V	ChangedDisplayComponent (see page 5542)	This is ChangedDisplayComponent, a member of class TWebDisplay.
V	GetDisplayComponent (see page 5542)	This is GetDisplayComponent, a member of class TWebDisplay.
	SetDisplayComponent (see page 5542)	This is SetDisplayComponent, a member of class TWebDisplay.

Public Methods

	Name	Description
V	Notification (see page 5542)	This is Notification, a member of class TWebDisplay.

52.1.52.3.1 TWebDisplay.Changed Method

Pascal

```
procedure Changed;
```

C++

```
__fastcall Changed();
```

Description

This is Changed, a member of class TWebDisplay.

52.1.52.3.2 TWebDisplay.ChangedDisplayComponent Method

Pascal

```
procedure ChangedDisplayComponent; virtual;
```

C++

```
virtual __fastcall ChangedDisplayComponent();
```

Description

This is ChangedDisplayComponent, a member of class TWebDisplay.

52.1.52.3.3 TWebDisplay.GetDisplayComponent Method

Pascal

```
function GetDisplayComponent: TComponent; virtual;
```

C++

```
virtual __fastcall TComponent * GetDisplayComponent();
```

Description

This is GetDisplayComponent, a member of class TWebDisplay.

52.1.52.3.4 TWebDisplay.Notification Method

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); virtual;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

This is Notification, a member of class TWebDisplay.

52.1.52.3.5 TWebDisplay.SetDisplayComponent Method

Pascal

```
procedure SetDisplayComponent(const Value: TComponent);
```

C++

```
__fastcall SetDisplayComponent(const TComponent * Value);
```

Description

This is SetDisplayComponent, a member of class TWebDisplay.

52.1.52.4 TWebDisplay Properties

The properties of the TWebDisplay class are listed here.

Public Properties

	Name	Description
	DisplayComponent (see page 5543)	This is DisplayComponent, a member of class TWebDisplay.
R	Parent (see page 5543)	This is Parent, a member of class TWebDisplay.

52.1.52.4.1 TWebDisplay.DisplayComponent Property

Pascal

```
property DisplayComponent: TComponent;
```

C++

```
__property TComponent * DisplayComponent;
```

Description

This is DisplayComponent, a member of class TWebDisplay.

52.1.52.4.2 TWebDisplay.Parent Property

Pascal

```
property Parent: TComponent;
```

C++

```
__property TComponent * Parent;
```

Description

This is Parent, a member of class TWebDisplay.

52.1.52.5 TWebDisplay Events

The events of the TWebDisplay class are listed here.

Public Events

	Name	Description
	OnChange (see page 5543)	This is OnChange, a member of class TWebDisplay.

52.1.52.5.1 TWebDisplay.OnChange Event

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

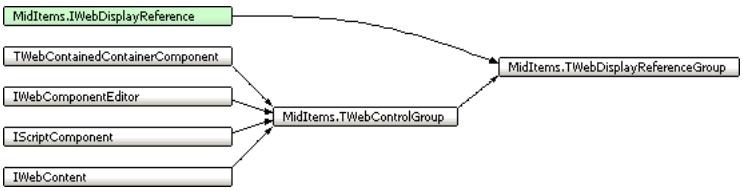
Description

This is OnChange, a member of class TWebDisplay.

52.1.53 TWebDisplayReferenceGroup Class

TWebDisplayReferenceGroup is the base class for Web items that arrange a set of controls that influence a control that displays data.

Class Hierarchy



Pascal

```
TWebDisplayReferenceGroup = class(TWebControlGroup, IWebDisplayReference);
```

C++

```
class TWebDisplayReferenceGroup : public TWebControlGroup, public IWebDisplayReference;
```

File

MidItems

Description

Use TWebDisplayReferenceGroup as a base class for Web items that generate the HTML to arrange a collection of button controls. Each TWebDisplayReferenceGroup object has an associated Web item that generates controls that display data in the final HTML document. The controls arranged by TWebDisplayReferenceGroup manipulate the information the display controls show.

In order to let other Web items use the HTML that the TWebDisplayReferenceGroup object generates, TWebDisplayReferenceGroup inherits the IWebContent interface from TWebControlGroup (see page 5510).

Do not create instances of TWebDisplayReferenceGroup. TWebDisplayReferenceGroup manages the Web items that generate buttons and the association to a display generator, but does not produce any content. Instead, use a descendant of TWebDisplayReferenceGroup such as TDataNavigator (see page 5307) (in InternetExpress applications) or TAdapterCommandGroup (in WebSnap applications).

See Also

TDataNavigator (see page 5307)

IWebContent

TAdapterCommandGroup

52.1.53.1 TWebDisplayReferenceGroup Members

The following tables list the members exposed by TWebDisplayReferenceGroup.

Protected Methods

	Name	Description
	AddElements (see page 5513)	Used internally to generate any script declarations needed by the group of controls.
	CanAddClass (see page 5513)	Specifies whether a Web item of a specified type can be added to the WebFieldControls (see page 5519) property list.
	ChangeFieldControls (see page 5514)	Responds when the group of HTML controls changes.
	Content (see page 5514)	Returns the HTML that defines the group of HTML controls.
V	GetDefaultWebComponents (see page 5515)	Returns the value of the DefaultWebComponents (see page 5518) property.
V	GetLayoutAttributes (see page 5515)	Returns an object that specifies how the generated group of controls should look.
	GetSubComponents (see page 5516)	Returns the value of the WebFieldControls (see page 5519) property.
	GetWebDisplayComponent (see page 5546)	This is GetWebDisplayComponent, a member of class TWebDisplayReferenceGroup.
V	ImplAddElements (see page 5516)	Provides the underlying implementation for the AddElements (see page 5513) method.
V	ImplCanAddClass (see page 5516)	Provides the underlying implementation for the CanAddClass (see page 5513) method.
V	ImplContent (see page 5517)	Provides the underlying implementation for the Content (see page 5514) method.
V	ImplGetSubComponents (see page 5517)	Provides the underlying implementation for the GetSubComponents (see page 5516) method.
V	Notification (see page 5546)	Forwards notification messages to all owned components.
V	SetDefaultWebComponents (see page 5518)	Sets the value of the DefaultWebComponents (see page 5518) property.
V	SetWebDisplayComponent (see page 5547)	This is SetWebDisplayComponent, a member of class TWebDisplayReferenceGroup.

Protected Properties

	Name	Description
	DefaultWebComponents (see page 5518)	Specifies the default value of the WebFieldControls (see page 5519) property when that property is not explicitly set.
R	WebDisplay (see page 5547)	This is WebDisplay, a member of class TWebDisplayReferenceGroup.
	WebDisplayComponent (see page 5547)	

Public Methods

	Name	Description
V	Create (see page 5545)	Creates an instance of TWebDisplayReferenceGroup (see page 5544).
V	Destroy (see page 5546)	Frees an instance of TWebDisplayReferenceGroup (see page 5544).

Public Properties

	Name	Description
R	WebFieldControls (see page 5519)	Lists the components that generate HTML controls for the Web control group.

52.1.53.2 TWebDisplayReferenceGroup.Create Constructor

Creates an instance of TWebDisplayReferenceGroup (see page 5544).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TWebDisplayReferenceGroup(TComponent * AOwner);
```

Description

Call TWebDisplayReferenceGroup (see page 5544) to instantiate TWebDisplayReferenceGroup (see page 5544) at runtime. TWebDisplayReferenceGroup (see page 5544) components added at design time are instantiated automatically.

52.1.53.3 TWebDisplayReferenceGroup.Destroy Destructor

Frees an instance of TWebDisplayReferenceGroup (see page 5544).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TWebDisplayReferenceGroup();
```

Description

Do not call Destroy directly. Instead, call Free, which checks whether the object is not nil before calling Destroy.

See Also

System::TObject::Free

52.1.53.4 TWebDisplayReferenceGroup Methods

The methods of the TWebDisplayReferenceGroup class are listed here.

Protected Methods

	Name	Description
	GetWebDisplayComponent (see page 5546)	This is GetWebDisplayComponent, a member of class TWebDisplayReferenceGroup.
V	Notification (see page 5546)	Forwards notification messages to all owned components.
V	SetWebDisplayComponent (see page 5547)	This is SetWebDisplayComponent, a member of class TWebDisplayReferenceGroup.

52.1.53.4.1 TWebDisplayReferenceGroup.GetWebDisplayComponent Method

Pascal

```
function GetWebDisplayComponent: TComponent;
```

C++

```
__fastcall TComponent * GetWebDisplayComponent();
```

Description

This is GetWebDisplayComponent, a member of class TWebDisplayReferenceGroup.

52.1.53.4.2 TWebDisplayReferenceGroup.Notification Method

Forwards notification messages to all owned components.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation. By default, components pass along the notification

to their owned components, if any.

A component can, if needed, act on the notification that a component is being inserted or removed. For example, if a component has object fields or properties that contain references to other components, it can check the notifications of component removals and invalidate those references as needed.

Note: Notification is not called for components that are freed implicitly (because their Owner is freed).

FreeNotification

InsertComponent

RemoveComponent

Owner

52.1.53.4.3 TWebDisplayReferenceGroup.SetWebDisplayComponent Method

Pascal

```
procedure SetWebDisplayComponent(const Value: TComponent); virtual;
```

C++

```
virtual __fastcall SetWebDisplayComponent(const TComponent * Value);
```

Description

This is SetWebDisplayComponent, a member of class TWebDisplayReferenceGroup.

52.1.53.5 TWebDisplayReferenceGroup Properties

The properties of the TWebDisplayReferenceGroup class are listed here.

Protected Properties

	Name	Description
	WebDisplay (see page 5547)	This is WebDisplay, a member of class TWebDisplayReferenceGroup.
	WebDisplayComponent (see page 5547)	

52.1.53.5.1 TWebDisplayReferenceGroup.WebDisplay Property

Pascal

```
property WebDisplay: TWebDisplay;
```

C++

```
__property TWebDisplay WebDisplay;
```

Description

This is WebDisplay, a member of class TWebDisplayReferenceGroup.

52.1.53.5.2 TWebDisplayReferenceGroup.WebDisplayComponent Property

Pascal

```
property WebDisplayComponent: TComponent;
```

C++

```
__property TComponent * WebDisplayComponent;
```

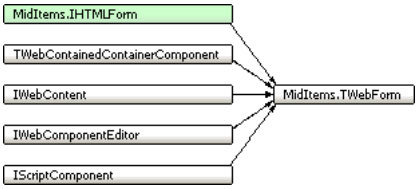
See Also

GetWebDisplayComponent (see page 5672)

52.1.54 TWebForm Class

TWebForm is the base class for Web items that create HTML forms in InternetExpress applications.

Class Hierarchy



Pascal

```
TWebForm = class(TWebContainedContainerComponent, IWebContent, IWebComponentEditor,
IScriptComponent, IHTMLForm);
```

C++

```
class TWebForm : public TWebContainedContainerComponent, public IWebContent, public
IWebComponentEditor, public IScriptComponent, public IHTMLForm;
```

File

MidItems

Description

Use TWebForm as a base class for components that generate the HTML statements defining a form that is contained in an HTML document. The list of Web items that generate content for an InternetExpress page producer can only contain descendants of TWebForm.

In order to allow the InternetExpress page producer to use the HTML generated by the TWebForm descendant, TWebForm implements the IWebContent interface. In order to allow other Web items to generate javascript that refers to form elements, TWebForm implements the IHTMLForm (see page 5655) interface.

Do not create instances of TWebForm. TWebForm relies on an abstract or, in C++ terminology, pure virtual method to generate the HTML form. Instead, create descendants of TWebForm such a TDataForm (see page 5298) or TQueryForm (see page 5421).

See Also

TQueryForm (see page 5421)

TDataForm (see page 5298)

TBasePageItemsProducer (see page 6390)

TInetXPageProducer (see page 5730)

IWebContent

IHTMLForm (see page 5655)

52.1.54.1 TWebForm Members

The following tables list the members exposed by TWebForm.

Protected Methods

	Name	Description
	AddElements (see page 5550)	Used internally to generate any javascript declarations needed by the form.
	CanAddClass (see page 5551)	Specifies whether a Web item of a specified type can be added to the WebComponents (see page 5558) property list.
	Content (see page 5551)	Returns the HTML that defines the HTML form.
V	GetDefaultWebComponents (see page 5552)	Returns nil (Delphi) or NULL (C++).
	GetHTMLFormName (see page 5552)	Returns the name of the generated HTML form.
	GetHTMLFormVarName (see page 5553)	Returns the name of the javascript variable that refers to the generated form.
V	GetLayoutAttributes (see page 5553)	Returns the object that specifies how the generated form should look.
	GetSubComponents (see page 5553)	Returns the value of the WebComponents (see page 5558) property.
	GetVisibleFields (see page 5554)	Returns the value of the VisibleFields (see page 5557) property.
V	ImplAddElements (see page 5554)	Provides the underlying implementation for the AddElements (see page 5550) method.
A	ImplCanAddClass (see page 5554)	Provides the underlying implementation for the CanAddClass (see page 5551) method.
A	ImplContent (see page 5555)	Provides the underlying implementation for the Content (see page 5551) method.
V	SetDefaultWebComponents (see page 5555)	Prevents an application from trying to assign a default set of Web items on the form.

Protected Properties

	Name	Description
R	VisibleFields (see page 5557)	Lists the Web items whose generated content appears in the HTML form.

Public Methods

	Name	Description
V	Create (see page 5549)	Creates and initializes an instance of TWebForm (see page 5548).
V	Destroy (see page 5550)	Frees an instance of TWebForm (see page 5548).

Public Properties

	Name	Description
	Custom (see page 5556)	Represents a tag option and its value in the generated FORM tag.
R	HTMLFormName (see page 5657)	Indicates the name of the generated HTML form.
R	HTMLFormVarName (see page 5657)	Indicates the name of the javascript variable that represents the HTML form.
	Style (see page 5556)	Adds style attributes to the generated form.
	StyleRule (see page 5557)	Applies a style in the page producer's style sheet to the button.
R	WebComponents (see page 5558)	Maintains a list of components that generate HTML content for the TWebForm (see page 5548) descendant.

52.1.54.2 TWebForm.Create Constructor

Creates and initializes an instance of TWebForm (see page 5548).

Pascal

```
constructor Create(AComponent: TComponent); override;
```

C++

```
virtual __fastcall TWebForm(TComponent * AComponent);
```

Description

Call Create to instantiate a TWebForm (see page 5548) descendant at runtime. TWebForm (see page 5548) descendants added at design time using the Web Page editor are instantiated automatically.

52.1.54.3 TWebForm.Destroy Destructor

Frees an instance of TWebForm (see page 5548).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TWebForm();
```

Description

Destroy removes the form generator from its parent's list of components that generate HTML before freeing the TWebForm (see page 5548) instance.

52.1.54.4 TWebForm Methods

The methods of the TWebForm class are listed here.

Protected Methods

	Name	Description
	AddElements (see page 5550)	Used internally to generate any javascript declarations needed by the form.
	CanAddClass (see page 5551)	Specifies whether a Web item of a specified type can be added to the WebComponents (see page 5558) property list.
	Content (see page 5551)	Returns the HTML that defines the HTML form.
V	GetDefaultWebComponents (see page 5552)	Returns nil (Delphi) or NULL (C++).
	GetHTMLFormName (see page 5552)	Returns the name of the generated HTML form.
	GetHTMLFormVarName (see page 5553)	Returns the name of the javascript variable that refers to the generated form.
V	GetLayoutAttributes (see page 5553)	Returns the object that specifies how the generated form should look.
	GetSubComponents (see page 5553)	Returns the value of the WebComponents (see page 5558) property.
	GetVisibleFields (see page 5554)	Returns the value of the VisibleFields (see page 5557) property.
V	ImplAddElements (see page 5554)	Provides the underlying implementation for the AddElements (see page 5550) method.
A	ImplCanAddClass (see page 5554)	Provides the underlying implementation for the CanAddClass (see page 5551) method.
A	ImplContent (see page 5555)	Provides the underlying implementation for the Content (see page 5551) method.
V	SetDefaultWebComponents (see page 5555)	Prevents an application from trying to assign a default set of Web items on the form.

52.1.54.4.1 TWebForm.AddElements Method

Used internally to generate any javascript declarations needed by the form.

Pascal

```
procedure AddElements(AddIntf: IAddScriptElements);
```

C++

```
__fastcall AddElements(IAddScriptElements AddIntf);
```

Description

The InternetExpress page producer calls AddElements when it generates the block of javascript declarations in its HTML document. This method allows the generated form to use javascript classes and methods.

AddElements calls on the virtual ImplAddElements (see page 5554) method, which uses the provided interface to return javascript declarations. Each TWebForm (see page 5548) descendant overrides ImplAddElements (see page 5554) to add any declarations it needs.

See Also

ImplAddElements (see page 5554)

TInetXPageProducer (see page 5730)

52.1.54.4.2 TWebForm.CanAddClass Method

Specifies whether a Web item of a specified type can be added to the WebComponents (see page 5558) property list.

Pascal

```
function CanAddClass(AParent: TComponent; AClass: TClass): Boolean;
```

C++

```
__fastcall Boolean CanAddClass(TComponent * AParent, TClass AClass);
```

Description

The Web page editor calls CanAddClass to determine what Web items can be added to supply content for the TWebForm (see page 5548) descendant. CanAddClass calls the virtual ImplCanAddClass (see page 5554) method to determine whether a class of Web item is valid.

AParent is the TWebForm (see page 5548) descendant to whose WebComponents (see page 5558) property the Web item will be added.

AClass is the class of the proposed child Web item.

CanAddClass returns true if the Web form can use content generated by a component of type AClass, false otherwise.

See Also

ImplCanAddClass (see page 5554)

WebComponents (see page 5558)

52.1.54.4.3 TWebForm.Content Method

Returns the HTML that defines the HTML form.

Pascal

```
function Content(Options: TWebContentOptions; Layout: TLayout): string;
```

C++

```
__fastcall UnicodeString Content(TWebContentOptions Options, TLayout Layout);
```

Description

Content implements the IWebContent method of the same name. This method allows the page producer to extract the HTML defining the form.

Content calls the virtual ImplContent (see page 5555) method to provide the HTML form it returns. Each TWebForm (see page 5548) descendant overrides ImplContent (see page 5555) to generate its particular HTML form. The generated HTML

can make use of any javascript declarations supplied by the AddElements (see page 5550) method.

Options contains a set of flags that limit what can be included in the generated HTML.

ParentLayout specifies a helper object that the caller supplies for determining how the component should format the HTML form it generates. Typically, this parameter is nil (Delphi) or NULL (C++) for forms.

Content returns a string of HTML defining the form.

See Also

ImplContent (see page 5555)

IWebContent

AddElements (see page 5550)

52.1.54.4.4 TWebForm.GetDefaultWebComponents Method

Returns nil (Delphi) or NULL (C++).

Pascal

```
function GetDefaultWebComponents: TWebComponentList; override;
```

C++

```
virtual __fastcall TWebComponentList GetDefaultWebComponents();
```

Description

GetDefaultWebComponents is implemented by all Web items that use sub Web items when generating HTML. (TWebForm (see page 5548) uses the subitems in the WebComponents (see page 5558) property). This method returns a list of Web items that are used by default when an application does not explicitly assign child Web items.

In TWebForm (see page 5548), GetDefaultWebComponents returns nil (Delphi) or NULL (C++) because Web forms do not any set of items that appear by default.

See Also

WebComponents (see page 5558)

GetDefaultWebComponents

52.1.54.4.5 TWebForm.GetHTMLFormName Method

Returns the name of the generated HTML form.

Pascal

```
function GetHTMLFormName: string;
```

C++

```
__fastcall UnicodeString GetHTMLFormName();
```

Description

TWebForm (see page 5548) uses GetHTMLFormName internally to specify the NAME option of the generated form and to declare a javascript variable that references the form.

GetHTMLFormName returns the value of the Name property.

See Also

GetHTMLFormVarName (see page 5553)

Name

52.1.54.4.6 TWebForm.GetHTMLFormVarName Method

Returns the name of the javascript variable that refers to the generated form.

Pascal

```
function GetHTMLFormVarName: string;
```

C++

```
__fastcall UnicodeString GetHTMLFormVarName();
```

Description

TWebForm (see page 5548) uses GetHTMLFormVarName internally to declare a javascript variable that references the form. GetHTMLFormVarName returns the value of the Name property.

See Also

GetHTMLFormName (see page 5552)

Name

52.1.54.4.7 TWebForm.GetLayoutAttributes Method

Returns the object that specifies how the generated form should look.

Pascal

```
function GetLayoutAttributes: TLayoutAttributes; virtual;
```

C++

```
virtual __fastcall TLayoutAttributes GetLayoutAttributes();
```

Description

GetLayoutAttributes is used internally by Web items to allow the layout object supplied by a parent (as a parameter to the Content (see page 5551) method) to take into account layout properties of the child component.

As implemented by TWebForm (see page 5548), GetLayoutAttributes returns nil (Delphi) or NULL (C++), because the layout at the form level does not make use of layout attributes.

See Also

Content (see page 5551)

52.1.54.4.8 TWebForm.GetSubComponents Method

Returns the value of the WebComponents (see page 5558) property.

Pascal

```
function GetSubComponents: TObject;
```

C++

```
__fastcall TObject * GetSubComponents();
```

Description

GetSubComponents returns the TWebForm (see page 5548)'s list of Web items that it uses to generate HTML content. This method is part of the mechanism that fits TWebForm (see page 5548) into a hierarchy of Web items, each of which generates

part of a larger HTML document.

See Also

WebComponents (see page 5558)

52.1.54.4.9 TWebForm.GetVisibleFields Method

Returns the value of the VisibleFields (see page 5557) property.

Pascal

```
function GetVisibleFields: TWebComponentList;
```

C++

```
__fastcall TWebComponentList GetVisibleFields();
```

Description

GetVisibleFields is the protected read implementation of the VisibleFields (see page 5557) property.

See Also

VisibleFields (see page 5557)

52.1.54.4.10 TWebForm.ImplAddElements Method

Provides the underlying implementation for the AddElements (see page 5550) method.

Pascal

```
procedure ImplAddElements(AddIntf: IAddScriptElements); virtual;
```

C++

```
virtual __fastcall ImplAddElements(IAddScriptElements AddIntf);
```

Description

The AddElements (see page 5550) method calls ImplAddElements to add any javascript declarations by calling the AddIntf interface. These declarations allow the generated display control to call javascript methods in response to user events by ensuring that the required methods are declared.

As implemented in TWebForm (see page 5548), ImplAddElements does nothing. TWebForm (see page 5548) descendants can override ImplAddElements to add any required declarations.

See Also

AddElements (see page 5550)

52.1.54.4.11 TWebForm.ImplCanAddClass Method

Provides the underlying implementation for the CanAddClass (see page 5551) method.

Pascal

```
function ImplCanAddClass(AParent: TComponent; AClass: TClass): Boolean; virtual; abstract;
```

C++

```
virtual __fastcall Boolean ImplCanAddClass(TComponent * AParent, TClass AClass) = 0;
```

Description

The CanAddClass (see page 5551) method calls ImpleCanAddClass to determine whether the TWebForm (see page 5548)

descendant can add a component of type AClass to its WebComponents (see page 5558) property list. AParent is the TWebForm (see page 5548) instance to which the component will be added.

In TWebForm (see page 5548), ImplCanAddClass is abstract or, in C++ terminology, pure virtual. TWebForm (see page 5548) descendants must override ImplCanAddClass to indicate what types of Web Items they can use when generating their HTML forms.

See Also

CanAddClass (see page 5551)

WebComponents (see page 5558)

52.1.54.4.12 TWebForm.ImplContent Method

Provides the underlying implementation for the Content (see page 5551) method.

Pascal

```
function ImplContent(Options: TWebContentOptions; Layout: TLayout): string; virtual; abstract;
```

C++

```
virtual __fastcall UnicodeString ImplContent(TWebContentOptions Options, TLayout Layout) = 0;
```

Description

The Content (see page 5551) method calls ImplContent to generate the HTML form. ImplContent is anabstract or, in C++ terminology, pure virtual method in TWebForm (see page 5548). TWebForm (see page 5548) descendants override it to generate the HTML form.

Options contains a set of flags that limit what can be included in the generated HTML.

ParentLayout specifies a helper object that the caller supplies for determining how the TWebForm (see page 5548) should format the HTML control it generates. Typically, this parameter is nil (Delphi) or NULL (C++) for forms.

ImplContent returns an HTML form definition.

See Also

Content (see page 5551)

AddElements (see page 5550)

52.1.54.4.13 TWebForm.SetDefaultWebComponents Method

Prevents an application from trying to assign a default set of Web items on the form.

Pascal

```
procedure SetDefaultWebComponents(AList: TWebComponentList); override;
```

C++

```
virtual __fastcall SetDefaultWebComponents(TWebComponentList AList);
```

Description

SetDefaultWebComponents is implemented by all Web items that use sub Web items when generating HTML. (TWebForm (see page 5548) uses the subitems in the WebComponents (see page 5558) property). This method assigns a list of Web items that are used by default when an application does not explicitly assign child Web items.

In TWebForm (see page 5548), SetDefaultWebComponents does nothing with the list supplied as the AList parameter. This is because web forms do not have default items.

See Also

WebComponents (see page 5558)

SetDefaultWebComponents

52.1.54.5 TWebForm Properties

The properties of the TWebForm class are listed here.

Protected Properties

	Name	Description
	VisibleFields (see page 5557)	Lists the Web items whose generated content appears in the HTML form.

Public Properties

	Name	Description
	Custom (see page 5556)	Represents a tag option and its value in the generated FORM tag.
	Style (see page 5556)	Adds style attributes to the generated form.
	StyleRule (see page 5557)	Applies a style in the page producer's style sheet to the button.
	WebComponents (see page 5558)	Maintains a list of components that generate HTML content for the TWebForm (see page 5548) descendant.

52.1.54.5.1 TWebForm.Custom Property

Represents a tag option and its value in the generated FORM tag.

Pascal

```
property Custom: string;
```

C++

```
__property UnicodeString Custom;
```

Description

Use Custom to represent one or more options that qualify the FORM tag generated by the TWebForm (see page 5548) descendant. Each option and its value has the form

```
OPTIONNAME=Value
```

The options specified by Custom should be separated by spaces. For example, to specify that the form includes files with the text it submits and indicate that the page returned after submitting the form goes into a separate window, use a Custom value such as the following:

```
ENCTYPE="multipart/form-data" TARGET="ResultFrame"
```

See Also

Style (see page 5556)

52.1.54.5.2 TWebForm.Style Property

Adds style attributes to the generated form.

Pascal

```
property Style: string;
```

C++

```
__property UnicodeString Style;
```

Description

Use Style to add a STYLE option that qualifies the FORM tag generated by the TWebForm (see page 5548) descendant. The Style option consists of one or more attribute descriptions such as

```
font-family: arial; font-weight: bold; font-size: 10px
```

These attributes are added to the generated FORM tag as the value of a STYLE option.

See Also

Custom (see page 5556)

StyleRule (see page 5557)

52.1.54.5.3 TWebForm.StyleRule Property

Applies a style in the page producer's style sheet to the button.

Pascal

```
property StyleRule: string;
```

C++

```
__property UnicodeString StyleRule;
```

Description

Use StyleRule to assign one of the user-defined styles in the HTML document's style sheet to the generated form. The value of StyleRule specifies one of the user-defined style names defined in the InternetExpress page producer's Styles or StylesFile property.

Note: To apply a style definition that is not included in the style sheet, use the Style (see page 5556) property.

See Also

Style (see page 5556)

Styles (see page 5716)

StylesFile (see page 5717)

52.1.54.5.4 TWebForm.VisibleFields Property

Lists the Web items whose generated content appears in the HTML form.

Pascal

```
property VisibleFields: TWebComponentList;
```

C++

```
__property TWebComponentList VisibleFields;
```

Description

VisibleFields is used internally when assembling the HTML form from the HTML generated by the form's Web items. For TWebForm (see page 5548), the value of VisibleFields is always the same as WebComponents (see page 5558).

Override GetVisibleFields (see page 5554) in a descendant class to provide a default set of that appear when the WebComponents (see page 5558) property is not set.

See Also

WebComponents (see page 5558)

52.1.54.5.5 TWebForm.WebComponents Property

Maintains a list of components that generate HTML content for the TWebForm (see page 5548) descendant.

Pascal

```
property WebComponents: TWebComponentList;
```

C++

```
__property TWebComponentList WebComponents;
```

Description

WebComponents lists the components that generate content for the Web form. Each of these components supports the IWebContent interface, and some can contain their own list of Web items that help them generate their content.

The type of items that can be added to the WebComponents list are restricted by the protected CanAddClass (see page 5551) method. Descendant classes override this method to indicate what types of items can be added to the list. For example, TQueryForm (see page 5421) limits the list to components that display or manipulate named values (TQueryButtons (see page 5412), TQueryFields) or layout groups that manage the layout of those items (TLayoutGroup (see page 5389)).

At design time, add components to the WebComponents property by bringing up the Web page editor for the containing TInetXPageProducer (see page 5730) component. Select the TWebForm (see page 5548) descendant in the editor, and use the editor to add child controls.

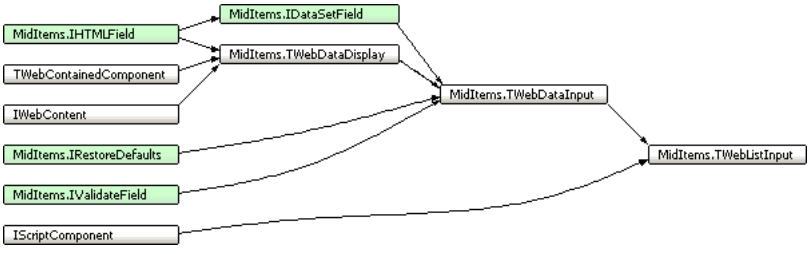
CanAddClass (see page 5551)

52.1.55 TWebListInput Class

TWebListInput is the base class for Web items that create HTML display controls which present a fixed set of possible values.

Class Hierarchy



Pascal

```
TWebListInput = class(TWebDataInput, IScriptComponent);
```

C++

```
class TWebListInput : public TWebDataInput, public IScriptComponent;
```

File

MidItems

Description

Use TWebListInput as a base class for components that generate HTML controls for displaying a fixed set of possible values from which a user can choose. TWebListInput descendants generate controls that are organized by TDataGrid (see page 5302), TFieldGroup (see page 5320), or TQueryFieldGroup (see page 5415).

TWebListInput defines or inherits properties and methods for

Specifying a field or parameter whose value the control displays.

Specifying the possible values from which the user can choose.

Generating a caption that describes the information displayed.

Customizing the appearance of the control that displays information.

Fitting the control into the tab order of the generated HTML form.

Fitting the component into a hierarchy of Web items that collectively generate the content of an HTML document.

In order to let other Web items to use the HTML control it generates, TWebListInput inherits the IWebContent interface from TWebDataDisplay (see page 5519).

Do not create instances of TWebListInput. Instead, use a descendant of TWebListInput such as TFieldRadioGroup (see page 5326), TQueryRadioGroup (see page 5425), TFieldSelectOptions (see page 5335), TQuerySelectOptions (see page 5437), or TSelectOptionsColumn (see page 5472).

TQuerySelectOptions (see page 5437)

TSelectOptionsColumn (see page 5472)

52.1.55.1 TWebListInput Members

The following tables list the members exposed by TWebListInput.

Protected Methods

	Name	Description
	AddElements (see page 5562)	This is AddElements, a member of class TWebListInput.
	Content (see page 5523)	Returns the HTML that defines the display control.
V	ControlContent (see page 5562)	This is ControlContent, a member of class TWebListInput.
V	EventContent (see page 5523)	This is EventContent, a member of class TWebDataDisplay.
V	EventContent (see page 5535)	This is EventContent, a member of class TWebDataInput.

	FindAssociatedField (see page 5535)	This is FindAssociatedField, a member of class TWebDataInput.
	FormatCaption (see page 5524)	This is FormatCaption, a member of class TWebDataDisplay.
	FormatInputs (see page 5562)	This is FormatInputs, a member of class TWebListInput.
	GetCaption (see page 5524)	Returns the value of the Caption (see page 5529) property.
	GetCaption (see page 5536)	Returns the value of the Caption property.
	GetFieldName (see page 5536)	This is GetFieldName, a member of class TWebDataInput.
	GetHTMLControlName (see page 5524)	Returns the name that other components can use to refer to the generated display control.
	GetHTMLForm (see page 5524)	Used internally to retrieve information about the form in which the display control is defined.
	GetLayoutAttributes (see page 5525)	Returns the value of the LayoutAttributes (see page 5531) property.
	GetParamName (see page 5536)	This is GetParamName, a member of class TWebDataInput.
	GetRowSetFieldAttributes (see page 5536)	This is GetRowSetFieldAttributes, a member of class TWebDataInput.
	GetSubComponents (see page 5563)	This is GetSubComponents, a member of class TWebListInput.
	GetXmlDisplayName (see page 5525)	Returns the name of the javascript object that uses TWebDataDisplay (see page 5519) to generate one of its display controls. Not used on Linux.
	GetXmlRowSetName (see page 5526)	Returns the name of the rowset in the XML data packet whose data is represented by the HTML this component generates. Not used on Linux.
	ImplAddElements (see page 5563)	This is ImplAddElements, a member of class TWebListInput.
	ImplContent (see page 5526)	Provides the underlying implementation for the Content (see page 5523) method.
	ImplGetFieldName (see page 5537)	This is ImplGetFieldName, a member of class TWebDataInput.
	ImplGetHTMLControlName (see page 5527)	Returns the name that other components can use to refer to the generated display control.
	ImplGetHTMLControlName (see page 5537)	Returns the name that other components can use to refer to the generated display control.
	ImplGetRowSetFieldAttributes (see page 5537)	This is ImplGetRowSetFieldAttributes, a member of class TWebDataInput.
	ImplRestoreDefaults (see page 5537)	This is ImplRestoreDefaults, a member of class TWebDataInput.
	LabelContent (see page 5528)	This is LabelContent, a member of class TWebDataDisplay.
	Notification (see page 5563)	Forwards notification messages to all owned components.
	RestoreDefaults (see page 5538)	This is RestoreDefaults, a member of class TWebDataInput.
	RestoreFieldDefaults (see page 5538)	This is RestoreFieldDefaults, a member of class TWebDataInput.
	SetCaption (see page 5528)	Sets the value of the Caption (see page 5529) property.
	SetCaption (see page 5538)	Sets the value of the Caption property.
	SetCaptionAttributes (see page 5529)	Sets the value of the CaptionAttributes (see page 5530) property.
	SetDataSet (see page 5564)	This is SetDataSet, a member of class TWebListInput.
	SetFieldName (see page 5538)	This is SetFieldName, a member of class TWebDataInput.
	SetItems (see page 5564)	This is SetItems, a member of class TWebListInput.
	SetParamName (see page 5539)	This is SetParamName, a member of class TWebDataInput.
	SetValues (see page 5564)	This is SetValues, a member of class TWebListInput.
	ValidateField (see page 5539)	This is ValidateField, a member of class TWebDataInput.

Protected Properties

	Name	Description
	CaptionPosition (see page 5530)	Specifies where the label appears relative to the generated display control.
	LayoutAttributes (see page 5531)	Encodes attributes that describe how the generated control should look.
	ParamName (see page 5540)	Specifies the name of the parameter whose value the generated control represents.

Public Methods

	Name	Description
	Create (see page 5561)	Creates and initializes an instance of TWebListInput (see page 5558).
	Destroy (see page 5561)	Frees an instance of TWebListInput (see page 5558).
	GetFieldName (see page 5648)	This is GetFieldName, a member of class IDataSetField.
	GetHTMLControlName (see page 5654)	Returns the name of the generated HTML <INPUT> control.
	GetRowSetFieldAttributes (see page 5649)	This is GetRowSetFieldAttributes, a member of class IDataSetField.

	IsColumn (see page 5527)	Indicates whether the component generates the controls that appear in the column of a grid.
	IsQueryField (see page 5528)	Indicates whether the component generates the controls that appear in a query form. Not used on Linux.
	RestoreDefaults (see page 5666)	This is RestoreDefaults, a member of class IRestoreDefaults.
	SetFieldName (see page 5649)	This is SetFieldName, a member of class IDataSetField.
	ValidateField (see page 5667)	This is ValidateField, a member of class IValidateField.

Public Properties

	Name	Description
	Caption (see page 5529)	Specifies the text of a label that indicates what information the generated control displays.
	CaptionAttributes (see page 5530)	Customizes the appearance of the generated control's label.
	Custom (see page 5530)	Represents a tag option and its value in the tag for the display control.
	DataSet (see page 5564)	Specifies a dataset that supplies the possible values listed in the generated control.
	FieldName (see page 5649)	This is FieldName, a member of class IDataSetField.
	FieldName (see page 5539)	Specifies the name of the field whose value the generated control represents.
	HTMLControlName (see page 5655)	Indicates the name of the generated HTML control.
	Items (see page 5565)	Lists the possible selections that appear in the generated control.
	ItemsField (see page 5565)	Indicates which field in DataSet (see page 5564) supplies the possible selections for the generated control.
	Style (see page 5531)	Adds style attributes to the generated display control.
	StyleRule (see page 5532)	This is StyleRule, a member of class TWebDataDisplay.
	TabIndex (see page 5532)	Determines the position of the generated control in the HTML form's tab order.
	Values (see page 5566)	Lists the possible values that can be assigned to the control.
	ValuesField (see page 5566)	Indicates which field in DataSet (see page 5564) supplies the possible values for the generated control.

52.1.55.2 TWebListInput.Create Constructor

Creates and initializes an instance of TWebListInput (see page 5558).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TWebListInput(TComponent * AOwner);
```

Description

Call Create to instantiate TWebListInput (see page 5558) at runtime. TWebListInput (see page 5558) descendants added at design time using the Web Page editor are instantiated automatically.

