899)	Multiplies two BCD values.
	BcdMultiply (see page 1899)	Multiplies two BCD values.
	BcdMultiply (see page 1899)	Multiplies two BCD values.
	BcdMultiply (see page 1899)	Multiplies two BCD values.
	BcdPrecision (see page 1900)	Returns the precision of a binary-coded decimal (BCD) value.
	BcdScale (see page 1900)	Returns the number of decimal places for a binary-coded decimal (BCD) value.
	BcdSubtract (see page 1901)	Subtracts one BCD value from another.
	BcdToBytes (see page 1901)	This is function FMTBcd.BcdToBytes.
	BCDToCurr (see page 1901)	Converts a binary-coded decimal value (BCD) to the corresponding Currency value.
	BcdToDouble (see page 1902)	Converts a binary-coded decimal value (BCD) to the corresponding double precision floating point value.
	BcdToInteger (see page 1902)	Converts a binary-coded decimal value (BCD) to an integer.
	BcdToStr (see page 1903)	Returns a string representation of a binary-coded decimal (BCD) value.
	BcdToStrF (see page 1903)	Returns a string representation of a binary-coded decimal (BCD) value that reflects specified formatting.
	CurrToBCD (see page 1904)	Converts a Currency value to the corresponding binary-coded decimal (BCD) value.
	DoubleToBcd (see page 1905)	Converts a double precision floating point value to the corresponding binary-coded decimal (BCD) value.
	DoubleToBcd (see page 1905)	Converts a double precision floating point value to the corresponding binary-coded decimal (BCD) value.
	FormatBcd (see page 1905)	Returns a string representation of a binary-coded decimal (BCD) value that reflects specified formatting.
	IntegerToBcd (see page 1906)	Converts an integer value to the corresponding binary-coded decimal (BCD) value.
	IsBcdNegative (see page 1906)	Indicates whether a binary-coded decimal (BCD) value is less than 0.
	NormalizeBcd (see page 1907)	Converts a BCD value into another BCD value with a specified precision and number of decimals.
	OldBCDToCurr (see page 1907)	This is function FMTBcd.OldBCDToCurr.
	OldCurrToBCD (see page 1908)	This is function FMTBcd.OldCurrToBCD.
	RoundAt (see page 1908)	This is function FMTBcd.RoundAt.
	StrToBcd (see page 1908)	Converts a string to the corresponding binary-coded decimal (BCD) value.
	TryStrToBcd (see page 1909)	Converts a string to the corresponding binary-coded decimal (BCD) value.
	VarFMTBcd (see page 1910)	Returns the TVarType constant that identifies the internal type of a Variant as a TBcd (see page 1913) value.
	VarFMTBcdCreate (see page 1910)	Creates a new Variant that stores its value internally as a TBcd (see page 1913) value.
	VarFMTBcdCreate (see page 1910)	Creates a new Variant that stores its value internally as a TBcd (see page 1913) value.

	VarFMTBcdCreate (see page 1910)	Creates a new Variant that stores its value internally as a TBcd (see page 1913) value.
	VarFMTBcdCreate (see page 1910)	Creates a new Variant that stores its value internally as a TBcd (see page 1913) value.
	VarFMTBcdCreate (see page 1910)	Creates a new Variant that stores its value internally as a TBcd (see page 1913) value.
	VarIsFMTBcd (see page 1911)	Indicates whether a specified Variant represents a TBcd (see page 1913) value.
	VarToBcd (see page 1911)	Converts a Variant into a TBcd (see page 1913) type.

6.2.1 FMTBcd.BcdAdd Function

Adds two TBcd (see page 1913) values.

Pascal

```
procedure BcdAdd(const bcdIn1: TBcd; const bcdIn2: TBcd; var bcdOut: TBcd);
```

C++

```
BcdAdd(const TBcd bcdIn1, const TBcd bcdIn2, TBcd bcdOut);
```

File

FMTBcd

Description

BcdAdd adds bcdIn1 to bcdIn2 and returns the result as bcdOut.

The return value is given a precision and number of decimal places that is sufficient to accurately represent the result of the addition. You can convert this to a specific precision and number of decimal places using the NormalizeBcd (see page 1907) procedure.

See Also

BcdSubtract

BcdMultiply

BcdDivide

NormalizeBcd

6.2.2 FMTBcd.BcdCompare Function

Compares two TBcd (see page 1913) values.

Pascal

```
function BcdCompare(const bcd1: TBcd; const bcd2: TBcd): Integer;
```

C++

```
int BcdCompare(const TBcd bcd1, const TBcd bcd2);
```

File

FMTBcd

Description

Call BcdCompare to compare two TBcd (see page 1913) values. The return value is indicated in the following table:

Return value	Condition
-1	bcd1< bcd2
0	bcd1= bcd2
1	bcd1 > bcd2

See Also

CompareValue

6.2.3 FMTBcd.BcdDivide Function

Divides one BCD value by another.

Pascal

```
procedure BcdDivide(Dividend: string; Divisor: string; var bcdOut: TBcd); overload;
procedure BcdDivide(const Dividend: TBcd; const Divisor: TBcd; var bcdOut: TBcd); overload;
procedure BcdDivide(const Dividend: TBcd; const Divisor: Double; var bcdOut: TBcd); overload;
procedure BcdDivide(const Dividend: TBcd; const Divisor: string; var bcdOut: TBcd); overload;
```

C++

```
BcdDivide(UnicodeString Dividend, UnicodeString Divisor, TBcd bcdOut);
BcdDivide(const TBcd Dividend, const TBcd Divisor, TBcd bcdOut);
BcdDivide(const TBcd Dividend, const Double Divisor, TBcd bcdOut);
BcdDivide(const TBcd Dividend, const UnicodeString Divisor, TBcd bcdOut);
```

File

FMTBcd

Description

BcdDivide divides Dividend by Divisor and returns the result as bcdOut.

The return value is given a precision and number of decimal places that is sufficient to accurately represent the result of the division, if possible. (The number of decimal places in the result, however, will never exceed 10.) You can convert this to a specific precision and number of decimal places using the NormalizeBcd (see page 1907) procedure.

BcdSubtract

BcdMultiply

BcdAdd

NormalizeBcd

6.2.4 FMTBcd.BcdFromBytes Function

Pascal

```
function BcdFromBytes(const AValue: TBytes): TBcd;
```

C++

```
TBcd BcdFromBytes(const TBytes AValue);
```

File

FMTBcd

Description

This is function FMTBcd.BcdFromBytes.

6.2.5 FMTBcd.BcdMultiply Function

Multiplies two BCD values.

Pascal

```
procedure BcdMultiply(const bcdIn1: TBcd; const bcdIn2: TBcd; var bcdOut: TBcd); overload;
procedure BcdMultiply(const bcdIn: TBcd; const DoubleIn: Double; var bcdOut: TBcd); overload;
procedure BcdMultiply(const bcdIn: TBcd; const StringIn: string; var bcdOut: TBcd); overload;
procedure BcdMultiply(StringIn1: string; StringIn2: string; var bcdOut: TBcd); overload;
```

C++

```
BcdMultiply(const TBcd bcdIn1, const TBcd bcdIn2, TBcd bcdOut);
BcdMultiply(const TBcd bcdIn, const Double DoubleIn, TBcd bcdOut);
BcdMultiply(const TBcd bcdIn, const UnicodeString StringIn, TBcd bcdOut);
BcdMultiply(UnicodeString StringIn1, UnicodeString StringIn2, TBcd bcdOut);
```

File

FMTBcd

Description

BcdMultiply multiplies the first two arguments and returns the result as bcdOut.

The return value is given a precision and number of decimal places that is sufficient to accurately represent the result of the multiplication, if possible. You can convert this to a specific precision and number of decimal places using the NormalizeBcd (see page 1907) procedure.

BcdAdd

NormalizeBcd

6.2.6 FMTBcd.BcdPrecision Function

Returns the precision of a binary-coded decimal (BCD) value.

Pascal

```
function BcdPrecision(const Bcd: TBcd): Word;
```

C++

```
Word BcdPrecision(const TBcd Bcd);
```

File

FMTBcd

Description

Use BcdPrecision to determine the number of significant digits in a specified BCD value.

See Also

BcdScale

IsBcdNegative

NormalizeBcd

6.2.7 FMTBcd.BcdScale Function

Returns the number of decimal places for a binary-coded decimal (BCD) value.

Pascal

```
function BcdScale(const Bcd: TBcd): Word;
```

C++

```
Word BcdScale(const TBcd Bcd);
```

File

FMTBcd

Description

Use BcdScale to determine the number of decimal places in a specified BCD value.

See Also

BcdPrecision

IsBcdNegative

NormalizeBcd

6.2.8 FMTBcd.BcdSubtract Function

Subtracts one BCD value from another.

Pascal

```
procedure BcdSubtract(const bcdIn1: TBcd; const bcdIn2: TBcd; var bcdOut: TBcd);
```

C++

```
BcdSubtract(const TBcd bcdIn1, const TBcd bcdIn2, TBcd bcdOut);
```

File

FMTBcd

Description

BcdSubtract subtracts bcdIn2 from bcdIn1 and returns the result as bcdOut.

The return value is given a precision and number of decimal places that is sufficient to accurately represent the result of the subtraction. You can convert this to a specific precision and number of decimal places using the NormalizeBcd (see page 1907) procedure.

See Also

BcdMultiply

BcdDivide

BcdAdd

NormalizeBcd

6.2.9 FMTBcd.BcdToBytes Function

Pascal

```
function BcdToBytes(const Value: TBcd): TBytes;
```

C++

```
TBytes BcdToBytes(const TBcd Value);
```

File

FMTBcd

Description

This is function FMTBcd.BcdToBytes.

6.2.10 FMTBcd.BCDToCurr Function

Converts a binary-coded decimal value (BCD) to the corresponding Currency value.

Pascal

```
function BCDToCurr(const BCD: TBcd; var Curr: Currency): Boolean;
```

C++

```
Boolean BCDToCurr(const TBcd BCD, Currency Curr);
```

File

FMTBcd

Description

Use BCDToCurr to convert a binary-coded decimal value, such as is stored in a physical BCD database field, into a Currency value, which is the representation used by TBCDField objects. BCDToCurr returns true if the BCD value passed as the BCD parameter is successfully converted into a Currency object which is passed out as the Curr parameter.

See Also

CurrToBCD

TBCDField

TField

6.2.11 FMTBcd.BcdToDouble Function

Converts a binary-coded decimal value (BCD) to the corresponding double precision floating point value.

Pascal

```
function BcdToDouble(const Bcd: TBcd): Double;
```

C++

```
Double BcdToDouble(const TBcd Bcd);
```

File

FMTBcd

Description

Use BcdToDouble to convert a binary-coded decimal value into a double precision floating point value. If the Bcd parameter represents a value that can't be expressed in double precision, BcdToDouble raises an exception.

See Also

DoubleToBcd

BCDToCurr

BCDToInteger

6.2.12 FMTBcd.BcdToInteger Function

Converts a binary-coded decimal value (BCD) to an integer.

Pascal

```
function BcdToInteger(const Bcd: TBcd; Truncate: Boolean = False): Integer;
```

C++

```
int BcdToInteger(const TBcd Bcd, Boolean Truncate = False);
```

File

FMTBcd

Description

Use BcdToInteger to convert a binary-coded decimal value into an integer.

Bcd is the value to convert.

Truncate indicates how to handle values that include a decimal portion. If Truncate is true, BcdToInteger truncates the value specified by Bcd and converts only the integer portion. If Truncate is false, BcdToInteger raises an exception if the Bcd parameter does not represent an integer value.

See Also

IntegerToBcd

BCDToCurr

BCDToDouble

6.2.13 FMTBcd.BcdToStr Function

Returns a string representation of a binary-coded decimal (BCD) value.

Pascal

```
function BcdToStr(const Bcd: TBcd): string; overload;
```

C++

```
UnicodeString BcdToStr(const TBcd Bcd);
```

File

FMTBcd

Description

Use BcdToStr to convert a binary-coded decimal value into a string. BcdToStr formats the string to display all of the digits stored in the BCD value.

See Also

BcdToStrF

StrToBcd

TryStrToBcd

6.2.14 FMTBcd.BcdToStrF Function

Returns a string representation of a binary-coded decimal (BCD) value that reflects specified formatting.

Pascal

```
function BcdToStrF(const Bcd: TBcd; Format: TFloatFormat; const Precision: Integer; const
Digits: Integer): string;
```

C++

```
UnicodeString BcdToStrF(const TBcd Bcd, TFloatFormat Format, const int Precision, const int
Digits);
```

File

FMTBcd

Description

Use BcdToStrF to convert a binary-coded decimal value into a string.

Value is the BCD value to convert to a string.

Format is the formatting code that indicates the overall type of formatting to use.

Precision indicates the maximum number of significant digits in the resulting string.

Digits indicates the maximum number of digits past the decimal point in the resulting string.

See Also

BcdToStr

StrToBcd

FloatToStrF

FormatBcd

TryStrToBcd

6.2.15 FMTBcd.CurrToBCD Function

Converts a Currency value to the corresponding binary-coded decimal (BCD) value.

Pascal

```
function CurrToBCD(const Curr: Currency; var BCD: TBcd; Precision: Integer = 32; Decimals:
Integer = 4): Boolean;
```

C++

```
Boolean CurrToBCD(const Currency Curr, TBcd BCD, int Precision = 32, int Decimals = 4);
```

File

FMTBcd

Description

Use CurrToBCD to convert a Currency value, such as is used by TBCDField objects, into a binary-coded decimal value, such as is stored in a physical BCD database field. CurrToBCD returns true if the Currency object passed as the Curr parameter is successfully converted into a BCD value and passed out as the BCD parameter. The Precision parameter specifies the number of digits represented in the BCD value, and the Decimals parameter specifies the number of those digits that are after the decimal point.

See Also

BCDToCurr

TBCDField

TField

6.2.16 FMTBcd.DoubleToBcd Function

Converts a double precision floating point value to the corresponding binary-coded decimal (BCD) value.

Pascal

```
function DoubleToBcd(const AValue: Double): TBcd; overload;
procedure DoubleToBcd(const AValue: Double; var bcd: TBcd); overload;
```

C++

```
TBcd DoubleToBcd(const Double AValue);
DoubleToBcd(const Double AValue, TBcd bcd);
```

File

FMTBcd

Description

Use DoubleToBcd to convert a double precision floating point value into a binary-coded decimal value. DoubleToBcd infers the number of decimal places and significant digits from the specified value aValue, using only as many as necessary. It never sets the number of significant digits to a value greater than 15.

aValue is the value to convert.

bcd returns the resulting BCD value when using the second syntax. When using the first syntax, the BCD value is the return value of the function.

See Also

BCDToDouble

CurrToBcd

IntegerToBcd

6.2.17 FMTBcd.FormatBcd Function

Returns a string representation of a binary-coded decimal (BCD) value that reflects specified formatting.

Pascal

```
function FormatBcd(const Format: string; Bcd: TBcd): string;
```

C++

```
UnicodeString FormatBcd(const UnicodeString Format, TBcd Bcd);
```

File

FMTBcd

Description

Use FormatBcd to convert a binary-coded decimal value into a string.

Format indicates how the resulting string should be formatted. It uses the same format specifiers as pertain to the FormatFloat function.

Bcd is the value to convert to a string.

See Also

BcdToStrF

FormatFloat

BcdToStr

TryStrToBcd

StrToBcd

6.2.18 FMTBcd.IntegerToBcd Function

Converts an integer value to the corresponding binary-coded decimal (BCD) value.

Pascal

```
function IntegerToBcd(const AValue: Integer): TBcd;
```

C++

```
TBcd IntegerToBcd(const int AValue);
```

File

FMTBcd

Description

Use IntegerToBcd to convert an integer into a binary-coded decimal value.

See Also

BCDToInteger

CurrToBcd

DoubleToBcd

6.2.19 FMTBcd.IsBcdNegative Function

Indicates whether a binary-coded decimal (BCD) value is less than 0.

Pascal

```
function IsBcdNegative(const Bcd: TBcd): Boolean;
```

C++

```
Boolean IsBcdNegative(const TBcd Bcd);
```

File

FMTBcd

Description

IsBcdNegative returns true if Bcd is less than 0, false if Bcd is greater than or equal to 0.

See Also

BcdPrecision

BcdScale

NormalizeBcd

6.2.20 FMTBcd.NormalizeBcd Function

Converts a BCD value into another BCD value with a specified precision and number of decimals.

Pascal

```
function NormalizeBcd(const InBcd: TBcd; var OutBcd: TBcd; const Prec: Word; const Scale:
Word): Boolean;
```

C++

```
Boolean NormalizeBcd(const TBcd InBcd, TBcd OutBcd, const Word Prec, const Word Scale);
```

File

FMTBcd

Description

Call NormalizeBcd to give a TBcd (see page 1913) value a specific precision and number of decimal places. If the specified precision or number of decimal places is less than that of the original BCD value, NormalizeBcd truncates the value (as opposed to rounding).

InBcd is the BCD value to convert.

OutBcd returns the resulting BCD value with the specified precision and decimal places.

Prec is the number of significant digits in OutBcd.

Scale is the number of decimal places in OutBcd.

NormalizeBcd returns true if the conversion can be made with no loss of precision. It returns false if the conversion required some digits to be truncated.

6.2.21 FMTBcd.OldBCDToCurr Function

Pascal

```
function OldBCDToCurr(const BCD: TBcd; var Curr: Currency): Boolean;
```

C++

```
Boolean OldBCDToCurr(const TBcd BCD, Currency Curr);
```

File

FMTBcd

Description

This is function FMTBcd.OldBCDToCurr.

6.2.22 FMTBcd.OldCurrToBCD Function

Pascal

```
function OldCurrToBCD(const Curr: Currency; var BCD: TBcd; Precision: Integer = 32; Decimals:
Integer = 4): Boolean;
```

C++

```
Boolean OldCurrToBCD(const Currency Curr, TBcd BCD, int Precision = 32, int Decimals = 4);
```

File

FMTBcd

Description

This is function FMTBcd.OldCurrToBCD.

6.2.23 FMTBcd.RoundAt Function

Pascal

```
function RoundAt(const Value: string; Position: SmallInt): string;
```

C++

```
UnicodeString RoundAt(const UnicodeString Value, SmallInt Position);
```

File

FMTBcd

Description

This is function FMTBcd.RoundAt.

6.2.24 FMTBcd.StrToBcd Function

Converts a string to the corresponding binary-coded decimal (BCD) value.

Pascal

```
function StrToBcd(const AValue: string): TBcd;
```

C++

```
TBcd StrToBcd(const UnicodeString AValue);
```

File

FMTBcd

Description

Use StrToBcd to convert a string into a binary-coded decimal value. The decimals and precision are inferred from the digits present in the string.

StrToBcd converts the string specified by aValue and returns the resulting BCD value. If aValue does not represent a value that can be expressed as a TBcd (see page 1913), StrToBcd raises an exception.

Tip: To convert a string to a Bcd value without raising an exception for invalid strings, use the TryStrToBcd (see page 1909) function instead.

See Also

BcdToStr

BcdToStrF

FormatBcd

TryStrToBcd

6.2.25 FMTBcd.TryStrToBcd Function

Converts a string to the corresponding binary-coded decimal (BCD) value.

Pascal

```
function TryStrToBcd(const AValue: string; var Bcd: TBcd): Boolean;
```

C++

```
Boolean TryStrToBcd(const UnicodeString AValue, TBcd Bcd);
```

File

FMTBcd

Description

Use TryStrToBcd to convert a string into a binary-coded decimal value. The decimals and precision are inferred from the digits present in the string.

TryStrToBcd converts the string specified by aValue and returns the resulting BCD value as Bcd.

TryStrToBcd returns true if it successfully converts aValue to a TBcd (see page 1913) value. If aValue can't be successfully converted to a TBcd (see page 1913) value, TryStrToBcd returns false.

See Also

BcdToStr

BcdToStrF

FormatBcd

StrToBcd

6.2.26 FMTBcd.VarFMTBcd Function

Returns the TVarType constant that identifies the internal type of a Variant as a TBcd (see page 1913) value.

Pascal

```
function VarFMTBcd: TVarType;
```

C++

```
TVarType VarFMTBcd();
```

File

FMTBcd

Description

VarFMTBcd returns the Variant type code that identifies a TBcd (see page 1913)-valued Variant. This is the value that the VarType function returns when the Variant stores its value as a TBcd (see page 1913) value.

The Variant type codes for custom Variants are dynamically allocated when the application loads the unit that implements them. VarFMTBcd allows the application to identify the Variant type code that is currently used for custom Variants that represent a BCD value. This type code, however, may not match the type code used by another application that uses a different set of custom Variant types.

See Also

VarIsFMTBcd

VarType

TBcd

VarToBcd

6.2.27 FMTBcd.VarFMTBcdCreate Function

Creates a new Variant that stores its value internally as a TBcd (see page 1913) value.

Pascal

```
procedure VarFMTBcdCreate(var ADest: Variant; const ABcd: TBcd); overload;
function VarFMTBcdCreate: Variant; overload;
function VarFMTBcdCreate(const AValue: string; Precision: Word; Scale: Word): Variant;
overload;
function VarFMTBcdCreate(const AValue: Double; Precision: Word = 18; Scale: Word = 4):
Variant; overload;
function VarFMTBcdCreate(const ABcd: TBcd): Variant; overload;
```

C++

```
VarFMTBcdCreate(Variant ADest, const TBcd ABcd);
Variant VarFMTBcdCreate();
Variant VarFMTBcdCreate(const UnicodeString AValue, Word Precision, Word Scale);
Variant VarFMTBcdCreate(const Double AValue, Word Precision = 18, Word Scale = 4);
Variant VarFMTBcdCreate(const TBcd ABcd);
```

File

FMTBcd

Description

Call VarBcdCreate to obtain a Variant that stores its value as a TBcd (see page 1913) value.

Using the first syntax, the Variant returned as aDest has the same value as ABcd.

Using the second syntax (passing no arguments), the returned Variant has a value of NullBcd (see page 1918).

Using the third syntax, the returned Variant has the same value as ABcd.

Using the fourth syntax, the returned Variant converts AValue (if necessary) to extract the value.

Using the remaining syntaxes, the AValue parameter is converted into a TBcd (see page 1913) value with the specified Precision and Scale and the result is the value of the Variant.

See Also

VarIsFMTBcd

VarToBcd

NullBcd

6.2.28 FMTBcd.VarIsFMTBcd Function

Indicates whether a specified Variant represents a TBcd (see page 1913) value.

Pascal

```
function VarIsFMTBcd(const AValue: Variant): Boolean; overload;
```

C++

```
Boolean VarIsFMTBcd(const Variant AValue);
```

File

FMTBcd

Description

VarIsBcd returns true if the Variant aValue stores its value internally as a TBcd (see page 1913) value. VarIsBcd returns false otherwise.

See Also

VarToBcd

TBcd

VarFMTBcd

6.2.29 FMTBcd.VarToBcd Function

Converts a Variant into a TBcd (see page 1913) type.

Pascal

```
function VarToBcd(const AValue: Variant): TBcd;
```

C++

```
TBcd VarToBcd(const Variant AValue);
```

File

FMTBcd

Description

Use VarDoubleAsBcd to obtain a TBcd (see page 1913) value from a Variant.

aValue is the Variant to convert.

See Also

VarIsFMTBcd

6.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Records

	Name	Description
	TBcd (see page 1913)	TBcd stores a binary coded decimal value.

6.3.1 FMTBcd.TBcd Record

TBcd stores a binary coded decimal value.

Pascal

```
TBcd = packed record
  Precision: Byte;
  SignSpecialPlaces: Byte;
  Fraction: packed array [0..31] of Byte;
end;
```

C++

```
struct TBcd {
  Byte Precision;
  Byte SignSpecialPlaces;
  packed array [0..31] of Byte Fraction;
};
```

File

FMTBcd

Description

TBcd represents a binary coded decimal value. It contains the following fields:

Field	Contents
Precision	The number of digits in the decimal version of the value.
SignSpecialPlaces	The sign bit (0 is positive, any other value negative)
Fraction	An array of BCD nibbles, 00 to 99 per byte, high nibble first. Only the first Precision nibbles are used.

You can create a Variant that represents a TBcd value using the VarFMTBcdCreate (see page 1910) function. In fact, the easiest way to manipulate TBcd values is to create Variants for them and use the built-in operators provided by the Variant type.

6.4 Types

The following table lists types in this documentation.

Types

Name	Description
PBcd (see page 1914)	This is type FMTBcd.PBcd.
TNibbleArray (see page 1914)	This is type FMTBcd.TNibbleArray.

6.4.1 FMTBcd.PBcd Type

Pascal

```
PBcd = ^TBcd;
```

C++

```
^TBcd PBcd;
```

File

FMTBcd

Description

This is type FMTBcd.PBcd.

6.4.2 FMTBcd.TNibbleArray Type

Pascal

```
TNibbleArray = array[0..63] of Byte;
```

C++

```
array[0..63] of Byte TNibbleArray;
```

File

FMTBcd

Description

This is type FMTBcd.TNibbleArray.

6.5 Constants

The following table lists constants in this documentation.

Constants

Name	Description
_DefaultDecimals (see page 1915)	This is constant FMTBcd._DefaultDecimals.
_NoDecimal (see page 1915)	This is constant FMTBcd._NoDecimal.
DefaultFMTBcdScale (see page 1916)	This is constant FMTBcd.DefaultFMTBcdScale.
MaxBcdPrecision (see page 1916)	This is constant FMTBcd.MaxBcdPrecision.
MaxBcdScale (see page 1916)	This is constant FMTBcd.MaxBcdScale.
MaxFMTBcdDigits (see page 1917)	This is constant FMTBcd.MaxFMTBcdDigits.
MaxFMTBcdFractionSize (see page 1917)	This is constant FMTBcd.MaxFMTBcdFractionSize.
MaxStringDigits (see page 1917)	This is constant FMTBcd.MaxStringDigits.
NullBcd (see page 1918)	Represents a NULL TBcd (see page 1913) value.
SizeOfFraction (see page 1918)	This is constant FMTBcd.SizeOfFraction.
SizeOfTBCD (see page 1918)	This is constant FMTBcd.SizeOfTBCD.

6.5.1 FMTBcd._DefaultDecimals Constant

Pascal

```
_DefaultDecimals = 10;
```

C++

```
_DefaultDecimals = 10;
```

File

FMTBcd

Description

This is constant FMTBcd._DefaultDecimals.

6.5.2 FMTBcd._NoDecimal Constant

Pascal

```
_NoDecimal = -255;
```

C++

```
_NoDecimal = -255;
```

File

FMTBcd

Description

This is constant FMTBcd._NoDecimal.

6.5.3 FMTBcd.DefaultFMTBcdScale Constant

Pascal

```
DefaultFMTBcdScale = 6;
```

C++

```
DefaultFMTBcdScale = 6;
```

File

FMTBcd

Description

This is constant FMTBcd.DefaultFMTBcdScale.

6.5.4 FMTBcd.MaxBcdPrecision Constant

Pascal

```
MaxBcdPrecision = 18;
```

C++

```
MaxBcdPrecision = 18;
```

File

FMTBcd

Description

This is constant FMTBcd.MaxBcdPrecision.

6.5.5 FMTBcd.MaxBcdScale Constant

Pascal

```
MaxBcdScale = 4;
```

C++

```
MaxBcdScale = 4;
```

File

FMTBcd

Description

This is constant FMTBcd.MaxBcdScale.

6.5.6 FMTBcd.MaxFMTBcdDigits Constant

Pascal

```
MaxFMTBcdDigits = 32;
```

C++

```
MaxFMTBcdDigits = 32;
```

File

FMTBcd

Description

This is constant FMTBcd.MaxFMTBcdDigits.

6.5.7 FMTBcd.MaxFMTBcdFractionSize Constant

Pascal

```
MaxFMTBcdFractionSize = 64;
```

C++

```
MaxFMTBcdFractionSize = 64;
```

File

FMTBcd

Description

This is constant FMTBcd.MaxFMTBcdFractionSize.

6.5.8 FMTBcd.MaxStringDigits Constant

Pascal

```
MaxStringDigits = 100;
```

C++

```
MaxStringDigits = 100;
```

File

FMTBcd

Description

This is constant FMTBcd.MaxStringDigits.

6.5.9 FMTBcd.NullBcd Constant

Represents a NULL TBcd (see page 1913) value.

Pascal

```
NullBcd: TBcd = (Precision: 0; SignSpecialPlaces: 0; Fraction:
(0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0));
```

C++

```
TBcd NullBcd = (Precision: 0; SignSpecialPlaces: 0; Fraction:
(0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0));
```

File

FMTBcd

Description

Use NullBcd to indicate an unknown or missing TBcd (see page 1913) value. NullBcd is a TBcd (see page 1913) with all its fields set to 0.

See Also

Null

6.5.10 FMTBcd.SizeOfFraction Constant

Pascal

```
SizeOfFraction = 32;
```

C++

```
SizeOfFraction = 32;
```

File

FMTBcd

Description

This is constant FMTBcd.SizeOfFraction.

6.5.11 FMTBcd.SizeOfTBCD Constant

Pascal

```
SizeOfTBCD = 2 + SizeOfFraction;
```

C++

```
SizeOfTBCD = 2 + SizeOfFraction;
```

File

FMTBcd

Description

This is constant FMTBcd.SizeOfTBCD.

7 Forms Namespace

This is namespace Forms.

Topics

Name	Description
Classes (see page 1924)	The following table lists classes in this documentation.
Interfaces (see page 2566)	The following table lists interfaces in this documentation.
Functions (see page 2574)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 2582)	The following table lists structs, records, enums in this documentation.
Types (see page 2595)	The following table lists types in this documentation.
Variables (see page 2612)	The following table lists variables in this documentation.

Classes

	Name	Description
	TApplication (see page 1924)	TApplication is the type used for a GUI windowed application.
	TControlScrollBar (see page 2009)	TControlScrollBar displays a horizontal or vertical scroll bar.
	TCustomActiveForm (see page 2024)	TCustomActiveForm is the base class for Active (see page 2145) Forms.
	TCustomDockForm (see page 2092)	TCustomDockForm is the default floating dock site class for TControl objects.
	TCustomForm (see page 2103)	TCustomForm is the base class from which to derive a window such as a form or dialog.
	TCustomFrame (see page 2237)	TCustomFrame is the base class from which TFrame (see page 2366) descends.
	TForm (see page 2241)	TForm represents a standard application window (form).
	TFrame (see page 2366)	TFrame is a container for components; it can be nested within forms or other frames.
	TGlassFrame (see page 2435)	TGlassFrame controls Windows Vista Aero glass effects.
	TMonitor (see page 2439)	TMonitor represents a monitor on which an application runs.
	TScreen (see page 2445)	TScreen represents the state of the screen in which an application runs.
	TScrollBox (see page 2483)	TScrollBox represents a scrolling area (a scroll box) in a window.
	TScrollingWinControl (see page 2554)	TScrollingWinControl is the base class for controls that support scrolling.

Functions

	Name	Description
	DisableTaskWindows (see page 2574)	This is function Forms.DisableTaskWindows.
	DoneCtl3D (see page 2574)	This is function Forms.DoneCtl3D.
	EnableTaskWindows (see page 2575)	This is function Forms.EnableTaskWindows.
	ForegroundTask (see page 2575)	Indicates whether the current thread is running in the foreground.

	GetParentForm (see page 2576)	Returns the form or property page that contains a specified control.
	InitCtl3D (see page 2576)	This is function Forms.InitCtl3D.
	IsAccel (see page 2576)	Indicates whether a particular character is an accelerator character (or hot key) within a given menu caption or other text string.
	KeyboardStateToShiftState (see page 2577)	Convert array of virtual keys to TShiftState.
	KeyboardStateToShiftState (see page 2577)	Convert array of virtual keys to TShiftState.
	KeyDataToShiftState (see page 2578)	Convert keyboard message data to TShiftState.
	KeysToShiftState (see page 2578)	Convert mouse event parameter to TShiftState.
	RestoreFocusState (see page 2579)	This is function Forms.RestoreFocusState.
	SaveFocusState (see page 2579)	This is function Forms.SaveFocusState.
	SetAutoSubClass (see page 2579)	This is function Forms.SetAutoSubClass.
	Subclass3DDlg (see page 2580)	This is function Forms.Subclass3DDlg.
	Subclass3DWnd (see page 2580)	This is function Forms.Subclass3DWnd.
	ValidParentForm (see page 2580)	Returns the form or property page that contains a specified control.

Interfaces

	Name	Description
	IDesignerHook (see page 2566)	IDesignerHook is an interface that allows component writers to interact with the form designer in the IDE.
	IOleForm (see page 2572)	IOleForm is designed to communicate with OLE containers. To embed a VCL form in an OLE container, CodeGear recommends using ActiveForms and TOleControl instead of IOleForm.

Structs, Records, Enums

	Name	Description
	TActiveFormBorderStyle (see page 2582)	Specifies the style of an active form's border.
	TBorderIcon (see page 2583)	TBorderIcons (see page 2596) and TBorderIcons (see page 2596) specify the buttons that appear on the title bar of a form window.
	TCloseAction (see page 2584)	TCloseAction describes how a form should respond when it is closed.
	TCMHintShowPause (see page 2584)	This is record Forms.TCMHintShowPause.
	TCursorRec (see page 2585)	This is record Forms.TCursorRec.
	TDefaultMonitor (see page 2585)	Specifies the monitor on which the form appears.
	TFormBorderStyle (see page 2586)	TFormBorderStyle is the type of the BorderStyle property for windows-only forms and TBorderStyle (see page 2597) is the type of the BorderStyle property for other controls in windows-only applications.
	TFormStyle (see page 2587)	TFormStyle describes form style.
	TMonitorDefaultTo (see page 2587)	TMonitorDefautlTo specifies which monitor to select when there is no match to the specified criteria.
	TPopupForm (see page 2588)	This is record Forms.TPopupForm.
	TPopupMode (see page 2588)	TPopupMode enumerates the possible values of a Form's PopupMode property.
	TPopupWnd (see page 2589)	This is record Forms.TPopupWnd.
	TPosition (see page 2590)	TPosition describes the positioning of a form.
	TPrintScale (see page 2591)	Represents the proportions of a printed form.
	TScrollBarKind (see page 2591)	TScrollBarKind indicates the orientation of a scrollbar.
	TScrollBarStyle (see page 2592)	TScrollBarStyle specifies a scroll bar style.
	TShowAction (see page 2592)	This is record Forms.TShowAction.
	TTileMode (see page 2593)	Represents how MDI child forms are arranged when the Tile method is called.
	TTimerMode (see page 2593)	This is record Forms.TTimerMode.
	TWindowState (see page 2594)	TWindowState indicates whether a form is maximized, minimized, or normally sized.

Types

Name	Description
PCursorRec (see page 2595)	This is type Forms.PCursorRec.
PHintInfo (see page 2596)	PHintInfo declares a pointer to a Help Window appearance record.
TBorderIcons (see page 2596)	TBorderIcons specifies the buttons that appear on the title bar of a form window.
TBorderStyle (see page 2597)	TBorderStyle is the type of the BorderStyle property for framed controls.

TCloseEvent (see page 2597)	TCloseEvent is the type of a form's OnClose event handle.
TCloseQueryEvent (see page 2598)	TCloseQueryEvent is used for event handlers that are called when a window is about to close.
TCursorRecType (see page 2598)	This is type Forms.TCursorRecType.
TCustomFormClass (see page 2599)	TCustomFormClass defines the metaclass for TCustomForm (see page 2103).
TCustomFrameClass (see page 2599)	TCustomFrameClass defines the metaclass for TCustomFrame (see page 2237).
TExceptionEvent (see page 2599)	TExceptionEvent is the type of event handlers that respond when the application traps an unhandled exception.
TFocusState (see page 2600)	This is type Forms.TFocusState.
TFormClass (see page 2600)	TFormClass defines the metaclass for TForm (see page 2241).
TFormState (see page 2601)	TFormState describes the possible state of a form.
TGetHandleEvent (see page 2601)	This is type Forms.TGetHandleEvent.
THelpEvent (see page 2602)	THelpEvent is the type of an OnHelp event handler.
THintInfo (see page 2602)	THintInfo is used to define the appearance and behavior of the Help window.
TIdleEvent (see page 2604)	TIdleEvent is the type of event handler that perform actions when the application is idle.
TMessageEvent (see page 2605)	TMessageEvent is the type of an OnMessage event handler.
TPopupFormArray (see page 2605)	This is type Forms.TPopupFormArray.
TPopupWndArray (see page 2605)	This is type Forms.TPopupWndArray.
TScrollBarInc (see page 2606)	TScrollBarInc represents a number of logical units on a TControlScrollBar (see page 2009).
TSetLayeredWindowAttributes (see page 2606)	This is type Forms.TSetLayeredWindowAttributes.
TSettingChangeEvent (see page 2607)	TSettingChangeEvent is the type of an OnSettingChange event handler.
TShortCutEvent (see page 2609)	TShortCutEvent is the type of an OnShortCut event handler.
TShowHintEvent (see page 2610)	TShowHintEvent is the type of the OnShowHint event handler.
TTaskWindowList (see page 2610)	This is type Forms.TTaskWindowList.
TWindowHook (see page 2611)	TWindowHook is the type for a dialog procedure.

Variables

Name	Description
Application (see page 2612)	Represents application-level information.
Ctl3DBtnWndProc (see page 2614)	This is variable Forms.Ctl3DBtnWndProc.
Ctl3DCtlColorEx (see page 2614)	This is variable Forms.Ctl3DCtlColorEx.
Ctl3DDlgFramePaint (see page 2614)	This is variable Forms.Ctl3DDlgFramePaint.
HintWindowClass (see page 2615)	Specifies the class for the window used to display help hints.
Screen (see page 2615)	Represents a screen device.
SetLayeredWindowAttributes (see page 2617)	This is variable Forms.SetLayeredWindowAttributes.

7.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TApplication (see page 1924)	TApplication is the type used for a GUI windowed application.
	TControlScrollBar (see page 2009)	TControlScrollBar displays a horizontal or vertical scroll bar.
	TCustomActiveForm (see page 2024)	TCustomActiveForm is the base class for Active (see page 2145) Forms (see page 1921).
	TCustomDockForm (see page 2092)	TCustomDockForm is the default floating dock site class for TControl objects.
	TCustomForm (see page 2103)	TCustomForm is the base class from which to derive a window such as a form or dialog.
	TCustomFrame (see page 2237)	TCustomFrame is the base class from which TFrame (see page 2366) descends.
	TForm (see page 2241)	TForm represents a standard application window (form).
	TFrame (see page 2366)	TFrame is a container for components; it can be nested within forms or other frames.
	TGlassFrame (see page 2435)	TGlassFrame controls Windows Vista Aero glass effects.
	TMonitor (see page 2439)	TMonitor represents a monitor on which an application runs.
	TScreen (see page 2445)	TScreen represents the state of the screen in which an application runs.
	TScrollBox (see page 2483)	TScrollBox represents a scrolling area (a scroll box) in a window.
	TScrollingWinControl (see page 2554)	TScrollingWinControl is the base class for controls that support scrolling.

7.1.1 TApplication Class

TApplication is the type used for a GUI windowed application.

Class Hierarchy

Pascal

```
[RootDesignerSerializerAttribute('', '', False)]
TApplication = class(TComponent);
```

C++

```
[RootDesignerSerializerAttribute('', '', False)]
class TApplication : public TComponent;
```

File

Forms

Description

TApplication encapsulates a windowed application. The methods and properties introduced in TApplication reflect the fundamentals established in the Windows operating system to create, run, sustain, and destroy an application. TApplication thereby simplifies the interface between the developer and the Windows environment. For this purpose, TApplication encapsulates behavior for

Windows message processing.

Context-sensitive online help.

Menu accelerator and key processing.

Exception handling.

Managing the fundamental parts defined by the Windows operating system for an application, such as MainWindow, WindowClass, and so on

Each GUI application automatically declares an Application (see page 2612) variable as the instance of the application. If the application is not a Web server application, control panel applet, or NT service application, this variable is of type TApplication.

TApplication does not appear on the Component palette, nor is it available in the form designer to visually manipulate; so it has no published properties. Nevertheless, some of its public properties can be set or modified at design time in the Forms (see page 1921) and Application (see page 2612) pages of the Project|Options dialog box. In addition, you can add a TApplicationEvents component to any form in the project to intercept the application's events, and supply event handlers using the IDE.

Note: For application-wide properties and methods that affect the display, see TScreen (see page 2445).

7.1.1.1 TApplication Members

The following tables list the members exposed by TApplication.

Protected Methods

	Name	Description
	Idle (see page 1945)	This is Idle, a member of class TApplication.
	IsDlgMsg (see page 1947)	This is IsDlgMsg, a member of class TApplication.

	IsHintMsg (see page 1947)	This is IsHintMsg, a member of class TApplication.
	IsKeyMsg (see page 1948)	This is IsKeyMsg, a member of class TApplication.
	IsMDIMsg (see page 1948)	This is IsMDIMsg, a member of class TApplication.
	IsPreProcessMessage (see page 1948)	This is IsPreProcessMessage, a member of class TApplication.
	IsShortCut (see page 1949)	This is IsShortCut, a member of class TApplication.

Public Events

	Name	Description
	OnActionExecute (see page 1990)	Occurs when an action's Execute method is called and its action list has not already handled it.
	OnActionUpdate (see page 1991)	Occurs when an action's Update method is called and its action list has not already handled it.
	OnActivate (see page 1992)	Occurs when an application becomes active.
	OnDeactivate (see page 1992)	Occurs when an application becomes inactive.
	OnException (see page 1993)	Occurs when an unhandled exception occurs in the application.
	OnGetActiveFormHandle (see page 1995)	This is OnGetActiveFormHandle, a member of class TApplication.
	OnGetMainFormHandle (see page 1995)	This is OnGetMainFormHandle, a member of class TApplication.
	OnHelp (see page 1995)	Occurs when the application receives a request for help.
	OnHint (see page 1997)	Occurs when the mouse pointer moves over a control or menu item that can display a Help Hint (see page 1976).
	OnIdle (see page 1998)	Occurs when an application becomes idle.
	OnMessage (see page 2003)	Occurs when the application receives a Windows message.
	OnMinimize (see page 2004)	Occurs when an application is minimized.
	OnModalBegin (see page 2006)	Occurs when a modal form is opened.
	OnModalEnd (see page 2006)	Occurs when a modal form is closed.
	OnRestore (see page 2006)	Occurs when the previously minimized application is restored to its normal size.
	OnSettingChange (see page 2007)	Occurs when Windows notifies the application that a system-wide setting has changed.
	OnShortCut (see page 2007)	Occurs when the user presses a key (before the OnKeyDown event).
	OnShowHint (see page 2008)	Occurs when the application is about to display the hint window for a Help Hint (see page 1976).

Public Methods

	Name	Description
	ActivateHint (see page 1930)	Displays a hint window for the control at a specified position.
	AddPopupForm (see page 1931)	This is AddPopupForm, a member of class TApplication.
	BringToFront (see page 1931)	Sets the last active window as the topmost window on the desktop above all other applications.
	CancelHint (see page 1931)	Cancels the display of a hint for a control.
	ControlDestroyed (see page 1931)	Notifies the application when a control is destroyed.
	Create (see page 1928)	Creates a new application.
	CreateForm (see page 1932)	Creates a new form.
	CreateHandle (see page 1934)	Generates a main window for the application if it does not already have one.
	Destroy (see page 1928)	Destroys the application instance and all of its associated memory.
	DoApplicationIdle (see page 1935)	Processes messages in the Message queue for certain events.
	ExecuteAction (see page 1935)	Generates an OnActionExecute (see page 1990) event.
	HandleException (see page 1935)	Provides default handling of exceptions for the application.
	HandleMessage (see page 1937)	Interrupts the execution of an application while Windows processes a message in the Windows message queue.
	HelpCommand (see page 1941)	Provides quick access to any of the Help commands in the WinHelp API (application programming interface).
	HelpContext (see page 1941)	Displays a specified help topic.
	HelpJump (see page 1942)	Displays a specified help topic.
	HelpKeyword (see page 1942)	Displays a specified help topic.
	HelpShowTableOfContents (see page 1943)	Shows the Table of Contents within the help system.
	HideHint (see page 1943)	Hides the current hint.
	HintMouseMessage (see page 1944)	Regulates the display of hint windows.

	HookMainWindow (see page 1944)	Enables a native Windows dialog box to receive messages sent to the application's main window.
	HookSynchronizeWakeup (see page 1944)	This is HookSynchronizeWakeup, a member of class TApplication.
	Initialize (see page 1945)	Provides an opportunity to initialize subsystems.
	IsRightToLeft (see page 1948)	Specifies whether the application adjusts its interface for Middle Eastern locales.
	MessageBox (see page 1949)	Displays a specified message to the user.
	Minimize (see page 1951)	Shrinks an application to the Windows task bar.
	ModalFinished (see page 1952)	Track closing of modal form.
	ModalStarted (see page 1952)	Track opening of modal form.
	NormalizeAllTopMosts (see page 1952)	Makes forms that have been designated as topmost forms (their FormStyle is fsStayOnTop) behave as if they were not topmost forms.
	NormalizeTopMosts (see page 1953)	Makes forms that have been designated as topmost forms (their FormStyle is fsStayOnTop) behave as if they were not topmost forms.
	ProcessMessages (see page 1954)	Interrupts the execution of an application so that it can process the message queue.
	RemovePopupForm (see page 1956)	This is RemovePopupForm, a member of class TApplication.
	Restore (see page 1957)	Restores a minimized application to its normal size.
	RestoreTopMosts (see page 1958)	Restores forms designated as fsStayOnTop to be topmost again.
	Run (see page 1959)	Executes the application.
	ShowException (see page 1961)	Displays a message box for exceptions that are not caught by application code.
	Terminate (see page 1962)	Ends application execution.
	UnhookMainWindow (see page 1964)	Releases a dialog procedure previously hooked by a call to the HookMainWindow (see page 1944) method.
	UnhookSynchronizeWakeup (see page 1964)	Removes the method that was assigned to the WakeMainThread variable by HookSynchronizeWakeup (see page 1944).
	UpdateAction (see page 1965)	Generates an OnActionUpdate (see page 1991) event.
	UseRightToLeftAlignment (see page 1966)	Specifies whether the application object is in a right-to-left alignment mode.
	UseRightToLeftReading (see page 1966)	Specifies whether the application object is in a right-to-left text mode.
	UseRightToLeftScrollBar (see page 1966)	Specifies whether the vertical scroll bar appears on the left side controls.