52.1.55.3 TWebListInput.Destroy Destructor

Frees an instance of TWebListInput (see page 5558).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TWebListInput();
```

Description

Do not call Destroy directly in an application. Instead, use the Free method, which checks that the component is not nil, and only

then calls Destroy.

System::TObject::Free

52.1.55.4 TWebListInput Methods

The methods of the TWebListInput class are listed here.

Protected Methods

	Name	Description
	AddElements (see page 5562)	This is AddElements, a member of class TWebListInput.
V	ControlContent (see page 5562)	This is ControlContent, a member of class TWebListInput.
A	FormatInputs (see page 5562)	This is FormatInputs, a member of class TWebListInput.
	GetSubComponents (see page 5563)	This is GetSubComponents, a member of class TWebListInput.
V	ImplAddElements (see page 5563)	This is ImplAddElements, a member of class TWebListInput.
V	Notification (see page 5563)	Forwards notification messages to all owned components.
	SetDataSet (see page 5564)	This is SetDataSet, a member of class TWebListInput.
	SetItems (see page 5564)	This is SetItems, a member of class TWebListInput.
	SetValues (see page 5564)	This is SetValues, a member of class TWebListInput.

52.1.55.4.1 TWebListInput.AddElements Method

Pascal

```
procedure AddElements(AddIntf: IAddScriptElements);
```

C++

```
__fastcall AddElements(IAddScriptElements AddIntf);
```

Description

This is AddElements, a member of class TWebListInput.

52.1.55.4.2 TWebListInput.ControlContent Method

Pascal

```
function ControlContent(Options: TWebContentOptions): string; override;
```

C++

```
virtual __fastcall UnicodeString ControlContent(TWebContentOptions Options);
```

Description

This is ControlContent, a member of class TWebListInput.

52.1.55.4.3 TWebListInput.FormatInputs Method

Pascal

```
function FormatInputs(ItemsStrings: TStrings; ValuesStrings: TStrings; Options:
TWebContentOptions): string; virtual; abstract;
```

C++

```
virtual __fastcall UnicodeString FormatInputs(TStrings ItemsStrings, TStrings ValuesStrings,
TWebContentOptions Options) = 0;
```

Description

This is FormatInputs, a member of class TWebListInput.

52.1.55.4.4 TWebListInput.GetSubComponents Method

Pascal

```
function GetSubComponents: TObject;
```

C++

```
__fastcall TObject * GetSubComponents();
```

Description

This is GetSubComponents, a member of class TWebListInput.

52.1.55.4.5 TWebListInput.ImplAddElements Method

Pascal

```
procedure ImplAddElements(AddIntf: IAddScriptElements); virtual;
```

C++

```
virtual __fastcall ImplAddElements(IAddScriptElements AddIntf);
```

Description

This is ImplAddElements, a member of class TWebListInput.

52.1.55.4.6 TWebListInput.Notification Method

Forwards notification messages to all owned components.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation. By default, components pass along the notification to their owned components, if any.

A component can, if needed, act on the notification that a component is being inserted or removed. For example, if a component has object fields or properties that contain references to other components, it can check the notifications of component removals and invalidate those references as needed.

Note: Notification is not called for components that are freed implicitly (because their Owner is freed).

FreeNotification

InsertComponent

RemoveComponent

Owner

52.1.55.4.7 TWebListInput.SetDataSet Method

Pascal

```
procedure SetDataSet(const Value: TDataSet);
```

C++

```
__fastcall SetDataSet(const TDataSet Value);
```

Description

This is SetDataSet, a member of class TWebListInput.

52.1.55.4.8 TWebListInput.SetItems Method

Pascal

```
procedure SetItems(const Value: TStrings);
```

C++

```
__fastcall SetItems(const TStrings Value);
```

Description

This is SetItems, a member of class TWebListInput.

52.1.55.4.9 TWebListInput.SetValues Method

Pascal

```
procedure SetValues(const Value: TStrings);
```

C++

```
__fastcall SetValues(const TStrings Value);
```

Description

This is SetValues, a member of class TWebListInput.

52.1.55.5 TWebListInput Properties

The properties of the TWebListInput class are listed here.

Public Properties

	Name	Description
	DataSet (see page 5564)	Specifies a dataset that supplies the possible values listed in the generated control.
	Items (see page 5565)	Lists the possible selections that appear in the generated control.
	ItemsField (see page 5565)	Indicates which field in DataSet (see page 5564) supplies the possible selections for the generated control.
	Values (see page 5566)	Lists the possible values that can be assigned to the control.
	ValuesField (see page 5566)	Indicates which field in DataSet (see page 5564) supplies the possible values for the generated control.

52.1.55.5.1 TWebListInput.DataSet Property

Specifies a dataset that supplies the possible values listed in the generated control.

Pascal

```
property DataSet: TDataSet;
```

C++

```
__property TDataSet DataSet;
```

Description

Use DataSet to specify a dataset from which the component can extract the selections that appear to the user and the underlying values they represent. The ItemsField (see page 5565) property specifies the field in this dataset that lists the selections that appear in the generated control. The ValuesField (see page 5566) property specifies the field in this dataset that lists the corresponding values that are assigned to the control.

Note: If the list of possible values is not available in a dataset, use the Items (see page 5565) and Values (see page 5566) properties instead to list the selections that appear to the user and the underlying values they represent.

See Also

ItemsField (see page 5565)

ValuesField (see page 5566)

Items (see page 5565)

Values (see page 5566)

52.1.55.5.2 TWebListInput.Items Property

Lists the possible selections that appear in the generated control.

Pascal

```
property Items: TStrings;
```

C++

```
__property TStrings Items;
```

Description

Use Items to supply a list of possible selections to the generated control. The end-user can choose from these selections to assign a value to the generated control. The value that is assigned comes from the corresponding entry in the Values (see page 5566) property.

Note: To use a dataset to supply items and values, rather than explicitly listing them in the Items and Values (see page 5566) properties, use the DataSet (see page 5564), ItemsField (see page 5565), and ValuesField (see page 5566) properties.

See Also

ItemsField (see page 5565)

Values (see page 5566)

DataSet (see page 5564)

ValuesField (see page 5566)

52.1.55.5.3 TWebListInput.ItemsField Property

Indicates which field in DataSet (see page 5564) supplies the possible selections for the generated control.

Pascal

```
property ItemsField: string;
```

C++

```
__property UnicodeString ItemsField;
```

Description

Use ItemsField to specify which field in the dataset specified by the DataSet (see page 5564) property contains selections that appear in the generated control. The end-user can choose from these selections to assign a value to the generated control. The value that is assigned comes from the field specified by the ValuesField (see page 5566) property.

Note: If the list of possible values is not available in a dataset, use the Items (see page 5565) and Values (see page 5566) properties instead to list the selections that appear to the user and the underlying values they represent.

See Also

Items (see page 5565)

Values (see page 5566)

DataSet (see page 5564)

ValuesField (see page 5566)

52.1.55.5.4 TWebListInput.Values Property

Lists the possible values that can be assigned to the control.

Pascal

```
property Values: TStrings;
```

C++

```
__property TStrings Values;
```

Description

Use Values to supply a list of possible values for the generated control. When the end-user chooses one of the selections listed by the Items (see page 5565) property, the control is assigned the corresponding value in the Values property.

Note: To use a dataset to supply items and values, rather than explicitly listing them in the Items (see page 5565) and Values properties, use the DataSet (see page 5564), ItemsField (see page 5565), and ValuesField (see page 5566) properties.

See Also

Items (see page 5565)

ItemsField (see page 5565)

DataSet (see page 5564)

ValuesField (see page 5566)

52.1.55.5.5 TWebListInput.ValuesField Property

Indicates which field in DataSet (see page 5564) supplies the possible values for the generated control.

Pascal

```
property ValuesField: string;
```

C++

```
__property UnicodeString ValuesField;
```

Description

Use ValuesField to specify which field in the dataset specified by the DataSet (see page 5564) property contains values that can be assigned to the generated control. When the end-user selects the corresponding value form the ItemsField (see page 5565) field, the control gets the value in the ValuesField field.

Note: If the list of possible values is not available in a dataset, use the Items (see page 5565) and Values (see page 5566) properties instead to list the selections that appear to the user and the underlying values they represent.

See Also

Items (see page 5565)

Values (see page 5566)

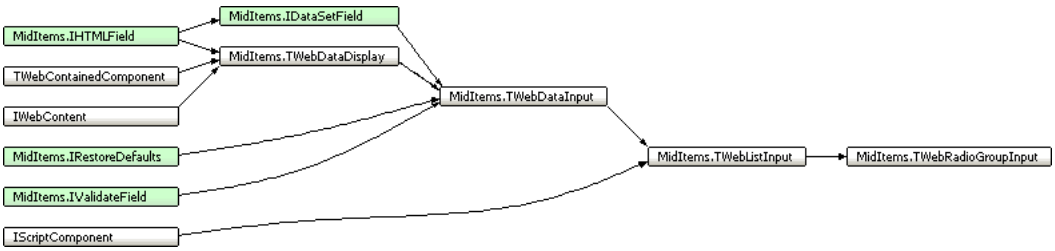
DataSet (see page 5564)

ItemsField (see page 5565)

52.1.56 TWebRadioGroupInput Class

TWebRadioGroupInput is the base class for Web items that create HTML radio group controls.

Class Hierarchy



Pascal

```
TWebRadioGroupInput = class(TWebListInput);
```

C++

```
class TWebRadioGroupInput : public TWebListInput;
```

File

MidItems

Description

Use TWebRadioGroupInput as a base class for components that generate HTML radio groups that represent field or parameter values. TWebRadioGroupInput descendants generate controls that are organized by TFieldGroup (see page 5320) or TQueryFieldGroup (see page 5415).

TWebRadioGroupInput defines or inherits properties and methods for

Specifying a field or parameter whose value the radio group displays.

Specifying the possible values from which the user can choose.

Generating a caption that describes the information displayed.

Customizing the appearance of the radio group.

Fitting the radio group into the tab order of the generated HTML form.

Fitting the component into a hierarchy of Web items that collectively generate the content of an HTML document.

In order to let other Web items to use the HTML control it generates, TWebRadioGroupInput inherits the IWebContent interface from TWebDataDisplay (see page 5519).

Do not create instances of TWebRadioGroupInput. Instead, use a descendant of TWebRadioGroupInput such as TFieldRadioGroup (see page 5326) or TQueryRadioGroup (see page 5425).

See Also

IWebContent

TFieldGroup (see page 5320)

TQueryFieldGroup (see page 5415)

TFieldRadioGroup (see page 5326)

TQUeryRadioGroup

52.1.56.1 TWebRadioGroupInput Members

The following tables list the members exposed by TWebRadioGroupInput.

Protected Methods

	Name	Description
	AddAttributes (see page 5570)	This is AddAttributes, a member of class TWebRadioGroupInput.
	AddElements (see page 5562)	This is AddElements, a member of class TWebListInput.
	Content (see page 5523)	Returns the HTML that defines the display control.
	ControlContent (see page 5523)	This is ControlContent, a member of class TWebDataDisplay.
	ControlContent (see page 5562)	This is ControlContent, a member of class TWebListInput.
	EventContent (see page 5571)	This is EventContent, a member of class TWebRadioGroupInput.
	FindAssociatedField (see page 5535)	This is FindAssociatedField, a member of class TWebDataInput.
	FormatCaption (see page 5524)	This is FormatCaption, a member of class TWebDataDisplay.
	FormatInputs (see page 5571)	This is FormatInputs, a member of class TWebRadioGroupInput.
	GetCaption (see page 5524)	Returns the value of the Caption (see page 5529) property.
	GetCaption (see page 5536)	Returns the value of the Caption property.
	GetCheckIndex (see page 5571)	This is GetCheckIndex, a member of class TWebRadioGroupInput.
	GetFieldName (see page 5536)	This is GetFieldName, a member of class TWebDataInput.
	GetHTMLControlName (see page 5524)	Returns the name that other components can use to refer to the generated display control.
	GetHTMLForm (see page 5524)	Used internally to retrieve information about the form in which the display control is defined.
	GetLayoutAttributes (see page 5525)	Returns the value of the LayoutAttributes (see page 5531) property.
	GetParamName (see page 5536)	This is GetParamName, a member of class TWebDataInput.
	GetRowSetFieldAttributes (see page 5536)	This is GetRowSetFieldAttributes, a member of class TWebDataInput.
	GetSubComponents (see page 5563)	This is GetSubComponents, a member of class TWebListInput.
	GetXmlDisplayName (see page 5525)	Returns the name of the javascript object that uses TWebDataDisplay (see page 5519) to generate one of its display controls. Not used on Linux.
	GetXmlRowSetName (see page 5526)	Returns the name of the rowset in the XML data packet whose data is represented by the HTML this component generates. Not used on Linux.
	ImplAddElements (see page 5563)	This is ImplAddElements, a member of class TWebListInput.

	ImplContent (see page 5526)	Provides the underlying implementation for the Content (see page 5523) method.
	ImplGetFieldName (see page 5537)	This is ImplGetFieldName, a member of class TWebDataInput.
	ImplGetHTMLControlName (see page 5527)	Returns the name that other components can use to refer to the generated display control.
	ImplGetHTMLControlName (see page 5537)	Returns the name that other components can use to refer to the generated display control.
	ImplGetRowSetFieldAttributes (see page 5571)	This is ImplGetRowSetFieldAttributes, a member of class TWebRadioGroupInput.
	ImplRestoreDefaults (see page 5537)	This is ImplRestoreDefaults, a member of class TWebDataInput.
	LabelContent (see page 5528)	This is LabelContent, a member of class TWebDataDisplay.
	Notification (see page 5563)	Forwards notification messages to all owned components.
	RestoreDefaults (see page 5538)	This is RestoreDefaults, a member of class TWebDataInput.
	RestoreFieldDefaults (see page 5571)	This is RestoreFieldDefaults, a member of class TWebRadioGroupInput.
	SetCaption (see page 5528)	Sets the value of the Caption (see page 5529) property.
	SetCaption (see page 5538)	Sets the value of the Caption property.
	SetCaptionAttributes (see page 5529)	Sets the value of the CaptionAttributes (see page 5530) property.
	SetDataSet (see page 5564)	This is SetDataSet, a member of class TWebListInput.
	SetFieldName (see page 5538)	This is SetFieldName, a member of class TWebDataInput.
	SetItems (see page 5564)	This is SetItems, a member of class TWebListInput.
	SetParamName (see page 5539)	This is SetParamName, a member of class TWebDataInput.
	SetValues (see page 5564)	This is SetValues, a member of class TWebListInput.
	ValidateField (see page 5539)	This is ValidateField, a member of class TWebDataInput.

Protected Properties

	Name	Description
	CaptionPosition (see page 5530)	Specifies where the label appears relative to the generated display control.
R	LayoutAttributes (see page 5531)	Encodes attributes that describe how the generated control should look.
	ParamName (see page 5540)	Specifies the name of the parameter whose value the generated control represents.

Public Methods

	Name	Description
	Create (see page 5570)	Creates and initializes an instance of TWebRadioGroupInput (see page 5567).
	Destroy (see page 5522)	Frees an instance of TWebDataDisplay (see page 5519).
	Destroy (see page 5561)	Frees an instance of TWebListInput (see page 5558).
	GetFieldName (see page 5648)	This is GetFieldName, a member of class IDataSetField.
	GetHTMLControlName (see page 5654)	Returns the name of the generated HTML <INPUT> control.
	GetRowSetFieldAttributes (see page 5649)	This is GetRowSetFieldAttributes, a member of class IDataSetField.
	IsColumn (see page 5527)	Indicates whether the component generates the controls that appear in the column of a grid.
	IsQueryField (see page 5528)	Indicates whether the component generates the controls that appear in a query form. Not used on Linux.
	RestoreDefaults (see page 5666)	This is RestoreDefaults, a member of class IRestoreDefaults.
	SetFieldName (see page 5649)	This is SetFieldName, a member of class IDataSetField.
	ValidateField (see page 5667)	This is ValidateField, a member of class IValidateField.

Public Properties

	Name	Description
	Caption (see page 5529)	Specifies the text of a label that indicates what information the generated control displays.
	CaptionAttributes (see page 5530)	Customizes the appearance of the generated control's label.
	Custom (see page 5530)	Represents a tag option and its value in the tag for the display control.
	DataSet (see page 5564)	Specifies a dataset that supplies the possible values listed in the generated control.
	DisplayColumns (see page 5572)	Specifies the number of radio buttons that appear in each row of the control.
	DisplayWidth (see page 5572)	Specifies the width of the radio group, in characters.
	FieldName (see page 5649)	This is FieldName, a member of class IDataSetField.

	FieldName (see page 5539)	Specifies the name of the field whose value the generated control represents.
R	HTMLControlName (see page 5655)	Indicates the name of the generated HTML control.
	Items (see page 5565)	Lists the possible selections that appear in the generated control.
	ItemsField (see page 5565)	Indicates which field in DataSet (see page 5564) supplies the possible selections for the generated control.
	ReadOnly (see page 5573)	Indicates whether end users can use the generated control to set values.
	Style (see page 5531)	Adds style attributes to the generated display control.
	StyleRule (see page 5532)	This is StyleRule, a member of class TWebDataDisplay.
	TabIndex (see page 5532)	Determines the position of the generated control in the HTML form's tab order.
	Values (see page 5566)	Lists the possible values that can be assigned to the control.
	ValuesField (see page 5566)	Indicates which field in DataSet (see page 5564) supplies the possible values for the generated control.

52.1.56.2 TWebRadioGroupInput.Create Constructor

Creates and initializes an instance of TWebRadioGroupInput (see page 5567).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TWebRadioGroupInput(TComponent * AOwner);
```

Description

Call Create to instantiate TWebRadioGroupInput (see page 5567) at runtime. TWebRadioGroupInput (see page 5567) descendants added at design time using the Web Page editor are instantiated automatically.

52.1.56.3 TWebRadioGroupInput Methods

The methods of the TWebRadioGroupInput class are listed here.

Protected Methods

	Name	Description
V	AddAttributes (see page 5570)	This is AddAttributes, a member of class TWebRadioGroupInput.
V	EventContent (see page 5571)	This is EventContent, a member of class TWebRadioGroupInput.
V	FormatInputs (see page 5571)	This is FormatInputs, a member of class TWebRadioGroupInput.
V	GetCheckIndex (see page 5571)	This is GetCheckIndex, a member of class TWebRadioGroupInput.
V	ImplGetRowSetFieldAttributes (see page 5571)	This is ImplGetRowSetFieldAttributes, a member of class TWebRadioGroupInput.
V	RestoreFieldDefaults (see page 5571)	This is RestoreFieldDefaults, a member of class TWebRadioGroupInput.

52.1.56.3.1 TWebRadioGroupInput.AddAttributes Method

Pascal

```
procedure AddAttributes(var Attrs: string); virtual;
```

C++

```
virtual __fastcall AddAttributes(UnicodeString Attrs);
```

Description

This is AddAttributes, a member of class TWebRadioGroupInput.

52.1.56.3.2 TWebRadioGroupInput.EventContent Method

Pascal

```
function EventContent(Options: TWebContentOptions): string; override;
```

C++

```
virtual __fastcall UnicodeString EventContent(TWebContentOptions Options);
```

Description

This is EventContent, a member of class TWebRadioGroupInput.

52.1.56.3.3 TWebRadioGroupInput.FormatInputs Method

Pascal

```
function FormatInputs(ItemsStrings: TStrings; ValuesStrings: TStrings; Options:
TWebContentOptions): string; override;
```

C++

```
virtual __fastcall UnicodeString FormatInputs(TStrings ItemsStrings, TStrings ValuesStrings,
TWebContentOptions Options);
```

Description

This is FormatInputs, a member of class TWebRadioGroupInput.

52.1.56.3.4 TWebRadioGroupInput.GetCheckIndex Method

Pascal

```
function GetCheckIndex(ItemsStrings: TStrings; ValuesStrings: TStrings): Integer; virtual;
```

C++

```
virtual __fastcall int GetCheckIndex(TStrings ItemsStrings, TStrings ValuesStrings);
```

Description

This is GetCheckIndex, a member of class TWebRadioGroupInput.

52.1.56.3.5 TWebRadioGroupInput.ImplGetRowSetFieldAttributes Method

Pascal

```
function ImplGetRowSetFieldAttributes(const FieldVarName: string): string; override;
```

C++

```
virtual __fastcall UnicodeString ImplGetRowSetFieldAttributes(const UnicodeString
FieldVarName);
```

Description

This is ImplGetRowSetFieldAttributes, a member of class TWebRadioGroupInput.

52.1.56.3.6 TWebRadioGroupInput.RestoreFieldDefaults Method

Pascal

```
procedure RestoreFieldDefaults(AField: TField); override;
```

C++

```
virtual __fastcall RestoreFieldDefaults(TField AField);
```

Description

This is RestoreFieldDefaults, a member of class TWebRadioGroupInput.

52.1.56.4 TWebRadioGroupInput Properties

The properties of the TWebRadioGroupInput class are listed here.

Public Properties

	Name	Description
	DisplayColumns (see page 5572)	Specifies the number of radio buttons that appear in each row of the control.
	DisplayWidth (see page 5572)	Specifies the width of the radio group, in characters.
	ReadOnly (see page 5573)	Indicates whether end users can use the generated control to set values.

52.1.56.4.1 TWebRadioGroupInput.DisplayColumns Property

Specifies the number of radio buttons that appear in each row of the control.

Pascal

```
property DisplayColumns: Integer;
```

C++

```
__property int DisplayColumns;
```

Description

Use DisplayColumns to specify how many radio buttons can appear in a single line of the radio group. If DisplayColumns is less than the number of items, the radio group displays its buttons in multiple rows.

See Also

ItemsField (see page 5565)

Items (see page 5565)

DisplayWidth (see page 5572)

52.1.56.4.2 TWebRadioGroupInput.DisplayWidth Property

Specifies the width of the radio group, in characters.

Pascal

```
property DisplayWidth: Integer;
```

C++

```
__property int DisplayWidth;
```

Description

Use DisplayWidth to limit the width of the generated control. TWebRadioGroup generates an INPUT tag of type RADIO to implement the radio group. DisplayWidth is added as a WIDTH option.

See Also

DisplayColumns (see page 5572)

Custom (see page 5530)

52.1.56.4.3 TWebRadioGroupInput.ReadOnly Property

Indicates whether end users can use the generated control to set values.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

Use ReadOnly to indicate whether users can change the value displayed by the radio group. TWebRadioGroup generates an INPUT tag of type RADIO to implement the radio group. ReadOnly is added as a READONLY option.

See Also

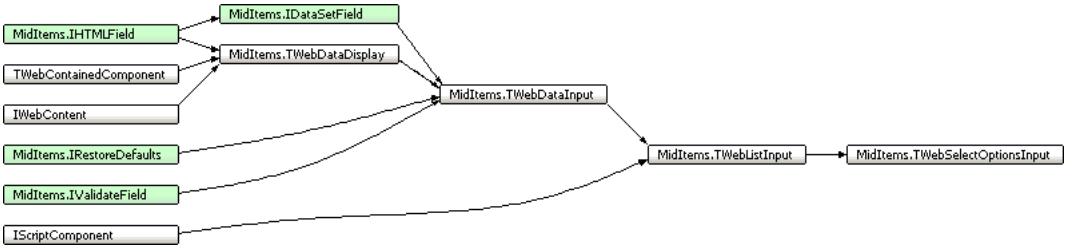
DisplayWidth (see page 5572)

Custom (see page 5530)

52.1.57 TWebSelectOptionsInput Class

TWebSelectOptionsInput is the base class for Web items that create HTML list controls.

Class Hierarchy



Pascal

```
TWebSelectOptionsInput = class(TWebListInput);
```

C++

```
class TWebSelectOptionsInput : public TWebListInput;
```

File

MidItems

Description

Use TWebSelectOptionsInput as a base class for components that generate HTML list controls that represent field or parameter values. TWebSelectOptionsInput descendants generate controls that are organized by TDataGrid (see page 5302), TFieldGroup (see page 5320), or TQueryFieldGroup (see page 5415).

TWebSelectOptionsInput defines or inherits properties and methods for

Specifying a field or parameter whose value the list box displays.

Specifying the possible values from which the user can choose.

Generating a caption that describes the information displayed.

Customizing the appearance of the list box.

Fitting the list box into the tab order of the generated HTML form.

Fitting the component into a hierarchy of Web items that collectively generate the content of an HTML document.

In order to let other Web items to use the HTML control it generates, TWebSelectOptionsInput inherits the IWebContent interface from TWebDataDisplay (see page 5519).

Do not create instances of TWebSelectOptionsInput. Instead, use a descendant of TWebSelectOptionsInput such as TFieldSelectOptions (see page 5335), TQuerySelectOptions (see page 5437), or TSelectOptionsColumn (see page 5472).

See Also

IWebContent

TFieldGroup (see page 5320)

TQueryFieldGroup (see page 5415)

TFieldSelectOptions (see page 5335)

TQUerySelectOptions

TDataGrid (see page 5302)

TSelectOptionsColumn (see page 5472)

52.1.57.1 TWebSelectOptionsInput Members

The following tables list the members exposed by TWebSelectOptionsInput.

Protected Methods

	Name	Description
	AddAttributes (see page 5576)	This is AddAttributes, a member of class TWebSelectOptionsInput.
	AddElements (see page 5562)	This is AddElements, a member of class TWebListInput.
	Content (see page 5523)	Returns the HTML that defines the display control.
	ControlContent (see page 5523)	This is ControlContent, a member of class TWebDataDisplay.
	ControlContent (see page 5562)	This is ControlContent, a member of class TWebListInput.
	EventContent (see page 5577)	This is EventContent, a member of class TWebSelectOptionsInput.
	FindAssociatedField (see page 5535)	This is FindAssociatedField, a member of class TWebDataInput.
	FormatCaption (see page 5524)	This is FormatCaption, a member of class TWebDataDisplay.
	FormatInputs (see page 5577)	This is FormatInputs, a member of class TWebSelectOptionsInput.
	GetCaption (see page 5524)	Returns the value of the Caption (see page 5529) property.
	GetCaption (see page 5536)	Returns the value of the Caption property.
	GetFieldName (see page 5536)	This is GetFieldName, a member of class TWebDataInput.
	GetHTMLControlName (see page 5524)	Returns the name that other components can use to refer to the generated display control.
	GetHTMLForm (see page 5524)	Used internally to retrieve information about the form in which the display control is defined.
	GetLayoutAttributes (see page 5525)	Returns the value of the LayoutAttributes (see page 5531) property.
	GetParamName (see page 5536)	This is GetParamName, a member of class TWebDataInput.
	GetRowSetFieldAttributes (see page 5536)	This is GetRowSetFieldAttributes, a member of class TWebDataInput.
	GetSelectIndex (see page 5577)	This is GetSelectIndex, a member of class TWebSelectOptionsInput.
	GetSubComponents (see page 5563)	This is GetSubComponents, a member of class TWebListInput.

	GetXmlDisplayName (see page 5525)	Returns the name of the javascript object that uses TWebDataDisplay (see page 5519) to generate one of its display controls. Not used on Linux.
	GetXmlRowSetName (see page 5526)	Returns the name of the rowset in the XML data packet whose data is represented by the HTML this component generates. Not used on Linux.
V	ImplAddElements (see page 5563)	This is ImplAddElements, a member of class TWebListInput.
V	ImplContent (see page 5526)	Provides the underlying implementation for the Content (see page 5523) method.
V	ImplGetFieldName (see page 5537)	This is ImplGetFieldName, a member of class TWebDataInput.
V	ImplGetHTMLControlName (see page 5527)	Returns the name that other components can use to refer to the generated display control.
V	ImplGetHTMLControlName (see page 5537)	Returns the name that other components can use to refer to the generated display control.
V	ImplGetRowSetFieldAttributes (see page 5537)	This is ImplGetRowSetFieldAttributes, a member of class TWebDataInput.
V	ImplRestoreDefaults (see page 5537)	This is ImplRestoreDefaults, a member of class TWebDataInput.
V	LabelContent (see page 5528)	This is LabelContent, a member of class TWebDataDisplay.
V	Notification (see page 5563)	Forwards notification messages to all owned components.
	RestoreDefaults (see page 5538)	This is RestoreDefaults, a member of class TWebDataInput.
V	RestoreFieldDefaults (see page 5538)	This is RestoreFieldDefaults, a member of class TWebDataInput.
V	SetCaption (see page 5528)	Sets the value of the Caption (see page 5529) property.
V	SetCaption (see page 5538)	Sets the value of the Caption property.
	SetCaptionAttributes (see page 5529)	Sets the value of the CaptionAttributes (see page 5530) property.
	SetDataSet (see page 5564)	This is SetDataSet, a member of class TWebListInput.
	SetFieldName (see page 5538)	This is SetFieldName, a member of class TWebDataInput.
	SetItems (see page 5564)	This is SetItems, a member of class TWebListInput.
	SetParamName (see page 5539)	This is SetParamName, a member of class TWebDataInput.
	SetValues (see page 5564)	This is SetValues, a member of class TWebListInput.
	ValidateField (see page 5539)	This is ValidateField, a member of class TWebDataInput.

Protected Properties

	Name	Description
	CaptionPosition (see page 5530)	Specifies where the label appears relative to the generated display control.
R	LayoutAttributes (see page 5531)	Encodes attributes that describe how the generated control should look.
	ParamName (see page 5540)	Specifies the name of the parameter whose value the generated control represents.

Public Methods

	Name	Description
V	Create (see page 5576)	Creates and initializes an instance of TWebSelectOptionsInput (see page 5573).
V	Destroy (see page 5522)	Frees an instance of TWebDataDisplay (see page 5519).
V	Destroy (see page 5561)	Frees an instance of TWebListInput (see page 5558).
	GetFieldName (see page 5648)	This is GetFieldName, a member of class IDataSetField.
	GetHTMLControlName (see page 5654)	Returns the name of the generated HTML <INPUT> control.
	GetRowSetFieldAttributes (see page 5649)	This is GetRowSetFieldAttributes, a member of class IDataSetField.
V	IsColumn (see page 5527)	Indicates whether the component generates the controls that appear in the column of a grid.
V	IsQueryField (see page 5528)	Indicates whether the component generates the controls that appear in a query form. Not used on Linux.
	RestoreDefaults (see page 5666)	This is RestoreDefaults, a member of class IRestoreDefaults.
	SetFieldName (see page 5649)	This is SetFieldName, a member of class IDataSetField.
	ValidateField (see page 5667)	This is ValidateField, a member of class IValidateField.

Public Properties

	Name	Description
	Caption (see page 5529)	Specifies the text of a label that indicates what information the generated control displays.
	CaptionAttributes (see page 5530)	Customizes the appearance of the generated control's label.
	Custom (see page 5530)	Represents a tag option and its value in the tag for the display control.

	DataSet (see page 5564)	Specifies a dataset that supplies the possible values listed in the generated control.
	DisplayRows (see page 5577)	Specifies the number of rows that appear in the generated list box.
	FieldName (see page 5649)	This is FieldName, a member of class IDataSetField.
	FieldName (see page 5539)	Specifies the name of the field whose value the generated control represents.
R	HTMLControlName (see page 5655)	Indicates the name of the generated HTML control.
	Items (see page 5565)	Lists the possible selections that appear in the generated control.
	ItemsField (see page 5565)	Indicates which field in DataSet (see page 5564) supplies the possible selections for the generated control.
	Style (see page 5531)	Adds style attributes to the generated display control.
	StyleRule (see page 5532)	This is StyleRule, a member of class TWebDataDisplay.
	TabIndex (see page 5532)	Determines the position of the generated control in the HTML form's tab order.
	Values (see page 5566)	Lists the possible values that can be assigned to the control.
	ValuesField (see page 5566)	Indicates which field in DataSet (see page 5564) supplies the possible values for the generated control.

52.1.57.2 TWebSelectOptionsInput.Create Constructor

Creates and initializes an instance of TWebSelectOptionsInput (see page 5573).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TWebSelectOptionsInput(TComponent * AOwner);
```

Description

Call Create to instantiate TWebSelectOptionsInput (see page 5573) at runtime. TWebSelectOptionsInput (see page 5573) descendants added at design time using the Web Page editor are instantiated automatically.

52.1.57.3 TWebSelectOptionsInput Methods

The methods of the TWebSelectOptionsInput class are listed here.

Protected Methods

	Name	Description
V	AddAttributes (see page 5576)	This is AddAttributes, a member of class TWebSelectOptionsInput.
V	EventContent (see page 5577)	This is EventContent, a member of class TWebSelectOptionsInput.
V	FormatInputs (see page 5577)	This is FormatInputs, a member of class TWebSelectOptionsInput.
V	GetSelectIndex (see page 5577)	This is GetSelectIndex, a member of class TWebSelectOptionsInput.

52.1.57.3.1 TWebSelectOptionsInput.AddAttributes Method

Pascal

```
procedure AddAttributes(var Attrs: string); virtual;
```

C++

```
virtual __fastcall AddAttributes(UnicodeString Attrs);
```

Description

This is AddAttributes, a member of class TWebSelectOptionsInput.

52.1.57.3.2 TWebSelectOptionsInput.EventContent Method

Pascal

```
function EventContent(Options: TWebContentOptions): string; override;
```

C++

```
virtual __fastcall UnicodeString EventContent(TWebContentOptions Options);
```

Description

This is EventContent, a member of class TWebSelectOptionsInput.

52.1.57.3.3 TWebSelectOptionsInput.FormatInputs Method

Pascal

```
function FormatInputs(ItemsStrings: TStrings; ValuesStrings: TStrings; Options:
TWebContentOptions): string; override;
```

C++

```
virtual __fastcall UnicodeString FormatInputs(TStrings ItemsStrings, TStrings ValuesStrings,
TWebContentOptions Options);
```

Description

This is FormatInputs, a member of class TWebSelectOptionsInput.

52.1.57.3.4 TWebSelectOptionsInput.GetSelectIndex Method

Pascal

```
function GetSelectIndex(ItemsStrings: TStrings; ValuesStrings: TStrings): Integer; virtual;
```

C++

```
virtual __fastcall int GetSelectIndex(TStrings ItemsStrings, TStrings ValuesStrings);
```

Description

This is GetSelectIndex, a member of class TWebSelectOptionsInput.

52.1.57.4 TWebSelectOptionsInput Properties

The properties of the TWebSelectOptionsInput class are listed here.

Public Properties

	Name	Description
	DisplayRows (see page 5577)	Specifies the number of rows that appear in the generated list box.

52.1.57.4.1 TWebSelectOptionsInput.DisplayRows Property

Specifies the number of rows that appear in the generated list box.

Pascal

```
property DisplayRows: Integer;
```

C++

```
__property int DisplayRows;
```

Description

Use DisplayRows to specify how many rows appear in the generated list control. If DisplayRows is less than the number of items, the generated list displays only DisplayRows options at one time, but can scroll to display the hidden items. If DisplayRows is 1, the generated control becomes a drop-down list box.

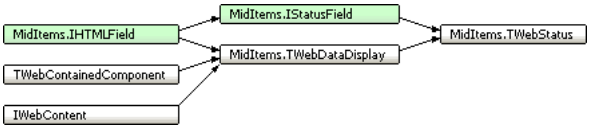
ItemsField (see page 5565)

Items (see page 5565)

52.1.58 TWebStatus Class

TWebStatus is the base class for Web items that indicate the status of records in an XML data packet.

Class Hierarchy



Pascal

```
TWebStatus = class(TWebDataDisplay, IStatusField);
```

C++

```
class TWebStatus : public TWebDataDisplay, public IStatusField;
```

File

MidItems

Description

Use TWebStatus as a base class for components that generate HTML controls which indicate whether records have been inserted or modified by the user. TWebStatus descendants generate controls that are added to TDataGrid (see page 5302) or TFieldGroup (see page 5320) to provide feedback about modifications to the underlying XML data packet.

TWebStatus defines or inherits properties and methods for

Generating a caption that describes the information displayed.

Customizing the appearance of the control.

Fitting the control into the tab order of the generated HTML form.

Fitting the component into a hierarchy of Web items that collectively generate the content of an HTML document.

In order to let other Web items to use the HTML control it generates, TWebStatus inherits the IWebContent interface from TWebDataDisplay (see page 5519).

Do not create instances of TWebStatus. Instead, use a descendant of TWebStatus such as TFieldStatus (see page 5344) or TStatusColumn (see page 5481).

See Also

IWebContent

TDataGrid (see page 5302)

TFieldGroup (see page 5320)

TFieldStatus (see page 5344)

TStatusColumn (see page 5481)

52.1.58.1 TWebStatus Members

The following tables list the members exposed by TWebStatus.

Protected Methods

	Name	Description
	Content (see page 5523)	Returns the HTML that defines the display control.
V	ControlContent (see page 5580)	This is ControlContent, a member of class TWebStatus.
V	EventContent (see page 5523)	This is EventContent, a member of class TWebDataDisplay.
V	FormatCaption (see page 5524)	This is FormatCaption, a member of class TWebDataDisplay.
V	GetCaption (see page 5581)	Returns the value of the Caption property.
	GetHTMLControlName (see page 5524)	Returns the name that other components can use to refer to the generated display control.
	GetHTMLForm (see page 5524)	Used internally to retrieve information about the form in which the display control is defined.
V	GetLayoutAttributes (see page 5525)	Returns the value of the LayoutAttributes (see page 5531) property.
	GetXmlDisplayName (see page 5525)	Returns the name of the javascript object that uses TWebDataDisplay (see page 5519) to generate one of its display controls. Not used on Linux.
	GetXmlRowSetName (see page 5526)	Returns the name of the rowset in the XML data packet whose data is represented by the HTML this component generates. Not used on Linux.
V	ImplContent (see page 5526)	Provides the underlying implementation for the Content (see page 5523) method.
V	ImplGetHTMLControlName (see page 5581)	Returns the name that other components can use to refer to the generated display control.
V	LabelContent (see page 5528)	This is LabelContent, a member of class TWebDataDisplay.
V	SetCaption (see page 5528)	Sets the value of the Caption (see page 5529) property.
	SetCaptionAttributes (see page 5529)	Sets the value of the CaptionAttributes (see page 5530) property.

Protected Properties

	Name	Description
R	LayoutAttributes (see page 5531)	Encodes attributes that describe how the generated control should look.

Public Methods

	Name	Description
V	Create (see page 5580)	Creates and initializes an instance of TWebStatus (see page 5578).
V	Destroy (see page 5522)	Frees an instance of TWebDataDisplay (see page 5519).
	GetHTMLControlName (see page 5654)	Returns the name of the generated HTML <INPUT> control.
	Identifier (see page 5581)	Returns the name under which record status information is stored in the XML data packet.
V	IsColumn (see page 5527)	Indicates whether the component generates the controls that appear in the column of a grid.
V	IsQueryField (see page 5528)	Indicates whether the component generates the controls that appear in a query form. Not used on Linux.

Public Properties

	Name	Description
	Caption (see page 5582)	Specifies the text of a label that indicates what information the generated control displays.
	CaptionAttributes (see page 5582)	Customizes the appearance of the generated control's label.
	CaptionPosition (see page 5583)	Specifies where the label appears relative to the generated display control.
	Custom (see page 5530)	Represents a tag option and its value in the tag for the display control.
	DisplayWidth (see page 5583)	Specifies the width, in characters, of the generated HTML control.
R	HTMLControlName (see page 5655)	Indicates the name of the generated HTML control.
	Style (see page 5531)	Adds style attributes to the generated display control.
	StyleRule (see page 5532)	This is StyleRule, a member of class TWebDataDisplay.
	TabIndex (see page 5532)	Determines the position of the generated control in the HTML form's tab order.

52.1.58.2 TWebStatus.Create Constructor

Creates and initializes an instance of TWebStatus (see page 5578).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TWebStatus(TComponent * AOwner);
```

Description

Call Create to instantiate TWebStatus (see page 5578) at runtime. TWebStatus (see page 5578) descendants added at design time using the Web Page editor are instantiated automatically.

52.1.58.3 TWebStatus Methods

The methods of the TWebStatus class are listed here.

Protected Methods

	Name	Description
V	ControlContent (see page 5580)	This is ControlContent, a member of class TWebStatus.
V	GetCaption (see page 5581)	Returns the value of the Caption property.
V	ImplGetHTMLControlName (see page 5581)	Returns the name that other components can use to refer to the generated display control.

Public Methods

	Name	Description
	Identifier (see page 5581)	Returns the name under which record status information is stored in the XML data packet.

52.1.58.3.1 TWebStatus.ControlContent Method

Pascal

```
function ControlContent(Options: TWebContentOptions): string; override;
```

C++

```
virtual __fastcall UnicodeString ControlContent(TWebContentOptions Options);
```

Description

This is ControlContent, a member of class TWebStatus.

52.1.58.3.2 TWebStatus.GetCaption Method

Returns the value of the Caption property.

Pascal

```
function GetCaption: string; override;
```

C++

```
virtual __fastcall UnicodeString GetCaption();
```

Description

GetCaption is the protected read implementation for the Caption property.

See Also

Caption (see page 5529)

52.1.58.3.3 TWebStatus.Identifier Method

Returns the name under which record status information is stored in the XML data packet.

Pascal

```
class function Identifier: string;
```

C++

```
__fastcall UnicodeString Identifier();
```

Description

Call Identifier to determine the name of the pseudo-field in the XML data packet that stores the status information displayed by the generated control.

52.1.58.3.4 TWebStatus.ImplGetHTMLControlName Method

Returns the name that other components can use to refer to the generated display control.

Pascal

```
function ImplGetHTMLControlName: string; override;
```

C++

```
virtual __fastcall UnicodeString ImplGetHTMLControlName();
```

Description

ImplGetHTMLControlName returns the name of the generated control. This value is assigned to a NAME option on the generated HTML tag.

ImplGetHTMLControlName returns the value of the Name property. TWebDataDisplay descendants can override this method to return a more meaningful value such as the name of the field or parameter displayed in the control.

See Also

Name

52.1.58.4 TWebStatus Properties

The properties of the TWebStatus class are listed here.

Public Properties

	Name	Description
	Caption (see page 5582)	Specifies the text of a label that indicates what information the generated control displays.
	CaptionAttributes (see page 5582)	Customizes the appearance of the generated control's label.
	CaptionPosition (see page 5583)	Specifies where the label appears relative to the generated display control.
	DisplayWidth (see page 5583)	Specifies the width, in characters, of the generated HTML control.

52.1.58.4.1 TWebStatus.Caption Property

Specifies the text of a label that indicates what information the generated control displays.

Pascal

```
property Caption: string;
```

C++

```
__property UnicodeString Caption;
```

Description

Use Caption to specify the text of the control's label.

See Also

CaptionAttributes (see page 5530)

CaptionPosition (see page 5530)

52.1.58.4.2 TWebStatus.CaptionAttributes Property

Customizes the appearance of the generated control's label.

Pascal

```
property CaptionAttributes: TCaptionAttributes;
```

C++

```
__property TCaptionAttributes CaptionAttributes;
```

Description

Use CaptionAttributes to customize the appearance of the control's label. CaptionAttributes defines a set of options that are added to an HTML SPAN tag surrounding the value of the Caption property.

See Also

Caption (see page 5529)

CaptionPosition (see page 5530)

HeadingAttributes (see page 5269)

52.1.58.4.3 TWebStatus.CaptionPosition Property

Specifies where the label appears relative to the generated display control.

Pascal

```
property CaptionPosition: TCaptionPosition;
```

C++

```
__property TCaptionPosition CaptionPosition;
```

Description

Use CaptionPosition to indicate where the label should appear relative to the control that displays information.

Note: CaptionPosition has no effect on column controls. The position of column labels is always in the table header.

See Also

CaptionAttributes (see page 5530)

Caption (see page 5529)

52.1.58.4.4 TWebStatus.DisplayWidth Property

Specifies the width, in characters, of the generated HTML control.

Pascal

```
property DisplayWidth: Integer;
```

C++

```
__property int DisplayWidth;
```

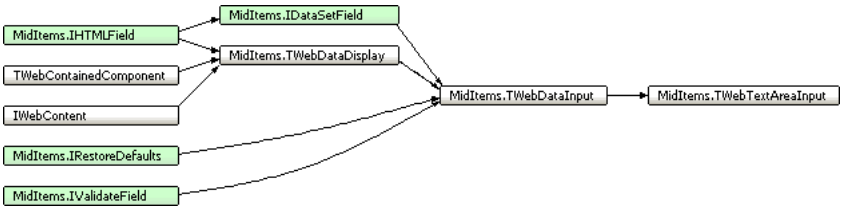
Description

Use DisplayWidth to control the width of the HTML control that displays record status information. By default, DisplayWidth is 1 because the TWebStatus (see page 5578) control values are one character (M for modified or I for inserted).

52.1.59 TWebTextAreaInput Class

TWebTextAreaInput is the base class for Web items that create HTML multi-line text controls.

Class Hierarchy



Pascal

```
TWebTextAreaInput = class(TWebDataInput);
```

C++

```
class TWebTextAreaInput : public TWebDataInput;
```

File

MidItems

Description

Use TWebTextAreaInput as a base class for components that generate HTML controls for displaying a field or parameter value in a multi-line text control. TWebTextAreaInput descendants generate controls that are organized by TDataGrid (see page 5302), TFieldGroup (see page 5320), or TQueryFieldGroup (see page 5415).

TWebTextAreaInput defines or inherits properties and methods for

Specifying a field or parameter whose value the control displays.

Generating a caption that describes the information displayed.

Customizing the appearance of the control that displays information.

Fitting the control into the tab order of the generated HTML form.

Fitting the component into a hierarchy of Web items that collectively generate the content of an HTML document.

In order to let other Web items to use the HTML control it generates, TWebTextAreaInput inherits the IWebContent interface from TWebDataDisplay (see page 5519).

Do not create instances of TWebTextAreaInput. Instead, use a descendant of TWebTextAreaInput such as TFieldTextArea (see page 5355), TQueryTextArea (see page 5458), or TTextAreaColumn (see page 5488).

See Also

IWebContent

TDataGrid (see page 5302)

TFieldGroup (see page 5320)

TQueryFieldGroup (see page 5415)

TFieldTextArea (see page 5355)

TQueryTextArea (see page 5458)

TTextAreaColumn (see page 5488)

52.1.59.1 TWebTextAreaInput Members

The following tables list the members exposed by TWebTextAreaInput.

Protected Methods

	Name	Description
	AddAttributes (see page 5586)	This is AddAttributes, a member of class TWebTextAreaInput.
	Content (see page 5523)	Returns the HTML that defines the display control.
	ControlContent (see page 5586)	This is ControlContent, a member of class TWebTextAreaInput.
	EventContent (see page 5587)	This is EventContent, a member of class TWebTextAreaInput.
	FindAssociatedField (see page 5535)	This is FindAssociatedField, a member of class TWebDataInput.
	FormatCaption (see page 5524)	This is FormatCaption, a member of class TWebDataDisplay.
	GetCaption (see page 5524)	Returns the value of the Caption (see page 5529) property.
	GetCaption (see page 5536)	Returns the value of the Caption property.
	GetFieldName (see page 5536)	This is GetFieldName, a member of class TWebDataInput.
	GetHTMLControlName (see page 5524)	Returns the name that other components can use to refer to the generated display control.

	GetHTMLForm (see page 5524)	Used internally to retrieve information about the form in which the display control is defined.
V	GetLayoutAttributes (see page 5525)	Returns the value of the LayoutAttributes (see page 5531) property.
V	GetParamName (see page 5536)	This is GetParamName, a member of class TWebDataInput.
	GetRowSetFieldAttributes (see page 5536)	This is GetRowSetFieldAttributes, a member of class TWebDataInput.
	GetXmlDisplayName (see page 5525)	Returns the name of the javascript object that uses TWebDataDisplay (see page 5519) to generate one of its display controls. Not used on Linux.
	GetXmlRowSetName (see page 5526)	Returns the name of the rowset in the XML data packet whose data is represented by the HTML this component generates. Not used on Linux.
V	ImplContent (see page 5526)	Provides the underlying implementation for the Content (see page 5523) method.
V	ImplGetFieldName (see page 5537)	This is ImplGetFieldName, a member of class TWebDataInput.
V	ImplGetHTMLControlName (see page 5527)	Returns the name that other components can use to refer to the generated display control.
V	ImplGetHTMLControlName (see page 5537)	Returns the name that other components can use to refer to the generated display control.
V	ImplGetRowSetFieldAttributes (see page 5587)	This is ImplGetRowSetFieldAttributes, a member of class TWebTextAreaInput.
V	ImplRestoreDefaults (see page 5537)	This is ImplRestoreDefaults, a member of class TWebDataInput.
V	LabelContent (see page 5528)	This is LabelContent, a member of class TWebDataDisplay.
	RestoreDefaults (see page 5538)	This is RestoreDefaults, a member of class TWebDataInput.
V	RestoreFieldDefaults (see page 5587)	This is RestoreFieldDefaults, a member of class TWebTextAreaInput.
V	SetCaption (see page 5528)	Sets the value of the Caption (see page 5529) property.
V	SetCaption (see page 5538)	Sets the value of the Caption property.
	SetCaptionAttributes (see page 5529)	Sets the value of the CaptionAttributes (see page 5530) property.
	SetFieldName (see page 5538)	This is SetFieldName, a member of class TWebDataInput.
	SetParamName (see page 5539)	This is SetParamName, a member of class TWebDataInput.
	ValidateField (see page 5539)	This is ValidateField, a member of class TWebDataInput.

Protected Properties

	Name	Description
	CaptionPosition (see page 5530)	Specifies where the label appears relative to the generated display control.
R	LayoutAttributes (see page 5531)	Encodes attributes that describe how the generated control should look.
	ParamName (see page 5540)	Specifies the name of the parameter whose value the generated control represents.

Public Methods

	Name	Description
V	Create (see page 5586)	Creates and initializes an instance of TWebTextAreaInput (see page 5583).
V	Destroy (see page 5522)	Frees an instance of TWebDataDisplay (see page 5519).
	GetFieldName (see page 5648)	This is GetFieldName, a member of class IDataSetField.
	GetHTMLControlName (see page 5654)	Returns the name of the generated HTML <INPUT> control.
	GetRowSetFieldAttributes (see page 5649)	This is GetRowSetFieldAttributes, a member of class IDataSetField.
V	IsColumn (see page 5527)	Indicates whether the component generates the controls that appear in the column of a grid.
V	IsQueryField (see page 5528)	Indicates whether the component generates the controls that appear in a query form. Not used on Linux.
	RestoreDefaults (see page 5666)	This is RestoreDefaults, a member of class IRestoreDefaults.
	SetFieldName (see page 5649)	This is SetFieldName, a member of class IDataSetField.
	ValidateField (see page 5667)	This is ValidateField, a member of class IValidateField.

Public Properties

	Name	Description
	Caption (see page 5529)	Specifies the text of a label that indicates what information the generated control displays.
	CaptionAttributes (see page 5530)	Customizes the appearance of the generated control's label.
	Custom (see page 5530)	Represents a tag option and its value in the tag for the display control.
	DisplayRows (see page 5588)	Specifies the height of the generated control.
	DisplayWidth (see page 5588)	Specifies the horizontal size of the generated control.

	FieldName (see page 5649)	This is FieldName, a member of class IDataSetField.
	FieldName (see page 5539)	Specifies the name of the field whose value the generated control represents.
R	HTMLControlName (see page 5655)	Indicates the name of the generated HTML control.
	ReadOnly (see page 5588)	Indicates whether end users can use the generated control to set values.
	Style (see page 5531)	Adds style attributes to the generated display control.
	StyleRule (see page 5532)	This is StyleRule, a member of class TWebDataDisplay.
	TabIndex (see page 5532)	Determines the position of the generated control in the HTML form's tab order.
	Wrap (see page 5588)	Specifies how the generated control treats lines that are longer than the display width.

52.1.59.2 TWebTextAreaInput.Create Constructor

Creates and initializes an instance of TWebTextAreaInput (see page 5583).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TWebTextAreaInput(TComponent * AOwner);
```

Description

Call Create to instantiate TWebTextAreaInput (see page 5583) at runtime. TWebTextAreaInput (see page 5583) descendants added at design time using the Web Page editor are instantiated automatically.

52.1.59.3 TWebTextAreaInput Methods

The methods of the TWebTextAreaInput class are listed here.

Protected Methods

	Name	Description
V	AddAttributes (see page 5586)	This is AddAttributes, a member of class TWebTextAreaInput.
V	ControlContent (see page 5586)	This is ControlContent, a member of class TWebTextAreaInput.
V	EventContent (see page 5587)	This is EventContent, a member of class TWebTextAreaInput.
V	ImplGetRowSetFieldAttributes (see page 5587)	This is ImplGetRowSetFieldAttributes, a member of class TWebTextAreaInput.
V	RestoreFieldDefaults (see page 5587)	This is RestoreFieldDefaults, a member of class TWebTextAreaInput.

52.1.59.3.1 TWebTextAreaInput.AddAttributes Method

Pascal

```
procedure AddAttributes(var Attrs: string); virtual;
```

C++

```
virtual __fastcall AddAttributes(UnicodeString Attrs);
```

Description

This is AddAttributes, a member of class TWebTextAreaInput.

52.1.59.3.2 TWebTextAreaInput.ControlContent Method

Pascal

```
function ControlContent(Options: TWebContentOptions): string; override;
```

C++

```
virtual __fastcall UnicodeString ControlContent(TWebContentOptions Options);
```

Description

This is ControlContent, a member of class TWebTextAreaInput.

52.1.59.3.3 TWebTextAreaInput.EventContent Method

Pascal

```
function EventContent(Options: TWebContentOptions): string; override;
```

C++

```
virtual __fastcall UnicodeString EventContent(TWebContentOptions Options);
```

Description

This is EventContent, a member of class TWebTextAreaInput.

52.1.59.3.4 TWebTextAreaInput.ImplGetRowSetFieldAttributes Method

Pascal

```
function ImplGetRowSetFieldAttributes(const FieldVarName: string): string; override;
```

C++

```
virtual __fastcall UnicodeString ImplGetRowSetFieldAttributes(const UnicodeString
FieldVarName);
```

Description

This is ImplGetRowSetFieldAttributes, a member of class TWebTextAreaInput.

52.1.59.3.5 TWebTextAreaInput.RestoreFieldDefaults Method

Pascal

```
procedure RestoreFieldDefaults(AField: TField); override;
```

C++

```
virtual __fastcall RestoreFieldDefaults(TField AField);
```

Description

This is RestoreFieldDefaults, a member of class TWebTextAreaInput.

52.1.59.4 TWebTextAreaInput Properties

The properties of the TWebTextAreaInput class are listed here.

Public Properties

	Name	Description
	DisplayRows (see page 5588)	Specifies the height of the generated control.
	DisplayWidth (see page 5588)	Specifies the horizontal size of the generated control.
	ReadOnly (see page 5588)	Indicates whether end users can use the generated control to set values.
	Wrap (see page 5588)	Specifies how the generated control treats lines that are longer than the display width.

52.1.59.4.1 TWebTextAreaInput.DisplayRows Property

Specifies the height of the generated control.

Pascal

```
property DisplayRows: Integer;
```

C++

```
__property int DisplayRows;
```

Description

Use DisplayRows to indicate the desired height of the generated HTML control. DisplayRows specifies the number of lines of text that can be displayed in the control. This value is assigned to the ROWS option of the generated TEXTAREA tag.

See Also

DisplayWidth (see page 5588)

52.1.59.4.2 TWebTextAreaInput.DisplayWidth Property

Specifies the horizontal size of the generated control.

Pascal

```
property DisplayWidth: Integer;
```

C++

```
__property int DisplayWidth;
```

Description

Use DisplayWidth to indicate the desired width of the generated HTML control. DisplayWidth specifies the number of characters that can be displayed in one line of the control. This value is assigned to the COLS option of the generated TEXTAREA tag.

See Also

DisplayRows (see page 5588)

52.1.59.4.3 TWebTextAreaInput.ReadOnly Property

Indicates whether end users can use the generated control to set values.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

Use ReadOnly to indicate whether users can change the value displayed by the generated control. This value determines whether there is a READONLY option added to the generated TEXTAREA tag.

52.1.59.4.4 TWebTextAreaInput.Wrap Property

Specifies how the generated control treats lines that are longer than the display width.

Pascal

```
property Wrap: TTextAreaWrap;
```

C++

```
__property TTextAreaWrap Wrap;
```

Description

Use Wrap to specify how the generated control formats lines that are longer than the number of characters specified by DisplayWidth (see page 5588). TWebTextAreaInput (see page 5583) uses Wrap to add a WRAP option to the generated TEXTAREA tag.

Wrap can have any of the following values:

Value	WRAP option value	Meaning
wrOff	OFF	The control does not wrap long lines. Only newline characters that are part of the text string cause the lines in the control to wrap.
wrPhysical	PHYSICAL	The control formats its text value by wrapping long lines so that no text is hidden. The control inserts carriage returns into the text string.
wrVirtual	VIRTUAL	The control formats its text value by wrapping long lines so that no text is hidden but does not change the actual value of the text string.

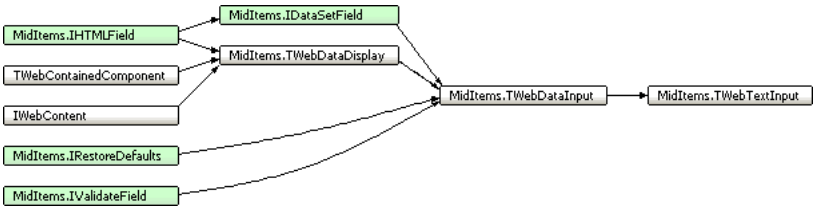
See Also

DisplayWidth (see page 5588)

52.1.60 TWebTextInput Class

TWebTextInput is the base class for Web items that create HTML single-line text controls.

Class Hierarchy



Pascal

```
TWebTextInput = class(TWebDataInput);
```

C++

```
class TWebTextInput : public TWebDataInput;
```

File

MidItems

Description

Use TWebTextInput as a base class for components that generate HTML controls for displaying a field or parameter value as a single-line text string. TWebTextInput descendants generate controls that are organized by TDataGrid (see page 5302),

TFieldGroup (see page 5320), or TQueryFieldGroup (see page 5415).

TWebTextInput defines or inherits properties and methods for

Specifying a field or parameter whose value the control displays.

Generating a caption that describes the information displayed.

Customizing the appearance of the control that displays information.

Fitting the control into the tab order of the generated HTML form.

Fitting the component into a hierarchy of Web items that collectively generate the content of an HTML document.

In order to let other Web items to use the HTML control it generates, TWebTextInput inherits the IWebContent interface from TWebDataDisplay (see page 5519).

Do not create instances of TWebTextInput. Instead, use a descendant of TWebTextInput such as TFieldText (see page 5349), TQueryText (see page 5449), or TTextColumn (see page 5495).

See Also

IWebContent

TDataGrid (see page 5302)

TFieldGroup (see page 5320)

TQueryFieldGroup (see page 5415)

TFieldText (see page 5349)

TQueryText (see page 5449)

TTextColumn (see page 5495)

52.1.60.1 TWebTextInput Members

The following tables list the members exposed by TWebTextInput.

Protected Methods

	Name	Description
	AddAttributes (see page 5592)	This is AddAttributes, a member of class TWebTextInput.
	Content (see page 5523)	Returns the HTML that defines the display control.
	ControlContent (see page 5592)	This is ControlContent, a member of class TWebTextInput.
	EventContent (see page 5523)	This is EventContent, a member of class TWebDataDisplay.
	EventContent (see page 5535)	This is EventContent, a member of class TWebDataInput.
	FindAssociatedField (see page 5535)	This is FindAssociatedField, a member of class TWebDataInput.
	FormatCaption (see page 5524)	This is FormatCaption, a member of class TWebDataDisplay.
	GetCaption (see page 5524)	Returns the value of the Caption (see page 5529) property.
	GetCaption (see page 5536)	Returns the value of the Caption property.
	GetFieldName (see page 5536)	This is GetFieldName, a member of class TWebDataInput.
	GetHTMLControlName (see page 5524)	Returns the name that other components can use to refer to the generated display control.
	GetHTMLForm (see page 5524)	Used internally to retrieve information about the form in which the display control is defined.
	GetLayoutAttributes (see page 5525)	Returns the value of the LayoutAttributes (see page 5531) property.
	GetParamName (see page 5536)	This is GetParamName, a member of class TWebDataInput.
	GetRowSetFieldAttributes (see page 5536)	This is GetRowSetFieldAttributes, a member of class TWebDataInput.
	GetXmlDisplayName (see page 5525)	Returns the name of the javascript object that uses TWebDataDisplay (see page 5519) to generate one of its display controls. Not used on Linux.

	GetXmlRowSetName (see page 5526)	Returns the name of the rowset in the XML data packet whose data is represented by the HTML this component generates. Not used on Linux.
V	ImplContent (see page 5526)	Provides the underlying implementation for the Content (see page 5523) method.
V	ImplGetFieldName (see page 5537)	This is ImplGetFieldName, a member of class TWebDataInput.
V	ImplGetHTMLControlName (see page 5527)	Returns the name that other components can use to refer to the generated display control.
V	ImplGetHTMLControlName (see page 5537)	Returns the name that other components can use to refer to the generated display control.
V	ImplGetRowSetFieldAttributes (see page 5593)	This is ImplGetRowSetFieldAttributes, a member of class TWebTextInput.
V	ImplRestoreDefaults (see page 5537)	This is ImplRestoreDefaults, a member of class TWebDataInput.
V	LabelContent (see page 5528)	This is LabelContent, a member of class TWebDataDisplay.
	RestoreDefaults (see page 5538)	This is RestoreDefaults, a member of class TWebDataInput.
V	RestoreFieldDefaults (see page 5593)	This is RestoreFieldDefaults, a member of class TWebTextInput.
V	SetCaption (see page 5528)	Sets the value of the Caption (see page 5529) property.
V	SetCaption (see page 5538)	Sets the value of the Caption property.
	SetCaptionAttributes (see page 5529)	Sets the value of the CaptionAttributes (see page 5530) property.
	SetFieldName (see page 5538)	This is SetFieldName, a member of class TWebDataInput.
	SetParamName (see page 5539)	This is SetParamName, a member of class TWebDataInput.
	ValidateField (see page 5539)	This is ValidateField, a member of class TWebDataInput.

Protected Properties

	Name	Description
	CaptionPosition (see page 5530)	Specifies where the label appears relative to the generated display control.
R	LayoutAttributes (see page 5531)	Encodes attributes that describe how the generated control should look.
	ParamName (see page 5540)	Specifies the name of the parameter whose value the generated control represents.

Public Methods

	Name	Description
V	Create (see page 5592)	Creates and initializes an instance of TWebTextInput (see page 5589).
V	Destroy (see page 5522)	Frees an instance of TWebDataDisplay (see page 5519).
	GetFieldName (see page 5648)	This is GetFieldName, a member of class IDataSetField.
	GetHTMLControlName (see page 5654)	Returns the name of the generated HTML <INPUT> control.
	GetRowSetFieldAttributes (see page 5649)	This is GetRowSetFieldAttributes, a member of class IDataSetField.
V	IsColumn (see page 5527)	Indicates whether the component generates the controls that appear in the column of a grid.
V	IsQueryField (see page 5528)	Indicates whether the component generates the controls that appear in a query form. Not used on Linux.
	RestoreDefaults (see page 5666)	This is RestoreDefaults, a member of class IRestoreDefaults.
	SetFieldName (see page 5649)	This is SetFieldName, a member of class IDataSetField.
	ValidateField (see page 5667)	This is ValidateField, a member of class IValidateField.

Public Properties

	Name	Description
	Caption (see page 5529)	Specifies the text of a label that indicates what information the generated control displays.
	CaptionAttributes (see page 5530)	Customizes the appearance of the generated control's label.
	Custom (see page 5593)	Represents a tag option and its value in the tag for the display control.
	DisplayWidth (see page 5594)	Specifies the horizontal size of the generated control.
	FieldName (see page 5649)	This is FieldName, a member of class IDataSetField.
	FieldName (see page 5539)	Specifies the name of the field whose value the generated control represents.
R	HTMLControlName (see page 5655)	Indicates the name of the generated HTML control.
	ReadOnly (see page 5594)	Indicates whether end users can use the generated control to set values.
	Style (see page 5594)	Adds style attributes to the generated display control.
	StyleRule (see page 5595)	This is StyleRule, a member of class TWebTextInput.
	TabIndex (see page 5532)	Determines the position of the generated control in the HTML form's tab order.

52.1.60.2 TWebTextInput.Create Constructor

Creates and initializes an instance of TWebTextInput (see page 5589).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TWebTextInput(TComponent * AOwner);
```

Description

Call Create to instantiate a TWebTextInput (see page 5589) descendant at runtime. TWebTextInput (see page 5589) descendants added at design time using the Web Page editor are instantiated automatically.

52.1.60.3 TWebTextInput Methods

The methods of the TWebTextInput class are listed here.

Protected Methods

	Name	Description
	AddAttributes (see page 5592)	This is AddAttributes, a member of class TWebTextInput.
	ControlContent (see page 5592)	This is ControlContent, a member of class TWebTextInput.
	ImplGetRowSetFieldAttributes (see page 5593)	This is ImplGetRowSetFieldAttributes, a member of class TWebTextInput.
	RestoreFieldDefaults (see page 5593)	This is RestoreFieldDefaults, a member of class TWebTextInput.

52.1.60.3.1 TWebTextInput.AddAttributes Method

Pascal

```
procedure AddAttributes(var Attrs: string); virtual;
```

C++

```
virtual __fastcall AddAttributes(UnicodeString Attrs);
```

Description

This is AddAttributes, a member of class TWebTextInput.

52.1.60.3.2 TWebTextInput.ControlContent Method

Pascal

```
function ControlContent(Options: TWebContentOptions): string; override;
```

C++

```
virtual __fastcall UnicodeString ControlContent(TWebContentOptions Options);
```

Description

This is ControlContent, a member of class TWebTextInput.

52.1.60.3.3 TWebTextInput.ImplGetRowSetFieldAttributes Method

Pascal

```
function ImplGetRowSetFieldAttributes(const FieldVarName: string): string; override;
```

C++

```
virtual __fastcall UnicodeString ImplGetRowSetFieldAttributes(const UnicodeString
FieldVarName);
```

Description

This is ImplGetRowSetFieldAttributes, a member of class TWebTextInput.

52.1.60.3.4 TWebTextInput.RestoreFieldDefaults Method

Pascal

```
procedure RestoreFieldDefaults(AField: TField); override;
```

C++

```
virtual __fastcall RestoreFieldDefaults(TField AField);
```

Description

This is RestoreFieldDefaults, a member of class TWebTextInput.

52.1.60.4 TWebTextInput Properties

The properties of the TWebTextInput class are listed here.

Public Properties

	Name	Description
	Custom (see page 5593)	Represents a tag option and its value in the tag for the display control.
	DisplayWidth (see page 5594)	Specifies the horizontal size of the generated control.
	ReadOnly (see page 5594)	Indicates whether end users can use the generated control to set values.
	Style (see page 5594)	Adds style attributes to the generated display control.
	StyleRule (see page 5595)	This is StyleRule, a member of class TWebTextInput.

52.1.60.4.1 TWebTextInput.Custom Property

Represents a tag option and its value in the tag for the display control.

Pascal

```
property Custom: string;
```

C++

```
__property UnicodeString Custom;
```

Description

TWebDataDisplay descendants generate different HTML tags to generate the control that displays information. Use Custom to add options that qualify the tag. Each option and its value has the form

OPTIONNAME=Value

The options specified by Custom should be separated by spaces. For example, to provide an INPUT control with an accelerator

key and align text to the bottom, you can set Custom to

ACCESSKEY=A ALIGN=BOTTOM

Note: To add custom options to the control's label, use the CaptionAttributes property instead.

See Also

Style (see page 5531)

stylerule (see page 5532)

CaptionAttributes (see page 5530)

52.1.60.4.2 TWebTextInput.DisplayWidth Property

Specifies the horizontal size of the generated control.

Pascal

```
property DisplayWidth: Integer;
```

C++

```
__property int DisplayWidth;
```

Description

Use DisplayWidth to indicate the desired width of the generated HTML control. DisplayWidth specifies the number of characters that can be displayed in the control.

Note: DisplayWidth controls the size of the generated control, not the size of the text that users can enter. If the user enters a string longer than DisplayWidth characters, the text scrolls in the control.

52.1.60.4.3 TWebTextInput.ReadOnly Property

Indicates whether end users can use the generated control to set values.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

Use ReadOnly to indicate whether users can change the value displayed by the generated control.

52.1.60.4.4 TWebTextInput.Style Property

Adds style attributes to the generated display control.

Pascal

```
property Style: string;
```

C++

```
__property UnicodeString Style;
```

Description

Use Style to specify display characteristics that affect the generated control. The Style option consists of one or more attribute descriptions such as

font-family: arial; font-weight: bold; font-size: 10px

These attributes are added to the HTML tag that generates the control as the value of a STYLE option.

Note: To add style attributes to the control's label, use the CaptionAttributes property instead.

See Also

Custom (see page 5530)

stylerule (see page 5532)

CaptionAttributes (see page 5530)

Setting Web Item Properties

52.1.60.4.5 TWebTextInput.StyleRule Property

Pascal

```
property StyleRule: string;
```

C++

```
__property UnicodeString StyleRule;
```

Description

This is StyleRule, a member of class TWebTextInput.

52.1.61 TXMLButton Class

TXMLButton is the base class for Web items that create HTML buttons that perform some action with the XML data packet.

Class Hierarchy

Pascal

```
TXMLButton = class(TWebButton);
```

C++

```
class TXMLButton : public TWebButton;
```

File

MidItems

Description

Use TXMLButton as a base class for components that generate the HTML statements defining a specialized button control for manipulating an XML data packet. TXMLButton defines properties and methods for

Generating the HTML code to define the button control.

Associating the button with an XML broker that fetches the XML data packet and responds to update messages.

Specifying tag attributes of the HTML button control, including those defined by a style sheet.

Fitting the component into a hierarchy of Web items, each of which generates part of a larger HTML document.

In order to allow other Web items to use the HTML generated by the button control, TXMLButton inherits support for the IWebContent interface from TWebButton (see page 5504).

Do not create instances of TXMLButton. TXMLButton relies on anabstract or, in C++ terminology, pure virtual method to generate the HTML statements defining a button control. Instead, create descendants of TXMLButton, such as TApplyUpdatesButton (see page 5250).

See Also

TApplyUpdatesButton (see page 5250)

IWebContent

52.1.61.1 TXMLButton Members

The following tables list the members exposed by TXMLButton.

Protected Methods

	Name	Description
	Content (see page 5506)	Returns the HTML that defines the button control.
V	GetCaption (see page 5597)	Returns the value of the Caption property.
V	GetLayoutAttributes (see page 5507)	Returns the layout object that specifies how the generated control should look.
	GetXMLBroker (see page 5598)	This is GetXMLBroker, a member of class TXMLButton.
	GetXMLUseParent (see page 5598)	This is GetXMLUseParent, a member of class TXMLButton.
A	ImplContent (see page 5507)	Provides the underlying implementation for the Content (see page 5506) method.
V	Notification (see page 5598)	Forwards notification messages to all owned components.
V	SetCaption (see page 5508)	Sets the value of the Caption (see page 5508) property.
	SetXMLBroker (see page 5599)	This is SetXMLBroker, a member of class TXMLButton.
	SetXMLUseParent (see page 5599)	This is SetXMLUseParent, a member of class TXMLButton.