Public Properties

	Name	Description
	ActionUpdateDelay (see page 1968)	Delays the call to DoActionIdle.
R	Active (see page 1968)	Specifies whether the application is active and has focus.
R	ActiveFormHandle (see page 1968)	Gives the Windows handle of the currently active form.
	AllowTesting (see page 1969)	Represents information for the IDE.
	AutoDragDocking (see page 1969)	Indicates whether dragged windows are automatically docked.
	BiDiKeyboard (see page 1969)	Specifies the name of the keyboard map that should be used in middle-east locales when text reads from right to left.
	BiDiMode (see page 1970)	Indicates the layout of the application when running under Middle Eastern versions of Windows.
R	CurrentHelpFile (see page 1970)	Indicates the current help file.
	DefaultFont (see page 1971)	This is DefaultFont, a member of class TApplication.
	DialogHandle (see page 1971)	Provides a mechanism for using non-VCL dialog boxes in an application.
	EnumAllWindowsOnActivateHint (see page 1972)	This is EnumAllWindowsOnActivateHint, a member of class TApplication.
R	ExeName (see page 1972)	Contains the file name of the application's executable file including path information.
	Handle (see page 1974)	Provides access to the window handle of the main form (window) of the application.
	HelpFile (see page 1974)	Specifies the name of the default file the application uses to display Help.
R	HelpSystem (see page 1976)	Provides access to the interface for working with the help system.
	Hint (see page 1976)	Specifies the text string that appears in the Help Hint box.
	HintColor (see page 1979)	Determines the color of the hint boxes for the Help Hints for the application.
	HintHidePause (see page 1980)	Specifies the time interval to wait before hiding the Help Hint (see page 1976) if the mouse has not moved from the control or menu item.
	HintPause (see page 1980)	Specifies the time interval that passes before the control's Help Hint (see page 1976) appears when the user places the mouse pointer on a control or menu item.

	HintShortCuts (see page 1980)	Specifies whether the application's pop-up hints include shortcut information.
	HintShortPause (see page 1981)	Specifies the time period to wait before bringing up a hint if another hint has already been shown.
	Icon (see page 1981)	Determines which icon represents the application on the Windows task bar.
R	MainForm (see page 1983)	Identifies which form in the application is the main window.
R	MainFormHandle (see page 1983)	Gives the Windows handle of the application main form.
	MainFormOnTaskBar (see page 1983)	Controls how Windows taskbar buttons are handled by VCL.
R	ModalLevel (see page 1985)	This is ModalLevel, a member of class TApplication.
	ModalPopupMode (see page 1985)	This is ModalPopupMode, a member of class TApplication.
	NonBiDiKeyboard (see page 1985)	Specifies the name of the keyboard map that should be used unless text reads from right to left.
R	PopupControlWnd (see page 1986)	This is PopupControlWnd, a member of class TApplication.
	ShowHint (see page 1986)	Determines whether Help Hints are enabled or disabled for the entire application.
	ShowMainForm (see page 1987)	Determines whether the application shows its main form on startup.
R	Terminated (see page 1988)	Reports whether the application is in the process of shutting down.
	Title (see page 1988)	Contains the text that appears below the icon representing the application when it is minimized.
	UpdateFormatSettings (see page 1989)	Specifies whether format settings are updated automatically when the user alters the system configuration.
	UpdateMetricSettings (see page 1989)	Specifies whether the settings used for the hint window font and the icon title font are updated.

7.1.1.2 TApplication.Create Constructor

Creates a new application.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TApplication(TComponent * AOwner);
```

Description

Do not call Create directly. Each GUI application automatically creates an instance of an application object.

For TApplication (see page 1924), the Create method initializes default values for some of its properties. It also prepares the application to run by setting up objects such as hint windows, the application icon, the main window handle, the instance handle, lists for managing child windows of the main window (form), and so on.

See Also

CreateForm (see page 1932)

CreateHandle (see page 1934)

Destroy (see page 1928)

Handle (see page 1974)

MainForm (see page 1983)

Run (see page 1959)

7.1.1.3 TApplication.Destroy Destructor

Destroys the application instance and all of its associated memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TApplication();
```

Description

Never call Application.Destroy or Application.Free. Instead, use the application's Terminate (see page 1962) method to end the application.

Destroy signals that the application has been deactivated before calling the inherited destructor. It then frees memory for hooked windows, the application instance, other object instances and lists that were created at application startup or that accumulated during execution

Since the Application (see page 2612) owns all forms (usually), it destroys these forms in its destructor.

See Also

Terminate (see page 1962)

Terminated (see page 1988)

OnDeactivate (see page 1992)

7.1.1.4 TApplication Methods

The methods of the TApplication class are listed here.

Protected Methods

	Name	Description
	Idle (see page 1945)	This is Idle, a member of class TApplication.
	IsDlgMsg (see page 1947)	This is IsDlgMsg, a member of class TApplication.
	IsHintMsg (see page 1947)	This is IsHintMsg, a member of class TApplication.
	IsKeyMsg (see page 1948)	This is IsKeyMsg, a member of class TApplication.
	IsMDIMsg (see page 1948)	This is IsMDIMsg, a member of class TApplication.
	IsPreProcessMessage (see page 1948)	This is IsPreProcessMessage, a member of class TApplication.
	IsShortCut (see page 1949)	This is IsShortCut, a member of class TApplication.

Public Methods

	Name	Description
	ActivateHint (see page 1930)	Displays a hint window for the control at a specified position.
	AddPopupForm (see page 1931)	This is AddPopupForm, a member of class TApplication.
	BringToFront (see page 1931)	Sets the last active window as the topmost window on the desktop above all other applications.
	CancelHint (see page 1931)	Cancels the display of a hint for a control.
	ControlDestroyed (see page 1931)	Notifies the application when a control is destroyed.
	CreateForm (see page 1932)	Creates a new form.
	CreateHandle (see page 1934)	Generates a main window for the application if it does not already have one.
	DoApplicationIdle (see page 1935)	Processes messages in the Message queue for certain events.
	ExecuteAction (see page 1935)	Generates an OnActionExecute (see page 1990) event.
	HandleException (see page 1935)	Provides default handling of exceptions for the application.
	HandleMessage (see page 1937)	Interrupts the execution of an application while Windows processes a message in the Windows message queue.
	HelpCommand (see page 1941)	Provides quick access to any of the Help commands in the WinHelp API (application programming interface).
	HelpContext (see page 1941)	Displays a specified help topic.

	HelpJump (see page 1942)	Displays a specified help topic.
	HelpKeyword (see page 1942)	Displays a specified help topic.
	HelpShowTableOfContents (see page 1943)	Shows the Table of Contents within the help system.
	HideHint (see page 1943)	Hides the current hint.
	HintMouseMessage (see page 1944)	Regulates the display of hint windows.
	HookMainWindow (see page 1944)	Enables a native Windows dialog box to receive messages sent to the application's main window.
	HookSynchronizeWakeup (see page 1944)	This is HookSynchronizeWakeup, a member of class TApplication.
	Initialize (see page 1945)	Provides an opportunity to initialize subsystems.
	IsRightToLeft (see page 1948)	Specifies whether the application adjusts its interface for Middle Eastern locales.
	MessageBox (see page 1949)	Displays a specified message to the user.
	Minimize (see page 1951)	Shrinks an application to the Windows task bar.
	ModalFinished (see page 1952)	Track closing of modal form.
	ModalStarted (see page 1952)	Track opening of modal form.
	NormalizeAllTopMosts (see page 1952)	Makes forms that have been designated as topmost forms (their FormStyle is fsStayOnTop) behave as if they were not topmost forms.
	NormalizeTopMosts (see page 1953)	Makes forms that have been designated as topmost forms (their FormStyle is fsStayOnTop) behave as if they were not topmost forms.
	ProcessMessages (see page 1954)	Interrupts the execution of an application so that it can process the message queue.
	RemovePopupForm (see page 1956)	This is RemovePopupForm, a member of class TApplication.
	Restore (see page 1957)	Restores a minimized application to its normal size.
	RestoreTopMosts (see page 1958)	Restores forms designated as fsStayOnTop to be topmost again.
	Run (see page 1959)	Executes the application.
	ShowException (see page 1961)	Displays a message box for exceptions that are not caught by application code.
	Terminate (see page 1962)	Ends application execution.
	UnhookMainWindow (see page 1964)	Releases a dialog procedure previously hooked by a call to the HookMainWindow (see page 1944) method.
	UnhookSynchronizeWakeup (see page 1964)	Removes the method that was assigned to the WakeMainThread variable by HookSynchronizeWakeup (see page 1944).
	UpdateAction (see page 1965)	Generates an OnActionUpdate (see page 1991) event.
	UseRightToLeftAlignment (see page 1966)	Specifies whether the application object is in a right-to-left alignment mode.
	UseRightToLeftReading (see page 1966)	Specifies whether the application object is in a right-to-left text mode.
	UseRightToLeftScrollBar (see page 1966)	Specifies whether the vertical scroll bar appears on the left side controls.

7.1.1.4.1 TApplication.ActivateHint Method

Displays a hint window for the control at a specified position.

Pascal

```
procedure ActivateHint(CursorPos: TPoint);
```

C++

```
__fastcall ActivateHint(TPoint CursorPos);
```

Description

ActivateHint locates the control or menu item at the position specified by CursorPos, where CursorPos represents a screen coordinates in pixels. After locating the control, ActivateHint displays the control's Hint (see page 1976) in a hint window.

See Also

THintWindow

Hint (see page 1976)

OnHint (see page 1997)

Hint

7.1.1.4.2 TApplication.AddPopupForm Method

Pascal

```
function AddPopupForm(APopupForm: TCustomForm): Integer;
```

C++

```
__fastcall int AddPopupForm(TCustomForm APopupForm);
```

Description

This is AddPopupForm, a member of class TApplication.

7.1.1.4.3 TApplication.BringToFront Method

Sets the last active window as the topmost window on the desktop above all other applications.

Pascal

```
procedure BringToFront;
```

C++

```
__fastcall BringToFront();
```

Description

Use BringToFront to find the window owned by the MainForm (see page 1983) that was last active and bring it to the foreground. BringToFront also tests to see if the window is visible and enabled before making it the topmost window.

See Also

BringToFront

MainForm (see page 1983)

7.1.1.4.4 TApplication.CancelHint Method

Cancels the display of a hint for a control.

Pascal

```
procedure CancelHint;
```

C++

```
__fastcall CancelHint();
```

Description

Applications rarely, if ever, call CancelHint directly. CancelHint is used internally to cancel the display of hints at appropriate times, such as when a window is not valid or when the application closes. CancelHint calls a series of routines that clean up the display and timing issues of the hint window for a control.

See Also

HideHint (see page 1943)

Hint (see page 1976)

7.1.1.4.5 TApplication.ControlDestroyed Method

Notifies the application when a control is destroyed.

Pascal

```
procedure ControlDestroyed(Control: TControl);
```

C++

```
__fastcall ControlDestroyed(TControl * Control);
```

Description

ControlDestroyed is for internal use and is called automatically by TControl. Do not call it directly.

ControlDestroyed notifies the application that the control passed as the Control parameter has been destroyed, so that the properties which refer to controls, such as MainForm (see page 1983) and ActiveCustomForm, can be updated to specify a valid object or nil (Delphi) or NULL (C++).

See Also

Destroy (see page 1928)

MainForm (see page 1983)

ActiveCustomForm (see page 2452)

7.1.1.4.6 TApplication.CreateForm Method

Creates a new form.

Pascal

```
procedure CreateForm(InstanceClass: TComponentClass; var Reference);
```

C++

```
__fastcall CreateForm(TComponentClass InstanceClass,  Reference);
```

Description

Call CreateForm to dynamically create a form at runtime. Developers do not need to add code for creating most forms, because typically one or more calls to CreateForm are added automatically to the project's source when using the form designer.

CreateForm creates a new form of the type specified by the FormClass parameter and assigns it to the variable given by the Reference parameter. The owner of the new form is the Application (see page 2612) object.

Note: By default, the form created by the first call to CreateForm in a project becomes the application's main form.

C++ Examples:

```
/*
This example shows progress of loading forms as an
application starts up. The code example is placed in the
project source (*_proj.cpp) file. To see project source, right
click on the executable file in the Project Manager and
select the View Source menu item.
You will need to set up your project with the following steps
before using the code example:
o          Add four additional forms to a default project.
o          Place a TProgressBar on Form5
o          Take the Project|Options|Forms menu option and place
               Form5 on the available forms list.
o          Change the code of your project (*_proj.cpp) file to
               look like the example.
*/
#include <vcl\vcl.h>
#include "Unit5.h"
```

```
#pragma hdrstop
//---------------------------------------------------------------------------
USEFORM("TAppCreateForm.cpp", Form1);
USERES("Project1.res");
USEFORM("Unit2.cpp", Form2);
USEFORM("Unit3.cpp", Form3);
USEFORM("Unit4.cpp", Form4);
USEFORM("Unit5.cpp", Form5);
//---------------------------------------------------------------------------
WINAPI WinMain(HINSTANCE, HINSTANCE, LPSTR, int)
{
  try
  {
    Application->Initialize();
    SetApplicationMainFormOnTaskBar(Application, true);
    Application->CreateForm(__classid(TForm5), &Form5);
    Form5->ProgressBar1->Max = 100;
    Form5->Show();   // show a splash screen contain ProgressBar control
    Form5->Update(); // force display of Form5
    Application->CreateForm(__classid(TForm1), &Form1);
    Form5->ProgressBar1->StepBy(25);
    Form5->Label1->Caption =  "Form1 loaded successfully.";
    Form5->Update(); // force display of Form5
    Sleep(3000);
    Application->CreateForm(__classid(TForm2), &Form2);
    Form5->ProgressBar1->StepBy(25);
    Form5->Label1->Caption =  "Form2 loaded successfully.";
    Form5->Update(); // force display of Form5
    Sleep(3000);
    Application->CreateForm(__classid(TForm3), &Form3);
    Form5->ProgressBar1->StepBy(25);
    Form5->Label1->Caption =  "Form3 loaded successfully.";
    Form5->Update(); // force display of Form5
    Sleep(3000);
    Application->CreateForm(__classid(TForm4), &Form4);
    Form5->ProgressBar1->StepBy(25);
    Form5->Label1->Caption =  "Form4 loaded successfully.";
    Form5->Update(); // force display of Form5
    Sleep(3000);
//  delete Form5;
    Application->Run();
  }
  catch (Exception &exception)
  {
    Application->ShowException(&exception);
  }
  return 0;
}
```

Delphi Examples:

```
{
This example shows progress of loading forms as an
application starts up. The code example is placed in the
project source (*.dpr) file.  To see project source, right
click on the executable file in the Project Manager and
select the View Source menu item.  You will need to set up
your project with the following steps before using the codeexample:    Add four additional
forms to a default project.
    Place a TProgressBar on Form5
    Take the Project|Options|Forms menu option and place
          Form5 on the available forms list.
    Change the code of your project (*.dpr) file to look
          like the example.
}
begin
  Application.Initialize;
```

```
with TForm5.Create(nil) do
try
  Application.MainFormOnTaskbar := True;
  ProgressBar1.Max := 100;
  Show;  // show a splash screen contain ProgressBar control
  Update; // force display of Form5
  Application.CreateForm(TForm1, Form1);
  ProgressBar1.StepBy(25);
  Label1.Caption :=  'Form1 loaded successfully.';
  Update; // force display of Form5
  Sleep(3000);
  Application.CreateForm(TForm2, Form2);
  ProgressBar1.StepBy(25);
  Label1.Caption :=  'Form2 loaded successfully.';
  Update; // force display of Form5
  Sleep(3000);
  Application.CreateForm(TForm3, Form3);
  ProgressBar1.StepBy(25);
  Label1.Caption :=  'Form3 loaded successfully.';
  Update; // force display of Form5
  Sleep(3000);
  Application.CreateForm(TForm4, Form4);
  ProgressBar1.StepBy(25);
  Label1.Caption :=  'Form4 loaded successfully.';
  Update; // force display of Form5
  Sleep(3000);
finally
  Free;
end;
Application.Run;
```

CreateHandle (see page 1934)

Handle (see page 1974)

MainForm (see page 1983)

Run (see page 1959)

7.1.1.4.7 TApplication.CreateHandle Method

Generates a main window for the application if it does not already have one.

Pascal

```
procedure CreateHandle;
```

C++

```
__fastcall CreateHandle();
```

Description

Do not call CreateHandle directly. In EXEs, the application's constructor calls CreateHandle. In DLLs it does not.

CreateHandle encapsulates much of what traditional Windows programs write in WinMain. For example, CreateHandle registers the Window Class, creates the application window and determines how the application window is shown.

See Also

Create (see page 1928)

CreateForm (see page 1932)

Handle (see page 1974)

MainForm (see page 1983)

Run (see page 1959)

7.1.1.4.8 TApplication.DoApplicationIdle Method

Processes messages in the Message queue for certain events.

Pascal

```
procedure DoApplicationIdle;
```

C++

```
__fastcall DoApplicationIdle();
```

Description

The DoApplicationIdle method forces a call to the protected method TApplication.Idle (see page 1945). Idle (see page 1945) triggers the event OnIdle (see page 1998), processes the events OnMouseEnter and OnMouseLeave, and updates the hints.

7.1.1.4.9 TApplication.ExecuteAction Method

Generates an OnActionExecute (see page 1990) event.

Pascal

```
function ExecuteAction(Action: TBasicAction): Boolean; reintroduce;
```

C++

```
__fastcall Boolean ExecuteAction(TBasicAction Action);
```

Description

When the user invokes an action, a series of calls ensues to respond to that action. First, the action list that contains the action generates an OnExecute event. If the action list does not handle the OnExecute event, then the action is routed to the Application (see page 2612) object's ExecuteAction method, which invokes the OnActionExecute (see page 1990) event handler. (The application's ExecuteAction method responds to all unhandled actions in the application.) If the OnActionExecute (see page 1990) event handler does not handle the action, then it is routed to the action's OnExecute event handler. If that does not handle the action, the active control's ExecuteAction method is called, followed (if necessary) by the active form's ExecuteAction method.

Do not call ExecuteAction. It is called automatically when the user invokes an action. The Action parameter specifies the action that was invoked. ExecuteAction checks whether the application knows how to perform its function, and if so, executes the action and returns true. Otherwise, ExecuteAction returns false, and the default processing for the action continues.

UpdateAction (see page 1965)

Execute

HandlesTarget

ExecuteAction

7.1.1.4.10 TApplication.HandleException Method

Provides default handling of exceptions for the application.

Pascal

```
procedure HandleException(Sender: TObject);
```

C++

```
__fastcall HandleException(TObject * Sender);
```

Description

If an exception passes through all the try blocks in the application code, the application automatically calls HandleException, which displays a dialog box indicating an error occurred. Unless the exception object is EAbort, HandleException calls the OnException (see page 1993) event handler, if one exists. Otherwise, it calls ShowException (see page 1961) to display a message dialog box indicating an error occurred.

To assign other exception handling code for the application, use the OnException (see page 1993) event handler.

Delphi Examples:

```
{
AllocateHWnd, DeallocateHWnd example
The following code is from the implementation of TTimer. It
shows how the timer component's constructor creates a hidden
window to respond to Timer messages and how the destructor
frees that window.
}
{
TTimer implements a WndProc method that becomes the window
procedure for the hidden window.
}
procedure MyTTimer.WndProc(var Msg: TMessage);
begin
  with Msg do
    if Msg = WM_TIMER then { check for timer messages }
      try
        Timer; { this calls the OnTimer event handler }
      except
        Application.HandleException(Self);
      end
    else
 { Any other messages are passed to DefWindowProc, which
 tells Windows to handle the message.
 Note that the first parameter, FWindowHandle, is the handle
 of the window receiving this message. It is obtained from the
 call to AllocateHWnd in the constructor. }
      Result := DefWindowProc(FWindowHandle, Msg, wParam, lParam);
end;
{
The TTimer constructor uses AllocateHWnd to create the
window and save its handle.
}
constructor MyTTimer.Create(AOwner: TComponent);
begin
  inherited Create(AOwner);
  FEnabled := True;
  FInterval := 1000;
  FWindowHandle := AllocateHWnd(WndProc);
end;

{ The TTimer destructor calls DeallocateHWnd to free the hidden window. }
destructor MyTTimer.Destroy;
begin
  FEnabled := False;
//  UpdateTimer; done by TTimer Destroy
  DeallocateHWnd(FWindowHandle);
  inherited Destroy;
end;
```

EAbort

OnException (see page 1993)

ShowException (see page 1961)

7.1.1.4.11 TApplication.HandleMessage Method

Interrupts the execution of an application while Windows processes a message in the Windows message queue.

Pascal

```
procedure HandleMessage;
```

C++

```
__fastcall HandleMessage();
```

Description

HandleMessage interrupts the execution of the application so that Windows can process a single message from the Windows message queue before returning control to the application. If the message queue is empty, HandleMessage generates an OnIdle (see page 1998) event and starts the process of updating the actions in the application.

Note: If the application goes idle, HandleMessage may take a long time to return. Therefore, do not call HandleMessage when waiting for something message-based while priority actions are also being processed. Instead, call ProcessMessages (see page 1954) when processing more than just messages.

C++ Examples:

```
/*
The following code demonstrates background processing using
the OnIdle event, and using the HandleMessage method to
permit messages or background processing to get through.
Note: You must add MyIdleHandler to the Form1 methods.
*/
// global variables to show the order of events
int  XPos, YPos, Delta;

// This is a utility procedure to display messages
// add this at the beginning of the unit

void StatusMsg(TForm *Form, TCanvas *Canvas, char *Message, bool Bkg)
{
  if (!Bkg)
    Canvas->Font->Style = TFontStyles() << fsBold; // foreground messages are bold
  Canvas->TextOut(XPos, YPos, Message);
  if (!Bkg)
    Canvas->Font->Style = TFontStyles();
  // change Xpos and YPos to prepare for the next message
  YPos += Delta;
  if (YPos >= Form->ClientHeight - 10)
  {
    YPos = 10;
    XPos += 180;
  }
  if (XPos >= Form->ClientWidth - 100)
  {
    if (Canvas->Font->Color == clRed)
      Canvas->Font->Color = clBlack;
    else
```

```
      Canvas->Font->Color = clRed;
    XPos = 10;
  }
}

/*
This is the OnCreate event handler for Form1.  It
initializes global values and sets the application's OnIdle
event handler
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Button1->Caption = "Do not yield";
  Button2->Caption  = "Handle Message";
  Application->OnIdle = MyIdleHandler;
  XPos = 10;
  YPos = 10;
  if (Canvas->Font->Height > 0)
    Delta = Canvas->Font->Height + 1;
  else
    Delta = 1 - Canvas->Font->Height;
}

/*
This is the OnIdle event handler. It is set in the Form's
OnCreate event handler, so you need only add it as a private
method of the form.  Usually it would perform some background
processing for the application.  This one simply writes a
message to let you know when it's there.
*/
void __fastcall TForm1::MyIdleHandler(TObject *Sender, bool &Done)
{
  StatusMsg(Form1, Canvas, "This represents a background process.", true);
}

/*
This is the OnClick event handler for Button1.  It
simulates a lengthy process
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int X, Y;
  StatusMsg(Form1, Canvas, "The Button1Click handler is starting", false);
  for (int I = 0; I < 100; I++)
  {
    randomize();
    for (int J = 0; J < 100; J++)
      Y = random(J);
    X = random(I);
  }
  StatusMsg(Form1, Canvas, "The Button1Click handler is done", false);
}

/*
This is the OnClick event handler for button2.  It
simulates a lengthy process that allows other messages to be
processed.
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  int X, Y;
  StatusMsg(Form1, Canvas, "The Button2Click handler is starting", false);
  for (int I = 0; I < 100; I++)
  {
    randomize();
    for (int J = 0; J < 100; J++)
```

```
    {
      Y = random(J);
    }
    // Yield to OnIdle or other messages
    Application->HandleMessage();
    X = random(I);
  }
  StatusMsg(Form1, Canvas, "The Button2Click handler is done", false);
}
```

Delphi Examples:

```
{
The following code demonstrates background processing using
the OnIdle event, and using the HandleMessage method to
permit messages or background processing to get through.
Note: You must add MyIdleHandler to the Form1 methods.
}
var
{ global variables to show the order of events. }
  XPos, YPos, Delta: integer;

{ This is a utility procedure to display messages }
{ add this at the beginning of the implementation section }
procedure StatusMsg(
  MyForm : TForm1; Canvas : TCanvas; Message : string; Bkg : Boolean);
begin
  if not bkg then
    Canvas.Font.Style := [fsBold]; {foreground messages are bold }
  Canvas.TextOut(XPos, YPos, Message);
  if not bkg then
    Canvas.Font.Style := [];
  { change Xpos and YPos to prepare for the next message }
  Ypos := Ypos + Delta;
  if YPos >= MyForm.ClientHeight - 10 then
  begin
    YPos := 10;
    Xpos := Xpos + 180;
  end;
  if (Xpos >= MyForm.ClientWidth - 100) then
  begin
    if (Canvas.Font.Color = clRed) then
      Canvas.Font.Color := clBlack
    else
      Canvas.Font.Color := clRed;
    Xpos := 10;
  end;
end;

{This is the Form's OnCreate event handler.  }
{ It initializes global variables and sets the  the OnIdle
event handler }
procedure TForm1.FormCreate(Sender: TObject);
begin
  Button1.Caption := 'Do not yield';
  Button2.Caption := 'Handle Message';
  Application.OnIdle:= MyIdleHandler;
  XPos := 10;
  YPos := 10;
  Delta := Abs(Canvas.Font.Height) + 1;
 end;

{
This is the OnIdle event handler. It is set in the Form's
OnCreate event handler, so you need only add it as a private
method of the form.  Usually it would perform some
background processing for the application.  This one simply
```

```
  writes a message to let you know when it's there.
  }
  procedure TForm1.MyIdleHandler(Sender: TObject; var Done: Boolean);
  begin
    StatusMsg(
      Form1, Canvas, 'This represents a background process.', True);
  end;

  {
  Set this method as the OnClick event handler of Button1.  It
  performs a calculation without yielding to other messages or
  idle time.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    I, J, X, Y: Word;
  begin
    StatusMsg(
      Form1, Canvas, 'The synchronous handler is starting', False);
    I := 0;
    J := 0;
    while I < 10 do
    begin
      Randomize;
      while J < 10 do
      begin
        Y := Random(J);
        Inc(J);
      end;
      X := Random(I);
      Inc(I);
    end;
    StatusMsg(
      Form1, Canvas, 'The synchronous handler is done', False);
  end;

  {
  Set this method as the OnClick event handler of Button2.  It
  performs a calculation but calls HandleMessage to allow idle
  time or asynchronous message processing.
  }
  procedure TForm1.Button2Click(Sender: TObject);
  var
    I, J, X, Y: Word;
  begin
   StatusMsg(
      Form1, Canvas, 'The asynchronous handler is starting', False);
    I := 0;
    J := 0;
    while I < 10 do
    begin
      Randomize;
      while J < 10 do
      begin
        Y := Random(J);
        Inc(J);
      end;
      X := Random(I);
      Inc(I);
      { yield to OnIdle or other messages }
      Application.HandleMessage;
    end;
    StatusMsg(
      Form1, Canvas, 'The asynchronous handler is done', False);
  end;
```

7.1.1.4.12 TApplication.HelpCommand Method

Provides quick access to any of the Help commands in the WinHelp API (application programming interface).

Pascal

```
function HelpCommand(Command: Integer; Data: Longint): Boolean;
```

C++

```
__fastcall Boolean HelpCommand(int Command, Longint Data);
```

Description

Use HelpCommand to send a command to WinHelp. Before sending the help command to the Windows help engine, HelpCommand generates an OnHelp (see page 1995) event on the active form or on TApplication (see page 1924). Finally, the command is forwarded to WinHelp if there is no OnHelp (see page 1995) event handler or if the OnHelp (see page 1995) event handler indicates that WinHelp should be called.

For information about Windows help commands and the data passed to them, see the WinHelp topic in the Windows Help system.

OnHelp (see page 2217)

7.1.1.4.13 TApplication.HelpContext Method

Displays a specified help topic.

Pascal

```
function HelpContext(Context: THelpContext): Boolean;
```

C++

```
__fastcall Boolean HelpContext(THelpContext Context);
```

Description

Use HelpContext to bring up the help topic specified by the Context parameter from the file specified in the CurrentHelpFile (see page 1970) property. HelpContext generates an OnHelp (see page 1995) event (either on the active form or on the application object itself). If there is no OnHelp (see page 1995) event handler, or if the event handler indicates that WinHelp should be called, then HelpContext invokes the Windows help engine, passing it the context ID.

For example, if the Context value is 714, the HelpContext method displays the screen with the context help ID of 714 in the help file specified by CurrentHelpFile (see page 1970).

HelpContext returns false if CurrentHelpFile (see page 1970) is an empty string, meaning the application has no help file assigned. In all other cases, HelpContext returns true.

HelpKeyword (see page 1942)

Help and Hint Properties

7.1.1.4.14 TApplication.HelpJump Method

Displays a specified help topic.

Pascal

```
function HelpJump(const JumpID: string): Boolean;
```

C++

```
__fastcall Boolean HelpJump(const UnicodeString JumpID);
```

Description

Call HelpJump to bring up a topic identified by its symbolic name. HelpJump displays the topic identified by the JumpID parameter from the file specified in the Current HelpFile (see page 1974) property. HelpJump generates an OnHelp (see page 1995) event (either on the active form or on the application object itself). If there is no OnHelp (see page 1995) event handler, or if the event handler indicates that WinHelp should be called, then HelpJump invokes the Windows help engine, passing it the topic name.

HelpJump returns false if CurrentHelpFile (see page 1970) is an empty string, meaning the application has no help file assigned. In all other cases, HelpJump returns true.

See Also

HelpCommand (see page 1941)

HelpContext (see page 1941)

HelpFile (see page 1974)

7.1.1.4.15 TApplication.HelpKeyword Method

Displays a specified help topic.

Pascal

```
function HelpKeyword(const Keyword: string): Boolean;
```

C++

```
__fastcall Boolean HelpKeyword(const UnicodeString Keyword);
```

Description

Use HelpKeyword to bring up the help topic specified by the Keyword parameter from the file specified in the CurrentHelpFile (see page 1970) property. HelpKeyword invokes the current help system, passing it the string specified by Keyword. If the current system is WinHelp, this displays the topic that has an Alink of Keyword.

HelpKeyword returns false if the current help system does not support the keyword lookups.

HelpCommand (see page 1941)

HelpKeyword

HelpFile (see page 1974)

HelpJump (see page 1942)

OnHelp (see page 1995)

CurrentHelpFile (see page 1970)

7.1.1.4.16 TApplication.HelpShowTableOfContents Method

Shows the Table of Contents within the help system.

Pascal

```
function HelpShowTableOfContents: Boolean;
```

C++

```
__fastcall Boolean HelpShowTableOfContents();
```

Description

Use HelpShowTableOfContents to bring up the table of contents for the help system specified in the CurrentHelpFile (see page 1970) property. This method is preferred to calling "Application.HelpSystem.ShowTableOfContents", which cannot be used as the first call into the help system.

7.1.1.4.17 TApplication.HideHint Method

Hides the current hint.

Pascal

```
procedure HideHint;
```

C++

```
__fastcall HideHint();
```

Description

Applications rarely, if ever, call HideHint directly. HideHint is used internally to hide the hint window at the appropriate times according to predetermined conditions and timer values. For example, CancelHint (see page 1931) calls HideHint.

See Also

CancelHint (see page 1931)

HintPause (see page 1980)

HintShortPause (see page 1981)

7.1.1.4.18 TApplication.HintMouseMessage Method

Regulates the display of hint windows.

Pascal

```
procedure HintMouseMessage(Control: TControl; var Message: TMessage);
```

C++

```
__fastcall HintMouseMessage(TControl * Control, TMessage Message);
```

Description

This method is called automatically when the mouse passes over a control with a Hint (see page 1976). Applications rarely, if ever, call HintMouseMessage directly. HintMouseMessage is used internally to manage the display of the hint windows.

See Also

CancelHint (see page 1931)

HintPause (see page 1980)

HintShortPause (see page 1981)

7.1.1.4.19 TApplication.HookMainWindow Method

Enables a native Windows dialog box to receive messages sent to the application's main window.

Pascal

```
procedure HookMainWindow(Hook: TWindowHook);
```

C++

```
__fastcall HookMainWindow(TWindowHook Hook);
```

Description

Use HookMainWindow to ensure that a native Windows dialog box behaves correctly as a child of the application, not as a stand-alone window. For example, switching among applications with Alt+Tab treats the application as a single task after calling HookMainWindow, rather than treating the native Windows dialog box as a separate task.

When the window identified by the Handle (see page 1974) property receives relevant dialog messages, it passes them to the dialog procedure passed as the Hook parameter.

There is no problem with leaving a dialog box hooked into the main window, even for extended periods. However, should the dialog box close, call the UnhookMainWindow (see page 1964) method to release the hook.

See Also

Handle (see page 1974)

UnhookMainWindow (see page 1964)

7.1.1.4.20 TApplication.HookSynchronizeWakeup Method

Pascal

```
procedure HookSynchronizeWakeup;
```

C++

```
__fastcall HookSynchronizeWakeup();
```

Description

This is HookSynchronizeWakeup, a member of class TApplication.

7.1.1.4.21 TApplication.Idle Method

Pascal

```
procedure Idle(const Msg: TMsg);
```

C++

```
__fastcall Idle(const TMsg Msg);
```

Description

This is Idle, a member of class TApplication.

7.1.1.4.22 TApplication.Initialize Method

Provides an opportunity to initialize subsystems.

Pascal

```
procedure Initialize;
```

C++

```
__fastcall Initialize();
```

Description

Initialize is the first method called by the project source file. It calls the InitProc procedure pointer. By default, the call to Initialize for the application does nothing because the default InitProc pointer is nil (Delphi) or NULL (C++) .

To use Initialize, the InitProc pointer must be predefined. This can be accomplished in one of two ways:

In Delphi, you can include a unit that assigns a procedure to InitProc in its initialization section, such as the ComObj unit. You can make this assignment in the initialization section of any of your units.

In both Delphi and C++, you can create a custom initialization procedure that assigns a value to the InitProc pointer, and add a call to this procedure to the project source prior to the call to Initialize. (In Delphi, you can add it to the initialization section of the unit in which it is declared. In C++, you can use the pragma startup directive in that unit.)

Warning: Only one instance of InitProc can be defined in an application. If more than one unit assigns a value to InitProc, only the last assignment will work. You can, however, call the previous value of InitProc from an initialization procedure, so that all initialization procedures are executed.

For projects that do not assign a value to InitProc, the call to Initialize can be safely deleted from the project source.

Note: Although Initialize is the first method called in the main project source code, it is not the first code that is executed in a GUI application. For example, in Delphi, the application first executes the initialization section of all the units used by the application.

C++ Examples:

```
/*
This example shows progress of loading forms as an
application starts up. The code example is placed in the
project source (*_proj.cpp) file. To see project source, right
click on the executable file in the Project Manager and
select the View Source menu item.
```

```
  You will need to set up your project with the following steps
  before using the code example:
  o          Add four additional forms to a default project.
  o          Place a TProgressBar on Form5
  o          Take the Project|Options|Forms menu option and place
                 Form5 on the available forms list.
  o          Change the code of your project (*_proj.cpp) file to
                 look like the example.
  */
  #include <vcl\vcl.h>
  #include "Unit5.h"
  #pragma hdrstop
  //---------------------------------------------------------------------------
  USEFORM("TAppCreateForm.cpp", Form1);
  USERES("Project1.res");
  USEFORM("Unit2.cpp", Form2);
  USEFORM("Unit3.cpp", Form3);
  USEFORM("Unit4.cpp", Form4);
  USEFORM("Unit5.cpp", Form5);
  //---------------------------------------------------------------------------
  WINAPI WinMain(HINSTANCE, HINSTANCE, LPSTR, int)
  {
    try
    {
      Application->Initialize();
      SetApplicationMainFormOnTaskBar(Application, true);
      Application->CreateForm(__classid(TForm5), &Form5);
      Form5->ProgressBar1->Max = 100;
      Form5->Show();   // show a splash screen contain ProgressBar control
      Form5->Update(); // force display of Form5
      Application->CreateForm(__classid(TForm1), &Form1);
      Form5->ProgressBar1->StepBy(25);
      Form5->Label1->Caption =  "Form1 loaded successfully.";
      Form5->Update(); // force display of Form5
      Sleep(3000);
      Application->CreateForm(__classid(TForm2), &Form2);
      Form5->ProgressBar1->StepBy(25);
      Form5->Label1->Caption =  "Form2 loaded successfully.";
      Form5->Update(); // force display of Form5
      Sleep(3000);
      Application->CreateForm(__classid(TForm3), &Form3);
      Form5->ProgressBar1->StepBy(25);
      Form5->Label1->Caption =  "Form3 loaded successfully.";
      Form5->Update(); // force display of Form5
      Sleep(3000);
      Application->CreateForm(__classid(TForm4), &Form4);
      Form5->ProgressBar1->StepBy(25);
      Form5->Label1->Caption =  "Form4 loaded successfully.";
      Form5->Update(); // force display of Form5
      Sleep(3000);
  //  delete Form5;
      Application->Run();
    }
    catch (Exception &exception)
    {
      Application->ShowException(&exception);
    }
    return 0;
  }
```

Delphi Examples:

```
  {
  This example shows progress of loading forms as an
  application starts up. The code example is placed in the
  project source (*.dpr) file.  To see project source, right
  click on the executable file in the Project Manager and
```

```
  select the View Source menu item.  You will need to set up
  your project with the following steps before using the codeexample:    Add four additional
  forms to a default project.
      Place a TProgressBar on Form5
      Take the Project|Options|Forms menu option and place
            Form5 on the available forms list.
      Change the code of your project (*.dpr) file to look
            like the example.
  }
  begin
    Application.Initialize;
    with TForm5.Create(nil) do
    try
      Application.MainFormOnTaskbar := True;
      ProgressBar1.Max := 100;
      Show;  // show a splash screen contain ProgressBar control
      Update; // force display of Form5
      Application.CreateForm(TForm1, Form1);
      ProgressBar1.StepBy(25);
      Label1.Caption :=  'Form1 loaded successfully.';
      Update; // force display of Form5
      Sleep(3000);
      Application.CreateForm(TForm2, Form2);
      ProgressBar1.StepBy(25);
      Label1.Caption :=  'Form2 loaded successfully.';
      Update; // force display of Form5
      Sleep(3000);
      Application.CreateForm(TForm3, Form3);
      ProgressBar1.StepBy(25);
      Label1.Caption :=  'Form3 loaded successfully.';
      Update; // force display of Form5
      Sleep(3000);
      Application.CreateForm(TForm4, Form4);
      ProgressBar1.StepBy(25);
      Label1.Caption :=  'Form4 loaded successfully.';
      Update; // force display of Form5
      Sleep(3000);
    finally
      Free;
    end;
    Application.Run;
```

7.1.1.4.23 TApplication.IsDlgMsg Method

Pascal

```
function IsDlgMsg(var Msg: TMsg): Boolean;
```

C++

```
__fastcall Boolean IsDlgMsg(TMsg Msg);
```

Description

This is IsDlgMsg, a member of class TApplication.

7.1.1.4.24 TApplication.IsHintMsg Method

Pascal

```
function IsHintMsg(var Msg: TMsg): Boolean;
```

C++

```
__fastcall Boolean IsHintMsg(TMsg Msg);
```

Description

This is IsHintMsg, a member of class TApplication.

7.1.1.4.25 TApplication.IsKeyMsg Method

Pascal

```
function IsKeyMsg(var Msg: TMsg): Boolean;
```

C++

```
__fastcall Boolean IsKeyMsg(TMsg Msg);
```

Description

This is IsKeyMsg, a member of class TApplication.

7.1.1.4.26 TApplication.IsMDIMsg Method

Pascal

```
function IsMDIMsg(var Msg: TMsg): Boolean;
```

C++

```
__fastcall Boolean IsMDIMsg(TMsg Msg);
```

Description

This is IsMDIMsg, a member of class TApplication.

7.1.1.4.27 TApplication.IsPreProcessMessage Method

Pascal

```
function IsPreProcessMessage(var Msg: TMsg): Boolean;
```

C++

```
__fastcall Boolean IsPreProcessMessage(TMsg Msg);
```

Description

This is IsPreProcessMessage, a member of class TApplication.

7.1.1.4.28 TApplication.IsRightToLeft Method

Specifies whether the application adjusts its interface for Middle Eastern locales.

Pascal

```
function IsRightToLeft: Boolean;
```

C++

```
__fastcall Boolean IsRightToLeft();
```

Description

Use IsRightToLeft to determine whether the application makes any adjustments of control alignment, text direction, or scroll bar placement. IsRightToLeft returns true if the application's BiDiMode (see page 1970) indicates that any of these should be

reversed and the application is running on a system with a Middle Eastern locale.

7.1.1.4.29 TApplication.IsShortCut Method

Pascal

```
function IsShortCut(var Message: TWMKey): Boolean;
```

C++

```
__fastcall Boolean IsShortCut(TWMKey Message);
```

Description

This is IsShortCut, a member of class TApplication.

7.1.1.4.30 TApplication.MessageBox Method

Displays a specified message to the user.

Pascal

```
function MessageBox(const Text: PChar; const Caption: PChar; Flags: Longint = MB_OK): Integer;
```

C++

```
__fastcall int MessageBox(const const char * Text, const const char * Caption, Longint Flags =
MB_OK);
```

Description

Use MessageBox to display a generic dialog box a message and one or more buttons. Caption is the caption of the dialog box and is optional.

MessageBox is an encapsulation of the Windows API MessageBox function. TApplication (see page 1924)'s encapsulation of MessageBox automatically supplies the missing window handle parameter needed for the Windows API function.

The value of the Text parameter is the message, which can be longer than 255 characters if necessary. Long messages are automatically wrapped in the message box.

The value of the Caption parameter is the caption that appears in the title bar of the dialog box. Captions can be longer than 255 characters, but don't wrap. A long caption results in a wide message box.

The Flags parameter specifies what buttons appear on the message box and the behavior (possible return values). The following table lists the possible values. These values can be combined to obtain the desired effect.

Value	Meaning
MB_ABORTRETRYIGNORE	The message box contains three push buttons: Abort, Retry, and Ignore.
MB_OK	The message box contains one push button: OK. This is the default.
MB_OKCANCEL	The message box contains two push buttons: OK and Cancel.
MB_RETRYCANCEL	The message box contains two push buttons: Retry and Cancel.
MB_YESNO	The message box contains two push buttons: Yes and No.
MB_YESNOCANCEL	The message box contains three push buttons: Yes, No, and Cancel.

MessageBox returns 0 if there isn't enough memory to create the message box. Otherwise it returns one of the following values:

ValueNumeric valueMeaning

Value	Numeric value	Meaning
IDOK	1	The user chose the OK button.
IDCANCEL	2	The user chose the Cancel button.
IDABORT	3	The user chose the Abort button.
IDRETRY	4	The user chose the Retry button.
IDIGNORE	5	The user chose the Ignore button.
IDYES	6	The user chose the Yes button.
IDNO	7	The user chose the No button.

C++ Examples:

```
/*
The following code causes "stay on top" forms to allow a
MessageBox to appear on top. After the message box is
closed, the topmost forms are restored so that they continue
to float to the top.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
Application->NormalizeTopMosts();
#ifdef _DELPHI_STRING_UNICODE
Application->MessageBox(L"This should be on top.", L"Look", MB_OKCANCEL);
#else
Application->MessageBox("This should be on top.", "Look", MB_OKCANCEL);
#endif
Application->RestoreTopMosts();
}
```

Delphi Examples:

```
{
The following code causes "stay on top" forms to allow a
MessageBox to appear on top. After the message box is
closed, the topmost forms are restored so that they continue
to float to the top.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  with Application do
  begin
    NormalizeTopMosts;
    MessageBox('This should be on top.', 'Look', MB_OK);    // [smbOK]
    RestoreTopMosts;
  end;
end;
```

7.1.1.4.31 TApplication.Minimize Method

Shrinks an application to the Windows task bar.

Pascal

```
procedure Minimize;
```

C++

```
__fastcall Minimize();
```

Description

Call Minimize to minimize the application. When the user minimizes the application, the Minimize method is automatically called.

Note: Don't confuse the Minimize method, which minimizes an entire application, with minimizing a form or window. To minimize, maximize, or restore a window or form, change the value of its WindowState property.