Protected Properties

	Name	Description
	DefaultCaption (see page 5599)	This is DefaultCaption, a member of class TXMLButton.
R	XMLData (see page 5600)	This is XMLData, a member of class TXMLButton.

Public Methods

	Name	Description
V	Create (see page 5596)	Creates and initializes an instance of TXMLButton (see page 5595).
V	Destroy (see page 5597)	Frees an instance of TXMLButton (see page 5595).

Public Properties

	Name	Description
	Caption (see page 5508)	Specifies the caption that appears on the button.
	Custom (see page 5509)	Represents a tag option and its value in the generated INPUT tag.
	Style (see page 5509)	Adds style attributes to the generated button control.
	StyleRule (see page 5510)	Applies a style in the page producer's style sheet to the button.
	XMLBroker (see page 5599)	Associates the XML button with an XML broker.
	XMLUseParent (see page 5600)	Specifies whether the XML button is associated with its parent's XML broker.

52.1.61.2 TXMLButton.Create Constructor

Creates and initializes an instance of TXMLButton (see page 5595).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TXMLButton(TComponent * AOwner);
```

Description

Call Create to instantiate an XML button at runtime. Web buttons added at design time using the Web Page editor are instantiated automatically.

52.1.61.3 TXMLButton.Destroy Destructor

Frees an instance of TXMLButton (see page 5595).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TXMLButton();
```

Description

Destroy removes the XML button from its parent's list of components that generate HTML before freeing the button instance.

52.1.61.4 TXMLButton Methods

The methods of the TXMLButton class are listed here.

Protected Methods

	Name	Description
	GetCaption (see page 5597)	Returns the value of the Caption property.
	GetXMLBroker (see page 5598)	This is GetXMLBroker, a member of class TXMLButton.
	GetXMLUseParent (see page 5598)	This is GetXMLUseParent, a member of class TXMLButton.
	Notification (see page 5598)	Forwards notification messages to all owned components.
	SetXMLBroker (see page 5599)	This is SetXMLBroker, a member of class TXMLButton.
	SetXMLUseParent (see page 5599)	This is SetXMLUseParent, a member of class TXMLButton.

52.1.61.4.1 TXMLButton.GetCaption Method

Returns the value of the Caption property.

Pascal

```
function GetCaption: string; override;
```

C++

```
virtual __fastcall UnicodeString GetCaption();
```

Description

GetCaption is the protected read implementation for the Caption property.

See Also

Caption (see page 5508)

SetCaption (see page 5508)

52.1.61.4.2 TXMLButton.GetXMLBroker Method

Pascal

```
function GetXMLBroker: TXMLBroker;
```

C++

```
__fastcall TXMLBroker GetXMLBroker();
```

Description

This is GetXMLBroker, a member of class TXMLButton.

52.1.61.4.3 TXMLButton.GetXMLUseParent Method

Pascal

```
function GetXMLUseParent: Boolean;
```

C++

```
__fastcall Boolean GetXMLUseParent();
```

Description

This is GetXMLUseParent, a member of class TXMLButton.

52.1.61.4.4 TXMLButton.Notification Method

Forwards notification messages to all owned components.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation. By default, components pass along the notification to their owned components, if any.

A component can, if needed, act on the notification that a component is being inserted or removed. For example, if a component has object fields or properties that contain references to other components, it can check the notifications of component removals and invalidate those references as needed.

Note: Notification is not called for components that are freed implicitly (because their Owner is freed).

See Also

FreeNotification

InsertComponent

RemoveComponent

Owner

52.1.61.4.5 TXMLButton.SetXMLBroker Method

Pascal

```
procedure SetXMLBroker(const Value: TXMLBroker);
```

C++

```
__fastcall SetXMLBroker(const TXMLBroker Value);
```

Description

This is SetXMLBroker, a member of class TXMLButton.

52.1.61.4.6 TXMLButton.SetXMLUseParent Method

Pascal

```
procedure SetXMLUseParent(const Value: Boolean);
```

C++

```
__fastcall SetXMLUseParent(const Boolean Value);
```

Description

This is SetXMLUseParent, a member of class TXMLButton.

52.1.61.5 TXMLButton Properties

The properties of the TXMLButton class are listed here.

Protected Properties

	Name	Description
	DefaultCaption (see page 5599)	This is DefaultCaption, a member of class TXMLButton.
R	XMLData (see page 5600)	This is XMLData, a member of class TXMLButton.

Public Properties

	Name	Description
	XMLBroker (see page 5599)	Associates the XML button with an XML broker.
	XMLUseParent (see page 5600)	Specifies whether the XML button is associated with its parent's XML broker.

52.1.61.5.1 TXMLButton.DefaultCaption Property

Pascal

```
property DefaultCaption: string;
```

C++

```
__property UnicodeString DefaultCaption;
```

Description

This is DefaultCaption, a member of class TXMLButton.

52.1.61.5.2 TXMLButton.XMLBroker Property

Associates the XML button with an XML broker.

Pascal

```
property XMLBroker: TXMLBroker;
```

C++

```
__property TXMLBroker XMLBroker;
```

Description

Set XMLBroker to specify the XML broker whose data packets the XML button manipulates.

When XML buttons are used by TDataNavigator (see page 5307), the data navigator already establishes a connection (indirectly) to an XML broker. If the XML button uses this same XML broker, you do not need to set the XMLBroker property. Instead, setting the XMLUseParent (see page 5600) property to true (the default) automatically associates the XML button with the same broker as the one associated with the navigator.

See Also

XMLUseParent (see page 5600)

52.1.61.5.3 TXMLButton.XMLData Property

Pascal

```
property XMLData: TXMLDataParent;
```

C++

```
__property TXMLDataParent XMLData;
```

Description

This is XMLData, a member of class TXMLButton.

52.1.61.5.4 TXMLButton.XMLUseParent Property

Specifies whether the XML button is associated with its parent's XML broker.

Pascal

```
property XMLUseParent: Boolean;
```

C++

```
__property Boolean XMLUseParent;
```

Description

Use XMLUseParent to indicate how the XML button determines the XML broker whose data packets it manipulates. When XMLUseParent is false, the XMLBroker (see page 5599) property must be set to indicate the XML broker. When XMLUseParent is true, the XML broker associated with the XML button's parent determines the associated XML broker.

The XML button's parent is the Web item (typically TDataNavigator (see page 5307)) that uses the XML button to assemble its own HTML content. The parent's associated broker may be defined through an indirect association. For example, the data navigator acts on another component, such as a field group, which has an associated broker.

If the parent does not have an associated XML broker, setting XMLUseParent to true sets the XMLBroker (see page 5599) property to nil (Delphi) or NULL (C++).

See Also

XMLBroker (see page 5599)

52.1.62 TXMLData Class

TXMLData manages the relationship between an XML broker and a Web item that represents a dataset in that XML broker's data packet.

Class Hierarchy

Pascal

```
TXMLData = class(TObject);
```

C++

```
class TXMLData : public TObject;
```

File

MidItems

Description

TXMLData represents the link to an XML broker for a Web item that is bound to a dataset in the XML broker's data packet. It is the base class for TXMLDataSet (see page 5608), which allows the Web item to bind to a dataset field nested in the XML broker's top-level dataset.

TXMLData does not support the ability to bind to a nested dataset field. Rather, it introduces the underlying support needed to keep track of the XML broker for components that supply this ability.

See Also

TXMLBroker

IDataSetComponent (see page 5644)

TXMLDataSet (see page 5608)

52.1.62.1 TXMLData Members

The following tables list the members exposed by TXMLData.

Protected Methods

	Name	Description
	Changed (see page 5602)	This is Changed, a member of class TXMLData.
	ChangedXMLBroker (see page 5603)	This is ChangedXMLBroker, a member of class TXMLData.
	GetXMLBroker (see page 5603)	This is GetXMLBroker, a member of class TXMLData.
	SetXMLBroker (see page 5603)	This is SetXMLBroker, a member of class TXMLData.

Public Events

	Name	Description
	OnChange (see page 5605)	Occurs when the XMLBroker (see page 5604) property changes.

Public Methods

	Name	Description
	Create (see page 5602)	Creates a new TXMLData (see page 5601) object.
	Notification (see page 5603)	Responds to notifications when objects are created or destroyed.

Public Properties

	Name	Description
	Parent (see page 5604)	Indicates the Web item that uses this object to represent its link to an XML broker.
	XMLBroker (see page 5604)	Specifies the XML broker that generates the dataset to which the associated Web item is bound.

52.1.62.2 TXMLData.Create Constructor

Creates a new TXMLData (see page 5601) object.

Pascal

```
constructor Create(AParent: TComponent);
```

C++

```
__fastcall TXMLData(TComponent * AParent);
```

Description

Most applications do not need to call the TXMLData (see page 5601) constructor. The Web item that uses the TXMLData (see page 5601) object to represent its link to a dataset instantiates this object.

The AParent parameter specifies the Web item that uses the TXMLData (see page 5601) object to link to an XML broker. This becomes the value of the Parent (see page 5604) property.

See Also

Parent (see page 5604)

52.1.62.3 TXMLData Methods

The methods of the TXMLData class are listed here.

Protected Methods

	Name	Description
	Changed (see page 5602)	This is Changed, a member of class TXMLData.
	ChangedXMLBroker (see page 5603)	This is ChangedXMLBroker, a member of class TXMLData.
	GetXMLBroker (see page 5603)	This is GetXMLBroker, a member of class TXMLData.
	SetXMLBroker (see page 5603)	This is SetXMLBroker, a member of class TXMLData.

Public Methods

	Name	Description
	Notification (see page 5603)	Responds to notifications when objects are created or destroyed.

52.1.62.3.1 TXMLData.Changed Method

Pascal

```
procedure Changed;
```

C++

```
__fastcall Changed();
```

Description

This is Changed, a member of class TXMLData.

52.1.62.3.2 TXMLData.ChangedXMLBroker Method

Pascal

```
procedure ChangedXMLBroker; virtual;
```

C++

```
virtual __fastcall ChangedXMLBroker();
```

Description

This is ChangedXMLBroker, a member of class TXMLData.

52.1.62.3.3 TXMLData.GetXMLBroker Method

Pascal

```
function GetXMLBroker: TXMLBroker; virtual;
```

C++

```
virtual __fastcall TXMLBroker GetXMLBroker();
```

Description

This is GetXMLBroker, a member of class TXMLData.

52.1.62.3.4 TXMLData.Notification Method

Responds to notifications when objects are created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); virtual;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method. It is called automatically when objects are created or destroyed. TXMLData (see page 5601) responds to notifications by setting the XMLBroker (see page 5604) property to nil (Delphi) or NULL (C++) if it is notified that this component is about to be destroyed.

See Also

XMLBroker (see page 5604)

52.1.62.3.5 TXMLData.SetXMLBroker Method

Pascal

```
procedure SetXMLBroker(const Value: TXMLBroker); virtual;
```

C++

```
virtual __fastcall SetXMLBroker(const TXMLBroker Value);
```

Description

This is SetXMLBroker, a member of class TXMLData.

52.1.62.4 TXMLData Properties

The properties of the TXMLData class are listed here.

Public Properties

	Name	Description
	Parent (see page 5604)	Indicates the Web item that uses this object to represent its link to an XML broker.
	XMLBroker (see page 5604)	Specifies the XML broker that generates the dataset to which the associated Web item is bound.

52.1.62.4.1 TXMLData.Parent Property

Indicates the Web item that uses this object to represent its link to an XML broker.

Pascal

```
property Parent: TComponent;
```

C++

```
__property TComponent * Parent;
```

Description

Read Parent to determine the Web item that uses this object to bind to a dataset from an XML broker. The value of Parent is set by the constructor.

See Also

XMLBroker (see page 5604)

Create (see page 5602)

52.1.62.4.2 TXMLData.XMLBroker Property

Specifies the XML broker that generates the dataset to which the associated Web item is bound.

Pascal

```
property XMLBroker: TXMLBroker;
```

C++

```
__property TXMLBroker XMLBroker;
```

Description

The Web item specified by the Parent (see page 5604) property sets XMLBroker to bind to an XML broker.

When the value of XMLBroker changes, the TXMLData (see page 5601) object generates an OnChange (see page 5605) event.

See Also

Parent (see page 5604)

OnChange (see page 5605)

52.1.62.5 TXMLData Events

The events of the TXMLData class are listed here.

Public Events

	Name	Description
	OnChange (see page 5605)	Occurs when the XMLBroker (see page 5604) property changes.

52.1.62.5.1 TXMLData.OnChange Event

Occurs when the XMLBroker (see page 5604) property changes.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write an OnChange event handler to respond immediately after the Web item specified by Parent (see page 5604) becomes bound to a different XML broker. This occurs when Parent (see page 5604) changes the XMLBroker (see page 5604) property explicitly in response to a change in its own properties, or when the XML broker object to which it is bound is destroyed.

See Also

XMLBroker (see page 5604)

Parent (see page 5604)

52.1.63 TXMLDataParent Class

Class Hierarchy

Pascal

```
TXMLDataParent = class(TXMLData);
```

C++

```
class TXMLDataParent : public TXMLData;
```

File

MidItems

Description

This is class MidItems.TXMLDataParent.

52.1.63.1 TXMLDataParent Members

The following tables list the members exposed by TXMLDataParent.

Protected Methods

	Name	Description
	Changed (see page 5602)	This is Changed, a member of class TXMLData.
	ChangedUseParent (see page 5606)	This is ChangedUseParent, a member of class TXMLDataParent.

	ChangedXMLBroker (see page 5606)	This is ChangedXMLBroker, a member of class TXMLDataParent.
	GetXMLBroker (see page 5607)	This is GetXMLBroker, a member of class TXMLDataParent.
	ParentXMLBroker (see page 5607)	This is ParentXMLBroker, a member of class TXMLDataParent.
	SetUseParent (see page 5607)	This is SetUseParent, a member of class TXMLDataParent.
	SetXMLBroker (see page 5603)	This is SetXMLBroker, a member of class TXMLData.

Public Events

	Name	Description
	OnChange (see page 5605)	Occurs when the XMLBroker (see page 5604) property changes.

Public Methods

	Name	Description
	Create (see page 5602)	Creates a new TXMLData (see page 5601) object.
	Notification (see page 5603)	Responds to notifications when objects are created or destroyed.

Public Properties

	Name	Description
	Parent (see page 5604)	Indicates the Web item that uses this object to represent its link to an XML broker.
	XMLBroker (see page 5604)	Specifies the XML broker that generates the dataset to which the associated Web item is bound.

Published Properties

	Name	Description
	UseParent (see page 5608)	This is UseParent, a member of class TXMLDataParent.

52.1.63.2 TXMLDataParent Methods

The methods of the TXMLDataParent class are listed here.

Protected Methods

	Name	Description
	ChangedUseParent (see page 5606)	This is ChangedUseParent, a member of class TXMLDataParent.
	ChangedXMLBroker (see page 5606)	This is ChangedXMLBroker, a member of class TXMLDataParent.
	GetXMLBroker (see page 5607)	This is GetXMLBroker, a member of class TXMLDataParent.
	ParentXMLBroker (see page 5607)	This is ParentXMLBroker, a member of class TXMLDataParent.
	SetUseParent (see page 5607)	This is SetUseParent, a member of class TXMLDataParent.

52.1.63.2.1 TXMLDataParent.ChangedUseParent Method

Pascal

```
procedure ChangedUseParent; virtual;
```

C++

```
virtual __fastcall ChangedUseParent();
```

Description

This is ChangedUseParent, a member of class TXMLDataParent.

52.1.63.2.2 TXMLDataParent.ChangedXMLBroker Method

Pascal

```
procedure ChangedXMLBroker; override;
```

C++

```
virtual __fastcall ChangedXMLBroker();
```

Description

This is ChangedXMLBroker, a member of class TXMLDataParent.

52.1.63.2.3 TXMLDataParent.GetXMLBroker Method

Pascal

```
function GetXMLBroker: TXMLBroker; override;
```

C++

```
virtual __fastcall TXMLBroker GetXMLBroker();
```

Description

This is GetXMLBroker, a member of class TXMLDataParent.

52.1.63.2.4 TXMLDataParent.ParentXMLBroker Method

Pascal

```
function ParentXMLBroker: TXMLBroker;
```

C++

```
__fastcall TXMLBroker ParentXMLBroker();
```

Description

This is ParentXMLBroker, a member of class TXMLDataParent.

52.1.63.2.5 TXMLDataParent.SetUseParent Method

Pascal

```
procedure SetUseParent(const Value: Boolean);
```

C++

```
__fastcall SetUseParent(const Boolean Value);
```

Description

This is SetUseParent, a member of class TXMLDataParent.

52.1.63.3 TXMLDataParent Properties

The properties of the TXMLDataParent class are listed here.

Published Properties

	Name	Description
	UseParent (see page 5608)	This is UseParent, a member of class TXMLDataParent.

52.1.63.3.1 TXMLDataParent.UseParent Property

Pascal

```
property UseParent: Boolean;
```

C++

```
__property Boolean UseParent;
```

Description

This is UseParent, a member of class TXMLDataParent.

52.1.64 TXMLDataSet Class

TXMLDataSet manages the relationship between a Web item and the XML dataset to which it is bound.

Class Hierarchy

Pascal

```
TXMLDataSet = class(TXMLData, INotifyConnectionChange);
```

C++

```
class TXMLDataSet : public TXMLData, public INotifyConnectionChange;
```

File

MidItems

Description

TXMLDataSet represents a Web item's link to an XML dataset. The Web item can be bound to an XML broker's data packet, or to a dataset field nested in an XML broker's data packet.

See Also

TXMLBroker

IDataSetComponent (see page 5644)

TXMLDisplayGroup (see page 5620)

52.1.64.1 TXMLDataSet Members

The following tables list the members exposed by TXMLDataSet.

Protected Methods

	Name	Description
	_AddRef (see page 5610)	This is _AddRef, a member of class TXMLDataSet.
	_Release (see page 5611)	This is _Release, a member of class TXMLDataSet.
	Changed (see page 5602)	This is Changed, a member of class TXMLData.
V	ChangedDataSetField (see page 5611)	This is ChangedDataSetField, a member of class TXMLDataSet.
V	ChangedXMLBroker (see page 5611)	This is ChangedXMLBroker, a member of class TXMLDataSet.

	CompareXMLData (see page 5611)	This is CompareXMLData, a member of class TXMLDataSet.
	ConnectionChange (see page 5611)	This is ConnectionChange, a member of class TXMLDataSet.
	CreateDataSet (see page 5612)	This is CreateDataSet, a member of class TXMLDataSet.
	FindDataSet (see page 5612)	This is FindDataSet, a member of class TXMLDataSet.
	GetDataSet (see page 5612)	This is GetDataSet, a member of class TXMLDataSet.
V	GetDataSetField (see page 5612)	This is GetDataSetField, a member of class TXMLDataSet.
	GetDataSetPath (see page 5613)	This is GetDataSetPath, a member of class TXMLDataSet.
V	GetXMLBroker (see page 5603)	This is GetXMLBroker, a member of class TXMLData.
V	QueryInterface (see page 5613)	This is QueryInterface, a member of class TXMLDataSet.
	SetDataSetField (see page 5613)	This is SetDataSetField, a member of class TXMLDataSet.
V	SetXMLBroker (see page 5613)	This is SetXMLBroker, a member of class TXMLDataSet.
	WrapperDataChange (see page 5613)	This is WrapperDataChange, a member of class TXMLDataSet.

Protected Properties

	Name	Description
R	Parent (see page 5615)	Indicates the Web item that uses this object to represent its link to an XML broker.

Public Events

	Name	Description
	OnChange (see page 5605)	Occurs when the XMLBroker (see page 5604) property changes.

Public Methods

	Name	Description
	Create (see page 5609)	Creates a new TXMLDataSet (see page 5608) object.
V	Destroy (see page 5610)	TXMLDataSetFrees the memory associated with the TXMLDataSet (see page 5608) object.
V	Notification (see page 5603)	Responds to notifications when objects are created or destroyed.

Public Properties

	Name	Description
R	DataSet (see page 5614)	Provides access to an interface for working with the associated dataset.
	DataSetField (see page 5614)	Identifies a nested dataset in the associated XML broker's data packet.
R	DataSetPath (see page 5615)	Represents the parsed value of the DataSetField (see page 5614) property.
	XMLBroker (see page 5604)	Specifies the XML broker that generates the dataset to which the associated Web item is bound.

52.1.64.2 TXMLDataSet.Create Constructor

Creates a new TXMLDataSet (see page 5608) object.

Pascal

```
constructor Create(AParent: TComponent);
```

C++

```
__fastcall TXMLDataSet(TComponent * AParent);
```

Description

Most applications do not need to call the TXMLDataSet (see page 5608) constructor. The Web item that uses the TXMLDataSet (see page 5608) object to represent its link to a dataset instantiates this object.

The AParent parameter specifies the Web item that uses the TXMLDataSet (see page 5608) object to link to an XML dataset. This becomes the value of the Parent (see page 5615) property.

See Also

Parent (see page 5604)

52.1.64.3 TXMLDataSet.Destroy Destructor

TXMLDataSetFrees the memory associated with the TXMLDataSet (see page 5608) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TXMLDataSet();
```

Description

Typically, applications do not free instances of TXMLDataSet (see page 5608). Instead, this object is freed by the Web item that uses it.

52.1.64.4 TXMLDataSet Methods

The methods of the TXMLDataSet class are listed here.

Protected Methods

	Name	Description
	_AddRef (see page 5610)	This is _AddRef, a member of class TXMLDataSet.
	_Release (see page 5611)	This is _Release, a member of class TXMLDataSet.
V	ChangedDataSetField (see page 5611)	This is ChangedDataSetField, a member of class TXMLDataSet.
V	ChangedXMLBroker (see page 5611)	This is ChangedXMLBroker, a member of class TXMLDataSet.
	CompareXMLData (see page 5611)	This is CompareXMLData, a member of class TXMLDataSet.
	ConnectionChange (see page 5611)	This is ConnectionChange, a member of class TXMLDataSet.
	CreateDataSet (see page 5612)	This is CreateDataSet, a member of class TXMLDataSet.
	FindDataSet (see page 5612)	This is FindDataSet, a member of class TXMLDataSet.
	GetDataSet (see page 5612)	This is GetDataSet, a member of class TXMLDataSet.
V	GetDataSetField (see page 5612)	This is GetDataSetField, a member of class TXMLDataSet.
	GetDataSetPath (see page 5613)	This is GetDataSetPath, a member of class TXMLDataSet.
V	QueryInterface (see page 5613)	This is QueryInterface, a member of class TXMLDataSet.
	SetDataSetField (see page 5613)	This is SetDataSetField, a member of class TXMLDataSet.
V	SetXMLBroker (see page 5613)	This is SetXMLBroker, a member of class TXMLDataSet.
	WrapperDataChange (see page 5613)	This is WrapperDataChange, a member of class TXMLDataSet.

52.1.64.4.1 TXMLDataSet._AddRef Method

Pascal

```
function _AddRef: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _AddRef();
```

Description

This is _AddRef, a member of class TXMLDataSet.

52.1.64.4.2 TXMLDataSet._Release Method

Pascal

```
function _Release: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _Release();
```

Description

This is _Release, a member of class TXMLDataSet.

52.1.64.4.3 TXMLDataSet.ChangedDataSetField Method

Pascal

```
procedure ChangedDataSetField; virtual;
```

C++

```
virtual __fastcall ChangedDataSetField();
```

Description

This is ChangedDataSetField, a member of class TXMLDataSet.

52.1.64.4.4 TXMLDataSet.ChangedXMLBroker Method

Pascal

```
procedure ChangedXMLBroker; override;
```

C++

```
virtual __fastcall ChangedXMLBroker();
```

Description

This is ChangedXMLBroker, a member of class TXMLDataSet.

52.1.64.4.5 TXMLDataSet.CompareXMLData Method

Pascal

```
function CompareXMLData(XMLDataSet: TXMLDataSet): Boolean;
```

C++

```
__fastcall Boolean CompareXMLData(TXMLDataSet XMLDataSet);
```

Description

This is CompareXMLData, a member of class TXMLDataSet.

52.1.64.4.6 TXMLDataSet.ConnectionChange Method

Pascal

```
procedure ConnectionChange(Sender: TComponent; Connecting: Boolean);
```

C++

```
__fastcall ConnectionChange(TComponent * Sender, Boolean Connecting);
```

Description

This is ConnectionChange, a member of class TXMLDataSet.

52.1.64.4.7 TXMLDataSet.CreateDataSet Method

Pascal

```
function CreateDataSet: IInetXWebDataSet;
```

C++

```
__fastcall IInetXWebDataSet CreateDataSet();
```

Description

This is CreateDataSet, a member of class TXMLDataSet.

52.1.64.4.8 TXMLDataSet.FindDataSet Method

Pascal

```
function FindDataSet: IInetXWebDataSet;
```

C++

```
__fastcall IInetXWebDataSet FindDataSet();
```

Description

This is FindDataSet, a member of class TXMLDataSet.

52.1.64.4.9 TXMLDataSet.GetDataSet Method

Pascal

```
function GetDataSet: IInetXWebDataSet;
```

C++

```
__fastcall IInetXWebDataSet GetDataSet();
```

Description

This is GetDataSet, a member of class TXMLDataSet.

52.1.64.4.10 TXMLDataSet.GetDataSetField Method

Pascal

```
function GetDataSetField: string; virtual;
```

C++

```
virtual __fastcall UnicodeString GetDataSetField();
```

Description

This is GetDataSetField, a member of class TXMLDataSet.

52.1.64.4.11 TXMLDataSet.GetDataSetPath Method

Pascal

```
function GetDataSetPath: TStrings;
```

C++

```
__fastcall TStrings GetDataSetPath();
```

Description

This is GetDataSetPath, a member of class TXMLDataSet.

52.1.64.4.12 TXMLDataSet.QueryInterface Method

Pascal

```
function QueryInterface(const IID: TGUID; out Obj): HResult; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT QueryInterface(const TGUID IID,  Obj);
```

Description

This is QueryInterface, a member of class TXMLDataSet.

52.1.64.4.13 TXMLDataSet.SetDataSetField Method

Pascal

```
procedure SetDataSetField(const Value: string);
```

C++

```
__fastcall SetDataSetField(const UnicodeString Value);
```

Description

This is SetDataSetField, a member of class TXMLDataSet.

52.1.64.4.14 TXMLDataSet.SetXMLBroker Method

Pascal

```
procedure SetXMLBroker(const Value: TXMLBroker); override;
```

C++

```
virtual __fastcall SetXMLBroker(const TXMLBroker Value);
```

Description

This is SetXMLBroker, a member of class TXMLDataSet.

52.1.64.4.15 TXMLDataSet.WrapperDataChange Method

Pascal

```
procedure WrapperDataChange(Sender: TObject);
```

C++

```
__fastcall WrapperDataChange(TObject * Sender);
```

Description

This is WrapperDataChange, a member of class TXMLDataSet.

52.1.64.5 TXMLDataSet Properties

The properties of the TXMLDataSet class are listed here.

Protected Properties

	Name	Description
	Parent (see page 5615)	Indicates the Web item that uses this object to represent its link to an XML broker.

Public Properties

	Name	Description
	DataSet (see page 5614)	Provides access to an interface for working with the associated dataset.
	DataSetField (see page 5614)	Identifies a nested dataset in the associated XML broker's data packet.
	DataSetPath (see page 5615)	Represents the parsed value of the DataSetField (see page 5614) property.

52.1.64.5.1 TXMLDataSet.DataSet Property

Provides access to an interface for working with the associated dataset.

Pascal

```
property DataSet: IInetXWebDataSet;
```

C++

```
__property IInetXWebDataSet DataSet;
```

Description

Use DataSet to manipulate the associated dataset. DataSet is an interface that provides information about the available fields and parameters of the dataset and lets you respond when this information changes.

An advantage of using the DataSet property is that it handles the task of identifying the correct dataset within the associated XML broker's data packet. This lets you treat nested datasets in the same way that you interact with the XML broker's main dataset.

See Also

XMLBroker

DataSetField (see page 5614)

52.1.64.5.2 TXMLDataSet.DataSetField Property

Identifies a nested dataset in the associated XML broker's data packet.

Pascal

```
property DataSetField: string;
```

C++

```
__property UnicodeString DataSetField;
```

Description

Use DataSetField, in conjunction with the XMLBroker (see page 5604) property, to identify the XML dataset that the TXMLDataSet (see page 5608) object represents. If the dataset is the dataset represented directly by the XML broker's data

packet, DataSetField is an empty string and the XMLBroker (see page 5604) property fully describes the dataset. If the dataset is a nested detail set, DataSetField indicates what detail dataset to use from the data packet associated with XMLBroker (see page 5604).

Specify the name of the dataset field as the value of DataSetField. If the dataset is the detail set of a detail set, you can use periods to qualify dataset field names. Thus, for example, if XMLBroker (see page 5604) represents a customer dataset with a nested Orders dataset field that has its own nested LineItems field, you can specify the LineItems dataset by setting DataSetField to

```
Orders.LineItems
```

See Also

XMLBroker

DataSet (see page 5614)

DataSetPath (see page 5615)

52.1.64.5.3 TXMLDataSet.DataSetPath Property

Represents the parsed value of the DataSetField (see page 5614) property.

Pascal

```
property DataSetPath: TStrings;
```

C++

```
__property TStrings DataSetPath;
```

Description

DataSetPath is a parsed version of the DataSetField (see page 5614) property, where each dataset field is a separate string in the TStrings object. The order of the strings indicates the level of nesting, where the first string names a dataset field in the XML broker's data packet, the second string names a dataset field in that nested dataset, and so on.

See Also

XMLBroker

DataSetField (see page 5614)

52.1.64.5.4 TXMLDataSet.Parent Property

Indicates the Web item that uses this object to represent its link to an XML broker.

Pascal

```
property Parent: TComponent;
```

C++

```
__property TComponent * Parent;
```

Description

Read Parent to determine the Web item that uses this object to bind to a dataset from an XML broker. The value of Parent is set by the constructor.

See Also

XMLBroker (see page 5604)

Create (see page 5602)

52.1.65 TXMLDataSetParent Class

Class Hierarchy

Pascal

```
TXMLDataSetParent = class(TXMLDataSet);
```

C++

```
class TXMLDataSetParent : public TXMLDataSet;
```

File

MidItems

Description

This is class MidItems.TXMLDataSetParent.

52.1.65.1 TXMLDataSetParent Members

The following tables list the members exposed by TXMLDataSetParent.

Protected Methods

	Name	Description
	_AddRef (see page 5610)	This is _AddRef, a member of class TXMLDataSet.
	_Release (see page 5611)	This is _Release, a member of class TXMLDataSet.
	Changed (see page 5602)	This is Changed, a member of class TXMLData.
V	ChangedDataSetField (see page 5617)	This is ChangedDataSetField, a member of class TXMLDataSetParent.
V	ChangedUseParent (see page 5618)	This is ChangedUseParent, a member of class TXMLDataSetParent.
V	ChangedXMLBroker (see page 5618)	This is ChangedXMLBroker, a member of class TXMLDataSetParent.
	CompareXMLData (see page 5611)	This is CompareXMLData, a member of class TXMLDataSet.
	ConnectionChange (see page 5611)	This is ConnectionChange, a member of class TXMLDataSet.
	CreateDataSet (see page 5612)	This is CreateDataSet, a member of class TXMLDataSet.
	FindDataSet (see page 5612)	This is FindDataSet, a member of class TXMLDataSet.
	GetDataSet (see page 5612)	This is GetDataSet, a member of class TXMLDataSet.
V	GetDataSetField (see page 5618)	This is GetDataSetField, a member of class TXMLDataSetParent.
	GetDataSetPath (see page 5613)	This is GetDataSetPath, a member of class TXMLDataSet.
V	GetXMLBroker (see page 5618)	This is GetXMLBroker, a member of class TXMLDataSetParent.
	ParentDataSetField (see page 5618)	This is ParentDataSetField, a member of class TXMLDataSetParent.
	ParentXMLBroker (see page 5619)	This is ParentXMLBroker, a member of class TXMLDataSetParent.
	ParentXMLDataSet (see page 5619)	This is ParentXMLDataSet, a member of class TXMLDataSetParent.
V	QueryInterface (see page 5613)	This is QueryInterface, a member of class TXMLDataSet.
	SetDataSetField (see page 5613)	This is SetDataSetField, a member of class TXMLDataSet.
	SetUseParent (see page 5619)	This is SetUseParent, a member of class TXMLDataSetParent.
V	SetXMLBroker (see page 5603)	This is SetXMLBroker, a member of class TXMLData.
V	SetXMLBroker (see page 5613)	This is SetXMLBroker, a member of class TXMLDataSet.
	WrapperDataChange (see page 5613)	This is WrapperDataChange, a member of class TXMLDataSet.

Protected Properties

	Name	Description
	Parent (see page 5615)	Indicates the Web item that uses this object to represent its link to an XML broker.
	UseParent (see page 5619)	This is UseParent, a member of class TXMLDataSetParent.

Public Events

	Name	Description
	OnChange (see page 5605)	Occurs when the XMLBroker (see page 5604) property changes.

Public Methods

	Name	Description
	Create (see page 5602)	Creates a new TXMLData (see page 5601) object.
	Create (see page 5609)	Creates a new TXMLDataSet (see page 5608) object.
	Destroy (see page 5610)	TXMLDataSetFrees the memory associated with the TXMLDataSet (see page 5608) object.
	Notification (see page 5603)	Responds to notifications when objects are created or destroyed.

Public Properties

	Name	Description
	DataSet (see page 5614)	Provides access to an interface for working with the associated dataset.
	DataSetField (see page 5614)	Identifies a nested dataset in the associated XML broker's data packet.
	DataSetPath (see page 5615)	Represents the parsed value of the DataSetField (see page 5614) property.
	Parent (see page 5604)	Indicates the Web item that uses this object to represent its link to an XML broker.
	XMLBroker (see page 5604)	Specifies the XML broker that generates the dataset to which the associated Web item is bound.

52.1.65.2 TXMLDataSetParent Methods

The methods of the TXMLDataSetParent class are listed here.

Protected Methods

	Name	Description
	ChangedDataSetField (see page 5617)	This is ChangedDataSetField, a member of class TXMLDataSetParent.
	ChangedUseParent (see page 5618)	This is ChangedUseParent, a member of class TXMLDataSetParent.
	ChangedXMLBroker (see page 5618)	This is ChangedXMLBroker, a member of class TXMLDataSetParent.
	GetDataSetField (see page 5618)	This is GetDataSetField, a member of class TXMLDataSetParent.
	GetXMLBroker (see page 5618)	This is GetXMLBroker, a member of class TXMLDataSetParent.
	ParentDataSetField (see page 5618)	This is ParentDataSetField, a member of class TXMLDataSetParent.
	ParentXMLBroker (see page 5619)	This is ParentXMLBroker, a member of class TXMLDataSetParent.
	ParentXMLDataSet (see page 5619)	This is ParentXMLDataSet, a member of class TXMLDataSetParent.
	SetUseParent (see page 5619)	This is SetUseParent, a member of class TXMLDataSetParent.

52.1.65.2.1 TXMLDataSetParent.ChangedDataSetField Method

Pascal

```
procedure ChangedDataSetField; override;
```

C++

```
virtual __fastcall ChangedDataSetField();
```

Description

This is ChangedDataSetField, a member of class TXMLDataSetParent.

52.1.65.2.2 TXMLDataSetParent.ChangedUseParent Method

Pascal

```
procedure ChangedUseParent; virtual;
```

C++

```
virtual __fastcall ChangedUseParent();
```

Description

This is ChangedUseParent, a member of class TXMLDataSetParent.

52.1.65.2.3 TXMLDataSetParent.ChangedXMLBroker Method

Pascal

```
procedure ChangedXMLBroker; override;
```

C++

```
virtual __fastcall ChangedXMLBroker();
```

Description

This is ChangedXMLBroker, a member of class TXMLDataSetParent.

52.1.65.2.4 TXMLDataSetParent.GetDataSetField Method

Pascal