C++ Examples:

```
/*
The following code minimizes an application when it's
deactivated. Note that AppDeactivate should be declared a
method of TForm1.  Click anywhere outside of the form
to deactivate it.
*/
void __fastcall TForm1::AppDeactivate(TObject *Sender)
{
  Application->Minimize();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnDeactivate = AppDeactivate;
}
```

Delphi Examples:

```
{
The following code minimizes an application when it's
deactivated. Note that AppDeactivate should be declared a
method of TForm1.  Click anywhere outside of the form
to deactivate it.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnDeactivate := AppDeactivate;
end;
procedure TForm1.AppDeactivate(Sender: TObject);
begin
  Application.Minimize;
end;
```

7.1.1.4.32 TApplication.ModalFinished Method

Track closing of modal form.

Pascal

```
procedure ModalFinished;
```

C++

```
__fastcall ModalFinished();
```

Description

Call ModalFinished to indicate that a modal form is being closed. ModalFinished is called by the ShowModal method of TCustomForm (see page 2103).

ModalFinished calls the OnModalEnd (see page 2006) event handler, if defined.

See Also

OnModalEnd (see page 2006)

ModalStarted (see page 1952)

ShowModal (see page 2139)

7.1.1.4.33 TApplication.ModalStarted Method

Track opening of modal form.

Pascal

```
procedure ModalStarted;
```

C++

```
__fastcall ModalStarted();
```

Description

Call ModalStarted to indicate that a modal form is being opened. ModalStarted is called by the ShowModal method of TCustomForm (see page 2103).

ModalStarted calls the OnModalStart event handler, if defined.

See Also

OnModalStart

ModalFinished (see page 1952)

ShowModal (see page 2139)

7.1.1.4.34 TApplication.NormalizeAllTopMosts Method

Makes forms that have been designated as topmost forms (their FormStyle is fsStayOnTop) behave as if they were not topmost forms.

Pascal

```
procedure NormalizeAllTopMosts;
```

C++

```
__fastcall NormalizeAllTopMosts();
```

Description

Use NormalizeAllTopMosts to allow other windows appear on top of a topmost form. Normally, topmost forms remain on top of other windows, and so may obscure other windows.

NormalizeAllTopMosts behaves like the NormalizeTopMosts (see page 1953) method, except that it also includes the application's Main Window.

See Also

FormStyle (see page 2162)

NormalizeTopMosts (see page 1953)

RestoreTopMosts (see page 1958)

MainForm (see page 1983)

7.1.1.4.35 TApplication.NormalizeTopMosts Method

Makes forms that have been designated as topmost forms (their FormStyle is fsStayOnTop) behave as if they were not topmost forms.

Pascal

```
procedure NormalizeTopMosts;
```

C++

```
__fastcall NormalizeTopMosts();
```

Description

Use NormalizeTopMosts to allow a message box or dialog box that is displayed using the Windows API functions (such as MessageBox (see page 1949) and MessageDlg) directly, appear on top of a topmost form. Otherwise the topmost form remains on top, and may obscure the message box.

Calling NormalizeTopMosts is not necessary when using functions to display message boxes.

To return the forms designated as fsStayOnTop to be topmost again, call RestoreTopMosts (see page 1958).

C++ Examples:

```
/*
The following code causes "stay on top" forms to allow a
MessageBox to appear on top. After the message box is
closed, the topmost forms are restored so that they continue
to float to the top.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
Application->NormalizeTopMosts();
#ifdef _DELPHI_STRING_UNICODE
Application->MessageBox(L"This should be on top.", L"Look", MB_OKCANCEL);
#else
Application->MessageBox("This should be on top.", "Look", MB_OKCANCEL);
#endif
Application->RestoreTopMosts();
}
```

Delphi Examples:

```
{
The following code causes "stay on top" forms to allow a
MessageBox to appear on top. After the message box is
closed, the topmost forms are restored so that they continue
```

```
to float to the top.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  with Application do
  begin
    NormalizeTopMosts;
    MessageBox('This should be on top.', 'Look', MB_OK);    // [smbOK]
    RestoreTopMosts;
  end;
end;
```

See Also

FormStyle (see page 2162)

RestoreTopMosts (see page 1958)

NormalizeAllTopMosts (see page 1952)

MessageBox (see page 1949)

MessageDlg

7.1.1.4.36 TApplication.ProcessMessages Method

Interrupts the execution of an application so that it can process the message queue.

Pascal

```
procedure ProcessMessages;
```

C++

```
__fastcall ProcessMessages();
```

Description

Call ProcessMessages to permit the application to process messages that are currently in the message queue. ProcessMessages cycles the Windows message loop until it is empty, and then returns control to the application.

Note: Neglecting message processing affects only the application calling ProcessMessages, not other applications. In lengthy operations, calling ProcessMessages periodically allows the application to respond to paint and other messages.

Note: ProcessMessages does not allow the application to go idle, whereas HandleMessage (see page 1937) does.

C++ Examples:

```
/*
This example uses two buttons that are long enough to
accommodate lengthy captions on a form. When the user clicks
the button with the caption Ignore Messages, the code begins
to generate a long series of random numbers. If the user
tries to resize the form while the handler is running,
nothing happens until the handler is finished. When the user
clicks the button with the caption Process Messages, more
random numbers are generated, but the application can still
respond to a series of events, such as resizing the form
and printing text.
Note: How quickly these event handlers run depends on the
microprocessor of your computer. A message appears on the
form informing you when the handler has finished executing.
*/
```

```
int magicnumber = 20;

void __fastcall TForm1::FormCreate(TObject* Sender)
{
  Button1->Caption = "Ignore Messages";
  Button2->Caption = "Handle Message";
}

void __fastcall TForm1::Button1Click(TObject* Sender)
{
  int x, y;
  Canvas->TextOut(10, 10, "The Button1Click handler has started");
  Application->ProcessMessages(); // Just to get out the
  Sleep(100);
  for (int i = 0; i < magicnumber; i++)
 {
    Randomize();
    for (int j = 0; j < magicnumber; j++)
    {
      Sleep(10);
      y = random(j);
    }
    x = random(i);
  }
  Canvas->TextOut(10, 10, "The Button1Click handler is finished   ");
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  int x, y;
  Canvas->TextOut(10, 10, "The Button2Click handler has started");
  for (int i = 0; i < magicnumber; i++)
  {
    Randomize();
    for (int j = 0; j < magicnumber; j++)
    {
      y = random(j);
      Sleep(10);
      Application->ProcessMessages();
    }
    x = random(i);
  }
  Canvas->TextOut(10, 10, "The Button2Click handler is finished   ");
}
```

Delphi Examples:

```
{
This example uses two buttons that are long enough to
accommodate lengthy captions on a form. When the user clicks
the button with the caption Ignore Messages, the code begins
to generate a long series of random numbers. If the user
tries to resize the form while the handler is running,
nothing happens until the handler is finished. When the user
clicks the button with the caption Process Messages, more
random numbers are generated, but the application can still
respond to a series of events, such as resizing the form
and printing text.
Note: How quickly these event handlers run depends on the
microprocessor of your computer. A message appears on the
form informing you when the handler has finished executing.
}
const magicnumber = 500;
procedure TForm1.FormCreate(Sender: TObject);
begin
  Button1.Caption := 'Ignore Messages';
```

```
    Button2.Caption := 'Process Messages';
  end;

  procedure TForm1.Button1Click(Sender: TObject);
  var
    I, J: Integer;
    X, Y: Word;
  begin
    I := 0;
    J := 0;
    Canvas.TextOut(10, 10, 'The Button1Click handler has started');
    Application.ProcessMessages; // Just to get the message out.
    while I < magicnumber do
    begin
      Randomize;
      while J < magicnumber do
      begin
        Sleep(10);
        Y := Random(J);
        Inc(J);
      end;
      X := Random(I);
      Inc(I);
    end;
    Canvas.TextOut(10, 10, 'The Button1Click handler is finished   ');
  end;

  procedure TForm1.Button2Click(Sender: TObject);
  var
    I, J: Integer;
    X, Y: Word;
  begin
    I := 0;
    J := 0;
    Canvas.TextOut(10, 10, 'The Button2Click handler has started');
    while I < magicnumber do
    begin
      Randomize;
      while J < magicnumber do
      begin
        Y := Random(J);
        Inc(J);
        Sleep(10);
        Application.ProcessMessages;
      end;
      X := Random(I);
      Inc(I);
    end;
    Canvas.TextOut(10, 10, 'The Button2Click handler is finished   ');
  end;
```

7.1.1.4.37 TApplication.RemovePopupForm Method

Pascal

```
procedure RemovePopupForm(APopupForm: TCustomForm);
```

C++

```
__fastcall RemovePopupForm(TCustomForm APopupForm);
```

Description

This is RemovePopupForm, a member of class TApplication.

7.1.1.4.38 TApplication.Restore Method

Restores a minimized application to its normal size.

Pascal

```
procedure Restore;
```

C++

```
__fastcall Restore();
```

Description

Use Restore to restore the application to its previous size before it was minimized. When the user restores the application to normal size, Restore is automatically called.

Note: Don't confuse the Restore method, which restores the entire application, with restoring a form or window to its original size. To minimize, maximize, and restore a window or form, change the value of its WindowState property.

C++ Examples:

```
/*
This example uses a timer on a form. When the application
runs and the user minimizes the application, the timer
starts and the application returns to its normal size when
an OnTimer event occurs.  The timer then shuts down until
the next time the form is minimized.  Be sure to declare the
AppStartTimer method as a public method of TForm1.  Place a
TTimer object in the form and enter Timer1Timer in the OnTimer
event.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnMinimize = AppStartTimer;
  Timer1->Interval = 1000;
}

void __fastcall TForm1::AppStartTimer(TObject *Sender)
{
  Timer1->Enabled = true;
}

//---------------------------------------------------------------------------
void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  Application->Restore();
  Timer1->Enabled = false;
}
```

Delphi Examples:

```
{
This example uses a timer on a form. When the application
runs and the user minimizes the application, the timer
starts and the application returns to its normal size when
an OnTimer event occurs.  The timer then shuts down until
the next time the form is minimized.  Be sure to declare the
AppStartTimer method as a public method of TForm1.  Place a
TTimer object in the form and enter Timer1Timer in the OnTimer
```

```
event.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnMinimize := AppStartTimer;
end;

procedure TForm1.AppStartTimer(Sender: TObject);
begin
  Timer1.Enabled := True;
end;

procedure TForm1.Timer1Timer(Sender: TObject);
begin
  Application.Restore;
  Timer1.Enabled := False;
end;
```

See Also

WindowState (see page 2195)

7.1.1.4.39 TApplication.RestoreTopMosts Method

Restores forms designated as fsStayOnTop to be topmost again.

Pascal

```
procedure RestoreTopMosts;
```

C++

```
__fastcall RestoreTopMosts();
```

Description

Use RestoreTopMosts to return forms that were originally designated as topmost forms (FormStyle is fsStayOnTop), then temporarily changed to be non-topmost forms with the NormalizeTopMosts (see page 1953) or NormalizeAllTopMosts (see page 1952) method, to a topmost position.

C++ Examples:

```
/*
The following code causes "stay on top" forms to allow a
MessageBox to appear on top. After the message box is
closed, the topmost forms are restored so that they continue
to float to the top.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
Application->NormalizeTopMosts();
#ifdef _DELPHI_STRING_UNICODE
Application->MessageBox(L"This should be on top.", L"Look", MB_OKCANCEL);
#else
Application->MessageBox("This should be on top.", "Look", MB_OKCANCEL);
#endif
Application->RestoreTopMosts();
}
```

Delphi Examples:

```
{
The following code causes "stay on top" forms to allow a
MessageBox to appear on top. After the message box is
closed, the topmost forms are restored so that they continue
to float to the top.
}
```

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  with Application do
  begin
    NormalizeTopMosts;
    MessageBox('This should be on top.', 'Look', MB_OK);    // [smbOK]
    RestoreTopMosts;
  end;
end;
```

See Also

NormalizeTopMosts (see page 1953)

NormalizeAllTopMosts (see page 1952)

7.1.1.4.40 TApplication.Run Method

Executes the application.

Pascal

```
procedure Run;
```

C++

```
__fastcall Run();
```

Description

Do not call Run. When creating a new project, The IDE automatically creates a main program block in the project file that calls the Run method. When the application is executed, the application's Run method is called.

Run contains the application's main message loop. The call to Run does not return until the application's message loop terminates.

C++ Examples:

```
/*
This example shows progress of loading forms as an
application starts up. The code example is placed in the
project source (*_proj.cpp) file. To see project source, right
click on the executable file in the Project Manager and
select the View Source menu item.
You will need to set up your project with the following steps
before using the code example:
o          Add four additional forms to a default project.
o          Place a TProgressBar on Form5
o          Take the Project|Options|Forms menu option and place
               Form5 on the available forms list.
o          Change the code of your project (*_proj.cpp) file to
               look like the example.
*/
#include <vcl\vcl.h>
#include "Unit5.h"
#pragma hdrstop
//---------------------------------------------------------------------------
USEFORM("TAppCreateForm.cpp", Form1);
USERES("Project1.res");
USEFORM("Unit2.cpp", Form2);
USEFORM("Unit3.cpp", Form3);
USEFORM("Unit4.cpp", Form4);
USEFORM("Unit5.cpp", Form5);
//---------------------------------------------------------------------------
WINAPI WinMain(HINSTANCE, HINSTANCE, LPSTR, int)
{
  try
```

```
  {
    Application->Initialize();
    SetApplicationMainFormOnTaskBar(Application, true);
    Application->CreateForm(__classid(TForm5), &Form5);
    Form5->ProgressBar1->Max = 100;
    Form5->Show();   // show a splash screen contain ProgressBar control
    Form5->Update(); // force display of Form5
    Application->CreateForm(__classid(TForm1), &Form1);
    Form5->ProgressBar1->StepBy(25);
    Form5->Label1->Caption =  "Form1 loaded successfully.";
    Form5->Update(); // force display of Form5
    Sleep(3000);
    Application->CreateForm(__classid(TForm2), &Form2);
    Form5->ProgressBar1->StepBy(25);
    Form5->Label1->Caption =  "Form2 loaded successfully.";
    Form5->Update(); // force display of Form5
    Sleep(3000);
    Application->CreateForm(__classid(TForm3), &Form3);
    Form5->ProgressBar1->StepBy(25);
    Form5->Label1->Caption =  "Form3 loaded successfully.";
    Form5->Update(); // force display of Form5
    Sleep(3000);
    Application->CreateForm(__classid(TForm4), &Form4);
    Form5->ProgressBar1->StepBy(25);
    Form5->Label1->Caption =  "Form4 loaded successfully.";
    Form5->Update(); // force display of Form5
    Sleep(3000);
//  delete Form5;
    Application->Run();
  }
  catch (Exception &exception)
  {
    Application->ShowException(&exception);
  }
  return 0;
}
```

Delphi Examples:

```
{
This example shows progress of loading forms as an
application starts up. The code example is placed in the
project source (*.dpr) file.  To see project source, right
click on the executable file in the Project Manager and
select the View Source menu item.  You will need to set up
your project with the following steps before using the codeexample:    Add four additional
forms to a default project.
    Place a TProgressBar on Form5
    Take the Project|Options|Forms menu option and place
          Form5 on the available forms list.
    Change the code of your project (*.dpr) file to look
          like the example.
}
begin
  Application.Initialize;
  with TForm5.Create(nil) do
  try
    Application.MainFormOnTaskbar := True;
    ProgressBar1.Max := 100;
    Show;  // show a splash screen contain ProgressBar control
    Update; // force display of Form5
    Application.CreateForm(TForm1, Form1);
    ProgressBar1.StepBy(25);
    Label1.Caption :=  'Form1 loaded successfully.';
    Update; // force display of Form5
    Sleep(3000);
    Application.CreateForm(TForm2, Form2);
```

```
    ProgressBar1.StepBy(25);
    Label1.Caption :=  'Form2 loaded successfully.';
    Update; // force display of Form5
    Sleep(3000);
    Application.CreateForm(TForm3, Form3);
    ProgressBar1.StepBy(25);
    Label1.Caption :=  'Form3 loaded successfully.';
    Update; // force display of Form5
    Sleep(3000);
    Application.CreateForm(TForm4, Form4);
    ProgressBar1.StepBy(25);
    Label1.Caption :=  'Form4 loaded successfully.';
    Update; // force display of Form5
    Sleep(3000);
  finally
    Free;
  end;
  Application.Run;
```

7.1.1.4.41 TApplication.ShowException Method

Displays a message box for exceptions that are not caught by application code.

Pascal

```
procedure ShowException(E: Exception);
```

C++

```
__fastcall ShowException(Exception E);
```

Description

The HandleException (see page 1935) method calls ShowException by default if no handler is specified for the OnException (see page 1993) event. If an exception handler filters exceptions, ShowException is called for those exceptions that are not filtered out.

To specify how exceptions are handled for an application, write a handler for the OnException (see page 1993) event.

Note: Calling ShowException is rarely necessary in a component-based application, since the default exception handler calls ShowException automatically.

C++ Examples:

```
/*
In addition to displaying the exception message, which
happens by default, the following code shuts down the
application when an exception is not caught and handled.
AppException should be declared a method of TForm1.
*/

#include <System.hpp>
#include <SysUtils.hpp>
```

```
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnException = AppException;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::AppException(TObject *Sender, Exception *E)
{
  Application->ShowException(E);
  Application->Terminate();
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  throw(Exception("Hardware error: Divide by 0"));
}
```

Delphi Examples:

```
{
In addition to displaying the exception message, which
happens by default, the following code shuts down the
application when an exception is not caught and handled.
AppException should be declared a method of TForm1.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnException := AppException;
end;

procedure TForm1.AppException(Sender: TObject; E: Exception);
begin
  Application.ShowException(E);
  Application.Terminate;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  raise EPasswordInvalid.Create('Incorrect password entered');
end;
```

See Also

HandleException (see page 1935)

OnException (see page 1993)

7.1.1.4.42 TApplication.Terminate Method

Ends application execution.

Pascal

```
procedure Terminate;
```

C++

```
__fastcall Terminate();
```

Description

Call Terminate to end the application programmatically. By calling Terminate rather than freeing the application object, you allow the application to shut down in an orderly fashion.

Terminate calls the Windows API PostQuitMessage function to perform an orderly shutdown of the application. Terminate is not immediate.

Terminate is called automatically on a WM_QUIT (see page 5204) message and when the main form closes.

C++ Examples:

```
/*
The following example beeps once for each "beep" passed in
on the command line.  The example terminates the application
if  "exit" is passed in on the command line.  Build the
project to generate a .exe file and then execute that file
from a command line: "ParamCount_proj beep beep exit".
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
//  Use print statements since you can't use the debugger.
//  MessageDlg(
//    "System ParamStr = " + AnsiString(System::ParamStr(i)),
//    mtConfirmation, TMsgDlgButtons() << mbOK, 0);
  for (int i=1;i<=ParamCount();i++)
  {
    if (LowerCase(ParamStr(i)) == "beep")
      Beep();
    else if (LowerCase(ParamStr(i)) == "exit")
      Application->Terminate();
  }
}
/*
In addition to displaying the exception message, which
happens by default, the following code shuts down the
application when an exception is not caught and handled.
AppException should be declared a method of TForm1.
*/

#include <System.hpp>
#include <SysUtils.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnException = AppException;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::AppException(TObject *Sender, Exception *E)
{
  Application->ShowException(E);
  Application->Terminate();
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  throw(Exception("Hardware error: Divide by 0"));
}
```

Delphi Examples:

```
{
The following example beeps once for each "beep" passed in
on the command line.  The example terminates the application
if  "exit" is passed in on the command line.  Build the
project to generate a .exe file and then execute that file
from a command line: "ParamCount_proj beep beep exit".
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
//  Use print statements since you can't use the debugger.
//  MessageDlg(
//    'System ParamCount = ' + IntToStr(System.ParamCount),
```

```
//    mtConfirmation, [mbOK], 0);
  for i := 1 to System.ParamCount do
  begin
    if LowerCase(ParamStr(i)) = 'beep' then
      Beep
    else if LowerCase(ParamStr(i)) = 'exit' then
      Application.Terminate;
    Sleep(250);
  end;
end;
{
In addition to displaying the exception message, which
happens by default, the following code shuts down the
application when an exception is not caught and handled.
AppException should be declared a method of TForm1.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnException := AppException;
end;

procedure TForm1.AppException(Sender: TObject; E: Exception);
begin
  Application.ShowException(E);
  Application.Terminate;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  raise EPasswordInvalid.Create('Incorrect password entered');
end;
```

See Also

Terminated (see page 1988)

7.1.1.4.43 TApplication.UnhookMainWindow Method

Releases a dialog procedure previously hooked by a call to the HookMainWindow (see page 1944) method.

Pascal

```
procedure UnhookMainWindow(Hook: TWindowHook);
```

C++

```
__fastcall UnhookMainWindow(TWindowHook Hook);
```

Description

Use UnhookMainWindow to release the hooked window. Specify the dialog procedure as the value of the Hook parameter.

The TWindowHook (see page 2611) type is the parameter type used for UnhookMainWindow. It is a method-pointer type used for the dialog-procedures of non-VCL dialog boxes. The dialog procedure is similar to a window procedure for a window, in that it processes messages for the dialog box, but its syntax is somewhat different.

For more information about Windows hooks see the SetWindowsEx and UnhookWindowsEx functions in the Windows Help File.

See Also

HookMainWindow (see page 1944)

7.1.1.4.44 TApplication.UnhookSynchronizeWakeup Method

Removes the method that was assigned to the WakeMainThread variable by HookSynchronizeWakeup (see page 1944).

Pascal

```
procedure UnhookSynchronizeWakeup;
```

C++

```
__fastcall UnhookSynchronizeWakeup();
```

Description

Applications rarely, if ever, call UnhookSynchronizeWakeup directly. UnhookSynchronizeWakeup is called from the TApplication (see page 1924) destructor. It resets the WakeMainThread variable to nil (Delphi) or NULL (C++) if that variable was set by the HookSynchronizeWakeup (see page 1944) method.

Warning: You should not modify WakeMainThread for GUI applications because a working handler has been assigned. Console applications may assign a handler to WakeMainThread if the application needs to be notified of a thread synchronization call. If your console application assigns a handler, this is an optimization that only accelerates deliver of notification that a synchronization request is available. You must use CheckSynchronize to perforrm the synchronization itself.

See Also

hooksynchronizewakeup (see page 1944)

WakeMainThread

Synchronize

7.1.1.4.45 TApplication.UpdateAction Method

Generates an OnActionUpdate (see page 1991) event.

Pascal

```
function UpdateAction(Action: TBasicAction): Boolean; reintroduce;
```

C++

```
__fastcall Boolean UpdateAction(TBasicAction Action);
```

Description

When the application is idle, it makes a series of calls to update the properties (such as whether it is enabled, checked, and so on) of every action that is linked to a visible control or menu item. First, that action list that contains the action generates an OnUpdate event. If the action list does not handle the OnUpdate event, then the action is routed to the Application (see page 2612) object's UpdateAction method, which invokes the OnActionUpdate (see page 1991) event handler. (The application's UpdateAction method responds to all unhandled actions in the application.) If the OnActionUpdate (see page 1991) event handler does not update the action, then it is routed to the action's OnUpdate event handler. If that does not update the action, the active control's UpdateAction method is called, followed (if necessary) by the active form's UpdateAction method.

Do not call UpdateAction. It is called automatically when the application is idle. The Action parameter specifies the action to be updated. UpdateAction returns true if the action's properties are updated and require no further processing. Otherwise, UpdateAction returns false, and the default action processing continues.

OnActionUpdate (see page 1991)

ExecuteAction (see page 1935)

UpdateTarget

HandlesTarget

InitiateAction

7.1.1.4.46 TApplication.UseRightToLeftAlignment Method

Specifies whether the application object is in a right-to-left alignment mode.

Pascal

```
function UseRightToLeftAlignment: Boolean;
```

C++

```
__fastcall Boolean UseRightToLeftAlignment();
```

Description

Use UseRightToLeftAlignment to determine whether the application's controls alignment is reversed so that they are aligned from right to left. UseRightToLeftAlignment returns true for Middle Eastern locales if the BiDiMode (see page 1970) property is bdRightToLeft. Otherwise, it returns false.

See Also

BiDiMode

7.1.1.4.47 TApplication.UseRightToLeftReading Method

Specifies whether the application object is in a right-to-left text mode.

Pascal

```
function UseRightToLeftReading: Boolean;
```

C++

```
__fastcall Boolean UseRightToLeftReading();
```

Description

Call UseRightToLeftReading to determine which style and text drawing flags (used in ExTextOut or DrawText) to set for the application's controls.

UseRightToLeftReading returns true for for Middle Eastern locales if the BiDiMode (see page 1970) property is not bdLeftToRight. Otherwise, it returns false.

See Also

BiDiMode

7.1.1.4.48 TApplication.UseRightToLeftScrollBar Method

Specifies whether the vertical scroll bar appears on the left side controls.

Pascal

```
function UseRightToLeftScrollBar: Boolean;
```

C++

```
__fastcall Boolean UseRightToLeftScrollBar();
```

Description

Call UseRightToLeftScrollBar to determine whether the vertical scroll bars appear on the left sides of the application's controls. When UseRightToLeftScrollBar returns true, the vertical scroll bars appear on the left sides of the controls. When UseRightToLeftScrollBar returns false, the vertical scroll bars appear on the right.

UseRightToLeftScrollBar returns true for Middle Eastern locales if BiDiMode (see page 1970) is bdRightToLeft or

bdRightToLeftNoAlign.

BiDiMode

7.1.1.5 TApplication Properties

The properties of the TApplication class are listed here.

Public Properties

	Name	Description
	ActionUpdateDelay (see page 1968)	Delays the call to DoActionIdle.
R	Active (see page 1968)	Specifies whether the application is active and has focus.
R	ActiveFormHandle (see page 1968)	Gives the Windows handle of the currently active form.
	AllowTesting (see page 1969)	Represents information for the IDE.
	AutoDragDocking (see page 1969)	Indicates whether dragged windows are automatically docked.
	BiDiKeyboard (see page 1969)	Specifies the name of the keyboard map that should be used in middle-east locales when text reads from right to left.
	BiDiMode (see page 1970)	Indicates the layout of the application when running under Middle Eastern versions of Windows.
R	CurrentHelpFile (see page 1970)	Indicates the current help file.
	DefaultFont (see page 1971)	This is DefaultFont, a member of class TApplication.
	DialogHandle (see page 1971)	Provides a mechanism for using non-VCL dialog boxes in an application.
	EnumAllWindowsOnActivateHint (see page 1972)	This is EnumAllWindowsOnActivateHint, a member of class TApplication.
R	ExeName (see page 1972)	Contains the file name of the application's executable file including path information.
	Handle (see page 1974)	Provides access to the window handle of the main form (window) of the application.
	HelpFile (see page 1974)	Specifies the name of the default file the application uses to display Help.
R	HelpSystem (see page 1976)	Provides access to the interface for working with the help system.
	Hint (see page 1976)	Specifies the text string that appears in the Help Hint box.
	HintColor (see page 1979)	Determines the color of the hint boxes for the Help Hints for the application.
	HintHidePause (see page 1980)	Specifies the time interval to wait before hiding the Help Hint (see page 1976) if the mouse has not moved from the control or menu item.
	HintPause (see page 1980)	Specifies the time interval that passes before the control's Help Hint (see page 1976) appears when the user places the mouse pointer on a control or menu item.
	HintShortCuts (see page 1980)	Specifies whether the application's pop-up hints include shortcut information.
	HintShortPause (see page 1981)	Specifies the time period to wait before bringing up a hint if another hint has already been shown.
	Icon (see page 1981)	Determines which icon represents the application on the Windows task bar.
R	MainForm (see page 1983)	Identifies which form in the application is the main window.
R	MainFormHandle (see page 1983)	Gives the Windows handle of the application main form.
	MainFormOnTaskBar (see page 1983)	Controls how Windows taskbar buttons are handled by VCL.
R	ModalLevel (see page 1985)	This is ModalLevel, a member of class TApplication.
	ModalPopupMode (see page 1985)	This is ModalPopupMode, a member of class TApplication.
	NonBiDiKeyboard (see page 1985)	Specifies the name of the keyboard map that should be used unless text reads from right to left.
R	PopupControlWnd (see page 1986)	This is PopupControlWnd, a member of class TApplication.
	ShowHint (see page 1986)	Determines whether Help Hints are enabled or disabled for the entire application.
	ShowMainForm (see page 1987)	Determines whether the application shows its main form on startup.
R	Terminated (see page 1988)	Reports whether the application is in the process of shutting down.
	Title (see page 1988)	Contains the text that appears below the icon representing the application when it is minimized.
	UpdateFormatSettings (see page 1989)	Specifies whether format settings are updated automatically when the user alters the system configuration.

	UpdateMetricSettings (see page 1989)	Specifies whether the settings used for the hint window font and the icon title font are updated.

7.1.1.5.1 TApplication.ActionUpdateDelay Property

Delays the call to DoActionIdle.

Pascal

```
property ActionUpdateDelay: Integer;
```

C++

```
__property int ActionUpdateDelay;
```

Description

Use ActionUpdateDelay to delay the call to DoActionIdle. The following example demonstrates the usefulness of this property:

1. Create (see page 1928) an MDI project with a main form, a MDI Child and a TAction class.
2. Link the TAction OnUpdate event to a method.
3. Run (see page 1959) the program and maximize the MDI child.

If you open Windows Task Manager, you can see that CPU usage for the MDI application is nearly 100%. However, if you set Application.ActionUpdateDelay to a non-zero value, the CPU usage for the application is significantly lower than 100%.

See Also

Building a VCL Forms MDI Application Using a Wizard

7.1.1.5.2 TApplication.Active Property

Specifies whether the application is active and has focus.

Pascal

```
property Active: Boolean;
```

C++

```
__property Boolean Active;
```

Description

Active is true while the application is active and false if it is not. Active is set to true in the constructor.

An application is active if the form or application has focus. An application becomes inactive when a window from a different application is about to become activated. When the application closes, Active is set to false in the destructor.

Note: Active is read-only.

See Also

OnActivate (see page 1992)

OnDeactivate (see page 1992)

7.1.1.5.3 TApplication.ActiveFormHandle Property

Gives the Windows handle of the currently active form.

Pascal

```
property ActiveFormHandle: HWND;
```

C++

```
__property HWND ActiveFormHandle;
```

Description

ActiveFormHandle gives the Windows handle of the currently active form.

See Also

MainFormHandle (see page 1983)

7.1.1.5.4 TApplication.AllowTesting Property

Represents information for the IDE.

Pascal

```
property AllowTesting: Boolean;
```

C++

```
__property Boolean AllowTesting;
```

Description

Do not use AllowTesting; it is for internal use only.

7.1.1.5.5 TApplication.AutoDragDocking Property

Indicates whether dragged windows are automatically docked.

Pascal

```
property AutoDragDocking: Boolean;
```

C++

```
__property Boolean AutoDragDocking;
```

Description

Set AutoDragDocking to enable drag-and-dock behavior when windows are dragged. When AutoDragDocking is true, dragged windows are automatically docked when the mouse is released over a docking site. When AutoDragDocking is false, dragged windows are only docked when the Ctrl key is pressed.

7.1.1.5.6 TApplication.BiDiKeyboard Property

Specifies the name of the keyboard map that should be used in middle-east locales when text reads from right to left.

Pascal

```
property BiDiKeyboard: string;
```

C++

```
__property UnicodeString BiDiKeyboard;
```

Description

This name is a string composed of the hexadecimal value of the language identifier (low word) and a device identifier (high word). For example, Saudi Arabian Arabic has a language identifier of 0x0401, so its primary layout is named "00000401".

This keyboard layout is only used when the application runs in a middle eastern locale and the value of BiDiMode (see page 1970) indicates that text should read from right to left.

See Also

BiDiMode (see page 1970)

NonBiDiKeyboard (see page 1985)

7.1.1.5.7 TApplication.BiDiMode Property

Indicates the layout of the application when running under Middle Eastern versions of Windows.

Pascal

```
property BiDiMode: TBiDiMode;
```

C++

```
__property TBiDiMode BiDiMode;
```

Description

Use BiDiMode to specify the bi-directional mode for the application. The bi-directional mode controls the direction in which text appears (left-to-right or right-to-left), the placement of vertical scroll bars, and the default alignment of text when the application runs in Middle Eastern locales.

The application's BiDiMode is used in the ShowMessage procedure and the MessageBox (see page 1949) method. It also serves as the ParentBiDiMode for forms and for popup menus that are not activated by a control.

See Also

ParentBiDiMode

ShowMessage

MessageBox (see page 1949)

7.1.1.5.8 TApplication.CurrentHelpFile Property

Indicates the current help file.

Pascal

```
property CurrentHelpFile: string;
```

C++

```
__property UnicodeString CurrentHelpFile;
```

Description

Read CurrentHelpFile to determine the name of the help file that is currently used by the application when it executes a help command (via the HelpCommand (see page 1941) method) or brings up context sensitive help (via the HelpContext (see page 1941) or HelpJump (see page 1942) method). If CurrentHelpFile is an empty string, the application ignores attempts to display Help.

If the active form has an associated help file, this is the value of CurrentHelpFile. Otherwise, CurrentHelpFile reflects the value of the application's HelpFile (see page 1974) property.

See Also

PropertyName

ActiveCustomForm (see page 2452)

HelpCommand (see page 1941)

HelpJump (see page 1942)

HelpSystem (see page 1976)

HelpContext (see page 1941)

7.1.1.5.9 TApplication.DefaultFont Property

Pascal

```
property DefaultFont: TFont;
```

C++

```
__property TFont DefaultFont;
```

Description

This is DefaultFont, a member of class TApplication.

7.1.1.5.10 TApplication.DialogHandle Property

Provides a mechanism for using non-VCL dialog boxes in an application.

Pascal

```
property DialogHandle: HWnd;
```

C++

```
__property HWnd DialogHandle;
```

Description

Use DialogHandle when displaying a modeless dialog box that was created using the CreateDialog API function. Assigning the handle of the modeless dialog box to DialogHandle allows the dialog to see messages from the application's message loop.

Assign the handle of the modeless dialog box to DialogHandle when it receives an activation message (WM_NCACTIVATE (see page 5189)) and set DialogHandle to zero when the dialog box receives a deactivation message.

Delphi Examples:

```
{
Here is replacement of the window procedure for Delphi's
encapsulation of the Windows search-and-replace common dialog
box. Click on Button2 to activate an open dialog and send
a WM_NCACTIVATE to FindReplaceWndProc.
}
function FindReplaceWndProc(Wnd: HWND; Msg, WParam, LParam: Longint): Longint; stdcall;

  function CallDefWndProc: Longint;
  begin
    Result := CallWindowProc(Pointer(GetProp(Wnd,
      MakeIntAtom(WndProcPtrAtom))), Wnd, Msg, WParam, LParam);
  end;

begin
  case Msg of
    WM_DESTROY:
      if Application.DialogHandle = Wnd then Application.DialogHandle := 0;
    WM_NCACTIVATE:
      if WParam <> 0 then
      begin
        if Application.DialogHandle = 0 then Application.DialogHandle := Wnd;
      end else
      begin
```

```
          if Application.DialogHandle = Wnd then Application.DialogHandle := 0;
        end;
      WM_NCDESTROY:
        begin
          Result := CallDefWndProc;
          RemoveProp(Wnd, MakeIntAtom(WndProcPtrAtom));

Handle (see page 1974)

7.1.1.5.11 TApplication.EnumAllWindowsOnActivateHint Property

Pascal

```
property EnumAllWindowsOnActivateHint: Boolean;
```

C++

```
__property Boolean EnumAllWindowsOnActivateHint;
```

Description

This is EnumAllWindowsOnActivateHint, a member of class TApplication.

7.1.1.5.12 TApplication.ExeName Property

Contains the file name of the application's executable file including path information.

Pascal

```
property ExeName: string;
```

C++

```
__property UnicodeString ExeName;
```

Description

Use ExeName to obtain the name of the executable file for the application. ExeName is the fully-qualified name, including the path to the application's executable.

The name of the application is the root name of the project with an .EXE extension. By default, this name is PROJECT1.EXE. To change the ExeName, save the project by the desired new root name and rebuild the application. ExeName will reflect the change to the project file name.

ExeName is a read-only property.

C++ Examples:

```
/*
This example copies a specified old file to a new file.  Add
a TSaveDialog to the form.  Also add two TEdits, two TLabels
and a TButton with the OnClick event named Save1Click. Change
the Old Path and New Path to move files outside the Debug
directory, Old File and New File will not take a relative path.
*/

#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Save1Click(TObject *Sender)
{
  AnsiString temp1 = Edit4->Text;
  AnsiString temp2 = ExtractFileName(Edit1->Text);
  AnsiString NewFileName = temp1 + temp2;
  AnsiString OldFileName =
    Edit3->Text + ExtractFileName(Edit2->Text);
  AnsiString Msg = Format("Copy %s to %s", ARRAYOFCONST((OldFileName, NewFileName)));
  if (MessageDlg(Msg, mtCustom, TMsgDlgButtons() << mbOK << mbCancel, 0) == mrOk)
  {
    std::auto_ptr<TFileStream> OldFile(new TFileStream(OldFileName, fmOpenRead |
fmShareDenyWrite));
    std::auto_ptr<TFileStream> NewFile(new TFileStream(NewFileName, fmCreate |
fmShareDenyRead));
    NewFile->CopyFrom(OldFile.get(), OldFile->Size);
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit3->Text = ExtractFilePath(Application->ExeName);
  Edit4->Text = Edit3->Text;
}
```

Delphi Examples:

```
{
This example copies a specified old file to a new file.  Add
a TSaveDialog to the form.  Also add two TEdits, two TLabels
and a TButton with the OnClick event named Save1Click. Change
the Old Path and New Path to move files outside the Debug
directory, Old File and New File will not take a relative path.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Edit3.Text := ExtractFilePath(Application.ExeName);
  Edit4.Text := Edit3.Text;
end;

procedure TForm1.Save1Click(Sender: TObject);
var
  NewFileName, OldFileName: string;
  temp1, temp2: string;
  Msg: string;
  NewFile: TFileStream;
  OldFile: TFileStream;
begin
  temp1 := Edit4.Text;
```

```
    temp2 := ExtractFileName(Edit1.Text);
    NewFileName := temp1 + temp2;
    OldFileName :=
      Edit3.Text + ExtractFileName(Edit2.Text);
    Msg := Format('Copy %s to %s?', [OldFileName, NewFileName]);
    if MessageDlg(Msg, mtCustom, mbOKCancel, 0) = mrOK then
    begin
      OldFile := TFileStream.Create(
        OldFileName, fmOpenRead or fmShareDenyWrite);
      try
        NewFile := TFileStream.Create(
          NewFileName, fmCreate or fmShareDenyRead);
        try
          NewFile.CopyFrom(OldFile, OldFile.Size);
        finally
          FreeAndNil(NewFile);
        end;
      finally
        FreeAndNil(OldFile);
      end;
    end;
  end;

Title (see page 1988)

7.1.1.5.13 TApplication.Handle Property

Provides access to the window handle of the main form (window) of the application.

Pascal

```
property Handle: HWnd;
```

C++

```
__property HWnd Handle;
```

Description

Use Handle when calling Windows API functions that require a parent window handle. For example, a DLL that displays its own top-level pop-up windows needs a parent window to display its windows in the application. Using the Handle property makes such windows part of the application, so that they are minimized, restored, enabled, and disabled with the application.

Note: When writing a DLL that uses VCL forms, assign the window handle of the host EXE's main window to the DLL's Application.HandleApplication->Handle property. This makes the DLL's form part of the host application. Never assign to the Handle property in an EXE.

See Also

DialogHandle (see page 1971)

MainForm (see page 1983)

7.1.1.5.14 TApplication.HelpFile Property

Specifies the name of the default file the application uses to display Help.

Pascal

```
property HelpFile: string;
```

C++

```
__property UnicodeString HelpFile;
```

Description

Use HelpFile to specify a default help file for applications that use the Help system. Either assign a file name to the HelpFile property at runtime, or specify a Help File on the Application (see page 2612) page of the Project|Options dialog box at design time.

The Help system specified by HelpSystem (see page 1976) displays help topics from the file specified by CurrentHelpFile (see page 1970). HelpFile supplies the value of CurrentHelpFile (see page 1970) unless there is a help file associated with the active form.

By default, HelpFile is a null string, and the application's Help method ignores attempts to display Help unless the active form has an associated help file.

C++ Examples:

```
/*
The following code changes the Help file depending on the
active form, before the help viewer is called. AppHelp is
assigned to the OnHelp event handler of Application in the
OnCreate event of Form1.
*/
bool __fastcall TForm1::AppHelp(Word Command, int Data, bool &CallHelp)
{
  Application->HelpFile = Screen->ActiveForm->Name + ".hlp";
  CallHelp = true;
  return true;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnHelp = AppHelp;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  const DATANOTFOUND = 714;
  Application->HelpContext(DATANOTFOUND);
}
```

Delphi Examples:

```
{
The following code changes the Help file depending on the
active form, before the help viewer is called. AppHelp is
assigned to the OnHelp event handler of Application in the
OnCreate event of Form1.
}
function TForm1.AppHelp(
  Command: Word; Data: Longint; var CallHelp: Boolean) : Boolean;
var helpstring : String;
begin
  helpstring := Screen.ActiveForm.Name + '.hlp';
  MessageDlg(
    'Using ' + helpstring + ' as the help file.',
    mtInformation, [mbOK], 0);
  Application.HelpFile := helpstring;
  CallHelp := True;
end;

procedure TForm1.Button1Click(Sender: TObject);
const DATANOTFOUND = 714;
begin
```

```
  Application.HelpContext(DATANOTFOUND);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnHelp := AppHelp;
end;
```

7.1.1.5.15 TApplication.HelpSystem Property

Provides access to the interface for working with the help system.

Pascal

```
property HelpSystem: IHelpSystem;
```

C++

```
__property IHelpSystem HelpSystem;
```

Description

TApplication (see page 1924) uses IHelpSystem (see page 3231) to interact with a Help system manager. This interface includes methods for displaying help topics based on a keyword or topic ID.

Applications can use the HelpSystem property to interact directly with the Help system manager, or they can use the application's help-oriented methods such as HelpCommand (see page 1941) and HelpJump (see page 1942).

HelpFile (see page 1974)

ShowTableOfContents (see page 3233)

7.1.1.5.16 TApplication.Hint Property

Specifies the text string that appears in the Help Hint box.

Pascal

```
property Hint: string;
```

C++

```
__property UnicodeString Hint;
```

Description

TApplication (see page 1924)'s Hint property is assigned the Hint value of the control or menu item that the mouse is currently moving over. It can also be assigned a string value that informs the user of some action, error, or other type of information. Therefore, use Hint either to:

Transfer hints from controls to another area of display, such as a status bar, using the OnHint (see page 1997) event handler. This reads the Hint property.

Indicate the status of the application while it is processing some action. This sets the Hint property.

Help Hints appear when the OnHint (see page 1997) event occurs. Therefore, if TApplication (see page 1924)'s Hint property is assigned to the status bar's caption, for example, the caption of the status bar control displays the current string value of the Hint property during an OnHint (see page 1997) event.

There are two parts to the Hint string: short and long. Short hints are used by pop-up tool tips. Long hints are used by the status bar, separated by the | character. Use the global functions GetShortHint and GetLongHint, from the Controls unit to extract the long and short hints from a hint string.

Note: When setting Hint to a message informing the user of an event occurring in the application, remember that, by default, the Hint string is reset to a control's Hint when the mouse cursor moves over a control.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
/*
Note:   It is not actually necessary to write an OnHint
event handler to display hints on the status bar. This can
be accomplished more simply by setting the status bar's
AutoHint property and SimplePanel property.
This shows how the OnHint event handler is declared as a
public method of the form.
*/
```

```
/*
Here is the code to add to the unit file.  It provides the
implementation of the DisplayHint method and assigns it to
the Application in the form's OnCreate event handler.
Note:   It is not actually necessary to write an OnHint event
handler to display hints on the status bar. This can be
accomplished more simply by setting the status bar's AutoHint
property.
*/
void __fastcall TForm1::DisplayHint(TObject *Sender)
{
  StatusBar1->SimpleText = GetLongHint(Application->Hint);
}

// Here is the form's OnCreate event handler.
// It assigns the application's OnHint event handler at
// runtime because the Application is not available in the
// Object Inspector
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnHint = DisplayHint;
}
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}
{
Note:   It is not actually necessary to write an OnHint
event handler to display hints on the status bar. This can
be accomplished more simply by setting the status bar's
AutoHint property and SimplePanel property.
This shows how the OnHint event handler is declared as a
public method of the form.
}
type

THintWindow

7.1.1.5.17 TApplication.HintColor Property

Determines the color of the hint boxes for the Help Hints for the application.

Pascal

```
property HintColor: TColor;
```

C++

```
__property TColor HintColor;
```

Description

Use HintColor to specify the hint box color. A default color value of clInfoBk (see page 2909) is set for the HintColor property in the constructor when the application is created. To change the HintColor, assign it a new TColor (see page 2878) value at runtime.

Tip: To further customize the hint window, create a custom descendant of THintWindow and assign it to the global HintWindowClass (see page 2615) variable.

Hint (see page 1976)

THintWindow

HintWindowClass (see page 2615)

7.1.1.5.18 TApplication.HintHidePause Property

Specifies the time interval to wait before hiding the Help Hint (see page 1976) if the mouse has not moved from the control or menu item.

Pascal