```
function GetDataSetField: string; override;
```

C++

```
virtual __fastcall UnicodeString GetDataSetField();
```

Description

This is GetDataSetField, a member of class TXMLDataSetParent.

52.1.65.2.5 TXMLDataSetParent.GetXMLBroker Method

Pascal

```
function GetXMLBroker: TXMLBroker; override;
```

C++

```
virtual __fastcall TXMLBroker GetXMLBroker();
```

Description

This is GetXMLBroker, a member of class TXMLDataSetParent.

52.1.65.2.6 TXMLDataSetParent.ParentDataSetField Method

Pascal

```
function ParentDataSetField: string;
```

C++

```
__fastcall UnicodeString ParentDataSetField();
```

Description

This is ParentDataSetField, a member of class TXMLDataSetParent.

52.1.65.2.7 TXMLDataSetParent.ParentXMLBroker Method

Pascal

```
function ParentXMLBroker: TXMLBroker;
```

C++

```
__fastcall TXMLBroker ParentXMLBroker();
```

Description

This is ParentXMLBroker, a member of class TXMLDataSetParent.

52.1.65.2.8 TXMLDataSetParent.ParentXMLDataSet Method

Pascal

```
function ParentXMLDataSet: TXMLDataSet;
```

C++

```
__fastcall TXMLDataSet ParentXMLDataSet();
```

Description

This is ParentXMLDataSet, a member of class TXMLDataSetParent.

52.1.65.2.9 TXMLDataSetParent.SetUseParent Method

Pascal

```
procedure SetUseParent(const Value: Boolean);
```

C++

```
__fastcall SetUseParent(const Boolean Value);
```

Description

This is SetUseParent, a member of class TXMLDataSetParent.

52.1.65.3 TXMLDataSetParent Properties

The properties of the TXMLDataSetParent class are listed here.

Protected Properties

	Name	Description
	UseParent (see page 5619)	This is UseParent, a member of class TXMLDataSetParent.

52.1.65.3.1 TXMLDataSetParent.UseParent Property

Pascal

```
property UseParent: Boolean;
```

C++

```
__property Boolean UseParent;
```

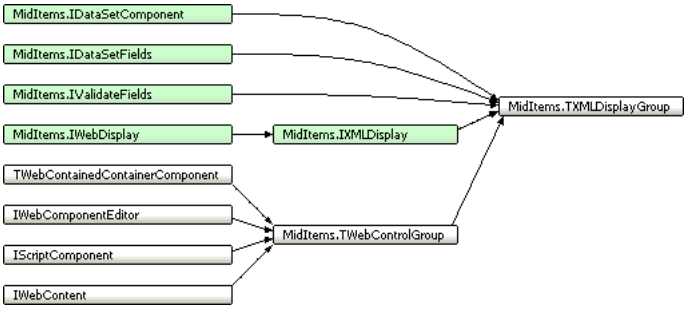
Description

This is UseParent, a member of class TXMLDataSetParent.

52.1.66 TXMLDisplayGroup Class

TXMLDisplayGroup is the base class for Web items that arrange a set of special-purpose controls in an HTML form.

Class Hierarchy



Pascal

```
TXMLDisplayGroup = class(TWebControlGroup, IDataSetComponent, IDataSetFields, IXMLDisplay,
IValidateFields);
```

C++

```
class TXMLDisplayGroup : public TWebControlGroup, public IDataSetComponent, public
IDataSetFields, public IXMLDisplay, public IValidateFields;
```

File

MidItems

Description

Use TXMLDisplayGroup as a base class for Web items that generate the HTML to arrange a collection of HTML controls. Each TXMLDisplayGroup object maintains a list of Web items that display information in the final HTML document. The XML display group arranges the controls that these items generate.

If the controls generated for TXMLDisplayGroup by its Web items represent database information, you can bind the XML display group to an XML data packet or dataset field within an XML data packet. The Web items can use that binding to determine the source of the data they display.

In order to let other Web items use the HTML that the TXMLDisplayGroup object generates, TXMLDisplayGroup inherits the IWebContent interface from TWebControlGroup (see page 5510).

Do not create instances of TXMLDisplayGroup. TXMLDisplayGroup manages the Web items that generate display controls, but does not produce any content. Instead, use a descendant of TXMLDisplayGroup that generates the HTML for its set of specialized controls such as TDataGrid (see page 5302), TFieldGroup (see page 5320) or TQueryFieldGroup (see page 5415).

See Also

TDataGrid (see page 5302)

TFieldGroup (see page 5320)

TQueryFieldGroup (see page 5415)

IWebContent

52.1.66.1 TXMLDisplayGroup Members

The following tables list the members exposed by TXMLDisplayGroup.

Protected Methods

	Name	Description
	AddElements (see page 5513)	Used internally to generate any script declarations needed by the group of controls.
	CanAddClass (see page 5513)	Specifies whether a Web item of a specified type can be added to the WebFieldControls (see page 5519) property list.
	ChangeFieldControls (see page 5514)	Responds when the group of HTML controls changes.
	Content (see page 5514)	Returns the HTML that defines the group of HTML controls.
	CreateDefaultFields (see page 5623)	This is CreateDefaultFields, a member of class TXMLDisplayGroup.
	FindField (see page 5623)	This is FindField, a member of class TXMLDisplayGroup.
	GetDataSet (see page 5624)	Returns the value of the DataSet property.
	GetDataSetField (see page 5624)	This is GetDataSetField, a member of class TXMLDisplayGroup.
	GetDefaultWebComponents (see page 5515)	Returns the value of the DefaultWebComponents (see page 5518) property.
	GetEnableValidateFields (see page 5624)	This is GetEnableValidateFields, a member of class TXMLDisplayGroup.
	GetFieldsList (see page 5624)	This is GetFieldsList, a member of class TXMLDisplayGroup.
	GetIsMultipleRecordView (see page 5625)	This is GetIsMultipleRecordView, a member of class TXMLDisplayGroup.
	GetLayoutAttributes (see page 5515)	Returns an object that specifies how the generated group of controls should look.
	GetSubComponents (see page 5516)	Returns the value of the WebFieldControls (see page 5519) property.
	GetVisibleFields (see page 5625)	This is GetVisibleFields, a member of class TXMLDisplayGroup.
	GetXMLBroker (see page 5625)	Returns the value of the XMLBroker property.
	GetXMLDataSet (see page 5625)	Returns the value of the XMLDataSet property.
	GetXMLDisplayName (see page 5626)	This is GetXMLDisplayName, a member of class TXMLDisplayGroup.
	GetXMLRowSetName (see page 5626)	This is GetXMLRowSetName, a member of class TXMLDisplayGroup.
	HasStatusField (see page 5626)	This is HasStatusField, a member of class TXMLDisplayGroup.
	ImplAddElements (see page 5626)	Provides the underlying implementation for the AddElements method.
	ImplCanAddClass (see page 5516)	Provides the underlying implementation for the CanAddClass (see page 5513) method.
	ImplContent (see page 5517)	Provides the underlying implementation for the Content (see page 5514) method.
	ImplGetSubComponents (see page 5627)	Provides the underlying implementation for the GetSubComponents method.
	ImplIsMultipleRecordView (see page 5627)	This is ImplIsMultipleRecordView, a member of class TXMLDisplayGroup.
	IsFieldInUse (see page 5627)	This is IsFieldInUse, a member of class TXMLDisplayGroup.
	Notification (see page 5628)	Forwards notification messages to all owned components.
	SetDataSetField (see page 5628)	This is SetDataSetField, a member of class TXMLDisplayGroup.
	SetDefaultWebComponents (see page 5518)	Sets the value of the DefaultWebComponents (see page 5518) property.
	SetEnableValidateFields (see page 5628)	This is SetEnableValidateFields, a member of class TXMLDisplayGroup.
	SetXMLBroker (see page 5629)	This is SetXMLBroker, a member of class TXMLDisplayGroup.
	ValidateDataSet (see page 5629)	This is ValidateDataSet, a member of class TXMLDisplayGroup.
	ValidateFields (see page 5629)	This is ValidateFields, a member of class TXMLDisplayGroup.
	XMLDataChange (see page 5629)	This is XMLDataChange, a member of class TXMLDisplayGroup.

Protected Properties

	Name	Description
	DefaultWebComponents (see page 5518)	Specifies the default value of the WebFieldControls (see page 5519) property when that property is not explicitly set.
	EnableValidateFields (see page 5630)	This is EnableValidateFields, a member of class TXMLDisplayGroup.

	XMLDataSet (see page 5631)	Indicates the TXMLDataSet object that represents the dataset to which the Web item is bound.

Public Methods

	Name	Description
	Create (see page 5622)	Creates and initializes an instance of TXMLDisplayGroup (see page 5620).
	Destroy (see page 5622)	Frees an instance of TXMLDisplayGroup (see page 5620).

Public Properties

	Name	Description
	DataSet (see page 5646)	Provides access to an interface for working with the associated dataset.
	IsMultipleRecordView (see page 5671)	
	IsMultipleRecordView (see page 5674)	
	VisibleFields (see page 5630)	Indicates the controls displayed by the HTML that the XML display group generates.
	WebFieldControls (see page 5519)	Lists the components that generate HTML controls for the Web control group.
	XMLDisplayName (see page 5675)	This is XMLDisplayName, a member of class IXMLDisplay.
	XMLRowSetName (see page 5675)	This is XMLRowSetName, a member of class IXMLDisplay.

Published Properties

	Name	Description
	XMLBroker (see page 5631)	Indicates the XML broker that fetches the data packets to which the Web item is bound.
	XMLDataSetField (see page 5631)	Binds the XML display group to a nested dataset from the XML data packet.

52.1.66.2 TXMLDisplayGroup.Create Constructor

Creates and initializes an instance of TXMLDisplayGroup (see page 5620).

Pascal

```
constructor Create(AComponent: TComponent); override;
```

C++

```
virtual __fastcall TXMLDisplayGroup(TComponent * AComponent);
```

Description

Call Create to instantiate TXMLDisplayGroup (see page 5620) at runtime. TXMLDisplayGroup (see page 5620) components added at design time using the Web Page editor are instantiated automatically.

52.1.66.3 TXMLDisplayGroup.Destroy Destructor

Frees an instance of TXMLDisplayGroup (see page 5620).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TXMLDisplayGroup();
```

Description

Do not call Destroy directly. Instead, call Free, which checks that the object is not nil before calling Destroy.

See Also

System::TObject::Free

52.1.66.4 TXMLDisplayGroup Methods

The methods of the TXMLDisplayGroup class are listed here.

Protected Methods

	Name	Description
	CreateDefaultFields (see page 5623)	This is CreateDefaultFields, a member of class TXMLDisplayGroup.
	FindField (see page 5623)	This is FindField, a member of class TXMLDisplayGroup.
	GetDataSet (see page 5624)	Returns the value of the DataSet property.
	GetDataSetField (see page 5624)	This is GetDataSetField, a member of class TXMLDisplayGroup.
	GetEnableValidateFields (see page 5624)	This is GetEnableValidateFields, a member of class TXMLDisplayGroup.
	GetFieldsList (see page 5624)	This is GetFieldsList, a member of class TXMLDisplayGroup.
	GetIsMultipleRecordView (see page 5625)	This is GetIsMultipleRecordView, a member of class TXMLDisplayGroup.
	GetVisibleFields (see page 5625)	This is GetVisibleFields, a member of class TXMLDisplayGroup.
	GetXMLBroker (see page 5625)	Returns the value of the XMLBroker property.
	GetXMLDataSet (see page 5625)	Returns the value of the XMLDataSet property.
	GetXMLDisplayName (see page 5626)	This is GetXMLDisplayName, a member of class TXMLDisplayGroup.
	GetXMLRowSetName (see page 5626)	This is GetXMLRowSetName, a member of class TXMLDisplayGroup.
	HasStatusField (see page 5626)	This is HasStatusField, a member of class TXMLDisplayGroup.
	ImplAddElements (see page 5626)	Provides the underlying implementation for the AddElements method.
	ImplGetSubComponents (see page 5627)	Provides the underlying implementation for the GetSubComponents method.
	ImplIsMultipleRecordView (see page 5627)	This is ImplIsMultipleRecordView, a member of class TXMLDisplayGroup.
	IsFieldInUse (see page 5627)	This is IsFieldInUse, a member of class TXMLDisplayGroup.
	Notification (see page 5628)	Forwards notification messages to all owned components.
	SetDataSetField (see page 5628)	This is SetDataSetField, a member of class TXMLDisplayGroup.
	SetEnableValidateFields (see page 5628)	This is SetEnableValidateFields, a member of class TXMLDisplayGroup.
	SetXMLBroker (see page 5629)	This is SetXMLBroker, a member of class TXMLDisplayGroup.
	ValidateDataSet (see page 5629)	This is ValidateDataSet, a member of class TXMLDisplayGroup.
	ValidateFields (see page 5629)	This is ValidateFields, a member of class TXMLDisplayGroup.
	XMLDataChange (see page 5629)	This is XMLDataChange, a member of class TXMLDisplayGroup.

52.1.66.4.1 TXMLDisplayGroup.CreateDefaultFields Method

Pascal

```
procedure CreateDefaultFields; virtual;
```

C++

```
virtual __fastcall CreateDefaultFields();
```

Description

This is CreateDefaultFields, a member of class TXMLDisplayGroup.

52.1.66.4.2 TXMLDisplayGroup.FindField Method

Pascal

```
function FindField(const AName: string): TComponent;
```

C++

```
__fastcall TComponent * FindField(const UnicodeString AName);
```

Description

This is FindField, a member of class TXMLDisplayGroup.

52.1.66.4.3 TXMLDisplayGroup.GetDataSet Method

Returns the value of the DataSet property.

Pascal

```
function GetDataSet: IInetXWebDataSet;
```

C++

```
__fastcall IInetXWebDataSet GetDataSet();
```

Description

GetDataSet is the read access method for the DataSet property.

See Also

DataSet (see page 5646)

52.1.66.4.4 TXMLDisplayGroup.GetDataSetField Method

Pascal

```
function GetDataSetField: string;
```

C++

```
__fastcall UnicodeString GetDataSetField();
```

Description

This is GetDataSetField, a member of class TXMLDisplayGroup.

52.1.66.4.5 TXMLDisplayGroup.GetEnableValidateFields Method

Pascal

```
function GetEnableValidateFields: Boolean;
```

C++

```
__fastcall Boolean GetEnableValidateFields();
```

Description

This is GetEnableValidateFields, a member of class TXMLDisplayGroup.

52.1.66.4.6 TXMLDisplayGroup.GetFieldsList Method

Pascal

```
procedure GetFieldsList(List: TStrings); virtual;
```

C++

```
virtual __fastcall GetFieldsList(TStrings List);
```

Description

This is GetFieldsList, a member of class TXMLDisplayGroup.

52.1.66.4.7 TXMLDisplayGroup.GetIsMultipleRecordView Method

Pascal

```
function GetIsMultipleRecordView: Boolean;
```

C++

```
__fastcall Boolean GetIsMultipleRecordView();
```

Description

This is GetIsMultipleRecordView, a member of class TXMLDisplayGroup.

52.1.66.4.8 TXMLDisplayGroup.GetVisibleFields Method

Pascal

```
function GetVisibleFields: TWebComponentList;
```

C++

```
__fastcall TWebComponentList GetVisibleFields();
```

Description

This is GetVisibleFields, a member of class TXMLDisplayGroup.

52.1.66.4.9 TXMLDisplayGroup.GetXMLBroker Method

Returns the value of the XMLBroker property.

Pascal

```
function GetXMLBroker: TXMLBroker;
```

C++

```
__fastcall TXMLBroker GetXMLBroker();
```

Description

GetXMLBroker is the read access method for the XMLBroker property.

See Also

XMLBroker (see page 5647)

52.1.66.4.10 TXMLDisplayGroup.GetXMLDataSet Method

Returns the value of the XMLDataSet property.

Pascal

```
function GetXMLDataSet: TXMLDataSet;
```

C++

```
__fastcall TXMLDataSet GetXMLDataSet();
```

Description

GetXMLDataSet is the read access method for the XMLDataSet property.

See Also

XMLDataSet (see page 5647)

52.1.66.4.11 TXMLDisplayGroup.GetXMLDisplayName Method

Pascal

```
function GetXMLDisplayName: string;
```

C++

```
__fastcall UnicodeString GetXMLDisplayName();
```

Description

This is GetXMLDisplayName, a member of class TXMLDisplayGroup.

52.1.66.4.12 TXMLDisplayGroup.GetXMLRowSetName Method

Pascal

```
function GetXMLRowSetName: string;
```

C++

```
__fastcall UnicodeString GetXMLRowSetName();
```

Description

This is GetXMLRowSetName, a member of class TXMLDisplayGroup.

52.1.66.4.13 TXMLDisplayGroup.HasStatusField Method

Pascal

```
function HasStatusField: Boolean;
```

C++

```
__fastcall Boolean HasStatusField();
```

Description

This is HasStatusField, a member of class TXMLDisplayGroup.

52.1.66.4.14 TXMLDisplayGroup.ImplAddElements Method

Provides the underlying implementation for the AddElements method.

Pascal

```
procedure ImplAddElements(AddIntf: IAddScriptElements); override;
```

C++

```
virtual __fastcall ImplAddElements(IAddScriptElements AddIntf);
```

Description

The AddElements method calls ImplAddElements to add any script declarations by calling the AddIntf interface. These declarations allow the generated display control to call script methods in response to user events by ensuring that the required methods are declared.

As implemented in TWebControlGroup, ImplAddElements does nothing. TWebControlGroup descendants override

ImplAddElements to add any required declarations.

See Also

AddElements (see page 5513)

52.1.66.4.15 TXMLDisplayGroup.ImplGetSubComponents Method

Provides the underlying implementation for the GetSubComponents method.

Pascal

```
function ImplGetSubComponents: TObject; override;
```

C++

```
virtual __fastcall TObject * ImplGetSubComponents();
```

Description

The GetSubComponents method calls ImplGetSubComponents to retrieve the value of WebFieldControls as a TObject. TWebControlGroup descendants override this method if the list is not simply the value of WebFieldControls. For example, some TWebControlGroup descendants supply a default value (DefaultWebComponents) when the WebFieldControls property list is empty.

ImplGetSubComponents returns the TWebComponentList object that contains all subitems of the Web control group.

See Also

GetSubComponents (see page 5516)

DefaultWebComponents (see page 5518)

WebFieldControls (see page 5519)

52.1.66.4.16 TXMLDisplayGroup.ImplIsMultipleRecordView Method

Pascal

```
function ImplIsMultipleRecordView: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean ImplIsMultipleRecordView();
```

Description

This is ImplIsMultipleRecordView, a member of class TXMLDisplayGroup.

52.1.66.4.17 TXMLDisplayGroup.IsFieldInUse Method

Pascal

```
function IsFieldInUse(AName: string): Boolean;
```

C++

```
__fastcall Boolean IsFieldInUse(UnicodeString AName);
```

Description

This is IsFieldInUse, a member of class TXMLDisplayGroup.

52.1.66.4.18 TXMLDisplayGroup.Notification Method

Forwards notification messages to all owned components.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation. By default, components pass along the notification to their owned components, if any.

A component can, if needed, act on the notification that a component is being inserted or removed. For example, if a component has object fields or properties that contain references to other components, it can check the notifications of component removals and invalidate those references as needed.

Note: Notification is not called for components that are freed implicitly (because their Owner is freed).

See Also

FreeNotification

InsertComponent

RemoveComponent

Owner

52.1.66.4.19 TXMLDisplayGroup.SetDataSetField Method

Pascal

```
procedure SetDataSetField(const Value: string);
```

C++

```
__fastcall SetDataSetField(const UnicodeString Value);
```

Description

This is SetDataSetField, a member of class TXMLDisplayGroup.

52.1.66.4.20 TXMLDisplayGroup.SetEnableValidateFields Method

Pascal

```
procedure SetEnableValidateFields(Value: Boolean);
```

C++

```
__fastcall SetEnableValidateFields(Boolean Value);
```

Description

This is SetEnableValidateFields, a member of class TXMLDisplayGroup.

52.1.66.4.21 TXMLDisplayGroup.SetXMLBroker Method

Pascal

```
procedure SetXMLBroker(const Value: TXMLBroker);
```

C++

```
__fastcall SetXMLBroker(const TXMLBroker Value);
```

Description

This is SetXMLBroker, a member of class TXMLDisplayGroup.

52.1.66.4.22 TXMLDisplayGroup.ValidateDataSet Method

Pascal

```
procedure ValidateDataSet;
```

C++

```
__fastcall ValidateDataSet();
```

Description

This is ValidateDataSet, a member of class TXMLDisplayGroup.

52.1.66.4.23 TXMLDisplayGroup.ValidateFields Method

Pascal

```
function ValidateFields(AddIntf: IAddScriptElements): Boolean;
```

C++

```
__fastcall Boolean ValidateFields(IAddScriptElements AddIntf);
```

Description

This is ValidateFields, a member of class TXMLDisplayGroup.

52.1.66.4.24 TXMLDisplayGroup.XMLDataChange Method

Pascal

```
procedure XMLDataChange(Sender: TObject); virtual;
```

C++

```
virtual __fastcall XMLDataChange(TObject * Sender);
```

Description

This is XMLDataChange, a member of class TXMLDisplayGroup.

52.1.66.5 TXMLDisplayGroup Properties

The properties of the TXMLDisplayGroup class are listed here.

Protected Properties

	Name	Description
	EnableValidateFields (see page 5630)	This is EnableValidateFields, a member of class TXMLDisplayGroup.
R	XMLDataSet (see page 5631)	Indicates the TXMLDataSet object that represents the dataset to which the Web item is bound.

Public Properties

	Name	Description
R	VisibleFields (see page 5630)	Indicates the controls displayed by the HTML that the XML display group generates.

Published Properties

	Name	Description
	XMLBroker (see page 5631)	Indicates the XML broker that fetches the data packets to which the Web item is bound.
	XMLDataSetField (see page 5631)	Binds the XML display group to a nested dataset from the XML data packet.

52.1.66.5.1 TXMLDisplayGroup.EnableValidateFields Property

Pascal

```
property EnableValidateFields: Boolean;
```

C++

```
__property Boolean EnableValidateFields;
```

Description

This is EnableValidateFields, a member of class TXMLDisplayGroup.

52.1.66.5.2 TXMLDisplayGroup.VisibleFields Property

Indicates the controls displayed by the HTML that the XML display group generates.

Pascal

```
property VisibleFields: TWebComponentList;
```

C++

```
__property TWebComponentList VisibleFields;
```

Description

Use VisibleFields to access the components that generate HTML controls for the XML display group. If a set of Web items is explicitly assigned to the WebFieldControls (see page 5519) property, VisibleFields has the same value as WebFieldControls (see page 5519). Otherwise, VisibleFields represents a set of default Web items that generate display controls for all the fields or parameters of the associated dataset or dataset field.

When no Web items are assigned to WebFieldControls (see page 5519), the default Web items in the VisibleFields list are specific to the TXMLDisplayGroup (see page 5620) descendant.

See Also

WebFieldControls (see page 5519)

xmlbroker (see page 5631)

XMLDataSetField (see page 5631)

52.1.66.5.3 TXMLDisplayGroup.XMLBroker Property

Indicates the XML broker that fetches the data packets to which the Web item is bound.

Pascal

```
property XMLBroker: TXMLBroker;
```

C++

```
__property TXMLBroker XMLBroker;
```

Description

Use XMLBroker to access the TXMLBroker object that fetches XML data packets from the application server. The XML broker can be used to obtain information about the source of the dataset, the form that contains the XML data packet, the javascript variables that represent this data packet, and so on.

Note: The dataset represented by the Web item may not correspond directly to the XML broker's dataset. It may be a nested dataset contained by that dataset. The XMLDataSet property indicates whether the dataset is nested, and if so, describes the field that represents it.

See Also

XMLDataSet (see page 5647)

DataSet (see page 5646)

52.1.66.5.4 TXMLDisplayGroup.XMLDataSet Property

Indicates the TXMLDataSet object that represents the dataset to which the Web item is bound.

Pascal

```
property XMLDataSet: TXMLDataSet;
```

C++

```
__property TXMLDataSet XMLDataSet;
```

Description

XMLDataSet describes how to locate the appropriate dataset, given the XML broker that provides its XML data packet. This dataset may be the main dataset of the XML broker, or it may be a nested dataset that is represented by a dataset field within that dataset (or a dataset field nested in a dataset field, and so on).

See Also

DataSet (see page 5646)

XMLBroker (see page 5647)

52.1.66.5.5 TXMLDisplayGroup.XMLDataSetField Property

Binds the XML display group to a nested dataset from the XML data packet.

Pascal

```
property XMLDataSetField: string;
```

C++

```
__property UnicodeString XMLDataSetField;
```

Description

Most XML display groups contain controls that represent database information. TDataGrid (see page 5302) and TFieldGroup (see page 5320) represent the fields from a dataset. By default, TQueryFieldGroup (see page 5415) represents the parameter values for a query or stored procedure or field values that filter a table. If the database information comes from the dataset represented by an XML broker's data packet, XMLDataSetField is an empty string and the XMLBroker (see page 5631) property fully describes the dataset. However, if the database information comes from a nested detail set, XMLDataSetField indicates what detail dataset to use from the data packet associated with XMLBroker (see page 5631).

Specify the name of the dataset field as the value of XMLDataSetField. If the XML display group is bound to the detail set of a detail set, you can use periods to qualify dataset field names. Thus, for example, if XMLBroker (see page 5631) represents a customer dataset with a nested Orders dataset field that has its own nested LineItems field, you can bind the XML display group to the LineItems dataset by setting XMLDataSetField to

```
Orders.LineItems
```

52.1.67 TXMLDisplayParent Class

Class Hierarchy

Pascal

```
TXMLDisplayParent = class(TWebDisplay);
```

C++

```
class TXMLDisplayParent : public TWebDisplay;
```

File

MidItems

Description

This is class MidItems.TXMLDisplayParent.

52.1.67.1 TXMLDisplayParent Members

The following tables list the members exposed by TXMLDisplayParent.

Protected Methods

	Name	Description
	Changed (see page 5542)	This is Changed, a member of class TWebDisplay.
V	ChangedDisplayComponent (see page 5633)	This is ChangedDisplayComponent, a member of class TXMLDisplayParent.
V	ChangedUseParent (see page 5634)	This is ChangedUseParent, a member of class TXMLDisplayParent.
V	GetDisplayComponent (see page 5634)	This is GetDisplayComponent, a member of class TXMLDisplayParent.
	SetDisplayComponent (see page 5542)	This is SetDisplayComponent, a member of class TWebDisplay.

	SetUseParent (see page 5634)	This is SetUseParent, a member of class TXMLDisplayParent.

Public Events

	Name	Description
	OnChange (see page 5543)	This is OnChange, a member of class TWebDisplay.

Public Methods

	Name	Description
	Create (see page 5633)	This is Create, a member of class TXMLDisplayParent.
V	Notification (see page 5542)	This is Notification, a member of class TWebDisplay.

Public Properties

	Name	Description
	DisplayComponent (see page 5543)	This is DisplayComponent, a member of class TWebDisplay.
R	Parent (see page 5543)	This is Parent, a member of class TWebDisplay.

Published Properties

	Name	Description
	UseParent (see page 5634)	This is UseParent, a member of class TXMLDisplayParent.

52.1.67.2 TXMLDisplayParent.Create Constructor

Pascal

```
constructor Create(AParent: TComponent);
```

C++

```
__fastcall TXMLDisplayParent(TComponent * AParent);
```

Description

This is Create, a member of class TXMLDisplayParent.

52.1.67.3 TXMLDisplayParent Methods

The methods of the TXMLDisplayParent class are listed here.

Protected Methods

	Name	Description
V	ChangedDisplayComponent (see page 5633)	This is ChangedDisplayComponent, a member of class TXMLDisplayParent.
V	ChangedUseParent (see page 5634)	This is ChangedUseParent, a member of class TXMLDisplayParent.
V	GetDisplayComponent (see page 5634)	This is GetDisplayComponent, a member of class TXMLDisplayParent.
	SetUseParent (see page 5634)	This is SetUseParent, a member of class TXMLDisplayParent.

52.1.67.3.1 TXMLDisplayParent.ChangedDisplayComponent Method

Pascal

```
procedure ChangedDisplayComponent; override;
```

C++

```
virtual __fastcall ChangedDisplayComponent();
```

Description

This is ChangedDisplayComponent, a member of class TXMLDisplayParent.

52.1.67.3.2 TXMLDisplayParent.ChangedUseParent Method

Pascal

```
procedure ChangedUseParent; virtual;
```

C++

```
virtual __fastcall ChangedUseParent();
```

Description

This is ChangedUseParent, a member of class TXMLDisplayParent.

52.1.67.3.3 TXMLDisplayParent.GetDisplayComponent Method

Pascal

```
function GetDisplayComponent: TComponent; override;
```

C++

```
virtual __fastcall TComponent * GetDisplayComponent();
```

Description

This is GetDisplayComponent, a member of class TXMLDisplayParent.

52.1.67.3.4 TXMLDisplayParent.SetUseParent Method

Pascal

```
procedure SetUseParent(const Value: Boolean);
```

C++

```
__fastcall SetUseParent(const Boolean Value);
```

Description

This is SetUseParent, a member of class TXMLDisplayParent.

52.1.67.4 TXMLDisplayParent Properties

The properties of the TXMLDisplayParent class are listed here.

Published Properties

	Name	Description
	UseParent (see page 5634)	This is UseParent, a member of class TXMLDisplayParent.

52.1.67.4.1 TXMLDisplayParent.UseParent Property

Pascal

```
property UseParent: Boolean;
```

C++

```
__property Boolean UseParent;
```

Description

This is UseParent, a member of class TXMLDisplayParent.

52.1.68 TXMLDisplayReferenceButton Class

TXMLDisplayReferenceButton is the base class for Web items that generate HTML buttons for influencing controls that display data.

Class Hierarchy

Pascal

```
TXMLDisplayReferenceButton = class(TWebButton);
```

C++

```
class TXMLDisplayReferenceButton : public TWebButton;
```

File

MidItems

Description

Use TXMLDisplayReferenceButton as a base class for components that generate the HTML statements defining a specialized button control for working with a data display control in the Web page produced by TInetXPageProducer (see page 5730).

TXMLDisplayReferenceButton defines properties and methods for

Generating the HTML code to define the button.

Associating the button with another Web item that generates a data display control.

Specifying tag attributes of the HTML button control, including those defined by a style sheet.

Fitting the component into a hierarchy of Web items, each of which generates part of a larger HTML document.

In order to allow other Web items to use the HTML generated by the button control, TXMLDisplayReferenceButton inherits support for the IWebContent interface from TWebButton (see page 5504).

Do not create instances of TXMLDisplayReferenceButton. TXMLDisplayReferenceButton relies on anabstract or, in C++ terminology, pure virtual method to generate the HTML statements defining a button control. Instead, create descendants of TXMLDisplayReferenceButton, such as TPostButton (see page 5396), TInsertButton (see page 5385), and so on.

TPriorPageButton (see page 5401)

TInsertButton (see page 5385)

TDeleteButton (see page 5318)

TUndoButton (see page 5502)

TPostButton (see page 5396)

IWebContent

TDataNavigator (see page 5307)

TResetQueryButton (see page 5469)

TSubmitQueryButton (see page 5486)

52.1.68.1 TXMLDisplayReferenceButton Members

The following tables list the members exposed by TXMLDisplayReferenceButton.

Protected Methods

	Name	Description
	Content (see page 5506)	Returns the HTML that defines the button control.
V	GetCaption (see page 5507)	Returns the value of the Caption (see page 5508) property.
	GetDisplayComponent (see page 5637)	This is GetDisplayComponent, a member of class TXMLDisplayReferenceButton.
	GetDisplayComponentParent (see page 5638)	This is GetDisplayComponentParent, a member of class TXMLDisplayReferenceButton.
V	GetLayoutAttributes (see page 5507)	Returns the layout object that specifies how the generated control should look.
	GetXmlDisplayName (see page 5638)	This is GetXmlDisplayName, a member of class TXMLDisplayReferenceButton.
A	ImplContent (see page 5507)	Provides the underlying implementation for the Content (see page 5506) method.
V	Notification (see page 5638)	Forwards notification messages to all owned components.
V	SetCaption (see page 5508)	Sets the value of the Caption (see page 5508) property.
	SetDisplayComponent (see page 5639)	This is SetDisplayComponent, a member of class TXMLDisplayReferenceButton.
	SetDisplayComponentParent (see page 5639)	This is SetDisplayComponentParent, a member of class TXMLDisplayReferenceButton.

Protected Properties

	Name	Description
R	XMLDisplay (see page 5640)	This is XMLDisplay, a member of class TXMLDisplayReferenceButton.

Public Methods

	Name	Description
V	Create (see page 5637)	Creates and initializes an instance of TXMLDisplayReferenceButton (see page 5635).
V	Destroy (see page 5637)	Frees an instance of TXMLDisplayReferenceButton (see page 5635).

Public Properties

	Name	Description
	Caption (see page 5508)	Specifies the caption that appears on the button.
	Custom (see page 5509)	Represents a tag option and its value in the generated INPUT tag.
	Style (see page 5509)	Adds style attributes to the generated button control.
	StyleRule (see page 5510)	Applies a style in the page producer's style sheet to the button.
	XMLComponent (see page 5639)	Associates the button with the component that generates the display control it influences.
	XMLUseParent (see page 5640)	Specifies whether the button is associated with its parent's display object.

52.1.68.2 TXMLDisplayReferenceButton.Create Constructor

Creates and initializes an instance of TXMLDisplayReferenceButton (see page 5635).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TXMLDisplayReferenceButton(TComponent * AOwner);
```

Description

Call Create to instantiate a dataset button at runtime. Buttons added at design time using the Web Page editor are instantiated automatically.

52.1.68.3 TXMLDisplayReferenceButton.Destroy Destructor

Frees an instance of TXMLDisplayReferenceButton (see page 5635).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TXMLDisplayReferenceButton();
```

Description

Destroy removes the button from its parent's list of components that generate HTML.

52.1.68.4 TXMLDisplayReferenceButton Methods

The methods of the TXMLDisplayReferenceButton class are listed here.

Protected Methods

	Name	Description
	GetDisplayComponent (see page 5637)	This is GetDisplayComponent, a member of class TXMLDisplayReferenceButton.
	GetDisplayComponentParent (see page 5638)	This is GetDisplayComponentParent, a member of class TXMLDisplayReferenceButton.
	GetXmlDisplayName (see page 5638)	This is GetXmlDisplayName, a member of class TXMLDisplayReferenceButton.
V	Notification (see page 5638)	Forwards notification messages to all owned components.
	SetDisplayComponent (see page 5639)	This is SetDisplayComponent, a member of class TXMLDisplayReferenceButton.
	SetDisplayComponentParent (see page 5639)	This is SetDisplayComponentParent, a member of class TXMLDisplayReferenceButton.

52.1.68.4.1 TXMLDisplayReferenceButton.GetDisplayComponent Method

Pascal

```
function GetDisplayComponent: TComponent;
```

C++

```
__fastcall TComponent * GetDisplayComponent();
```

Description

This is GetDisplayComponent, a member of class TXMLDisplayReferenceButton.

52.1.68.4.2 TXMLDisplayReferenceButton.GetDisplayComponentParent Method

Pascal

```
function GetDisplayComponentParent: Boolean;
```

C++

```
__fastcall Boolean GetDisplayComponentParent();
```

Description

This is GetDisplayComponentParent, a member of class TXMLDisplayReferenceButton.

52.1.68.4.3 TXMLDisplayReferenceButton.GetXmlDisplayName Method

Pascal

```
function GetXmlDisplayName: string;
```

C++

```
__fastcall UnicodeString GetXmlDisplayName();
```

Description

This is GetXmlDisplayName, a member of class TXMLDisplayReferenceButton.

52.1.68.4.4 TXMLDisplayReferenceButton.Notification Method

Forwards notification messages to all owned components.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation. By default, components pass along the notification to their owned components, if any.

A component can, if needed, act on the notification that a component is being inserted or removed. For example, if a component has object fields or properties that contain references to other components, it can check the notifications of component removals and invalidate those references as needed.

Note: Notification is not called for components that are freed implicitly (because their Owner is freed).

See Also

FreeNotification

InsertComponent

RemoveComponent

Owner

52.1.68.4.5 TXMLDisplayReferenceButton.SetDisplayComponent Method

Pascal

```
procedure SetDisplayComponent(const Value: TComponent);
```

C++

```
__fastcall SetDisplayComponent(const TComponent * Value);
```

Description

This is SetDisplayComponent, a member of class TXMLDisplayReferenceButton.