```
property HintHidePause: Integer;
```

C++

```
__property int HintHidePause;
```

Description

Use HintHidePause to specify a wait time in milliseconds, which is different from the default value of 2500 ms or 2 1/2 seconds that is set in the constructor. The Help Hint (see page 1976) for the control or menu item is specified in the Hint (see page 1976) property.

Note: The default is a predefined constant value that is several times longer than HintPause (see page 1980).

See Also

Hint (see page 1976)

HintPause (see page 1980)

HintShortPause (see page 1981)

7.1.1.5.19 TApplication.HintPause Property

Specifies the time interval that passes before the control's Help Hint (see page 1976) appears when the user places the mouse pointer on a control or menu item.

Pascal

```
property HintPause: Integer;
```

C++

```
__property int HintPause;
```

Description

Use HintPause to change the default pause time of 500 ms or 1/2 second that is set in the constructor. When assigning a value to HintPause, specify the interval in milliseconds. The Help Hint (see page 1976) displayed at the end of the pause is specified in the Hint (see page 1976) property.

See Also

HintHidePause (see page 1980)

Hint (see page 1976)

HintShortPause (see page 1981)

7.1.1.5.20 TApplication.HintShortCuts Property

Specifies whether the application's pop-up hints include shortcut information.

Pascal

```
property HintShortCuts: Boolean;
```

C++

```
__property Boolean HintShortCuts;
```

Description

Use HintShortCuts to specify whether the application's pop-up hints include shortcut information. If HintShortCuts is true, the shortcut information is displayed. For example, if HintShortCuts is true, the hint for the Cut command might be "Cut (Ctrl+X)" instead of "Cut".

7.1.1.5.21 TApplication.HintShortPause Property

Specifies the time period to wait before bringing up a hint if another hint has already been shown.

Pascal

```
property HintShortPause: Integer;
```

C++

```
__property int HintShortPause;
```

Description

Use HintShortPause to reduce the flicker when moving the mouse quickly over a set of buttons that all have help hints on. Specify a value in milliseconds that is different from the default value of 50 ms that is set in the constructor.

See Also

HintHidePause (see page 1980)

Hint (see page 1976)

HintPause (see page 1980)

7.1.1.5.22 TApplication.Icon Property

Determines which icon represents the application on the Windows task bar.

Pascal

```
property Icon: TIcon;
```

C++

```
__property TIcon Icon;
```

Description

Use Icon to assign a specific icon to represent the application. Set the Icon property by either:

Assigning it a TIcon (see page 2768) at runtime.

Loading an icon on the Application (see page 2612) page of the Project|Options dialog box at design time.

Icon represents the application when it is minimized and appears either on the Windows desktop or task bar.

C++ Examples:

```
/*
The following code allows the user to use a dialog box to
redefine the icon for the application at run time. When the
user clicks Button1, OpenDialog1 executes and the user
specifies an icon filename. The Icon is then assigned to the
application.  At runtime, click Button1 to select the icon,
then minimize the application to see the icon.
*/
```

```
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  OpenPictureDialog1->DefaultExt = GraphicExtension(__classid(TIcon));
  OpenPictureDialog1->FileName = GraphicFileMask(__classid(TIcon));
  OpenPictureDialog1->Filter = GraphicFilter(__classid(TIcon));
  OpenPictureDialog1->Options.Clear();
  OpenPictureDialog1->Options << ofFileMustExist << ofHideReadOnly << ofNoChangeDir;
  while (true)
  {
    if (OpenPictureDialog1->Execute())
    {
      if (!OpenPictureDialog1->Options.Contains(ofExtensionDifferent))
      {
        Application->Icon->LoadFromFile(OpenPictureDialog1->FileName);
        break;
      }
      else // reset Options to remove ofExtensionDifferent
      {
        OpenPictureDialog1->Options.Clear();
        OpenPictureDialog1->Options << ofFileMustExist << ofHideReadOnly << ofNoChangeDir;
      }
    }
    else // user cancelled
      break;
  }
}
```

Delphi Examples:

```
{
The following code allows the user to use a dialog box to
redefine the icon for the application at run time. When the
user clicks Button1, OpenDialog1 executes and the user
specifies an icon filename. The Icon is then assigned to the
application.  At runtime, click Button1 to select the icon,
then minimize the application to see the icon.
}
procedure TForm1.Button1Click(Sender: TObject);
var
Done: Boolean;
filenamestring : String;
begin
  OpenPictureDialog1.DefaultExt := GraphicExtension(TIcon);
  filenamestring := GraphicFileMask(TIcon);
  OpenPictureDialog1.FileName := filenamestring;
  OpenPictureDialog1.Filter := GraphicFilter(TIcon);
  OpenPictureDialog1.Options := [ ofFileMustExist, ofHideReadOnly, ofNoChangeDir ];
  Done := False;
  while not Done do
  begin
  if OpenPictureDialog1.Execute then
    begin
    if not (ofExtensionDifferent in OpenPictureDialog1.Options) then
      begin
      Application.Icon.LoadFromFile(OpenPictureDialog1.FileName);
      Done := True;
      end
    else
//      OpenPictureDialog1.Options := OpenPictureDialog1.Options - ofExtensionDifferent;
    end
  else { User cancelled }
    Done := True;
  end;
end;
```

7.1.1.5.23 TApplication.MainForm Property

Identifies which form in the application is the main window.

Pascal

```
property MainForm: TForm;
```

C++

```
__property TForm * MainForm;
```

Description

Use MainForm to determine the form that acts as the application's main window. The main form is the first form created in the main body of the application. When the main form closes, the application terminates.

When a new project is created, Form1 automatically becomes the value of the MainForm property. To assign a different form to the MainForm property, use the Forms (see page 1921) page of the Project|Options dialog box at design time. MainForm cannot be modified at runtime; it is read-only.

7.1.1.5.24 TApplication.MainFormHandle Property

Gives the Windows handle of the application main form.

Pascal

```
property MainFormHandle: HWND;
```

C++

```
__property HWND MainFormHandle;
```

Description

MainFormHandle gives the Windows handle of the application main form.

See Also

ActiveFormHandle (see page 1968)

7.1.1.5.25 TApplication.MainFormOnTaskBar Property

Controls how Windows taskbar buttons are handled by VCL.

Pascal

```
property MainFormOnTaskBar: Boolean;
```

C++

```
__property Boolean MainFormOnTaskBar;
```

Description

The MainFormOnTaskBar property controls how Windows taskbar buttons are handled by VCL.

If the property is true, a taskbar button represents the application's main form and displays its caption. If false, a taskbar button represents the application's (hidden) main window and bears the application's Title (see page 1988).

MainFormOnTaskBar must be true to use Windows Vista Aero effects. These include live taskbar thumbnails, Dynamic Windows, Windows Flip, and Windows Flip 3D.

If a change to default behavior is required, MainFormOnTaskBar should be set in the .dpr file after Application.Initialize (see page 1945) and before main form creation. The MainFormOnTaskBar setting is intended to persist for the life of the application; later runtime changes of this property could result in unexpected behavior.

MainFormOnTaskBar defaults to `True` for applications created in Delphi 2007 and later products and `False` for earlier products.

The property can be applied to older applications. Note that it affects the Z-order of your MainForm (see page 1983) in case your application depends on this.

To update existing VCL applications, add the following line to the project's .dpr file after `Application.Initialize (see page 1945);`:

```
Application.MainFormOnTaskbar := True;
```

This line is automatically added to new projects.

For further information, see http://www.microsoft.com/windows/products/windowsvista/features/experiences/aero.mspx.

Delphi Examples:

```
{
This example shows progress of loading forms as an
application starts up. The code example is placed in the
project source (*.dpr) file.  To see project source, right
click on the executable file in the Project Manager and
select the View Source menu item.  You will need to set up
your project with the following steps before using the codeexample:    Add four additional
forms to a default project.
    Place a TProgressBar on Form5
    Take the Project|Options|Forms menu option and place
          Form5 on the available forms list.
    Change the code of your project (*.dpr) file to look
          like the example.
}
begin
  Application.Initialize;
  with TForm5.Create(nil) do
  try
    Application.MainFormOnTaskbar := True;
    ProgressBar1.Max := 100;
    Show;  // show a splash screen contain ProgressBar control
    Update; // force display of Form5
    Application.CreateForm(TForm1, Form1);
    ProgressBar1.StepBy(25);
    Label1.Caption :=  'Form1 loaded successfully.';
    Update; // force display of Form5
    Sleep(3000);
    Application.CreateForm(TForm2, Form2);
    ProgressBar1.StepBy(25);
```

```
    Label1.Caption :=  'Form2 loaded successfully.';
    Update; // force display of Form5
    Sleep(3000);
    Application.CreateForm(TForm3, Form3);
    ProgressBar1.StepBy(25);
    Label1.Caption :=  'Form3 loaded successfully.';
    Update; // force display of Form5
    Sleep(3000);
    Application.CreateForm(TForm4, Form4);
    ProgressBar1.StepBy(25);
    Label1.Caption :=  'Form4 loaded successfully.';
    Update; // force display of Form5
    Sleep(3000);
  finally
    Free;
  end;
  Application.Run;
```

Pascal

```
property ModalPopupMode: TPopupMode;
```

C++

```
__property TPopupMode ModalPopupMode;
```

Description

This is ModalPopupMode, a member of class TApplication.

7.1.1.5.28 TApplication.NonBiDiKeyboard Property

Specifies the name of the keyboard map that should be used unless text reads from right to left.

Pascal

```
property NonBiDiKeyboard: string;
```

C++

```
__property UnicodeString NonBiDiKeyboard;
```

Description

Use NonBiDiKeyboard to specify the keyboard map that should be used. This name is a string composed of the hexadecimal value of the language identifier (low word) and a device identifier (high word). For example, U.S. English has a language

identifier of 0x0409, so the primary U.S. English layout is named "00000409". Variants of U.S. English layout (such as the Dvorak layout) are named "00010409", "00020409", and so on.

If the application is running in a middle eastern locale and the value of BiDiMode (see page 1970) indicates that text should read from right to left, the application uses BiDiKeyboard (see page 1969) instead.

See Also

BiDiMode (see page 1970)

BiDiKeyboard (see page 1969)

7.1.1.5.29 TApplication.PopupControlWnd Property

Pascal

```
property PopupControlWnd: HWND;
```

C++

```
__property HWND PopupControlWnd;
```

Description

This is PopupControlWnd, a member of class TApplication.

7.1.1.5.30 TApplication.ShowHint Property

Determines whether Help Hints are enabled or disabled for the entire application.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

Use ShowHints to choose when to display Help Hints. If ShowHint is true, Help Hints are enabled; if ShowHint is false, Help Hints are disabled. The default value is true. Help Hints are specified in the Hint (see page 1976) property.

Setting ShowHint for the application to false disables all Help Hints, regardless of the value of the ShowHint properties for individual controls.

Tip: You can customize the hint window by creating a custom descendant of THintWindow and assigning it to the global HintWindowClass (see page 2615) variable.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
```

```
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}
```

See Also

Hint (see page 1976)

OnHint (see page 1997)

ParentShowHint

ShowHint

THintWindow

7.1.1.5.31 TApplication.ShowMainForm Property

Determines whether the application shows its main form on startup.

Pascal

```
property ShowMainForm: Boolean;
```

C++

```
__property Boolean ShowMainForm;
```

Description

Use ShowMainForm to control whether and when the application shows its main form.

The default value of true is set in the constructor. When ShowMainForm is true, the main window shows automatically when the application starts. The MainForm (see page 1983) property specifies which form is the main form.

To hide the main form at startup, set ShowMainForm to false in the main project file before the call to the Run (see page 1959) method. Make sure that the Visible property of the form is also false.

See Also

Create (see page 1928)

MainForm (see page 1983)

Run (see page 1959)

Visible

Hiding the Main Form

7.1.1.5.32 TApplication.Terminated Property

Reports whether the application is in the process of shutting down.

Pascal

```
property Terminated: Boolean;
```

C++

```
__property Boolean Terminated;
```

Description

Terminated is used when calling the ProcessMessages (see page 1954) method so that the application doesn't perform unnecessary actions after the shut-down process has been triggered. ProcessMessages (see page 1954) sets Terminated to true when it receives a WM_QUIT (see page 5204) message.

An application usually receives a WM_QUIT (see page 5204) message because the main window of the application has closed, or because the Terminate (see page 1962) method has been called.

Note: For applications using calculation-intensive loops, call ProcessMessages (see page 1954) periodically, and also check Terminated to determine whether to abort the calculation and allow the application to terminate.

See Also

ProcessMessages (see page 1954)

Terminate (see page 1962)

7.1.1.5.33 TApplication.Title Property

Contains the text that appears below the icon representing the application when it is minimized.

Pascal

```
property Title: string;
```

C++

```
__property UnicodeString Title;
```

Description

Use the Title property to modify the name of the text string appearing below the icon of the application. The default value is taken from the DLL or EXE file name at runtime.

Set the Title at runtime, or enter the value of the Title property on the Application (see page 2612) page of the Project | Options dialog box.

C++ Examples:

```
/*
This code displays the name of your project in an edit box:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Edit1->Text = Application->Title;
}
```

Delphi Examples:

```
{
This code displays the name of your project in an edit box:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Edit1.Text := Application.Title;
end;
```

See Also

ExeName (see page 1972)

Icon (see page 1981)

7.1.1.5.34 TApplication.UpdateFormatSettings Property

Specifies whether format settings are updated automatically when the user alters the system configuration.

Pascal

```
property UpdateFormatSettings: Boolean;
```

C++

```
__property Boolean UpdateFormatSettings;
```

Description

Use UpdateFormatSettings to control automatic updating of format settings. The default of true is set in the constructor. UpdateFormatSettings is checked when the application receives a WM_WININICHANGE (see page 5219) message.

Using the default format settings is recommended. These settings are initialized to the Windows local settings.

See Also

variables

7.1.1.5.35 TApplication.UpdateMetricSettings Property

Specifies whether the settings used for the hint window font and the icon title font are updated.

Pascal

```
property UpdateMetricSettings: Boolean;
```

C++

```
__property Boolean UpdateMetricSettings;
```

Description

Use UpdateMetricSettings to specify whether or not the hint window font and the icon title font on the desk top should be updated to reflect the system settings when those settings are changed.

The initial value of true is set in the constructor.

7.1.1.6 TApplication Events

The events of the TApplication class are listed here.

Public Events

	Name	Description
	OnActionExecute (see page 1990)	Occurs when an action's Execute method is called and its action list has not already handled it.
	OnActionUpdate (see page 1991)	Occurs when an action's Update method is called and its action list has not already handled it.
	OnActivate (see page 1992)	Occurs when an application becomes active.
	OnDeactivate (see page 1992)	Occurs when an application becomes inactive.
	OnException (see page 1993)	Occurs when an unhandled exception occurs in the application.
	OnGetActiveFormHandle (see page 1995)	This is OnGetActiveFormHandle, a member of class TApplication.
	OnGetMainFormHandle (see page 1995)	This is OnGetMainFormHandle, a member of class TApplication.
	OnHelp (see page 1995)	Occurs when the application receives a request for help.
	OnHint (see page 1997)	Occurs when the mouse pointer moves over a control or menu item that can display a Help Hint (see page 1976).
	OnIdle (see page 1998)	Occurs when an application becomes idle.
	OnMessage (see page 2003)	Occurs when the application receives a Windows message.
	OnMinimize (see page 2004)	Occurs when an application is minimized.
	OnModalBegin (see page 2006)	Occurs when a modal form is opened.
	OnModalEnd (see page 2006)	Occurs when a modal form is closed.
	OnRestore (see page 2006)	Occurs when the previously minimized application is restored to its normal size.
	OnSettingChange (see page 2007)	Occurs when Windows notifies the application that a system-wide setting has changed.
	OnShortCut (see page 2007)	Occurs when the user presses a key (before the OnKeyDown event).
	OnShowHint (see page 2008)	Occurs when the application is about to display the hint window for a Help Hint (see page 1976).

7.1.1.6.1 TApplication.OnActionExecute Event

Occurs when an action's Execute method is called and its action list has not already handled it.

Pascal

```
property OnActionExecute: TActionEvent;
```

C++

```
__property TActionEvent OnActionExecute;
```

Description

Use the OnExecute event handler to respond when a user invokes actions whose action lists do not have OnExecute event handlers.

If the action list that contains the action does not handle it in an OnExecute event handler, then the action is routed to the Application (see page 2612) object's ExecuteAction (see page 1935) method, which invokes the OnActionExecute event handler. (The application's ExecuteAction (see page 1935) method applies to all actions in the application.)

The Handled parameter of the event handler returns false by default. If the handler handles the event, it should change Handled to true, thereby preventing further attempts to handle the action. When the event handler exits with Handled set to false, the action's OnExecute event occurs. If the action remains unhandled after that, the active control's ExecuteAction (see page 1935) method is called to allow the action to execute with an identified target. Finally, the active form's ExecuteAction (see page 1935) method is called if all other handlers do not handle the action.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

OnActionUpdate (see page 1991)

ExecuteAction (see page 1935)

OnExecute

OnExecute

ExecuteAction

OnActionExecute

What Happens When an Action Fires

7.1.1.6.2 TApplication.OnActionUpdate Event

Occurs when an action's Update method is called and its action list has not already handled it.

Pascal

```
property OnActionUpdate: TActionEvent;
```

C++

```
__property TActionEvent OnActionUpdate;
```

Description

Use the OnActionUpdate event handler to update the properties of an action when the application is idle if the action's action list does not handle it in an OnUpdate event handler.

If the action list that contains the action does not update it in an OnUpdate event handler, the action is routed to the Application (see page 2612) object's UpdateAction (see page 1965) method, which invokes the OnActionUpdate event handler. (The application's UpdateAction (see page 1965) method applies to all actions in the application.)

The Handled parameter of the event handler returns false by default. If the handler updates the event, it should change Handled to true, thereby ending the processing of the action. When the event handler exits with Handled set to false, the action's OnUpdate event occurs. If the action is not updated after that, the active control's UpdateAction (see page 1965) method is called to allow the target to update the action. Finally, the active form's UpdateAction (see page 1965) method is called if all other handlers do not handle the action.

Note: OnActionUpdate occurs after the application's OnIdle (see page 1998) event.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

OnActionUpdate

7.1.1.6.3 TApplication.OnActivate Event

Occurs when an application becomes active.

Pascal

```
property OnActivate: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnActivate;
```

Description

Write an OnActivate event handler to perform special processing when the application becomes active.

An application becomes active when it is initially run or when focus moves from another Windows application back to any window of the application.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

See Also

Active (see page 1968)

OnDeactivate (see page 1992)

OnActivate

7.1.1.6.4 TApplication.OnDeactivate Event

Occurs when an application becomes inactive.

Pascal

```
property OnDeactivate: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDeactivate;
```

Description

Write an OnDeactivate event handler to perform any special processing that should occur immediately before the application is deactivated. The OnDeactivate event occurs when the user switches from the application to another Windows application.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

C++ Examples:

```
/*
The following code minimizes an application when it's
deactivated. Note that AppDeactivate should be declared a
method of TForm1.  Click anywhere outside of the form
to deactivate it.
*/
void __fastcall TForm1::AppDeactivate(TObject *Sender)
{
  Application->Minimize();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnDeactivate = AppDeactivate;
}
```

Delphi Examples:

```
{
The following code minimizes an application when it's
deactivated. Note that AppDeactivate should be declared a
method of TForm1.  Click anywhere outside of the form
to deactivate it.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnDeactivate := AppDeactivate;
end;
procedure TForm1.AppDeactivate(Sender: TObject);
begin
  Application.Minimize;
end;
```

See Also

Active (see page 1968)

OnActivate (see page 1992)

OnDeactivate

7.1.1.6.5 TApplication.OnException Event

Occurs when an unhandled exception occurs in the application.

Pascal

```
property OnException: TExceptionEvent;
```

C++

```
__property TExceptionEvent OnException;
```

Description

Use OnException to change the default behavior that occurs when an exception is not handled by application code. The OnException event handler is called automatically in the HandleException (see page 1935) method.

OnException only handles exceptions that occur during message processing. Exceptions that occur before or after the execution of the application's Run (see page 1959) method do not generate OnException events.

If an exception passes through the tryblocks in the application code, the application automatically calls the HandleException (see page 1935) method. Unless the exception object is EAbort, HandleException (see page 1935) calls the OnException

handler, if one exists. Otherwise, it calls ShowException (see page 1961) to display a message box indicating an error occurred.

TExceptionEvent (see page 2599) is the type of the OnException event. It points to a method that handles exceptions in the application. The Sender parameter is the object that raised the exception, and E is the exception object.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

C++ Examples:

```
/*
In addition to displaying the exception message, which
happens by default, the following code shuts down the
application when an exception is not caught and handled.
AppException should be declared a method of TForm1.
*/

#include <System.hpp>
#include <SysUtils.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnException = AppException;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::AppException(TObject *Sender, Exception *E)
{
  Application->ShowException(E);
  Application->Terminate();
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  throw(Exception("Hardware error: Divide by 0"));
}
```

Delphi Examples:

```
{
In addition to displaying the exception message, which
happens by default, the following code shuts down the
application when an exception is not caught and handled.
AppException should be declared a method of TForm1.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnException := AppException;
end;

procedure TForm1.AppException(Sender: TObject; E: Exception);
begin
  Application.ShowException(E);
  Application.Terminate;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  raise EPasswordInvalid.Create('Incorrect password entered');
end;
```

HandleException (see page 1935)

ShowException (see page 1961)

OnException

7.1.1.6.6 TApplication.OnGetActiveFormHandle Event

Pascal

```
property OnGetActiveFormHandle: TGetHandleEvent;
```

C++

```
__property TGetHandleEvent OnGetActiveFormHandle;
```

Description

This is OnGetActiveFormHandle, a member of class TApplication.

7.1.1.6.7 TApplication.OnGetMainFormHandle Event

Pascal

```
property OnGetMainFormHandle: TGetHandleEvent;
```

C++

```
__property TGetHandleEvent OnGetMainFormHandle;
```

Description

This is OnGetMainFormHandle, a member of class TApplication.

7.1.1.6.8 TApplication.OnHelp Event

Occurs when the application receives a request for help.

Pascal

```
property OnHelp: THelpEvent;
```

C++

```
__property THelpEvent OnHelp;
```

Description

Write an OnHelp event handler to perform special processing when the user requests help. The HelpContext (see page 1941) and the HelpJump (see page 1942) methods automatically trigger the OnHelp event.

Set CallHelp to true if the application should still invoke the help system after the event. Set CallHelp to false to prevent the default response by the help system. All application help methods go through OnHelp. The application calls the help system only if OnHelp's CallHelp parameter returns true or if no OnHelp event handler is assigned.