52.1.68.4.6 TXMLDisplayReferenceButton.SetDisplayComponentParent Method

Pascal

```
procedure SetDisplayComponentParent(const Value: Boolean);
```

C++

```
__fastcall SetDisplayComponentParent(const Boolean Value);
```

Description

This is SetDisplayComponentParent, a member of class TXMLDisplayReferenceButton.

52.1.68.5 TXMLDisplayReferenceButton Properties

The properties of the TXMLDisplayReferenceButton class are listed here.

Protected Properties

	Name	Description
	XMLDisplay (see page 5640)	This is XMLDisplay, a member of class TXMLDisplayReferenceButton.

Public Properties

	Name	Description
	XMLComponent (see page 5639)	Associates the button with the component that generates the display control it influences.
	XMLUseParent (see page 5640)	Specifies whether the button is associated with its parent's display object.

52.1.68.5.1 TXMLDisplayReferenceButton.XMLComponent Property

Associates the button with the component that generates the display control it influences.

Pascal

```
property XMLComponent: TComponent;
```

C++

```
__property TComponent * XMLComponent;
```

Description

Set XMLComponent to specify the Web item that generates a display control that the button influences.

Note: Typically, descendants of TXMLDisplayReferenceButton (see page 5635) are used by a descendant of TXMLDisplayReferenceGroup (see page 5640), which has its own XMLComponent property. If the button influences this same component, you need not set the XMLComponent property. Instead, setting the XMLUseParent (see page 5640) property to true (the default) sets XMLComponent to the value of the parent's XMLComponent property.

See Also

XMLUseParent (see page 5640)

52.1.68.5.2 TXMLDisplayReferenceButton.XMLDisplay Property

Pascal

```
property XMLDisplay: TXMLDisplayParent;
```

C++

```
__property TXMLDisplayParent XMLDisplay;
```

Description

This is XMLDisplay, a member of class TXMLDisplayReferenceButton.

52.1.68.5.3 TXMLDisplayReferenceButton.XMLUseParent Property

Specifies whether the button is associated with its parent's display object.

Pascal

```
property XMLUseParent: Boolean;
```

C++

```
__property Boolean XMLUseParent;
```

Description

Use XMLUseParent to indicate how the dataset button determines the component that it influences. When XMLUseParent is false, the XMLComponent (see page 5639) property must be set to indicate the display component. When XMLUseParent is true, the button influences the component specified by its parent's XMLComponent (see page 5639) property.

The button's parent is the Web item that uses the button to assemble its own HTML content (typically a TDataNavigator (see page 5307) or TQueryButtons (see page 5412) object). If the parent does not have an associated display component, setting XMLUseParent to true sets the XMLComponent (see page 5639) property to nil (Delphi) or NULL (C++).

See Also

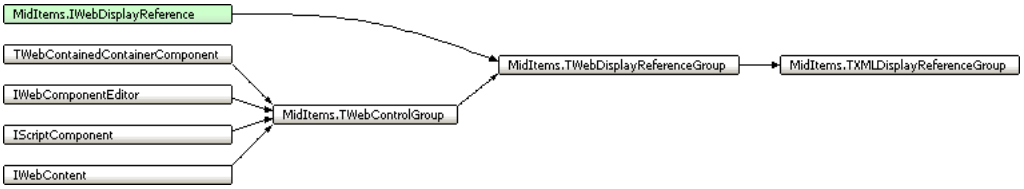
XMLComponent (see page 5639)

XMLComponent (see page 5643)

52.1.69 TXMLDisplayReferenceGroup Class

TXMLDisplayReferenceGroup is the base class for Web items that arrange a set of button controls that influence a control that displays data.

Class Hierarchy



Pascal

```
TXMLDisplayReferenceGroup = class(TWebDisplayReferenceGroup);
```

C++

```
class TXMLDisplayReferenceGroup : public TWebDisplayReferenceGroup;
```

File

MidItems

Description

Use TXMLDisplayReferenceGroup as a base class for Web items that generate the HTML to arrange a collection of button controls. Each TXMLDisplayGroup (see page 5620) object has an associated Web item that generates controls that display data in the final HTML document. The buttons arranged by TXMLDisplayReferenceGroup manipulate the information the display controls show.

In order to let other Web items use the HTML that the TXMLDisplayReferenceGroup object generates, TXMLDisplayReferenceGroup inherits the IWebContent interface from TWebControlGroup (see page 5510).

Do not create instances of TXMLDisplayReferenceGroup. TXMLDisplayReferenceGroup manages the Web items that generate buttons and the association to a display generator, but does not produce any content. Instead, use a descendant of TXMLDisplayReferenceGroup that generates the HTML for its set of specialized buttons such as TDataNavigator (see page 5307) or TQueryButtons (see page 5412).

See Also

TDataNavigator (see page 5307)

IWebContent

52.1.69.1 TXMLDisplayReferenceGroup Members

The following tables list the members exposed by TXMLDisplayReferenceGroup.

Protected Methods

	Name	Description
	AddElements (see page 5513)	Used internally to generate any script declarations needed by the group of controls.
	CanAddClass (see page 5513)	Specifies whether a Web item of a specified type can be added to the WebFieldControls (see page 5519) property list.
	ChangeFieldControls (see page 5514)	Responds when the group of HTML controls changes.
	Content (see page 5514)	Returns the HTML that defines the group of HTML controls.
V	GetDefaultWebComponents (see page 5515)	Returns the value of the DefaultWebComponents (see page 5518) property.
V	GetLayoutAttributes (see page 5515)	Returns an object that specifies how the generated group of controls should look.
	GetSubComponents (see page 5516)	Returns the value of the WebFieldControls (see page 5519) property.
	GetWebDisplayComponent (see page 5546)	This is GetWebDisplayComponent, a member of class TWebDisplayReferenceGroup.

	ImplAddElements (see page 5642)	Provides the underlying implementation for the AddElements method.
	ImplCanAddClass (see page 5516)	Provides the underlying implementation for the CanAddClass (see page 5513) method.
	ImplContent (see page 5517)	Provides the underlying implementation for the Content (see page 5514) method.
	ImplGetSubComponents (see page 5517)	Provides the underlying implementation for the GetSubComponents (see page 5516) method.
	Notification (see page 5546)	Forwards notification messages to all owned components.
	SetDefaultWebComponents (see page 5518)	Sets the value of the DefaultWebComponents (see page 5518) property.
	SetWebDisplayComponent (see page 5547)	This is SetWebDisplayComponent, a member of class TWebDisplayReferenceGroup.

Protected Properties

	Name	Description
	DefaultWebComponents (see page 5518)	Specifies the default value of the WebFieldControls (see page 5519) property when that property is not explicitly set.
R	WebDisplay (see page 5547)	This is WebDisplay, a member of class TWebDisplayReferenceGroup.
	WebDisplayComponent (see page 5547)	

Public Methods

	Name	Description
	Create (see page 5512)	Creates and initializes an instance of TWebControlGroup (see page 5510).
	Create (see page 5545)	Creates an instance of TWebDisplayReferenceGroup (see page 5544).
	Destroy (see page 5512)	Frees an instance of TWebControlGroup (see page 5510).
	Destroy (see page 5546)	Frees an instance of TWebDisplayReferenceGroup (see page 5544).
	GetWebDisplayComponent (see page 5672)	This is GetWebDisplayComponent, a member of class IWebDisplayReference.

Public Properties

	Name	Description
R	WebDisplayComponent (see page 5672)	
R	WebFieldControls (see page 5519)	Lists the components that generate HTML controls for the Web control group.
	XMLComponent (see page 5643)	Associates the group with a component that generates HTML display controls.

52.1.69.2 TXMLDisplayReferenceGroup Methods

The methods of the TXMLDisplayReferenceGroup class are listed here.

Protected Methods

	Name	Description
	ImplAddElements (see page 5642)	Provides the underlying implementation for the AddElements method.

52.1.69.2.1 TXMLDisplayReferenceGroup.ImplAddElements Method

Provides the underlying implementation for the AddElements method.

Pascal

```
procedure ImplAddElements(AddIntf: IAddScriptElements); override;
```

C++

```
virtual __fastcall ImplAddElements(IAddScriptElements AddIntf);
```

Description

The AddElements method calls ImplAddElements to add any script declarations by calling the AddIntf interface. These declarations allow the generated display control to call script methods in response to user events by ensuring that the required methods are declared.

As implemented in TWebControlGroup, ImplAddElements does nothing. TWebControlGroup descendants override ImplAddElements to add any required declarations.

See Also

AddElements (see page 5513)

52.1.69.3 TXMLDisplayReferenceGroup Properties

The properties of the TXMLDisplayReferenceGroup class are listed here.

Public Properties

	Name	Description
	XMLComponent (see page 5643)	Associates the group with a component that generates HTML display controls.

52.1.69.3.1 TXMLDisplayReferenceGroup.XMLComponent Property

Associates the group with a component that generates HTML display controls.

Pascal

```
property XMLComponent: TComponent;
```

C++

```
__property TComponent * XMLComponent;
```

Description

Use XMLComponent to associate the group of buttons with a Web item that generates the display controls those buttons influence. Typical values of XMLComponent are TFieldGroup (see page 5320) or TDataGrid (see page 5302).

If all the buttons arranged by the TXMLDisplayReferenceGroup (see page 5640) object operate on the same set of display controls, it is most efficient to specify the Web item generating these controls as the value of XMLComponent. Then, each button uses this value to determine its associated display controls when its XMLUseParent property is true. Any buttons that do not operate on the display controls generated by XMLComponent can set their own XMLComponent property to another Web item.

See Also

XMLComponent (see page 5639)

XMLUseParent (see page 5640)

TFieldGroup (see page 5320)

TDataGrid (see page 5302)

TQueryFieldGroup (see page 5415)

52.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IDataSetComponent (see page 5644)	IDataSetComponent defines the methods that bind a Web item to an XML broker.
	IDataSetField (see page 5648)	This is class MidItems.IDataSetField.
	IDataSetFields (see page 5650)	This is class MidItems.IDataSetFields.
	IFormatColumn (see page 5652)	This is class MidItems.IFormatColumn.
	IHTMLField (see page 5653)	IHTMLField is an interface that must be implemented by Web items that generate <INPUT> elements.
	IHTMLForm (see page 5655)	IHTMLForm is an interface that must be implemented by Web items that generate forms.
	IInetXWebDataSet (see page 5657)	IInetXWebDataSet lets a Web item interact with information about a dataset in an XML broker's data packet.
	IQueryField (see page 5661)	This is class MidItems.IQueryField.
	IQueryFields (see page 5664)	This is class MidItems.IQueryFields.
	IQueryForm (see page 5665)	This is class MidItems.IQueryForm.
	IRestoreDefaults (see page 5665)	This is class MidItems.IRestoreDefaults.
	IStatusField (see page 5666)	This is class MidItems.IStatusField.
	IValidateField (see page 5667)	This is class MidItems.IValidateField.
	IValidateFields (see page 5668)	This is class MidItems.IValidateFields.
	IWebDisplay (see page 5670)	
	IWebDisplayReference (see page 5671)	
	IXMLDisplay (see page 5673)	This is class MidItems.IXMLDisplay.

52.2.1 IDataSetComponent Interface

IDataSetComponent defines the methods that bind a Web item to an XML broker.

Class Hierarchy

Pascal

```
IDataSetComponent = interface;
```

C++

```
__interface IDataSetComponent;
```

File

MidItems

Description

The TXMLDisplayGroup (see page 5620) class implements IDataSetComponent to provide information about the dataset from which its child controls obtain their data. The child Web items use this information to determine the default data binding.

Most Web items that generate a group of data-aware controls inherit the support for IDataSetComponent from TXMLDisplayGroup (see page 5620).

See Also

TXMLDisplayGroup (see page 5620)

TXMLBroker

52.2.1.1 IDataSetComponent Members

The following tables list the members exposed by IDataSetComponent.

Public Methods

	Name	Description
	GetDataSet (see page 5645)	Returns the value of the DataSet (see page 5646) property.
	GetXMLBroker (see page 5645)	Returns the value of the XMLBroker (see page 5647) property.
	GetXMLDataSet (see page 5646)	Returns the value of the XMLDataSet (see page 5647) property.

Public Properties

	Name	Description
R	DataSet (see page 5646)	Provides access to an interface for working with the associated dataset.
R	XMLBroker (see page 5647)	Indicates the XML broker that fetches the data packets to which the Web item is bound.
R	XMLDataSet (see page 5647)	Indicates the TXMLDataSet (see page 5608) object that represents the dataset to which the Web item is bound.

52.2.1.2 IDataSetComponent Methods

The methods of the IDataSetComponent class are listed here.

Public Methods

	Name	Description
	GetDataSet (see page 5645)	Returns the value of the DataSet (see page 5646) property.
	GetXMLBroker (see page 5645)	Returns the value of the XMLBroker (see page 5647) property.
	GetXMLDataSet (see page 5646)	Returns the value of the XMLDataSet (see page 5647) property.

52.2.1.2.1 IDataSetComponent.GetDataSet Method

Returns the value of the DataSet (see page 5646) property.

Pascal

```
function GetDataSet: IInetXWebDataSet;
```

C++

```
__fastcall IInetXWebDataSet GetDataSet();
```

Description

GetDataSet is the read access method for the DataSet (see page 5646) property.

See Also

DataSet (see page 5646)

52.2.1.2.2 IDataSetComponent.GetXMLBroker Method

Returns the value of the XMLBroker (see page 5647) property.

Pascal

```
function GetXMLBroker: TXMLBroker;
```

C++

```
__fastcall TXMLBroker GetXMLBroker();
```

Description

GetXMLBroker is the read access method for the XMLBroker (see page 5647) property.

See Also

XMLBroker (see page 5647)

52.2.1.2.3 IDataSetComponent.GetXMLDataSet Method

Returns the value of the XMLDataSet (see page 5647) property.

Pascal

```
function GetXMLDataSet: TXMLDataSet;
```

C++

```
__fastcall TXMLDataSet GetXMLDataSet();
```

Description

GetXMLDataSet is the read access method for the XMLDataSet (see page 5647) property.

See Also

XMLDataSet (see page 5647)

52.2.1.3 IDataSetComponent Properties

The properties of the IDataSetComponent class are listed here.

Public Properties

	Name	Description
R	DataSet (see page 5646)	Provides access to an interface for working with the associated dataset.
R	XMLBroker (see page 5647)	Indicates the XML broker that fetches the data packets to which the Web item is bound.
R	XMLDataSet (see page 5647)	Indicates the TXMLDataSet (see page 5608) object that represents the dataset to which the Web item is bound.

52.2.1.3.1 IDataSetComponent.DataSet Property

Provides access to an interface for working with the associated dataset.

Pascal

```
property DataSet: IInetXWebDataSet;
```

C++

```
__property IInetXWebDataSet DataSet;
```

Description

The child Web items of the item that implements IDataSetComponent (see page 5644) use the DataSet property to obtain information about the dataset to which they are bound and to respond when this information changes. This information includes

details about the available fields and parameters in the dataset to which they can be bound.

See Also

XMLDataSet (see page 5647)

52.2.1.3.2 IDataSetComponent.XMLBroker Property

Indicates the XML broker that fetches the data packets to which the Web item is bound.

Pascal

```
property XMLBroker: TXMLBroker;
```

C++

```
__property TXMLBroker XMLBroker;
```

Description

Use XMLBroker to access the TXMLBroker object that fetches XML data packets from the application server. The XML broker can be used to obtain information about the source of the dataset, the form that contains the XML data packet, the javascript variables that represent this data packet, and so on.

Note: The dataset represented by the Web item may not correspond directly to the XML broker's dataset. It may be a nested dataset contained by that dataset. The XMLDataSet (see page 5647) property indicates whether the dataset is nested, and if so, describes the field that represents it.

See Also

XMLDataSet (see page 5647)

DataSet (see page 5646)

52.2.1.3.3 IDataSetComponent.XMLDataSet Property

Indicates the TXMLDataSet (see page 5608) object that represents the dataset to which the Web item is bound.

Pascal

```
property XMLDataSet: TXMLDataSet;
```

C++

```
__property TXMLDataSet XMLDataSet;
```

Description

XMLDataSet describes how to locate the appropriate dataset, given the XML broker that provides its XML data packet. This dataset may be the main dataset of the XML broker, or it may be a nested dataset that is represented by a dataset field within that dataset (or a dataset field nested in a dataset field, and so on).

See Also

DataSet (see page 5646)

XMLBroker (see page 5647)

52.2.2 IDataSetField Interface

Class Hierarchy

Pascal

```
IDataSetField = interface(IHTMLField);
```

C++

```
__interface IDataSetField : public IHTMLField;
```

File

MidItems

Description

This is class MidItems.IDataSetField.

52.2.2.1 IDataSetField Members

The following tables list the members exposed by IDataSetField.

Public Methods

	Name	Description
	GetFieldName (see page 5648)	This is GetFieldName, a member of class IDataSetField.
	GetHTMLControlName (see page 5654)	Returns the name of the generated HTML <INPUT> control.
	GetRowSetFieldAttributes (see page 5649)	This is GetRowSetFieldAttributes, a member of class IDataSetField.
	SetFieldName (see page 5649)	This is SetFieldName, a member of class IDataSetField.

Public Properties

	Name	Description
	FieldName (see page 5649)	This is FieldName, a member of class IDataSetField.
R	HTMLControlName (see page 5655)	Indicates the name of the generated HTML control.

52.2.2.2 IDataSetField Methods

The methods of the IDataSetField class are listed here.

Public Methods

	Name	Description
	GetFieldName (see page 5648)	This is GetFieldName, a member of class IDataSetField.
	GetRowSetFieldAttributes (see page 5649)	This is GetRowSetFieldAttributes, a member of class IDataSetField.
	SetFieldName (see page 5649)	This is SetFieldName, a member of class IDataSetField.

52.2.2.2.1 IDataSetField.GetFieldName Method

Pascal

```
function GetFieldName: string;
```

C++

```
__fastcall UnicodeString GetFieldName();
```

Description

This is GetFieldName, a member of class IDataSetField.

52.2.2.2.2 IDataSetField.GetRowSetFieldAttributes Method

Pascal

```
function GetRowSetFieldAttributes(const FieldVarName: string): string;
```

C++

```
__fastcall UnicodeString GetRowSetFieldAttributes(const UnicodeString FieldVarName);
```

Description

This is GetRowSetFieldAttributes, a member of class IDataSetField.

52.2.2.2.3 IDataSetField.SetFieldName Method

Pascal

```
procedure SetFieldName(AFieldName: string);
```

C++

```
__fastcall SetFieldName(UnicodeString AFieldName);
```

Description

This is SetFieldName, a member of class IDataSetField.

52.2.2.3 IDataSetField Properties

The properties of the IDataSetField class are listed here.

Public Properties

	Name	Description
	FieldName (see page 5649)	This is FieldName, a member of class IDataSetField.

52.2.2.3.1 IDataSetField.FieldName Property

Pascal

```
property FieldName: string;
```

C++

```
__property UnicodeString FieldName;
```

Description

This is FieldName, a member of class IDataSetField.

52.2.3 IDataSetFields Interface

Class Hierarchy

Pascal

```
IDataSetFields = interface;
```

C++

```
__interface IDataSetFields;
```

File

MidItems

Description

This is class MidItems.IDataSetFields.

52.2.3.1 IDataSetFields Members

The following tables list the members exposed by IDataSetFields.

Public Methods

	Name	Description
	GetFieldsList (see page 5651)	This is GetFieldsList, a member of class IDataSetFields.
	GetVisibleFields (see page 5651)	This is GetVisibleFields, a member of class IDataSetFields.
	HasStatusField (see page 5651)	This is HasStatusField, a member of class IDataSetFields.
	IsFieldInUse (see page 5651)	This is IsFieldInUse, a member of class IDataSetFields.
	ValidateDataSet (see page 5651)	This is ValidateDataSet, a member of class IDataSetFields.

Public Properties

	Name	Description
	VisibleFields (see page 5652)	This is VisibleFields, a member of class IDataSetFields.

52.2.3.2 IDataSetFields Methods

The methods of the IDataSetFields class are listed here.

Public Methods

	Name	Description
	GetFieldsList (see page 5651)	This is GetFieldsList, a member of class IDataSetFields.
	GetVisibleFields (see page 5651)	This is GetVisibleFields, a member of class IDataSetFields.
	HasStatusField (see page 5651)	This is HasStatusField, a member of class IDataSetFields.
	IsFieldInUse (see page 5651)	This is IsFieldInUse, a member of class IDataSetFields.
	ValidateDataSet (see page 5651)	This is ValidateDataSet, a member of class IDataSetFields.

52.2.3.2.1 IDataSetFields.GetFieldsList Method

Pascal

```
procedure GetFieldsList(AList: TStrings);
```

C++

```
__fastcall GetFieldsList(TStrings AList);
```

Description

This is GetFieldsList, a member of class IDataSetFields.

52.2.3.2.2 IDataSetFields.GetVisibleFields Method

Pascal

```
function GetVisibleFields: TWebComponentList;
```

C++

```
__fastcall TWebComponentList GetVisibleFields();
```

Description

This is GetVisibleFields, a member of class IDataSetFields.

52.2.3.2.3 IDataSetFields.HasStatusField Method

Pascal

```
function HasStatusField: Boolean;
```

C++

```
__fastcall Boolean HasStatusField();
```

Description

This is HasStatusField, a member of class IDataSetFields.

52.2.3.2.4 IDataSetFields.IsFieldInUse Method

Pascal

```
function IsFieldInUse(AName: string): Boolean;
```

C++

```
__fastcall Boolean IsFieldInUse(UnicodeString AName);
```

Description

This is IsFieldInUse, a member of class IDataSetFields.

52.2.3.2.5 IDataSetFields.ValidateDataSet Method

Pascal

```
procedure ValidateDataSet;
```

C++

```
__fastcall ValidateDataSet();
```

Description

This is ValidateDataSet, a member of class IDataSetFields.

52.2.3.3 IDataSetFields Properties

The properties of the IDataSetFields class are listed here.

Public Properties

	Name	Description
	VisibleFields (see page 5652)	This is VisibleFields, a member of class IDataSetFields.

52.2.3.3.1 IDataSetFields.VisibleFields Property

Pascal

```
property VisibleFields: TWebComponentList;
```

C++

```
__property TWebComponentList VisibleFields;
```

Description

This is VisibleFields, a member of class IDataSetFields.

52.2.4 IFormatColumn Interface

Class Hierarchy

MidItems.IFormatColumn

Pascal

```
IFormatColumn = interface;
```

C++

```
__interface IFormatColumn;
```

File

MidItems

Description

This is class MidItems.IFormatColumn.

52.2.4.1 IFormatColumn Members

The following tables list the members exposed by IFormatColumn.

Public Methods

	Name	Description
	FormatColumnData (see page 5653)	This is FormatColumnData, a member of class IFormatColumn.
	FormatColumnHeading (see page 5653)	This is FormatColumnHeading, a member of class IFormatColumn.

52.2.4.2 IFormatColumn Methods

The methods of the IFormatColumn class are listed here.

Public Methods

	Name	Description
	FormatColumnData (see page 5653)	This is FormatColumnData, a member of class IFormatColumn.
	FormatColumnHeading (see page 5653)	This is FormatColumnHeading, a member of class IFormatColumn.

52.2.4.2.1 IFormatColumn.FormatColumnData Method

Pascal

```
function FormatColumnData(const Content: string; Options: TWebContentOptions): string;
```

C++

```
__fastcall UnicodeString FormatColumnData(const UnicodeString Content, TWebContentOptions
Options);
```

Description

This is FormatColumnData, a member of class IFormatColumn.

52.2.4.2.2 IFormatColumn.FormatColumnHeading Method

Pascal

```
function FormatColumnHeading(Options: TWebContentOptions): string;
```

C++

```
__fastcall UnicodeString FormatColumnHeading(TWebContentOptions Options);
```

Description

This is FormatColumnHeading, a member of class IFormatColumn.

52.2.5 IHTMLField Interface

IHTMLField is an interface that must be implemented by Web items that generate <INPUT> elements.

Class Hierarchy

MidItems.IHTMLField

Pascal

```
IHTMLField = interface;
```

C++

```
__interface IHTMLField;
```

File

MidItems

Description

The TWebDataDisplay (see page 5519) class implements IHTMLField to provide information about information about the HTML control it represents. This interface is used when generating javascript that refers to the control.

Most Web items that generate HTML <INPUT> elements inherit the support for IHTMLField from TWebDataDisplay (see page 5519). However, when writing custom Web items that generate <INPUT> tags but that do not descend from TWebDataDisplay (see page 5519), component writers must ensure that the Web item supports the IHTMLField interface.

See Also

TWebDataDisplay (see page 5519)

52.2.5.1 IHTMLField Members

The following tables list the members exposed by IHTMLField.

Public Methods

	Name	Description
	GetHTMLControlName (see page 5654)	Returns the name of the generated HTML <INPUT> control.

Public Properties

	Name	Description
R	HTMLControlName (see page 5655)	Indicates the name of the generated HTML control.

52.2.5.2 IHTMLField Methods

The methods of the IHTMLField class are listed here.

Public Methods

	Name	Description
	GetHTMLControlName (see page 5654)	Returns the name of the generated HTML <INPUT> control.

52.2.5.2.1 IHTMLField.GetHTMLControlName Method

Returns the name of the generated HTML <INPUT> control.

Pascal

```
function GetHTMLControlName: string;
```

C++

```
__fastcall UnicodeString GetHTMLControlName();
```

Description

GetHTMLFormName is the read access method for the HTMLControlName (see page 5655) property.

See Also

HTMLControlName (see page 5655)

52.2.5.3 IHTMLField Properties

The properties of the IHTMLField class are listed here.

Public Properties

	Name	Description
	HTMLControlName (see page 5655)	Indicates the name of the generated HTML control.

52.2.5.3.1 IHTMLField.HTMLControlName Property

Indicates the name of the generated HTML control.

Pascal

```
property HTMLControlName: string;
```

C++

```
__property UnicodeString HTMLControlName;
```

Description

HTMLControlName is the value of the NAME option on the generated <INPUT> tag. This value is used when creating javascript references to the control.

52.2.6 IHTMLForm Interface

IHTMLForm is an interface that must be implemented by Web items that generate forms.

Class Hierarchy

MidItems.IHTMLForm

Pascal

```
IHTMLForm = interface;
```

C++

```
__interface IHTMLForm;
```

File

MidItems

Description

Web items that produce forms (such as TQueryForm (see page 5421) or TDataForm (see page 5298)) must implement the IHTML form interface. This interface allows other Web items to access information about form elements when generating javascript declarations and method calls.

See Also

TQueryForm (see page 5421)

TDataForm (see page 5298)

52.2.6.1 IHTMLForm Members

The following tables list the members exposed by IHTMLForm.

Public Methods

	Name	Description
	GetHTMLFormName (see page 5656)	Returns the name of the generated HTML form.
	GetHTMLFormVarName (see page 5656)	Returns the name of the javascript variable that refers to the generated form.

Public Properties

	Name	Description
R	HTMLFormName (see page 5657)	Indicates the name of the generated HTML form.
R	HTMLFormVarName (see page 5657)	Indicates the name of the javascript variable that represents the HTML form.

52.2.6.2 IHTMLForm Methods

The methods of the IHTMLForm class are listed here.

Public Methods

	Name	Description
	GetHTMLFormName (see page 5656)	Returns the name of the generated HTML form.
	GetHTMLFormVarName (see page 5656)	Returns the name of the javascript variable that refers to the generated form.

52.2.6.2.1 IHTMLForm.GetHTMLFormName Method

Returns the name of the generated HTML form.

Pascal

```
function GetHTMLFormName: string;
```

C++

```
__fastcall UnicodeString GetHTMLFormName();
```

Description

GetHTMLFormName is the read access method for the HTMLFormName (see page 5657) property.

See Also

HTMLFormName (see page 5657)

52.2.6.2.2 IHTMLForm.GetHTMLFormVarName Method

Returns the name of the javascript variable that refers to the generated form.

Pascal

```
function GetHTMLFormVarName: string;
```

C++

```
__fastcall UnicodeString GetHTMLFormVarName();
```

Description

GetHTMLFormVarName is the read access method for the HTMLFormVarName (see page 5657) property.

See Also

HTMLFormVarName (see page 5657)

52.2.6.3 IHTMLForm Properties

The properties of the IHTMLForm class are listed here.

Public Properties

	Name	Description
	HTMLFormName (see page 5657)	Indicates the name of the generated HTML form.
	HTMLFormVarName (see page 5657)	Indicates the name of the javascript variable that represents the HTML form.

52.2.6.3.1 IHTMLForm.HTMLFormName Property

Indicates the name of the generated HTML form.

Pascal

```
property HTMLFormName: string;
```

C++

```
__property UnicodeString HTMLFormName;
```

Description

HTMLFormName is the value of the NAME option on the generated form. Other Web items can use this property when they need to refer to the form name. For example, this property is used to declare the javascript variable that represents the form.

See Also

HTMLFormVarName (see page 5657)

52.2.6.3.2 IHTMLForm.HTMLFormVarName Property

Indicates the name of the javascript variable that represents the HTML form.

Pascal

```
property HTMLFormVarName: string;
```

C++

```
__property UnicodeString HTMLFormVarName;
```

Description

HTMLFormVarName is the value of the javascript variable for the form. Other Web items can use this property when they need to refer to the form in generated javascript code.

See Also

HTMLFormName (see page 5657)

52.2.7 IInetXWebDataSet Interface

IInetXWebDataSet lets a Web item interact with information about a dataset in an XML broker's data packet.

Class Hierarchy

Pascal

```
IInetXWebDataSet = interface;
```

C++

```
__interface IInetXWebDataSet;
```

File

MidItems

Description

Web items use the IInetXWebDataSet interface (formerly known as IMidasWebDataSet (see page 5684)) to obtain information about a dataset supplied by an XML broker. By using this interface, the Web item does not need to worry about whether the dataset is the top-level dataset in the XML data packet or a nested dataset in that data packet.

IInetXWebDataSet defines methods for obtaining information about the fields and parameters of the associated dataset. It also defines methods for assigning an event handler that receives notifications when this information changes.

Note: VCL Method declarations that use IInetXWebDataSet use the _di_IInetXWebDataSet type instead. This type is a DelphiInterface wrapper around the IInetXWebDataSet interface:

```
typedef System::DelphiInterfaceDelphiInterface_object< IInetXWebDataSet >
_di_IInetXWebDataSet;
```

See Also

TXMLDataSet (see page 5608)

TXMLBroker

52.2.7.1 IInetXWebDataSet Members

The following tables list the members exposed by IInetXWebDataSet.

Public Methods

	Name	Description
	AddOnDataChange (see page 5659)	Adds an event handler to the list of event handlers that are called when the fields or parameters of the dataset change.
	FetchParams (see page 5659)	Tells the XML broker that manages the associated dataset to fetch parameter values from the application server.
	FieldCount (see page 5659)	Returns the number of fields in the associated dataset.
	Fields (see page 5660)	Returns the set of fields in the associated dataset.
	ParamCount (see page 5660)	Returns the number of parameters for the associated dataset.
	Params (see page 5660)	Returns the set of parameters in the associated dataset.
	RemoveOnDataChange (see page 5661)	Removes an event handler from the list of event handlers that are called when the fields or parameters of the dataset change.

52.2.7.2 IInetXWebDataSet Methods

The methods of the IInetXWebDataSet class are listed here.

Public Methods

	Name	Description
	AddOnDataChange (see page 5659)	Adds an event handler to the list of event handlers that are called when the fields or parameters of the dataset change.

	FetchParams (see page 5659)	Tells the XML broker that manages the associated dataset to fetch parameter values from the application server.
	FieldCount (see page 5659)	Returns the number of fields in the associated dataset.
	Fields (see page 5660)	Returns the set of fields in the associated dataset.
	ParamCount (see page 5660)	Returns the number of parameters for the associated dataset.
	Params (see page 5660)	Returns the set of parameters in the associated dataset.
	RemoveOnDataChange (see page 5661)	Removes an event handler from the list of event handlers that are called when the fields or parameters of the dataset change.

52.2.7.2.1 IInetXWebDataSet.AddOnDataChange Method

Adds an event handler to the list of event handlers that are called when the fields or parameters of the dataset change.

Pascal

```
procedure AddOnDataChange(const Value: TNotifyEvent);
```

C++

```
__fastcall AddOnDataChange(const TNotifyEvent Value);
```

Description

Call AddOnDataChange to specify an event handler that is called when the fields or parameters of the dataset change. This allows Web items to update their data bindings to reflect changes in the associated data packet.

Value specifies the event handler that is added to the list.

See Also

RemoveOnDataChange (see page 5661)

52.2.7.2.2 IInetXWebDataSet.FetchParams Method

Tells the XML broker that manages the associated dataset to fetch parameter values from the application server.

Pascal

```
procedure FetchParams;
```

C++

```
__fastcall FetchParams();
```

Description

Call FetchParams to tell the XML broker to fetch parameter values from the application server. This ensures that the Params (see page 5660) method returns the current values of any parameters on the server.

See Also

FetchParams

Params (see page 5660)

52.2.7.2.3 IInetXWebDataSet.FieldCount Method

Returns the number of fields in the associated dataset.

Pascal

```
function FieldCount: Integer;
```

C++

```
__fastcall int FieldCount();
```

Description

Call FieldCount to determine the number of fields returned by the Fields (see page 5660) method. This is the number of fields in the XML data packet belonging to the associated dataset.

See Also

Fields (see page 5660)

52.2.7.2.4 IInetXWebDataSet.Fields Method

Returns the set of fields in the associated dataset.

Pascal

```
function Fields: TFields;
```

C++

```
__fastcall TFields Fields();
```

Description

Call Fields to obtain access to the field objects (TField) that represent the fields in the XML data packet. Each field object can be used to read the value of the field, determine its type, and so on.

See Also

FieldCount (see page 5659)

52.2.7.2.5 IInetXWebDataSet.ParamCount Method

Returns the number of parameters for the associated dataset.

Pascal

```
function ParamCount: Integer;
```

C++

```
__fastcall int ParamCount();
```

Description

Call ParamCount to determine the number of parameters returned by the Params (see page 5660) method. This is the number of parameters in the XML data packet belonging to the associated dataset.

See Also

Params (see page 5660)

52.2.7.2.6 IInetXWebDataSet.Params Method

Returns the set of parameters in the associated dataset.

Pascal

```
function Params: TParams;
```

C++

```
__fastcall TParams Params();
```

Description

Call Params to obtain access to the parameter objects (TParam) that represent the parameters in the XML data packet. Each parameter object can be used to read the value of the parameter, determine its type, and so on.

See Also

ParamCount (see page 5660)

FetchParams (see page 5659)

52.2.7.2.7 IInetXWebDataSet.RemoveOnDataChange Method

Removes an event handler from the list of event handlers that are called when the fields or parameters of the dataset change.

Pascal

```
procedure RemoveOnDataChange(const Value: TNotifyEvent);
```

C++

```
__fastcall RemoveOnDataChange(const TNotifyEvent Value);
```

Description

Call RemoveOnDataChange to remove an event handler that was added using the AddOnDataChange (see page 5659) method.

Value specifies the event handler to remove from the list.

See Also

AddOnDataChange (see page 5659)

52.2.8 IQueryField Interface

Class Hierarchy

Pascal

```
IQueryField = interface(IHTMLField);
```

C++

```
__interface IQueryField : public IHTMLField;
```

File

MidItems

Description

This is class MidItems.IQueryField.

52.2.8.1 IQueryField Members

The following tables list the members exposed by IQueryField.

Public Methods

	Name	Description
	GetHTMLControlName (see page 5654)	Returns the name of the generated HTML <INPUT> control.
	GetParamName (see page 5662)	This is GetParamName, a member of class IQueryField.
	GetText (see page 5662)	This is GetText, a member of class IQueryField.
	SetParamName (see page 5662)	This is SetParamName, a member of class IQueryField.
	SetText (see page 5663)	This is SetText, a member of class IQueryField.

Public Properties

	Name	Description
R	HTMLControlName (see page 5655)	Indicates the name of the generated HTML control.
	ParamName (see page 5663)	This is ParamName, a member of class IQueryField.
	Text (see page 5663)	This is Text, a member of class IQueryField.

52.2.8.2 IQueryField Methods

The methods of the IQueryField class are listed here.

Public Methods

	Name	Description
	GetParamName (see page 5662)	This is GetParamName, a member of class IQueryField.
	GetText (see page 5662)	This is GetText, a member of class IQueryField.
	SetParamName (see page 5662)	This is SetParamName, a member of class IQueryField.
	SetText (see page 5663)	This is SetText, a member of class IQueryField.

52.2.8.2.1 IQueryField.GetParamName Method

Pascal

```
function GetParamName: string;
```

C++

```
__fastcall UnicodeString GetParamName();
```

Description

This is GetParamName, a member of class IQueryField.

52.2.8.2.2 IQueryField.GetText Method

Pascal

```
function GetText: string;
```

C++

```
__fastcall UnicodeString GetText();
```

Description

This is GetText, a member of class IQueryField.

52.2.8.2.3 IQueryField.SetParamName Method

Pascal

```
procedure SetParamName(AParamName: string);
```

C++

```
__fastcall SetParamName(UnicodeString AParamName);
```

Description

This is SetParamName, a member of class IQueryField.

52.2.8.2.4 IQueryField.SetText Method

Pascal

```
procedure SetText(const Value: string);
```

C++

```
__fastcall SetText(const UnicodeString Value);
```

Description

This is SetText, a member of class IQueryField.

52.2.8.3 IQueryField Properties

The properties of the IQueryField class are listed here.

Public Properties

	Name	Description
	ParamName (see page 5663)	This is ParamName, a member of class IQueryField.
	Text (see page 5663)	This is Text, a member of class IQueryField.

52.2.8.3.1 IQueryField.ParamName Property

Pascal

```
property ParamName: string;
```

C++

```
__property UnicodeString ParamName;
```

Description

This is ParamName, a member of class IQueryField.

52.2.8.3.2 IQueryField.Text Property

Pascal

```
property Text: string;
```

C++

```
__property UnicodeString Text;
```

Description

This is Text, a member of class IQueryField.

52.2.9 IQueryFields Interface

Class Hierarchy

Pascal

```
IQueryFields = interface;
```

C++

```
__interface IQueryFields;
```

File

MidItems

Description

This is class MidItems.IQueryFields.

52.2.9.1 IQueryFields Members

The following tables list the members exposed by IQueryFields.

Public Methods

	Name	Description
	GetParamsList (see page 5664)	This is GetParamsList, a member of class IQueryFields.
	IsParamInUse (see page 5665)	This is IsParamInUse, a member of class IQueryFields.
	ValidateDataSet (see page 5665)	This is ValidateDataSet, a member of class IQueryFields.

52.2.9.2 IQueryFields Methods

The methods of the IQueryFields class are listed here.

Public Methods

	Name	Description
	GetParamsList (see page 5664)	This is GetParamsList, a member of class IQueryFields.
	IsParamInUse (see page 5665)	This is IsParamInUse, a member of class IQueryFields.
	ValidateDataSet (see page 5665)	This is ValidateDataSet, a member of class IQueryFields.

52.2.9.2.1 IQueryFields.GetParamsList Method

Pascal

```
procedure GetParamsList(AList: TStrings);
```

C++

```
__fastcall GetParamsList(TStrings AList);
```

Description

This is GetParamsList, a member of class IQueryFields.

52.2.9.2.2 IQueryFields.IsParamInUse Method

Pascal

```
function IsParamInUse(AName: string): Boolean;
```

C++

```
__fastcall Boolean IsParamInUse(UnicodeString AName);
```

Description

This is IsParamInUse, a member of class IQueryFields.

52.2.9.2.3 IQueryFields.ValidateDataSet Method

Pascal

```
procedure ValidateDataSet;
```

C++

```
__fastcall ValidateDataSet();
```

Description

This is ValidateDataSet, a member of class IQueryFields.

52.2.10 IQueryForm Interface

Class Hierarchy

MidItems.IQueryForm

Pascal

```
IQueryForm = interface;
```

C++

```
__interface IQueryForm;
```

File

MidItems

Description

This is class MidItems.IQueryForm.

52.2.11 IRestoreDefaults Interface

Class Hierarchy

MidItems.IRestoreDefaults

Pascal

```
IRestoreDefaults = interface;
```

C++

```
__interface IRestoreDefaults;
```

File

MidItems

Description

This is class MidItems.IRestoreDefaults.

52.2.11.1 IRestoreDefaults Members

The following tables list the members exposed by IRestoreDefaults.

Public Methods

	Name	Description
	RestoreDefaults (see page 5666)	This is RestoreDefaults, a member of class IRestoreDefaults.

52.2.11.2 IRestoreDefaults Methods

The methods of the IRestoreDefaults class are listed here.

Public Methods

	Name	Description
	RestoreDefaults (see page 5666)	This is RestoreDefaults, a member of class IRestoreDefaults.

52.2.11.2.1 IRestoreDefaults.RestoreDefaults Method

Pascal

```
procedure RestoreDefaults;
```

C++

```
__fastcall RestoreDefaults();
```

Description

This is RestoreDefaults, a member of class IRestoreDefaults.

52.2.12 IStatusField Interface

Class Hierarchy

Pascal

```
IStatusField = interface(IHTMLField);
```

C++

```
__interface IStatusField : public IHTMLField;
```

File

MidItems

Description

This is class MidItems.IStatusField.

52.2.13 IValidateField Interface

Class Hierarchy

MidItems.IValidateField

Pascal

```
IValidateField = interface;
```

C++

```
__interface IValidateField;
```

File

MidItems

Description

This is class MidItems.IValidateField.

52.2.13.1 IValidateField Members

The following tables list the members exposed by IValidateField.

Public Methods

	Name	Description
	ValidateField (see page 5667)	This is ValidateField, a member of class IValidateField.

52.2.13.2 IValidateField Methods

The methods of the IValidateField class are listed here.

Public Methods

	Name	Description
	ValidateField (see page 5667)	This is ValidateField, a member of class IValidateField.

52.2.13.2.1 IValidateField.ValidateField Method

Pascal

```
function ValidateField(DataSet: IInetXWebDataSet; AddIntf: IAddScriptElements): Boolean;
```

C++

```
__fastcall Boolean ValidateField(IInetXWebDataSet DataSet, IAddScriptElements AddIntf);
```

Description

This is ValidateField, a member of class IValidateField.

52.2.14 IValidateFields Interface

Class Hierarchy

Pascal

```
IValidateFields = interface;
```

C++

```
__interface IValidateFields;
```

File

MidItems

Description

This is class MidItems.IValidateFields.

52.2.14.1 IValidateFields Members

The following tables list the members exposed by IValidateFields.

Public Methods

	Name	Description
	GetEnableValidateFields (see page 5669)	This is GetEnableValidateFields, a member of class IValidateFields.
	SetEnableValidateFields (see page 5669)	This is SetEnableValidateFields, a member of class IValidateFields.
	ValidateFields (see page 5669)	This is ValidateFields, a member of class IValidateFields.

Public Properties

	Name	Description
	EnableValidateFields (see page 5669)	This is EnableValidateFields, a member of class IValidateFields.

52.2.14.2 IValidateFields Methods

The methods of the IValidateFields class are listed here.

Public Methods

	Name	Description
	GetEnableValidateFields (see page 5669)	This is GetEnableValidateFields, a member of class IValidateFields.
	SetEnableValidateFields (see page 5669)	This is SetEnableValidateFields, a member of class IValidateFields.
	ValidateFields (see page 5669)	This is ValidateFields, a member of class IValidateFields.

52.2.14.2.1 IValidateFields.GetEnableValidateFields Method

Pascal

```
function GetEnableValidateFields: Boolean;
```

C++

```
__fastcall Boolean GetEnableValidateFields();
```

Description

This is GetEnableValidateFields, a member of class IValidateFields.

52.2.14.2.2 IValidateFields.SetEnableValidateFields Method

Pascal

```
procedure SetEnableValidateFields(Value: Boolean);
```

C++

```
__fastcall SetEnableValidateFields(Boolean Value);
```

Description

This is SetEnableValidateFields, a member of class IValidateFields.

52.2.14.2.3 IValidateFields.ValidateFields Method

Pascal

```
function ValidateFields(AddIntf: IAddScriptElements): Boolean;
```

C++

```
__fastcall Boolean ValidateFields(IAddScriptElements AddIntf);
```

Description

This is ValidateFields, a member of class IValidateFields.

52.2.14.3 IValidateFields Properties

The properties of the IValidateFields class are listed here.

Public Properties

	Name	Description
	EnableValidateFields (see page 5669)	This is EnableValidateFields, a member of class IValidateFields.

52.2.14.3.1 IValidateFields.EnableValidateFields Property

Pascal

```
property EnableValidateFields: Boolean;
```

C++

```
__property Boolean EnableValidateFields;
```

Description

This is EnableValidateFields, a member of class IValidateFields.

52.2.15 IWebDisplay Interface

Class Hierarchy

Pascal

```
IWebDisplay = interface;
```

C++

```
__interface IWebDisplay;
```

File

MidItems

TWebDisplay (see page 5540)

52.2.15.1 IWebDisplay Members

The following tables list the members exposed by IWebDisplay.

Public Methods

	Name	Description
	GetIsMultipleRecordView (see page 5670)	This is GetIsMultipleRecordView, a member of class IWebDisplay.

Public Properties

	Name	Description
	IsMultipleRecordView (see page 5671)	

52.2.15.2 IWebDisplay Methods

The methods of the IWebDisplay class are listed here.

Public Methods

	Name	Description
	GetIsMultipleRecordView (see page 5670)	This is GetIsMultipleRecordView, a member of class IWebDisplay.

52.2.15.2.1 IWebDisplay.GetIsMultipleRecordView Method

Pascal

```
function GetIsMultipleRecordView: Boolean;
```

C++

```
__fastcall Boolean GetIsMultipleRecordView();
```

Description

This is GetIsMultipleRecordView, a member of class IWebDisplay.

52.2.15.3 IWebDisplay Properties

The properties of the IWebDisplay class are listed here.

Public Properties

	Name	Description
	IsMultipleRecordView (see page 5671)	

52.2.15.3.1 IWebDisplay.IsMultipleRecordView Property

Pascal

```
property IsMultipleRecordView: Boolean;
```

C++

```
__property Boolean IsMultipleRecordView;
```

Description

.

See Also

GetIsMultipleRecordView (see page 5670)

52.2.16 IWebDisplayReference Interface

Class Hierarchy

MidItems.IWebDisplayReference

Pascal

```
IWebDisplayReference = interface;
```

C++

```
__interface IWebDisplayReference;
```

File

MidItems

52.2.16.1 IWebDisplayReference Members

The following tables list the members exposed by IWebDisplayReference.

Public Methods

	Name	Description
	GetWebDisplayComponent (see page 5672)	This is GetWebDisplayComponent, a member of class IWebDisplayReference.

Public Properties

	Name	Description
	WebDisplayComponent (see page 5672)	

52.2.16.2 IWebDisplayReference Methods

The methods of the IWebDisplayReference class are listed here.

Public Methods

	Name	Description
	GetWebDisplayComponent (see page 5672)	This is GetWebDisplayComponent, a member of class IWebDisplayReference.

52.2.16.2.1 IWebDisplayReference.GetWebDisplayComponent Method

Pascal

```
function GetWebDisplayComponent: TComponent;
```

C++

```
__fastcall TComponent * GetWebDisplayComponent();
```

Description

This is GetWebDisplayComponent, a member of class IWebDisplayReference.

52.2.16.3 IWebDisplayReference Properties

The properties of the IWebDisplayReference class are listed here.

Public Properties

	Name	Description
	WebDisplayComponent (see page 5672)	

52.2.16.3.1 IWebDisplayReference.WebDisplayComponent Property

Pascal

```
property WebDisplayComponent: TComponent;
```

C++

```
__property TComponent * WebDisplayComponent;
```

See Also

GetWebDisplayComponent (see page 5672)

52.2.17 IXMLDisplay Interface

Class Hierarchy

Pascal

```
IXMLDisplay = interface(IWebDisplay);
```

C++

```
__interface IXMLDisplay : public IWebDisplay;
```

File

MidItems

Description

This is class MidItems.IXMLDisplay.

52.2.17.1 IXMLDisplay Members

The following tables list the members exposed by IXMLDisplay.

Public Methods

	Name	Description
	GetIsMultipleRecordView (see page 5673)	This is GetIsMultipleRecordView, a member of class IXMLDisplay.
	GetXMLDisplayName (see page 5674)	This is GetXMLDisplayName, a member of class IXMLDisplay.
	GetXMLRowSetName (see page 5674)	This is GetXMLRowSetName, a member of class IXMLDisplay.

Public Properties

	Name	Description
R	IsMultipleRecordView (see page 5674)	
R	XMLDisplayName (see page 5675)	This is XMLDisplayName, a member of class IXMLDisplay.
R	XMLRowSetName (see page 5675)	This is XMLRowSetName, a member of class IXMLDisplay.

52.2.17.2 IXMLDisplay Methods

The methods of the IXMLDisplay class are listed here.

Public Methods

	Name	Description
	GetIsMultipleRecordView (see page 5673)	This is GetIsMultipleRecordView, a member of class IXMLDisplay.
	GetXMLDisplayName (see page 5674)	This is GetXMLDisplayName, a member of class IXMLDisplay.
	GetXMLRowSetName (see page 5674)	This is GetXMLRowSetName, a member of class IXMLDisplay.

52.2.17.2.1 IXMLDisplay.GetIsMultipleRecordView Method

Pascal

```
function GetIsMultipleRecordView: Boolean;
```

C++

```
__fastcall Boolean GetIsMultipleRecordView();
```

Description

This is GetIsMultipleRecordView, a member of class IXMLDisplay.

52.2.17.2.2 IXMLDisplay.GetXMLDisplayName Method

Pascal

```
function GetXMLDisplayName: string;
```

C++

```
__fastcall UnicodeString GetXMLDisplayName();
```

Description

This is GetXMLDisplayName, a member of class IXMLDisplay.

52.2.17.2.3 IXMLDisplay.GetXMLRowSetName Method

Pascal

```
function GetXMLRowSetName: string;
```

C++

```
__fastcall UnicodeString GetXMLRowSetName();
```

Description

This is GetXMLRowSetName, a member of class IXMLDisplay.

52.2.17.3 IXMLDisplay Properties

The properties of the IXMLDisplay class are listed here.

Public Properties

	Name	Description
R	IsMultipleRecordView (see page 5674)	
R	XMLDisplayName (see page 5675)	This is XMLDisplayName, a member of class IXMLDisplay.
R	XMLRowSetName (see page 5675)	This is XMLRowSetName, a member of class IXMLDisplay.

52.2.17.3.1 IXMLDisplay.IsMultipleRecordView Property

Pascal

```
property IsMultipleRecordView: Boolean;
```

C++

```
__property Boolean IsMultipleRecordView;
```

Description

.

See Also

GetIsMultipleRecordView (see page 5670)

52.2.17.3.2 IXMLDisplay.XMLDisplayName Property

Pascal

```
property XMLDisplayName: string;
```

C++

```
__property UnicodeString XMLDisplayName;
```

Description

This is XMLDisplayName, a member of class IXMLDisplay.

52.2.17.3.3 IXMLDisplay.XMLRowSetName Property

Pascal

```
property XMLRowSetName: string;
```

C++

```
__property UnicodeString XMLRowSetName;
```

Description

This is XMLRowSetName, a member of class IXMLDisplay.

52.3 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	AddBoolAttrib (see page 5676)	This is function MidItems.AddBoolAttrib.
	AddCustomAttrib (see page 5676)	This is function MidItems.AddCustomAttrib.
	AddIntAttrib (see page 5677)	This is function MidItems.AddIntAttrib.
	AddQuotedAttrib (see page 5677)	This is function MidItems.AddQuotedAttrib.
	AddStringAttrib (see page 5677)	This is function MidItems.AddStringAttrib.
	CanAddClassHelper (see page 5678)	This is function MidItems.CanAddClassHelper.
	CreateDefaultButtonClasses (see page 5678)	This is function MidItems.CreateDefaultButtonClasses.
	DeclareSubmitForm (see page 5678)	This is function MidItems.DeclareSubmitForm.
	FindDispatcher (see page 5679)	This is function MidItems.FindDispatcher.
	FindProducer (see page 5679)	This is function MidItems.FindProducer.
	FormatColumnData (see page 5679)	This is function MidItems.FormatColumnData.
	FormatColumnHeading (see page 5680)	This is function MidItems.FormatColumnHeading.
	GetItemValuesFromDataSet (see page 5680)	This is function MidItems.GetItemValuesFromDataSet.

52.3.1 MidItems.AddBoolAttrib Function

Pascal

```
procedure AddBoolAttrib(var Attribs: string; const Attrib: string; Value: Boolean);
```

C++

```
AddBoolAttrib(UnicodeString Attribs, const UnicodeString Attrib, Boolean Value);
```

File

MidItems

Description

This is function MidItems.AddBoolAttrib.

52.3.2 MidItems.AddCustomAttrib Function

Pascal

```
procedure AddCustomAttrib(var Attribs: string; Value: string);
```

C++

```
AddCustomAttrib(UnicodeString Attribs, UnicodeString Value);
```

File

MidItems

Description

This is function MidItems.AddCustomAttrib.

52.3.3 MidItems.AddIntAttrib Function

Pascal

```
procedure AddIntAttrib(var Attribs: string; const Attrib: string; Value: Integer);
```

C++

```
AddIntAttrib(UnicodeString Attribs, const UnicodeString Attrib, int Value);
```

File

MidItems

Description

This is function MidItems.AddIntAttrib.

52.3.4 MidItems.AddQuotedAttrib Function

Pascal

```
procedure AddQuotedAttrib(var Attribs: string; const Attrib: string; const Value: string);
```

C++

```
AddQuotedAttrib(UnicodeString Attribs, const UnicodeString Attrib, const UnicodeString Value);
```

File

MidItems

Description

This is function MidItems.AddQuotedAttrib.

52.3.5 MidItems.AddStringAttrib Function

Pascal

```
procedure AddStringAttrib(var Attribs: string; const Attrib: string; const Value: string);
```

C++

```
AddStringAttrib(UnicodeString Attribs, const UnicodeString Attrib, const UnicodeString Value);
```

File

MidItems

Description

This is function MidItems.AddStringAttrib.

52.3.6 MidItems.CanAddClassHelper Function

Pascal

```
function CanAddClassHelper(AEditor: TComponent; AParent: TComponent; AClass: TClass): Boolean;
```

C++

```
Boolean CanAddClassHelper(TComponent * AEditor, TComponent * AParent, TClass AClass);
```

File

MidItems

Description

This is function MidItems.CanAddClassHelper.

52.3.7 MidItems.CreateDefaultButtonClasses Function

Pascal

```
procedure CreateDefaultButtonClasses(const Classes: array of TWebButtonClass; Container:
TWebComponentList);
```

C++

```
CreateDefaultButtonClasses(const array of TWebButtonClass Classes, TWebComponentList
Container);
```

File

MidItems

Description

This is function MidItems.CreateDefaultButtonClasses.

52.3.8 MidItems.DeclareSubmitForm Function

Pascal

```
procedure DeclareSubmitForm(Component: TComponent; XMLBroker: TXMLBroker; AddIntf:
IAddScriptElements);
```

C++

```
DeclareSubmitForm(TComponent * Component, TXMLBroker XMLBroker, IAddScriptElements AddIntf);
```

File

MidItems

Description

This is function MidItems.DeclareSubmitForm.

52.3.9 MidItems.FindDispatcher Function

Pascal

```
function FindDispatcher(Component: TComponent): IWebDispatcherAccess;
```

C++

```
IWebDispatcherAccess FindDispatcher(TComponent * Component);
```

File

MidItems

Description

This is function MidItems.FindDispatcher.

52.3.10 MidItems.FindProducer Function

Pascal

```
function FindProducer(Component: TComponent): TCustomContentProducer;
```

C++

```
TCustomContentProducer FindProducer(TComponent * Component);
```

File

MidItems

Description

This is function MidItems.FindProducer.

52.3.11 MidItems.FormatColumnData Function

Pascal

```
function FormatColumnData(Field: TWebDataDisplay; Content: string): string;
```

C++

```
UnicodeString FormatColumnData(TWebDataDisplay Field, UnicodeString Content);
```

File

MidItems

Description

This is function MidItems.FormatColumnData.

52.3.12 MidItems.FormatColumnHeading Function

Pascal

```
function FormatColumnHeading(Field: TWebDataDisplay): string;
```

C++

```
UnicodeString FormatColumnHeading(TWebDataDisplay Field);
```

File

MidItems

Description

This is function MidItems.FormatColumnHeading.

52.3.13 MidItems.GetItemValuesFromDataSet Function

Pascal

```
function GetItemValuesFromDataSet(DataSet: TDataSet; const ItemsField: string; const
ValuesField: string; var ItemsStrings: TStrings; var ValuesStrings: TStrings): Boolean;
```

C++

```
Boolean GetItemValuesFromDataSet(TDataSet DataSet, const UnicodeString ItemsField, const
UnicodeString ValuesField, TStrings ItemsStrings, TStrings ValuesStrings);
```

File

MidItems

Description

This is function MidItems.GetItemValuesFromDataSet.

52.4 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TCaptionPosition (see page 5681)	TCaptionPosition indicates the relative position of a label to the HTML control it labels.
	TFormMethod (see page 5682)	TFormMethod represents the method attribute on the <form> tag of an HTML form.
	TLayoutState (see page 5682)	This is record MidItems.TLayoutState.
	TTextAreaWrap (see page 5683)	TTextAreaWrap indicates how an HTML display control should treat items that are too wide for the physical width of the control.

52.4.1 MidItems.TCaptionPosition Enumeration

TCaptionPosition indicates the relative position of a label to the HTML control it labels.

Pascal

```
TCaptionPosition = (
  capLeft,
  capRight,
  capAbove,
  capBelow
);
```

C++

```
enum TCaptionPosition {
  capLeft,
  capRight,
  capAbove,
  capBelow
};
```

File

MidItems

Description

TCaptionPosition can have one of the following values.

Value	Meaning
capLeft	The caption appears to the left of the HTML control.
capRight	The caption appears to the right of the HTML control.
capAbove	The caption appears above the HTML control.
capBelow	The caption appears below the HTML control.

52.4.2 MidItems.TFormMethod Enumeration

TFormMethod represents the method attribute on the <form> tag of an HTML form.

Pascal

```
TFormMethod = (
  fmPost,
  fmGet
);
```

C++

```
enum TFormMethod {
  fmPost,
  fmGet
};
```

File

MidItems

Description

HTML forms include a <form> tag that distinguishes them from other types of HTML pages. This<form> tag includes a method attribute, which determines the method header of the HTTP request message that the form sends to its server. The method type corresponds to the MethodType property of the HTTP request message.

Components that generate HTML forms use TFormMethod to specify the method attribute of the <form> tag they generate, and hence the method header of the messages that they send to the server.

The following table describes the possible values:

Value	Corresponding MethodType	Meaning
fmPost	mtPost	The value of the method attribute is 'post'. The form submits messages that post displayed values to the server application. Named value pairs are passed as content fields of the HTTP message.
fmGet	mtGet	The value of the method attribute is 'get'. The form submits messages that request values it can display. Named value pairs are supplied as query fields in the URL.

See Also

TWebRequest

52.4.3 MidItems.TLayoutState Enumeration

Pascal

```
TLayoutState = (
  lsUnknown,
  lsFields,
  lsButtons
);
```

C++

```
enum TLayoutState {
```

```
    lsUnknown,
    lsFields,
    lsButtons
  };
```

File

MidItems

Description

This is record MidItems.TLayoutState.

52.4.4 MidItems.TTextAreaWrap Enumeration

TTextAreaWrap indicates how an HTML display control should treat items that are too wide for the physical width of the control.

Pascal

```
  TTextAreaWrap = (
    wrOff,
    wrPhysical,
    wrVirtual
  );
```

C++

```
  enum TTextAreaWrap {
    wrOff,
    wrPhysical,
    wrVirtual
  };
```

File

MidItems

Description

TTextAreaWrap can have one of the following values.

Value	Meaning
wrOff	The control does not wrap long lines. Only newline characters that are part of the text string cause the lines in the control to wrap.
wrPhysical	The control formats its text value by wrapping long lines so that no text is hidden. The control inserts carriage returns into the text string.
wrVirtual	The control formats its text value by wrapping long lines so that no text is hidden but does not change the actual value of the text string.

52.5 Types

The following table lists types in this documentation.

Types

Name	Description
IMidasWebDataSet (see page 5684)	This is type MidItems.IMidasWebDataSet.
TWebButtonClass (see page 5684)	This is type MidItems.TWebButtonClass.
TWebDataDisplayClass (see page 5685)	This is type MidItems.TWebDataDisplayClass.
TWebDataInputClass (see page 5685)	This is type MidItems.TWebDataInputClass.
TWebStatusClass (see page 5685)	This is type MidItems.TWebStatusClass.

52.5.1 MidItems.IMidasWebDataSet Type

Pascal

```
IMidasWebDataSet = IInetXWebDataSet;
```

C++

```
IInetXWebDataSet IMidasWebDataSet;
```

File

MidItems

Description

This is type MidItems.IMidasWebDataSet.

52.5.2 MidItems.TWebButtonClass Type

Pascal

```
TWebButtonClass = class of TWebButton;
```

C++

```
TWebButton TWebButtonClass;
```

File

MidItems

Description

This is type MidItems.TWebButtonClass.

52.5.3 MidItems.TWebDataDisplayClass Type

Pascal

```
TWebDataDisplayClass = class of TWebDataDisplay;
```

C++

```
TWebDataDisplay TWebDataDisplayClass;
```

File

MidItems

Description

This is type MidItems.TWebDataDisplayClass.

52.5.4 MidItems.TWebDataInputClass Type

Pascal

```
TWebDataInputClass = class of TWebDataInput;
```

C++

```
TWebDataInput TWebDataInputClass;
```

File

MidItems

Description

This is type MidItems.TWebDataInputClass.

52.5.5 MidItems.TWebStatusClass Type

Pascal

```
TWebStatusClass = class of TWebStatus;
```

C++

```
TWebStatus TWebStatusClass;
```

File

MidItems

Description

This is type MidItems.TWebStatusClass.

52.6 Constants

The following table lists constants in this documentation.

Constants

Name	Description
FormMethodNames (see page 5686)	This is constant MidItems.FormMethodNames.
HTMLAlignValues (see page 5687)	This is constant MidItems.HTMLAlignValues.
HTMLVAlignValues (see page 5687)	This is constant MidItems.HTMLVAlignValues.
sActionAttr (see page 5687)	This is constant MidItems.sActionAttr.
sAlignAttr (see page 5688)	This is constant MidItems.sAlignAttr.
sBgColorAttr (see page 5688)	This is constant MidItems.sBgColorAttr.
sBorderAttr (see page 5688)	This is constant MidItems.sBorderAttr.
sCellPaddingAttr (see page 5689)	This is constant MidItems.sCellPaddingAttr.
sCellSpacingAttr (see page 5689)	This is constant MidItems.sCellSpacingAttr.
sCheckedAttr (see page 5689)	This is constant MidItems.sCheckedAttr.
sClassAttr (see page 5690)	This is constant MidItems.sClassAttr.
sColsAttr (see page 5690)	This is constant MidItems.sColsAttr.
sColSpanAttr (see page 5690)	This is constant MidItems.sColSpanAttr.
sEncTypeAttr (see page 5691)	This is constant MidItems.sEncTypeAttr.
sImageHeightAttr (see page 5691)	This is constant MidItems.sImageHeightAttr.
sImageWidthAttr (see page 5691)	This is constant MidItems.sImageWidthAttr.
sMaxLengthAttr (see page 5692)	This is constant MidItems.sMaxLengthAttr.
sMethodAttr (see page 5692)	This is constant MidItems.sMethodAttr.
sMultipleAttr (see page 5692)	This is constant MidItems.sMultipleAttr.
sNameAttr (see page 5693)	This is constant MidItems.sNameAttr.
sOnClickAttr (see page 5693)	This is constant MidItems.sOnClickAttr.
sReadOnlyAttr (see page 5693)	This is constant MidItems.sReadOnlyAttr.
sRowsAttr (see page 5694)	This is constant MidItems.sRowsAttr.
sSelectedAttr (see page 5694)	This is constant MidItems.sSelectedAttr.
sSizeAttr (see page 5694)	This is constant MidItems.sSizeAttr.
sStyleAttr (see page 5695)	This is constant MidItems.sStyleAttr.
sTabIndexAttr (see page 5695)	This is constant MidItems.sTabIndexAttr.
sTypeAttr (see page 5695)	This is constant MidItems.sTypeAttr.
sVAlignAttr (see page 5696)	This is constant MidItems.sVAlignAttr.
sValueAttr (see page 5696)	This is constant MidItems.sValueAttr.
sWidthAttr (see page 5696)	This is constant MidItems.sWidthAttr.
sWrapAttr (see page 5697)	This is constant MidItems.sWrapAttr.
TextAreaWrap (see page 5697)	This is constant MidItems.TextAreaWrap.

52.6.1 MidItems.FormMethodNames Constant

Pascal

```
FormMethodNames: array[TFormMethod] of string = ('POST', 'GET');
```

C++

```
array[TFormMethod] of string FormMethodNames = ('POST', 'GET');
```

File

MidItems

Description

This is constant MidItems.FormMethodNames.

52.6.2 MidItems.HTMLAlignValues Constant

Pascal

```
HTMLAlignValues: array[THTMLAlign] of string = ('', 'left', 'right', 'center');
```

C++

```
array[THTMLAlign] of string HTMLAlignValues = ('', 'left', 'right', 'center');
```

File

MidItems

Description

This is constant MidItems.HTMLAlignValues.

52.6.3 MidItems.HTMLVAlignValues Constant

Pascal

```
HTMLVAlignValues: array[THTMLVAlign] of string = ('', 'top', 'middle', 'bottom', 'baseline');
```

C++

```
array[THTMLVAlign] of string HTMLVAlignValues = ('', 'top', 'middle', 'bottom', 'baseline');
```

File

MidItems

Description

This is constant MidItems.HTMLVAlignValues.

52.6.4 MidItems.sActionAttr Constant

Pascal

```
sActionAttr = 'action';
```

C++

```
sActionAttr = 'action';
```

File

MidItems

Description

This is constant MidItems.sActionAttr.

52.6.5 MidItems.sAlignAttr Constant

Pascal

```
sAlignAttr = 'align';
```

C++

```
sAlignAttr = 'align';
```

File

MidItems

Description

This is constant MidItems.sAlignAttr.

52.6.6 MidItems.sBgColorAttr Constant

Pascal

```
sBgColorAttr = 'bgcolor';
```

C++

```
sBgColorAttr = 'bgcolor';
```

File

MidItems

Description

This is constant MidItems.sBgColorAttr.

52.6.7 MidItems.sBorderAttr Constant

Pascal

```
sBorderAttr = 'border';
```

C++

```
sBorderAttr = 'border';
```

File

MidItems

Description

This is constant MidItems.sBorderAttr.

52.6.8 MidItems.sCellPaddingAttr Constant

Pascal

```
sCellPaddingAttr = 'cellpadding';
```

C++

```
sCellPaddingAttr = 'cellpadding';
```

File

MidItems

Description

This is constant MidItems.sCellPaddingAttr.

52.6.9 MidItems.sCellSpacingAttr Constant

Pascal

```
sCellSpacingAttr = 'cellspacing';
```

C++

```
sCellSpacingAttr = 'cellspacing';
```

File

MidItems

Description

This is constant MidItems.sCellSpacingAttr.

52.6.10 MidItems.sCheckedAttr Constant

Pascal

```
sCheckedAttr = 'checked';
```

C++

```
sCheckedAttr = 'checked';
```

File

MidItems

Description

This is constant MidItems.sCheckedAttr.

52.6.11 MidItems.sClassAttr Constant

Pascal

```
sClassAttr = 'class';
```

C++

```
sClassAttr = 'class';
```

File

MidItems

Description

This is constant MidItems.sClassAttr.

52.6.12 MidItems.sColsAttr Constant

Pascal

```
sColsAttr = 'cols';
```

C++

```
sColsAttr = 'cols';
```

File

MidItems

Description

This is constant MidItems.sColsAttr.

52.6.13 MidItems.sColSpanAttr Constant

Pascal

```
sColSpanAttr = 'colspan';
```

C++

```
sColSpanAttr = 'colspan';
```

File

MidItems

Description

This is constant MidItems.sColSpanAttr.

52.6.14 MidItems.sEncTypeAttr Constant

Pascal

```
sEncTypeAttr = 'enctype';
```

C++

```
sEncTypeAttr = 'enctype';
```

File

MidItems

Description

This is constant MidItems.sEncTypeAttr.

52.6.15 MidItems.sImageHeightAttr Constant

Pascal

```
sImageHeightAttr = 'imageheight';
```

C++

```
sImageHeightAttr = 'imageheight';
```

File

MidItems

Description

This is constant MidItems.sImageHeightAttr.

52.6.16 MidItems.sImageWidthAttr Constant

Pascal

```
sImageWidthAttr = 'imagewidth';
```

C++

```
sImageWidthAttr = 'imagewidth';
```

File

MidItems

Description

This is constant MidItems.sImageWidthAttr.

52.6.17 MidItems.sMaxLengthAttr Constant

Pascal

```
sMaxLengthAttr = 'maxlength';
```

C++

```
sMaxLengthAttr = 'maxlength';
```

File

MidItems

Description

This is constant MidItems.sMaxLengthAttr.

52.6.18 MidItems.sMethodAttr Constant

Pascal

```
sMethodAttr = 'method';
```

C++

```
sMethodAttr = 'method';
```

File

MidItems

Description

This is constant MidItems.sMethodAttr.

52.6.19 MidItems.sMultipleAttr Constant

Pascal

```
sMultipleAttr = 'multiple';
```

C++

```
sMultipleAttr = 'multiple';
```

File

MidItems

Description

This is constant MidItems.sMultipleAttr.

52.6.20 MidItems.sNameAttr Constant

Pascal

```
sNameAttr = 'name';
```

C++

```
sNameAttr = 'name';
```

File

MidItems

Description

This is constant MidItems.sNameAttr.

52.6.21 MidItems.sOnClickAttr Constant

Pascal

```
sOnClickAttr = 'onclick';
```

C++

```
sOnClickAttr = 'onclick';
```

File

MidItems

Description

This is constant MidItems.sOnClickAttr.

52.6.22 MidItems.sReadOnlyAttr Constant

Pascal

```
sReadOnlyAttr = 'readonly';
```

C++

```
sReadOnlyAttr = 'readonly';
```

File

MidItems

Description

This is constant MidItems.sReadOnlyAttr.

52.6.23 MidItems.sRowsAttr Constant

Pascal

```
sRowsAttr = 'rows';
```

C++

```
sRowsAttr = 'rows';
```

File

MidItems

Description

This is constant MidItems.sRowsAttr.

52.6.24 MidItems.sSelectedAttr Constant

Pascal

```
sSelectedAttr = 'selected';
```

C++

```
sSelectedAttr = 'selected';
```

File

MidItems

Description

This is constant MidItems.sSelectedAttr.

52.6.25 MidItems.sSizeAttr Constant

Pascal

```
sSizeAttr = 'size';
```

C++

```
sSizeAttr = 'size';
```

File

MidItems

Description

This is constant MidItems.sSizeAttr.

52.6.26 MidItems.sStyleAttr Constant

Pascal

```
sStyleAttr = 'style';
```

C++

```
sStyleAttr = 'style';
```

File

MidItems

Description

This is constant MidItems.sStyleAttr.

52.6.27 MidItems.sTabIndexAttr Constant

Pascal

```
sTabIndexAttr = 'tabindex';
```

C++

```
sTabIndexAttr = 'tabindex';
```

File

MidItems

Description

This is constant MidItems.sTabIndexAttr.

52.6.28 MidItems.sTypeAttr Constant

Pascal

```
sTypeAttr = 'type';
```

C++

```
sTypeAttr = 'type';
```

File

MidItems

Description

This is constant MidItems.sTypeAttr.

52.6.29 MidItems.sVAlignAttr Constant

Pascal

```
sVAlignAttr = 'valign';
```

C++

```
sVAlignAttr = 'valign';
```

File

MidItems

Description

This is constant MidItems.sVAlignAttr.

52.6.30 MidItems.sValueAttr Constant

Pascal

```
sValueAttr = 'value';
```

C++

```
sValueAttr = 'value';
```

File

MidItems

Description

This is constant MidItems.sValueAttr.