The event handler returns true if it succeeds, false if it fails.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

C++ Examples:

```
/*
The following code changes the Help file depending on the
active form, before the help viewer is called. AppHelp is
```

```
  assigned to the OnHelp event handler of Application in the
  OnCreate event of Form1.
  */
  bool __fastcall TForm1::AppHelp(Word Command, int Data, bool &CallHelp)
  {
    Application->HelpFile = Screen->ActiveForm->Name + ".hlp";
    CallHelp = true;
    return true;
  }

  void __fastcall TForm1::FormCreate(TObject *Sender)
  {
    Application->OnHelp = AppHelp;
  }

  void __fastcall TForm1::Button1Click(TObject *Sender)
  {
    const DATANOTFOUND = 714;
    Application->HelpContext(DATANOTFOUND);
  }
```

Delphi Examples:

```
  {
  The following code changes the Help file depending on the
  active form, before the help viewer is called. AppHelp is
  assigned to the OnHelp event handler of Application in the
  OnCreate event of Form1.
  }
  function TForm1.AppHelp(
    Command: Word; Data: Longint; var CallHelp: Boolean) : Boolean;
  var helpstring : String;
  begin
    helpstring := Screen.ActiveForm.Name + '.hlp';
    MessageDlg(
      'Using ' + helpstring + ' as the help file.',
      mtInformation, [mbOK], 0);
    Application.HelpFile := helpstring;
    CallHelp := True;
  end;

  procedure TForm1.Button1Click(Sender: TObject);
  const DATANOTFOUND = 714;
  begin
    Application.HelpContext(DATANOTFOUND);
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    Application.OnHelp := AppHelp;
  end;
```

OnHelp

InvokeHelp

7.1.1.6.9 TApplication.OnHint Event

Occurs when the mouse pointer moves over a control or menu item that can display a Help Hint (see page 1976).

Pascal

```
property OnHint: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnHint;
```

Description

Write an OnHint event handler to perform special processing when the mouse pauses over a control or menu item whose Hint (see page 1976) property is not an empty string.

A common use of the OnHint event is to display the value of a control or menu item's Hint (see page 1976) property in another control. Note that it is not necessary to use an OnHint event handler to display hints on a status bar (TStatusBar): TStatusBar will automatically display hints if you set its AutoHint property to true.

The Hint (see page 1976) property of a control can specify both a short Help Hint (see page 1976) and a (usually) longer hint that appears elsewhere because of code in an OnHint event handler.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

Tip: Component writers can respond to the automatically-fired THintAction action in a component's ExecuteAction (see page 1935) method rather than relying on an OnHint event handler.

C++ Examples:

```
/*
Note:   It is not actually necessary to write an OnHint
event handler to display hints on the status bar. This can
be accomplished more simply by setting the status bar's
AutoHint property and SimplePanel property.
This shows how the OnHint event handler is declared as a
public method of the form.
*/

/*
Here is the code to add to the unit file.  It provides the
implementation of the DisplayHint method and assigns it to
the Application in the form's OnCreate event handler.
Note:   It is not actually necessary to write an OnHint event
handler to display hints on the status bar. This can be
accomplished more simply by setting the status bar's AutoHint
property.
*/
void __fastcall TForm1::DisplayHint(TObject *Sender)
{
  StatusBar1->SimpleText = GetLongHint(Application->Hint);
}

// Here is the form's OnCreate event handler.
// It assigns the application's OnHint event handler at
// runtime because the Application is not available in the
// Object Inspector
void __fastcall TForm1::FormCreate(TObject *Sender)
{
```

```
  Application->OnHint = DisplayHint;
}
```

Delphi Examples:

```
{
Note:   It is not actually necessary to write an OnHint
event handler to display hints on the status bar. This can
be accomplished more simply by setting the status bar's
AutoHint property and SimplePanel property.
This shows how the OnHint event handler is declared as a
public method of the form.
}

7.1.1.6.10 TApplication.OnIdle Event

Occurs when an application becomes idle.

Pascal

```
property OnIdle: TIdleEvent;
```

C++

```
__property TIdleEvent OnIdle;
```

Description

Write an OnIdle event handler to perform special processing when an application is idle. An application is idle when it is not processing code. For example, an application is idle when it is waiting for input from the user.

OnIdle is called only once, as the application transitions into an idle state. It is not called continuously unless the Done parameter is set to false. Applications that set Done to false consume an inordinate amount of CPU time, which affects overall system performance.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

C++ Examples:

```
/*
The following code demonstrates background processing using
the OnIdle event, and using the HandleMessage method to
permit messages or background processing to get through.
Note: You must add MyIdleHandler to the Form1 methods.
*/
// global variables to show the order of events
int  XPos, YPos, Delta;

// This is a utility procedure to display messages
// add this at the beginning of the unit

void StatusMsg(TForm *Form, TCanvas *Canvas, char *Message, bool Bkg)
{
  if (!Bkg)
    Canvas->Font->Style = TFontStyles() << fsBold; // foreground messages are bold
  Canvas->TextOut(XPos, YPos, Message);
  if (!Bkg)
    Canvas->Font->Style = TFontStyles();
  // change Xpos and YPos to prepare for the next message
  YPos += Delta;
  if (YPos >= Form->ClientHeight - 10)
  {
    YPos = 10;
    XPos += 180;
  }
  if (XPos >= Form->ClientWidth - 100)
  {
    if (Canvas->Font->Color == clRed)
      Canvas->Font->Color = clBlack;
    else
      Canvas->Font->Color = clRed;
    XPos = 10;
  }
}

/*
This is the OnCreate event handler for Form1.  It
initializes global values and sets the application's OnIdle
event handler
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
```

```
{
  Button1->Caption = "Do not yield";
  Button2->Caption  = "Handle Message";
  Application->OnIdle = MyIdleHandler;
  XPos = 10;
  YPos = 10;
  if (Canvas->Font->Height > 0)
    Delta = Canvas->Font->Height + 1;
  else
    Delta = 1 - Canvas->Font->Height;
}

/*
This is the OnIdle event handler. It is set in the Form's
OnCreate event handler, so you need only add it as a private
method of the form.  Usually it would perform some background
processing for the application.  This one simply writes a
message to let you know when it's there.
*/
void __fastcall TForm1::MyIdleHandler(TObject *Sender, bool &Done)
{
  StatusMsg(Form1, Canvas, "This represents a background process.", true);
}

/*
This is the OnClick event handler for Button1.  It
simulates a lengthy process
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int X, Y;
  StatusMsg(Form1, Canvas, "The Button1Click handler is starting", false);
  for (int I = 0; I < 100; I++)
  {
    randomize();
    for (int J = 0; J < 100; J++)
      Y = random(J);
    X = random(I);
  }
  StatusMsg(Form1, Canvas, "The Button1Click handler is done", false);
}

/*
This is the OnClick event handler for button2.  It
simulates a lengthy process that allows other messages to be
processed.
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  int X, Y;
  StatusMsg(Form1, Canvas, "The Button2Click handler is starting", false);
  for (int I = 0; I < 100; I++)
  {
    randomize();
    for (int J = 0; J < 100; J++)
    {
      Y = random(J);
    }
    // Yield to OnIdle or other messages
    Application->HandleMessage();
    X = random(I);
  }
  StatusMsg(Form1, Canvas, "The Button2Click handler is done", false);
}
```

Delphi Examples:

```
{
The following code demonstrates background processing using
the OnIdle event, and using the HandleMessage method to
permit messages or background processing to get through.
Note: You must add MyIdleHandler to the Form1 methods.
}
var
{ global variables to show the order of events. }
  XPos, YPos, Delta: integer;

{ This is a utility procedure to display messages }
{ add this at the beginning of the implementation section }
procedure StatusMsg(
  MyForm : TForm1; Canvas : TCanvas; Message : string; Bkg : Boolean);
begin
  if not bkg then
    Canvas.Font.Style := [fsBold]; {foreground messages are bold }
  Canvas.TextOut(XPos, YPos, Message);
  if not bkg then
    Canvas.Font.Style := [];
  { change Xpos and YPos to prepare for the next message }
  Ypos := Ypos + Delta;
  if YPos >= MyForm.ClientHeight - 10 then
  begin
    YPos := 10;
    Xpos := Xpos + 180;
  end;
  if (Xpos >= MyForm.ClientWidth - 100) then
  begin
    if (Canvas.Font.Color = clRed) then
      Canvas.Font.Color := clBlack
    else
      Canvas.Font.Color := clRed;
    Xpos := 10;
  end;
end;

{This is the Form's OnCreate event handler.  }
{ It initializes global variables and sets the  the OnIdle
event handler }
procedure TForm1.FormCreate(Sender: TObject);
begin
  Button1.Caption := 'Do not yield';
  Button2.Caption := 'Handle Message';
  Application.OnIdle:= MyIdleHandler;
  XPos := 10;
  YPos := 10;
  Delta := Abs(Canvas.Font.Height) + 1;
 end;

{
This is the OnIdle event handler. It is set in the Form's
OnCreate event handler, so you need only add it as a private
method of the form.  Usually it would perform some
background processing for the application.  This one simply
writes a message to let you know when it's there.
}
procedure TForm1.MyIdleHandler(Sender: TObject; var Done: Boolean);
begin
  StatusMsg(
    Form1, Canvas, 'This represents a background process.', True);
end;

{
Set this method as the OnClick event handler of Button1.  It
performs a calculation without yielding to other messages or
```

```
  idle time.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    I, J, X, Y: Word;
  begin
    StatusMsg(
      Form1, Canvas, 'The synchronous handler is starting', False);
    I := 0;
    J := 0;
    while I < 10 do
    begin
      Randomize;
      while J < 10 do
      begin
        Y := Random(J);
        Inc(J);
      end;
      X := Random(I);
      Inc(I);
    end;
    StatusMsg(
      Form1, Canvas, 'The synchronous handler is done', False);
  end;

  {
  Set this method as the OnClick event handler of Button2.  It
  performs a calculation but calls HandleMessage to allow idle
  time or asynchronous message processing.
  }
  procedure TForm1.Button2Click(Sender: TObject);
  var
    I, J, X, Y: Word;
  begin
   StatusMsg(
      Form1, Canvas, 'The asynchronous handler is starting', False);
    I := 0;
    J := 0;
    while I < 10 do
    begin
      Randomize;
      while J < 10 do
      begin
        Y := Random(J);
        Inc(J);
      end;
      X := Random(I);
      Inc(I);
      { yield to OnIdle or other messages }
      Application.HandleMessage;
    end;
    StatusMsg(
      Form1, Canvas, 'The asynchronous handler is done', False);
  end;
```

7.1.1.6.11 TApplication.OnMessage Event

Occurs when the application receives a Windows message.

Pascal

```
property OnMessage: TMessageEvent;
```

C++

```
__property TMessageEvent OnMessage;
```

Description

Use OnMessage to trap any or all Windows messages posted to all windows in the application. The OnMessage event occurs when an application receives a Windows message. An OnMessage event handler allows an application to respond to messages other than those declared in the events for TApplication (see page 1924). If the application doesn't have a specific handler for an incoming message, the message is dispatched to the window for which it was intended, and Windows handles the message.

Note: OnMessage only receives messages that are posted to the message queue, not those sent directly with the Windows API SendMessage function.

Warning: Caution:Thousands of messages per second flow though this event. Be careful when coding the handler, because it can affect the performance of the entire application.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

C++ Examples:

```
/*
The following code handles a custom message that the
application sends to itself when a file is ready for reading.
*/
const WM_FILEREADY = WM_USER + 2000;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  const PAnsiChar Path = "../overview.rtf";
  PostMessage(Application->Handle, WM_FILEREADY, 0, int(Path));
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnMessage = AppMessage;
}

void __fastcall TForm1::AppMessage(tagMSG &Msg, bool &Handled)
{
  if (Msg.message == WM_FILEREADY)
  {
    Memo1->Lines->LoadFromFile(AnsiString((char *)Msg.lParam));
    Handled = true;
  }
/*
For all other messages, Handled remains False so that other
message handlers can respond.
*/
}
```

Delphi Examples:

```
{
The following code handles a custom message that the
application sends to itself when a file is ready for reading.
}
const WM_FILEREADY = WM_USER + 2000;
procedure TForm1.Button1Click(Sender: TObject);
const Path: PChar = 'OverView.RTF';
begin
  PostMessage(Application.Handle, WM_FILEREADY, 0, integer(Path));
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnMessage := AppMessage;
end;

procedure TForm1.AppMessage(var Msg: TMsg; var Handled: Boolean);
var msgStr: String;
begin
  if Msg.hwnd = Application.Handle then
  begin
    if Msg.message = WM_FILEREADY then
    begin
      msgStr:= PChar(Msg.lParam);
      Memo1.Lines.LoadFromFile(msgStr);
      Handled := True;
    end;
  end;
  { for all other messages, Handled remains False }
  { so that other message handlers can respond }
end;
```

7.1.1.6.12 TApplication.OnMinimize Event

Occurs when an application is minimized.

Pascal

```
property OnMinimize: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMinimize;
```

Description

Write an OnMinimize event handler to perform special processing when the application is minimized. The application is minimized, either because the user minimizes the main window, or because of a call to the Minimize (see page 1951) method. The Icon (see page 1981) property determines the icon that represents the minimized application.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

C++ Examples:

```
/*
This example uses a timer on a form. When the application
runs and the user minimizes the application, the timer
starts and the application returns to its normal size when
an OnTimer event occurs.  The timer then shuts down until
the next time the form is minimized.  Be sure to declare the
AppStartTimer method as a public method of TForm1.  Place a
TTimer object in the form and enter Timer1Timer in the OnTimer
event.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnMinimize = AppStartTimer;
  Timer1->Interval = 1000;
}

void __fastcall TForm1::AppStartTimer(TObject *Sender)
{
  Timer1->Enabled = true;
}

//---------------------------------------------------------------------------
void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  Application->Restore();
  Timer1->Enabled = false;
}
```

Delphi Examples:

```
{
This example uses a timer on a form. When the application
runs and the user minimizes the application, the timer
starts and the application returns to its normal size when
an OnTimer event occurs.  The timer then shuts down until
the next time the form is minimized.  Be sure to declare the
AppStartTimer method as a public method of TForm1.  Place a
TTimer object in the form and enter Timer1Timer in the OnTimer
event.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.OnMinimize := AppStartTimer;
end;

procedure TForm1.AppStartTimer(Sender: TObject);
begin
  Timer1.Enabled := True;
end;

procedure TForm1.Timer1Timer(Sender: TObject);
begin
  Application.Restore;
  Timer1.Enabled := False;
end;
```

OnMinimize

7.1.1.6.13 TApplication.OnModalBegin Event

Occurs when a modal form is opened.

Pascal

```
property OnModalBegin: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnModalBegin;
```

Description

Write an OnModalBegin event handler to perform special processing when a modal form is opened.

See Also

OnModalEnd (see page 2006)

ModalStarted (see page 1952)

7.1.1.6.14 TApplication.OnModalEnd Event

Occurs when a modal form is closed.

Pascal

```
property OnModalEnd: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnModalEnd;
```

Description

Write an OnModalEnd event handler to perform special processing when a modal form is closed.

See Also

OnModalBegin (see page 2006)

ModalStarted (see page 1952)

7.1.1.6.15 TApplication.OnRestore Event

Occurs when the previously minimized application is restored to its normal size.

Pascal

```
property OnRestore: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnRestore;
```

Description

Write an OnRestore event handler to perform special processing when the application is restored from the minimized state in which it appears as an icon. An application is restored either because the user restores the application, or because the application calls the Restore (see page 1957) method.

Note: Don't confuse restoring an application with restoring a form or window to its original size. To minimize, maximize, and restore a window or form, change the value of the WindowState property.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

See Also

Icon (see page 1981)

Minimize (see page 1951)

Restore (see page 1957)

OnRestore

WindowState (see page 2195)

7.1.1.6.16 TApplication.OnSettingChange Event

Occurs when Windows notifies the application that a system-wide setting has changed.

Pascal

```
property OnSettingChange: TSettingChangeEvent;
```

C++

```
__property TSettingChangeEvent OnSettingChange;
```

Description

Use OnSettingChange to respond when Windows informs the application that a system-wide setting or policy has changed.

7.1.1.6.17 TApplication.OnShortCut Event

Occurs when the user presses a key (before the OnKeyDown event).

Pascal

```
property OnShortCut: TShortCutEvent;
```

C++

```
__property TShortCutEvent OnShortCut;
```

Description

Use OnShortCut to dispatch shortcut keystrokes before the form or its controls handle them. When the user presses a key, the application can dispatch it as a shortcut key instead of allowing the standard keystroke processing (OnKeyDown, OnKeyPress, and OnKeyUp). Built-in shortcut processing is provided for menu shortcuts and actions associated with the form. OnShortCut lets the application implement additional shortcuts.

If the OnShortCut event handler responds to the keystroke, set its Handled parameter to true. This prevents the keystroke from being passed on to menus or actions associated with the application. It also prevents the standard keystroke processing in the same way that a menu or action shortcut does.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

OnKeyDown

OnShortCut

7.1.1.6.18 TApplication.OnShowHint Event

Occurs when the application is about to display the hint window for a Help Hint (see page 1976).

Pascal

```
property OnShowHint: TShowHintEvent;
```

C++

```
__property TShowHintEvent OnShowHint;
```

Description

Write an OnShowHint event handler to change the appearance and behavior of Help Hints.

In the event handler, set the HintStr parameter to change the text of the Help Hint (see page 1976). To obtain the text of a hint for a particular control, call the GetLongHint or GetShortHint function, and assign the result to HintStr.

Use the CanShow parameter to permit or prevent the Help Hint (see page 1976) from displaying.

Note: You can also respond to this event using the TApplicationEvents component, which allows you to assign an event handler using the IDE.

C++ Examples:

```
/*
This example uses three speed buttons on a panel. The code
changes the color, width, and position of the text in the
Help Hint for the third speed button. Set the ShowHint
property of each speed button to true and give a value to
the Hint property of each.  You must declare the DoShow
method in the type declaration of the form. Once it is
declared, write the code for the DoShow method in the
implementation part of the unit. Finally, in the OnCreate
event handler for the form, assign the method to the
OnShowHint event of the application.
*/
void __fastcall TForm1::DoShowHint(UnicodeString &HintStr, bool &CanShow, THintInfo &HintInfo)
{
  if (HintInfo.HintControl == SpeedButton3)
  {
    HintInfo.HintColor = clAqua;// Changes only for this hint
    HintInfo.HintMaxWidth = 120; // Hint text word wraps if width is greater than 120
    HintInfo.HintPos.x += SpeedButton3->Width; // Move hint to right edge
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->ShowHint = true;
  Application->OnShowHint = DoShowHint;
}
```

Delphi Examples:

```
{
This example uses three speed buttons on a panel. The code
changes the color, width, and position of the text in the
Help Hint for the third speed button. Set the ShowHint
property of each speed button to true and give a value to
the Hint property of each.  You must declare the DoShow
method in the type declaration of the form. Once it is
declared, write the code for the DoShow method in the
```

```
  implementation part of the unit. Finally, in the OnCreate
  event handler for the form, assign the method to the
  OnShowHint event of the application.
  }

  procedure TForm1.DoShowHint(var HintStr: String; var CanShow: Boolean; var HintInfo:
  THintInfo);
  begin
    if HintInfo.HintControl = SpeedButton3 then
    begin
      with HintInfo do
      begin
        HintColor := clAqua;{ Changes only for this hint }
        HintMaxWidth := 120;{Hint text word wraps if width is greater than 120 }
        Inc(HintPos.X, SpeedButton3.Width); { Move hint to right edge }
      end;
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    Application.ShowHint := True;
    Application.OnShowHint := DoShowHint;
  end;
```

7.1.2 TControlScrollBar Class

TControlScrollBar displays a horizontal or vertical scroll bar.

Class Hierarchy

Pascal

```
TControlScrollBar = class(TPersistent);
```

C++

```
class TControlScrollBar : public TPersistent;
```

File

Forms

Description

Use TControlScrollBar to control the scroll bar in a scrolling windowed control such as TForm (see page 2241) or TScrollBox (see page 2483). TControlScrollBar introduces properties that control the size of the scrollable region and the position to which that region is scrolled, and when the scroll bar appears.

TScrollBar

7.1.2.1 TControlScrollBar Members

The following tables list the members exposed by TControlScrollBar.

Public Methods

	Name	Description
	Assign (see page 2011)	Copies the contents of a TControlScrollBar (see page 2009) instance to another TControlScrollBar (see page 2009).
	ChangeBiDiPosition (see page 2011)	Changes the position of a horizontal scroll bar to match the current bi-directional mode.
	IsScrollBarVisible (see page 2011)	Returns true if the scroll bar is visible.

Public Properties

	Name	Description
	Kind (see page 2015)	Indicates whether the scroll bar is horizontal or vertical.
	ScrollPos (see page 2020)	Indicates the position of the thumb tab.

Published Properties

	Name	Description
	ButtonSize (see page 2012)	Specifies the sizes of the buttons in the scroll bar.
	Color (see page 2013)	Specifies the scroll bar's color.
	Increment (see page 2013)	Determines how far the display moves when the user clicks one of the small end arrows on the scroll bar.
	Margin (see page 2015)	Determines when a scroll bar is generated.
	ParentColor (see page 2016)	Specifies whether the scroll bar should.
	Position (see page 2017)	Specifies the position of the thumb tab on the scroll bar.
	Range (see page 2018)	Determines how far the scrolling region of the associated control can move.
	Size (see page 2021)	Specifies the scroll bar's size.
	Smooth (see page 2021)	Specifies whether the amount the associated control scrolls is dynamically computed.
	Style (see page 2022)	Specifies the scroll bar's style.
	ThumbSize (see page 2022)	This is ThumbSize, a member of class TControlScrollBar.
	Tracking (see page 2022)	Determines whether the form or scroll box moves before the thumb tab is released.
	Visible (see page 2022)	Determines whether the scroll bar appears.

7.1.2.2 TControlScrollBar Methods

The methods of the TControlScrollBar class are listed here.

Public Methods

	Name	Description
	Assign (see page 2011)	Copies the contents of a TControlScrollBar (see page 2009) instance to another TControlScrollBar (see page 2009).

	ChangeBiDiPosition (see page 2011)	Changes the position of a horizontal scroll bar to match the current bi-directional mode.
	IsScrollBarVisible (see page 2011)	Returns true if the scroll bar is visible.

7.1.2.2.1 TControlScrollBar.Assign Method

Copies the contents of a TControlScrollBar (see page 2009) instance to another TControlScrollBar (see page 2009).

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Assign copies the Visible (see page 2022), Range (see page 2018), Position (see page 2017), and Increment (see page 2013) properties from the source object to the TControlScrollBar (see page 2009) instance. If the Source parameter is not another scroll bar, Assign calls the TPersistent Assign method, which allows the source object to copy properties if it has an AssignTo method that knows how to copy to a control scroll bar.

See Also

Assign

AssignTo

Position (see page 2017)

Visible (see page 2022)

Range (see page 2018)

7.1.2.2.2 TControlScrollBar.ChangeBiDiPosition Method

Changes the position of a horizontal scroll bar to match the current bi-directional mode.

Pascal

```
procedure ChangeBiDiPosition;
```

C++

```
__fastcall ChangeBiDiPosition();
```

Description

Use ChangeBiDiPosition to change the position of a horizontal scroll bar to reflect the current bi-directional mode of its associated scrolling windowed control.