52.6.31 MidItems.sWidthAttr Constant

Pascal

```
sWidthAttr = 'width';
```

C++

```
sWidthAttr = 'width';
```

File

MidItems

Description

This is constant MidItems.sWidthAttr.

52.6.32 MidItems.sWrapAttr Constant

Pascal

```
sWrapAttr = 'wrap';
```

C++

```
sWrapAttr = 'wrap';
```

File

MidItems

Description

This is constant MidItems.sWrapAttr.

52.6.33 MidItems.TextAreaWrap Constant

Pascal

```
TextAreaWrap: array[TTextAreaWrap] of string = ('OFF', 'PHYSICAL', 'VIRTUAL');
```

C++

```
array[TTextAreaWrap] of string TextAreaWrap = ('OFF', 'PHYSICAL', 'VIRTUAL');
```

File

MidItems

Description

This is constant MidItems.TextAreaWrap.

53 MidProd Namespace

This is namespace MidProd.

Topics

Name	Description
Classes (see page 5701)	The following table lists classes in this documentation.
Functions (see page 5741)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 5742)	The following table lists structs, records, enums in this documentation.
Types (see page 5743)	The following table lists types in this documentation.
Constants (see page 5745)	The following table lists constants in this documentation.

Classes

	Name	Description
	TBaseInetXPageProducer (see page 5701)	TBaseInetXPageProducer is an base class for InternetExpress page producer classes.
	TCustomInetXPageProducer (see page 5720)	TCustomInetXPageProducer is the base class for page producers that display live database information in an InternetExpress application.
	TInetXPageElements (see page 5727)	This is class MidProd.TInetXPageElements.
	TInetXPageProducer (see page 5730)	TInetXPageProducer assembles an HTML document that represents live database information from an application server.
	TMidasPageProducer (see page 5740)	TMidasPageProducer assembles an HTML document that represents live database information from an application server.

Constants

Name	Description
sXMLBroker (see page 5745)	This is constant MidProd.sXMLBroker.
sXMLReadyVar (see page 5745)	This is constant MidProd.sXMLReadyVar.

Functions

	Name	Description
	AddStdIncludes (see page 5741)	This is function MidProd.AddStdIncludes.
	PathInfoToRelativePath (see page 5741)	This is function MidProd.PathInfoToRelativePath.

Structs, Records, Enums

	Name	Description
	TStdInclude (see page 5742)	This is record MidProd.TStdInclude.

Types

Name	Description
TBaseMidasPageProducer (see page 5743)	This is type MidProd.TBaseMidasPageProducer.
TCustomMidasPageProducer (see page 5743)	This is type MidProd.TCustomMidasPageProducer.
TMidasPageElements (see page 5744)	This is type MidProd.TMidasPageElements.
TStdIncludes (see page 5744)	This is type MidProd.TStdIncludes.
TXMLDataEvent (see page 5744)	This is type MidProd.TXMLDataEvent.

53.1 Classes

The following table lists classes in this documentation.

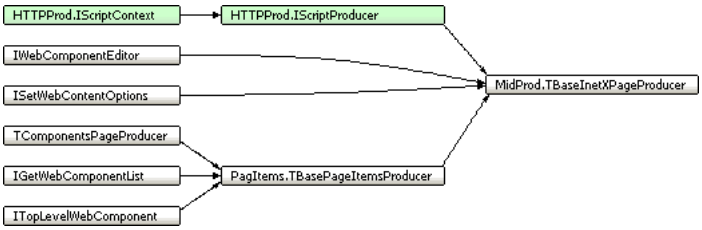
Classes

	Name	Description
	TBaseInetXPageProducer (see page 5701)	TBaseInetXPageProducer is an base class for InternetExpress page producer classes.
	TCustomInetXPageProducer (see page 5720)	TCustomInetXPageProducer is the base class for page producers that display live database information in an InternetExpress application.
	TInetXPageElements (see page 5727)	This is class MidProd.TInetXPageElements.
	TInetXPageProducer (see page 5730)	TInetXPageProducer assembles an HTML document that represents live database information from an application server.
	TMidasPageProducer (see page 5740)	TMidasPageProducer assembles an HTML document that represents live database information from an application server.

53.1.1 TBaseInetXPageProducer Class

TBaseInetXPageProducer is an base class for InternetExpress page producer classes.

Class Hierarchy



Pascal

```
TBaseInetXPageProducer = class(TBasePageItemsProducer, IWebComponentEditor, IScriptProducer,
ISetWebContentOptions);
```

C++

```
class TBaseInetXPageProducer : public TBasePageItemsProducer, public IWebComponentEditor,
public IScriptProducer, public ISetWebContentOptions;
```

File

MidProd

Description

Do not create instances of TBaseInetXPageProducer. Instead, use one of its descendant classes, such as TInetXPageProducer (see page 5730).

TBaseInetXPageProducer introduces the logic for working with an XML broker to obtain database information and for translating the special HTML-transparent tags that are used in InternetExpress applications. Unlike its immediate descendant (TCustomInetXPageProducer (see page 5720)) however, TBaseInetXPageProducer does not initialize the HTMLDoc property to the default template for an InternetExpress application, although it dynamically generates the InternetExpress-specific tags.

You can use TBaseInetXPageProducer as a base class when writing a page producer that does not use the default template, but

which translates InternetExpress tags into HTML and javascript.

See Also

TInetXPageProducer (see page 5730)

TXMLBroker

53.1.1.1 TBaseInetXPageProducer Members

The following tables list the members exposed by TBaseInetXPageProducer.

Protected Methods

	Name	Description
	AddIncludes (see page 5705)	This is AddIncludes, a member of class TBaseInetXPageProducer.
	AddScriptComponents (see page 5705)	This is AddScriptComponents, a member of class TBaseInetXPageProducer.
	CanAddClass (see page 5705)	Indicates whether a specified class can be used as a child Web item.
	CreatePageElements (see page 5706)	This is CreatePageElements, a member of class TBaseInetXPageProducer.
	CreateScriptManager (see page 5707)	This is CreateScriptManager, a member of class TBaseInetXPageProducer.
	DeclareFunctions (see page 5707)	This is DeclareFunctions, a member of class TBaseInetXPageProducer.
	DeclareIncludes (see page 5707)	This is DeclareIncludes, a member of class TBaseInetXPageProducer.
	DeclareRowSets (see page 5707)	This is DeclareRowSets, a member of class TBaseInetXPageProducer.
	DeclareScript (see page 5708)	This is DeclareScript, a member of class TBaseInetXPageProducer.
	DeclareStyles (see page 5708)	This is DeclareStyles, a member of class TBaseInetXPageProducer.
	DeclareWarnings (see page 5708)	This is DeclareWarnings, a member of class TBaseInetXPageProducer.
	DeclareXMLDocuments (see page 5708)	This is DeclareXMLDocuments, a member of class TBaseInetXPageProducer.
	DeclareXMLIslands (see page 5708)	This is DeclareXMLIslands, a member of class TBaseInetXPageProducer.
	DoAfterGetContent (see page 5709)	This is DoAfterGetContent, a member of class TBaseInetXPageProducer.
	DoAfterGetXMLData (see page 5709)	This is DoAfterGetXMLData, a member of class TBaseInetXPageProducer.
	DoBeforeGetContent (see page 5709)	This is DoBeforeGetContent, a member of class TBaseInetXPageProducer.
	DoBeforeGetXMLData (see page 5709)	This is DoBeforeGetXMLData, a member of class TBaseInetXPageProducer.
	DoTagEvent (see page 5710)	This is DoTagEvent, a member of class TBaseInetXPageProducer.
	GeneratePageElements (see page 5711)	This is GeneratePageElements, a member of class TBaseInetXPageProducer.
	GetChildren (see page 6392)	This is GetChildren, a member of class TBasePageItemsProducer.
	GetComponentList (see page 6392)	This is GetComponentList, a member of class TBasePageItemsProducer.
	GetContentOptions (see page 5711)	This is GetContentOptions, a member of class TBaseInetXPageProducer.
	GetDefaultComponentList (see page 6392)	This is GetDefaultComponentList, a member of class TBasePageItemsProducer.
	GetDefaultTemplate (see page 5711)	This is GetDefaultTemplate, a member of class TBaseInetXPageProducer.
	GetScriptManager (see page 5712)	This is GetScriptManager, a member of class TBaseInetXPageProducer.
	GetUseXMLIslands (see page 5712)	This is GetUseXMLIslands, a member of class TBaseInetXPageProducer.
	GetXMLDelta (see page 5713)	This is GetXMLDelta, a member of class TBaseInetXPageProducer.
	GetXMLErrors (see page 5713)	This is GetXMLErrors, a member of class TBaseInetXPageProducer.
	ImplCanAddClass (see page 5713)	This is ImplCanAddClass, a member of class TBaseInetXPageProducer.
	SetChildOrder (see page 6393)	This is SetChildOrder, a member of class TBasePageItemsProducer.
	SetWebContentOptions (see page 5714)	This is SetWebContentOptions, a member of class TBaseInetXPageProducer.

Protected Properties

	Name	Description
	PageElements (see page 5716)	This is PageElements, a member of class TBaseInetXPageProducer.
	ScriptManager (see page 5716)	This is ScriptManager, a member of class TBaseInetXPageProducer.

Public Events

	Name	Description
	OnAfterGetContent (see page 5718)	Occurs after the page producer generates its HTML document.

	OnAfterGetXMLData (see page 5718)	Occurs after the page producer translates fetches an XML data packet from an XML broker.
	OnBeforeGetContent (see page 5719)	Occurs when the Content method is called.
	OnBeforeGetXMLData (see page 5719)	Occurs before the page producer fetches an XML data packet from an XML broker.

Public Methods

	Name	Description
V	ContentFromStream (see page 5706)	Returns the content produced in response to input read from a stream.
V	Create (see page 5703)	Creates an instance of a TBaseInetXPageProducer (see page 5701).
V	Destroy (see page 5704)	Destroys the instance of the TBasePageItemsProducer.
	Evaluate (see page 3509)	This is Evaluate, a member of class IScriptProducer.
V	FindXMLBroker (see page 5710)	Returns the XML broker that supplies the data packet specified by a DATAPACKET tag.
V	FindXMLBrokerName (see page 5710)	Returns the name of an XML broker given the parameters in a DATAPACKET tag..
	GetContent (see page 3509)	This is GetContent, a member of class IScriptProducer.
	GetErrors (see page 3509)	This is GetErrors, a member of class IScriptProducer.
	GetHTMLBlock (see page 3510)	This is GetHTMLBlock, a member of class IScriptProducer.
	GetHTMLBlockCount (see page 3510)	This is GetHTMLBlockCount, a member of class IScriptProducer.
V	GetRequiredTags (see page 5711)	Returns the default set of HTML-transparent tags for an InternetExpress page producer.
	GetWebModuleContext (see page 3507)	This is GetWebModuleContext, a member of class IScriptContext.
V	GetXMLData (see page 5712)	Obtains an XML data packet from a specified XML broker.
	HandleScriptError (see page 3510)	This is HandleScriptError, a member of class IScriptProducer.
	ParseStream (see page 3510)	This is ParseStream, a member of class IScriptProducer.
	ParseString (see page 3510)	This is ParseString, a member of class IScriptProducer.
	ReplaceTags (see page 3511)	This is ReplaceTags, a member of class IScriptProducer.
	SetContent (see page 3511)	This is SetContent, a member of class IScriptProducer.
	SetIncludePathURL (see page 5713)	Assigns a value to the IncludePathURL (see page 5715) property.
	SetStyles (see page 5714)	Assigns a value to the Styles (see page 5716) property.
	SetStylesFile (see page 5714)	Assigns a value to the StylesFile (see page 5717) property.
	Write (see page 3511)	This is the overview for the Write method overload.
	WriteItem (see page 3512)	This is WriteItem, a member of class IScriptProducer.

Public Properties

	Name	Description
	Content (see page 3512)	This is Content, a member of class IScriptProducer.
	EnableXMLIslands (see page 5715)	Specifies whether XML data packets should be declared using XML islands if the requesting browser supports them.
R	Errors (see page 3512)	This is Errors, a member of class IScriptProducer.
R	HTMLBlockCount (see page 3513)	This is HTMLBlockCount, a member of class IScriptProducer.
R	HTMLBlocks (see page 3513)	This is HTMLBlocks, a member of class IScriptProducer.
	IncludePathURL (see page 5715)	Indicates the URL where the javascript libraries are installed.
	Styles (see page 5716)	Defines the styles that can be used by the page producer and its Web items.
	StylesFile (see page 5717)	Specifies a file containing the individual styles for the page producer's style sheet.
R	WebModuleContext (see page 3507)	This is WebModuleContext, a member of class IScriptContext.
R	WebPageItems (see page 6393)	Maintains a list of components that generate HTML content for the producer.

53.1.1.2 TBaseInetXPageProducer.Create Constructor

Creates an instance of a TBaseInetXPageProducer (see page 5701).

Pascal

```
constructor Create(AComponent: TComponent); override;
```

C++

```
virtual __fastcall TBaseInetXPageProducer(TComponent * AComponent);
```

Description

Call Create to instantiate a TBaseInetXPageProducer (see page 5701) component at runtime if it was not created at design time.

AOwner is the component, typically the Web module, that becomes the value of this page producer's Owner property. The Owner is responsible for freeing the TBaseInetXPageProducer (see page 5701) instance.

See Also

Owner

53.1.1.3 TBaseInetXPageProducer.Destroy Destructor

Destroys the instance of the TBasePageItemsProducer.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TBaseInetXPageProducer();
```

Description

Do not call Destroy directly. Instead call Free, which checks that the TBasePageItemsProducer reference is not nil before calling Destroy.

See Also

Create (see page 6391)

System::TObject::Free

53.1.1.4 TBaseInetXPageProducer Methods

The methods of the TBaseInetXPageProducer class are listed here.

Protected Methods

	Name	Description
	AddIncludes (see page 5705)	This is AddIncludes, a member of class TBaseInetXPageProducer.
	AddScriptComponents (see page 5705)	This is AddScriptComponents, a member of class TBaseInetXPageProducer.
	CanAddClass (see page 5705)	Indicates whether a specified class can be used as a child Web item.
	CreatePageElements (see page 5706)	This is CreatePageElements, a member of class TBaseInetXPageProducer.
	CreateScriptManager (see page 5707)	This is CreateScriptManager, a member of class TBaseInetXPageProducer.
	DeclareFunctions (see page 5707)	This is DeclareFunctions, a member of class TBaseInetXPageProducer.
	DeclareIncludes (see page 5707)	This is DeclareIncludes, a member of class TBaseInetXPageProducer.
	DeclareRowSets (see page 5707)	This is DeclareRowSets, a member of class TBaseInetXPageProducer.
	DeclareScript (see page 5708)	This is DeclareScript, a member of class TBaseInetXPageProducer.
	DeclareStyles (see page 5708)	This is DeclareStyles, a member of class TBaseInetXPageProducer.
	DeclareWarnings (see page 5708)	This is DeclareWarnings, a member of class TBaseInetXPageProducer.
	DeclareXMLDocuments (see page 5708)	This is DeclareXMLDocuments, a member of class TBaseInetXPageProducer.
	DeclareXMLIslands (see page 5708)	This is DeclareXMLIslands, a member of class TBaseInetXPageProducer.
	DoAfterGetContent (see page 5709)	This is DoAfterGetContent, a member of class TBaseInetXPageProducer.

	DoAfterGetXMLData (see page 5709)	This is DoAfterGetXMLData, a member of class TBaseInetXPageProducer.
	DoBeforeGetContent (see page 5709)	This is DoBeforeGetContent, a member of class TBaseInetXPageProducer.
	DoBeforeGetXMLData (see page 5709)	This is DoBeforeGetXMLData, a member of class TBaseInetXPageProducer.
V	DoTagEvent (see page 5710)	This is DoTagEvent, a member of class TBaseInetXPageProducer.
V	GeneratePageElements (see page 5711)	This is GeneratePageElements, a member of class TBaseInetXPageProducer.
V	GetContentOptions (see page 5711)	This is GetContentOptions, a member of class TBaseInetXPageProducer.
V	GetDefaultTemplate (see page 5711)	This is GetDefaultTemplate, a member of class TBaseInetXPageProducer.
	GetScriptManager (see page 5712)	This is GetScriptManager, a member of class TBaseInetXPageProducer.
V	GetUseXMLIslands (see page 5712)	This is GetUseXMLIslands, a member of class TBaseInetXPageProducer.
	GetXMLDelta (see page 5713)	This is GetXMLDelta, a member of class TBaseInetXPageProducer.
	GetXMLErrors (see page 5713)	This is GetXMLErrors, a member of class TBaseInetXPageProducer.
V	ImplCanAddClass (see page 5713)	This is ImplCanAddClass, a member of class TBaseInetXPageProducer.
	SetWebContentOptions (see page 5714)	This is SetWebContentOptions, a member of class TBaseInetXPageProducer.

Public Methods

	Name	Description
V	ContentFromStream (see page 5706)	Returns the content produced in response to input read from a stream.
V	FindXMLBroker (see page 5710)	Returns the XML broker that supplies the data packet specified by a DATAPACKET tag.
V	FindXMLBrokerName (see page 5710)	Returns the name of an XML broker given the parameters in a DATAPACKET tag..
V	GetRequiredTags (see page 5711)	Returns the default set of HTML-transparent tags for an InternetExpress page producer.
V	GetXMLData (see page 5712)	Obtains an XML data packet from a specified XML broker.
	SetIncludePathURL (see page 5713)	Assigns a value to the IncludePathURL (see page 5715) property.
	SetStyles (see page 5714)	Assigns a value to the Styles (see page 5716) property.
	SetStylesFile (see page 5714)	Assigns a value to the StylesFile (see page 5717) property.

53.1.1.4.1 TBaseInetXPageProducer.AddIncludes Method

Pascal

```
procedure AddIncludes; virtual;
```

C++

```
virtual __fastcall AddIncludes();
```

Description

This is AddIncludes, a member of class TBaseInetXPageProducer.

53.1.1.4.2 TBaseInetXPageProducer.AddScriptComponents Method

Pascal

```
procedure AddScriptComponents; virtual;
```

C++

```
virtual __fastcall AddScriptComponents();
```

Description

This is AddScriptComponents, a member of class TBaseInetXPageProducer.

53.1.1.4.3 TBaseInetXPageProducer.CanAddClass Method

Indicates whether a specified class can be used as a child Web item.

Pascal

```
function CanAddClass(AParent: TComponent; AClass: TClass): Boolean;
```

C++

```
__fastcall Boolean CanAddClass(TComponent * AParent, TClass AClass);
```

Description

The Web page editor calls CanAddClass to determine what Web items can be added to supply content for the Web item that implements this interface.

AParent is the Web item that will act as a parent to the added Web item.

AClass is the class of the proposed child Web item.

CanAddClass returns true if the Web item can use content generated by a component of type AClass, false otherwise.

53.1.1.4.4 TBaseInetXPageProducer.ContentFromStream Method

Returns the content produced in response to input read from a stream.

Pascal

```
function ContentFromStream(InStream: TStream): string; override;
```

C++

```
virtual __fastcall UnicodeString ContentFromStream(TStream InStream);
```

Description

Call ContentFromStream to retrieve the content produced by the content producer based on the information provided by the Stream parameter. ContentFromStream

1. Generates an OnBeforeGetContent (see page 5719) event.
2. Translates the HTML template that is the value of Stream, using information produced by the items listed in the WebPageItems property.
3. Generates an OnAfterGetContent (see page 5718) event.
4. Returns the HTML produced in step 2.

See Also

Content (see page 3466)

OnBeforeGetContent (see page 5719)

WebPageItems (see page 6393)

OnAfterGetContent (see page 5718)

53.1.1.4.5 TBaseInetXPageProducer.CreatePageElements Method

Pascal

```
function CreatePageElements: TInetxPageElements; virtual;
```

C++

```
virtual __fastcall TInetxPageElements CreatePageElements();
```

Description

This is CreatePageElements, a member of class TBaseInetXPageProducer.

53.1.1.4.6 TBaseInetXPageProducer.CreateScriptManager Method

Pascal

```
function CreateScriptManager(Options: TWebContentOptions): TObject; virtual;
```

C++

```
virtual __fastcall TObject * CreateScriptManager(TWebContentOptions Options);
```

Description

This is CreateScriptManager, a member of class TBaseInetXPageProducer.

53.1.1.4.7 TBaseInetXPageProducer.DeclareFunctions Method

Pascal

```
function DeclareFunctions: string; virtual;
```

C++

```
virtual __fastcall UnicodeString DeclareFunctions();
```

Description

This is DeclareFunctions, a member of class TBaseInetXPageProducer.

53.1.1.4.8 TBaseInetXPageProducer.DeclareIncludes Method

Pascal

```
function DeclareIncludes: string; virtual;
```

C++

```
virtual __fastcall UnicodeString DeclareIncludes();
```

Description

This is DeclareIncludes, a member of class TBaseInetXPageProducer.

53.1.1.4.9 TBaseInetXPageProducer.DeclareRowSets Method

Pascal

```
function DeclareRowSets: string; virtual;
```

C++

```
virtual __fastcall UnicodeString DeclareRowSets();
```

Description

This is DeclareRowSets, a member of class TBaseInetXPageProducer.

53.1.1.4.10 TBaseInetXPageProducer.DeclareScript Method

Pascal

```
function DeclareScript(XMLIslands: Boolean): string; virtual;
```

C++

```
virtual __fastcall UnicodeString DeclareScript(Boolean XMLIslands);
```

Description

This is DeclareScript, a member of class TBaseInetXPageProducer.

53.1.1.4.11 TBaseInetXPageProducer.DeclareStyles Method

Pascal

```
function DeclareStyles: string; virtual;
```

C++

```
virtual __fastcall UnicodeString DeclareStyles();
```

Description

This is DeclareStyles, a member of class TBaseInetXPageProducer.

53.1.1.4.12 TBaseInetXPageProducer.DeclareWarnings Method

Pascal

```
function DeclareWarnings(Warnings: TStrings): string; virtual;
```

C++

```
virtual __fastcall UnicodeString DeclareWarnings(TStrings Warnings);
```

Description

This is DeclareWarnings, a member of class TBaseInetXPageProducer.

53.1.1.4.13 TBaseInetXPageProducer.DeclareXMLDocuments Method

Pascal

```
function DeclareXMLDocuments: string; virtual;
```

C++

```
virtual __fastcall UnicodeString DeclareXMLDocuments();
```

Description

This is DeclareXMLDocuments, a member of class TBaseInetXPageProducer.

53.1.1.4.14 TBaseInetXPageProducer.DeclareXMLIslands Method

Pascal

```
function DeclareXMLIslands: string; virtual;
```

C++

```
virtual __fastcall UnicodeString DeclareXMLIslands();
```

Description

This is DeclareXMLIslands, a member of class TBaseInetXPageProducer.

53.1.1.4.15 TBaseInetXPageProducer.DoAfterGetContent Method

Pascal

```
procedure DoAfterGetContent;
```

C++

```
__fastcall DoAfterGetContent();
```

Description

This is DoAfterGetContent, a member of class TBaseInetXPageProducer.

53.1.1.4.16 TBaseInetXPageProducer.DoAfterGetXMLData Method

Pascal

```
procedure DoAfterGetXMLData(XMLBroker: TXMLBroker; var OwnerData: OleVariant);
```

C++

```
__fastcall DoAfterGetXMLData(TXMLBroker XMLBroker, OleVariant OwnerData);
```

Description

This is DoAfterGetXMLData, a member of class TBaseInetXPageProducer.

53.1.1.4.17 TBaseInetXPageProducer.DoBeforeGetContent Method

Pascal

```
procedure DoBeforeGetContent;
```

C++

```
__fastcall DoBeforeGetContent();
```

Description

This is DoBeforeGetContent, a member of class TBaseInetXPageProducer.

53.1.1.4.18 TBaseInetXPageProducer.DoBeforeGetXMLData Method

Pascal

```
procedure DoBeforeGetXMLData(XMLBroker: TXMLBroker; var OwnerData: OleVariant);
```

C++

```
__fastcall DoBeforeGetXMLData(TXMLBroker XMLBroker, OleVariant OwnerData);
```

Description

This is DoBeforeGetXMLData, a member of class TBaseInetXPageProducer.

53.1.1.4.19 TBaseInetXPageProducer.DoTagEvent Method

Pascal

```
procedure DoTagEvent(Tag: TTag; const TagString: string; TagParams: TStrings; var ReplaceText:
string); override;
```

C++

```
virtual __fastcall DoTagEvent(TTag Tag, const UnicodeString TagString, TStrings TagParams,
UnicodeString ReplaceText);
```

Description

This is DoTagEvent, a member of class TBaseInetXPageProducer.

53.1.1.4.20 TBaseInetXPageProducer.FindXMLBroker Method

Returns the XML broker that supplies the data packet specified by a DATAPACKET tag.

Pascal

```
function FindXMLBroker(TagParams: TStrings): TXMLBroker; virtual;
```

C++

```
virtual __fastcall TXMLBroker FindXMLBroker(TStrings TagParams);
```

Description

The page producer translates HTML-transparent tags of the form

```
<#DATAPACKET XMLBroker=BrokerName>
```

into the XML returned by the XML broker. To do so, it calls FindXMLBroker to locate the XML broker specified by the XMLBroker parameter.

TagParams is a set of Name=Value pairs. This comes from the parameter portion of the DATAPACKET tag.

FindXMLBroker returns the XML broker with the name specified by the XMLBroker parameter. If TagParams does not contain a string of the form XMLBroker=BrokerName, FindXMLBroker returns nil (Delphi) or NULL (C++).

See Also

FindXMLBrokerName (see page 5710)

GetXMLData (see page 5712)

53.1.1.4.21 TBaseInetXPageProducer.FindXMLBrokerName Method

Returns the name of an XML broker given the parameters in a DATAPACKET tag..

Pascal

```
function FindXMLBrokerName(TagParams: TStrings): string; virtual;
```

C++

```
virtual __fastcall UnicodeString FindXMLBrokerName(TStrings TagParams);
```

Description

The page producer translates HTML-transparent tags of the form

```
<#DATAPACKET XMLBroker=BrokerName>
```

into the XML returned by the XML broker. To do so, it calls FindXMLBrokerName to parse the parameters for the value of the

XMLBroker parameter.

TagParams is a set of Name=Value pairs. This comes from the parameter portion of the DATAPACKET tag.

FindXMLBrokerName returns the value string from the XMLBroker parameter. If TagParams does not contain a string of the form XMLBroker=BrokerName, FindXMLBrokerName returns an empty string.

See Also

FindXMLBroker (see page 5710)

GetXMLData (see page 5712)

53.1.1.4.22 TBaseInetXPageProducer.GeneratePageElements Method

Pascal

```
procedure GeneratePageElements; virtual;
```

C++

```
virtual __fastcall GeneratePageElements();
```

Description

This is GeneratePageElements, a member of class TBaseInetXPageProducer.

53.1.1.4.23 TBaseInetXPageProducer.GetContentOptions Method

Pascal

```
function GetContentOptions(var Owned: Boolean): TWebContentOptions; override;
```

C++

```
virtual __fastcall TWebContentOptions GetContentOptions(Boolean Owned);
```

Description

This is GetContentOptions, a member of class TBaseInetXPageProducer.

53.1.1.4.24 TBaseInetXPageProducer.GetDefaultTemplate Method

Pascal

```
function GetDefaultTemplate: string; virtual;
```

C++

```
virtual __fastcall UnicodeString GetDefaultTemplate();
```

Description

This is GetDefaultTemplate, a member of class TBaseInetXPageProducer.

53.1.1.4.25 TBaseInetXPageProducer.GetRequiredTags Method

Returns the default set of HTML-transparent tags for an InternetExpress page producer.

Pascal

```
class function GetRequiredTags: string; virtual;
```

C++

```
virtual __fastcall UnicodeString GetRequiredTags();
```

Description

GetRequiredTags dynamically generates the InternetExpress-specific tags that form the basis of an InternetExpress page producer's default template.

GetRequiredTags returns the string

```
<#INCLUDES> <#STYLES> <#WARNINGS> <#FORMS> <#SCRIPT>
```

See Also

HTMLDoc (see page 5726)

Content (see page 5723)

53.1.1.4.26 TBaseInetXPageProducer.GetScriptManager Method

Pascal

```
function GetScriptManager: IScriptManager;
```

C++

```
__fastcall IScriptManager GetScriptManager();
```

Description

This is GetScriptManager, a member of class TBaseInetXPageProducer.

53.1.1.4.27 TBaseInetXPageProducer.GetUseXMLIslands Method

Pascal

```
function GetUseXMLIslands: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean GetUseXMLIslands();
```

Description

This is GetUseXMLIslands, a member of class TBaseInetXPageProducer.

53.1.1.4.28 TBaseInetXPageProducer.GetXMLData Method

Obtains an XML data packet from a specified XML broker.

Pascal

```
function GetXMLData(XMLBroker: TXMLBroker; XMLOptions: TXMLOptions): string; virtual;
```

C++

```
virtual __fastcall UnicodeString GetXMLData(TXMLBroker XMLBroker, TXMLOptions XMLOptions);
```

Description

GetXMLData first generates an OnBeforeGetXMLData (see page 5719) event. It then calls the RequestRecords method of the XML broker specified by XMLBroker, passing in the formatting options specified by XMLOptions. Finally, it generates an OnAfterGetXMLData (see page 5718) event.

GetXMLData returns the XML data packet that XMLBroker supplies.

See Also

OnAfterGetXMLData (see page 5718)

OnBeforeGetXMLData (see page 5719)

Content (see page 3466)

RequestRecords

53.1.1.4.29 TBaseInetXPageProducer.GetXMLDelta Method

Pascal

```
function GetXMLDelta(XMLBroker: TXMLBroker): string;
```

C++

```
__fastcall UnicodeString GetXMLDelta(TXMLBroker XMLBroker);
```

Description

This is GetXMLDelta, a member of class TBaseInetXPageProducer.

53.1.1.4.30 TBaseInetXPageProducer.GetXMLErrors Method

Pascal

```
function GetXMLErrors(XMLBroker: TXMLBroker): string;
```

C++

```
__fastcall UnicodeString GetXMLErrors(TXMLBroker XMLBroker);
```

Description

This is GetXMLErrors, a member of class TBaseInetXPageProducer.

53.1.1.4.31 TBaseInetXPageProducer.ImplCanAddClass Method

Pascal

```
function ImplCanAddClass(AParent: TComponent; AClass: TClass): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean ImplCanAddClass(TComponent * AParent, TClass AClass);
```

Description

This is ImplCanAddClass, a member of class TBaseInetXPageProducer.

53.1.1.4.32 TBaseInetXPageProducer.SetIncludePathURL Method

Assigns a value to the IncludePathURL (see page 5715) property.

Pascal

```
procedure SetIncludePathURL(const Value: string);
```

C++

```
__fastcall SetIncludePathURL(const UnicodeString Value);
```

Description

SetIncludePathURL is the write implementation of the IncludePathURL (see page 5715) property.

See Also

IncludePathURL (see page 5715)

53.1.1.4.33 TBaseInetXPageProducer.SetStyles Method

Assigns a value to the Styles (see page 5716) property.

Pascal

```
procedure SetStyles(Value: TStrings);
```

C++

```
__fastcall SetStyles(TStrings Value);
```

Description

SetStyles is the write implementation of the Styles (see page 5716) property.

See Also

Styles (see page 5716)

53.1.1.4.34 TBaseInetXPageProducer.SetStylesFile Method

Assigns a value to the StylesFile (see page 5717) property.

Pascal

```
procedure SetStylesFile(const Value: TFileName);
```

C++

```
__fastcall SetStylesFile(const TFileName Value);
```

Description

SetStylesFile is the write implementation of the StylesFile (see page 5717) property.

See Also

StylesFile (see page 5717)

53.1.1.4.35 TBaseInetXPageProducer.SetWebContentOptions Method

Pascal

```
procedure SetWebContentOptions(AOptions: TWebContentOptions);
```

C++

```
__fastcall SetWebContentOptions(TWebContentOptions AOptions);
```

Description

This is SetWebContentOptions, a member of class TBaseInetXPageProducer.

53.1.1.5 TBaseInetXPageProducer Properties

The properties of the TBaseInetXPageProducer class are listed here.

Protected Properties

	Name	Description
	PageElements (see page 5716)	This is PageElements, a member of class TBaseInetXPageProducer.
	ScriptManager (see page 5716)	This is ScriptManager, a member of class TBaseInetXPageProducer.

Public Properties

	Name	Description
	EnableXMLIslands (see page 5715)	Specifies whether XML data packets should be declared using XML islands if the requesting browser supports them.
	IncludePathURL (see page 5715)	Indicates the URL where the javascript libraries are installed.
	Styles (see page 5716)	Defines the styles that can be used by the page producer and its Web items.
	StylesFile (see page 5717)	Specifies a file containing the individual styles for the page producer's style sheet.

53.1.1.5.1 TBaseInetXPageProducer.EnableXMLIslands Property

Specifies whether XML data packets should be declared using XML islands if the requesting browser supports them.

Pascal

```
property EnableXMLIslands: Boolean;
```

C++

```
__property Boolean EnableXMLIslands;
```

Description

Set EnableXMLIslands to indicate whether the XML in the generated HTML document should be declared using XML islands. XML islands are only used if the document is created in response to a request message whose headers indicate that the browser supports XML islands.

Set EnableXMLIslands to false to prevent the page producer from declaring XML islands even if the requesting browser supports them.

See Also

GetXMLData (see page 5712)

Content (see page 3466)

53.1.1.5.2 TBaseInetXPageProducer.IncludePathURL Property

Indicates the URL where the javascript libraries are installed.

Pascal

```
property IncludePathURL: string;
```

C++

```
__property UnicodeString IncludePathURL;
```

Description

Set IncludePathURL to indicate where the javascript libraries are installed. The page producer uses this value to create HTML statements that include the libraries in the generated HTML document. These statements have the form

```
<SCRIPT language=Javascript type="text/javascript" SRC="IncludePathURL/xmldb.js"> </SCRIPT>
```

The javascript libraries define classes and methods that allow the HTML document to interpret XML data packets if the Web browser is not XML-enabled, and that enable controls in the document to navigate the data, post changes, and apply updates.

Creating Web Pages with an InternetExpress Page Producer

53.1.1.5.3 TBaseInetXPageProducer.PageElements Property

Pascal

```
property PageElements: TInetxPageElements;
```

C++

```
__property TInetxPageElements PageElements;
```

Description

This is PageElements, a member of class TBaseInetXPageProducer.

53.1.1.5.4 TBaseInetXPageProducer.ScriptManager Property

Pascal

```
property ScriptManager: IScriptManager;
```

C++

```
__property IScriptManager ScriptManager;
```

Description

This is ScriptManager, a member of class TBaseInetXPageProducer.

53.1.1.5.5 TBaseInetXPageProducer.Styles Property

Defines the styles that can be used by the page producer and its Web items.

Pascal

```
property Styles: TStrings;
```

C++

```
__property TStrings Styles;
```

Description

Use Styles to define a style sheet for the HTML document produced by TBaseInetXPageProducer (see page 5701). Each string in the TStrings object specifies a specific style by giving a style selector followed by a set of attributes in curly braces. These definitions can define styles for standard HTML elements such as

```
H2 B  {color: red}
```

or they can define styles that you name, such as

```
.MyStyle  {font-family: arial; font-weight: bold; font-size: 18px }
```

Note that user-defined style names must begin with a dot.

Styles for standard elements are applied automatically to HTML that uses the tag or tags that form the style selector. User-defined styles can be applied by setting the StyleRule property of a Web item to the user-defined style name that forms the selector.

Note: If you are sharing a set of styles between multiple page producers or multiple applications, you can define the styles in a file. To define the styles in a file, use the StylesFile (see page 5717) property instead. If StylesFile (see page 5717) is defined, it takes precedence over the Styles property.

Customizing the InternetExpress Page Producer Template

Setting Web Item Properties

53.1.1.5.6 TBaseInetXPageProducer.StylesFile Property

Specifies a file containing the individual styles for the page producer's style sheet.

Pascal

```
property StylesFile: TFileName;
```

C++

```
__property TFileName StylesFile;
```

Description

Set StylesFile to the name of a file containing the style definitions used by the page producer. The page producer uses these style definitions to declare a style sheet in the HTML document it generates.

Styles (see page 5716) for standard elements are applied automatically to HTML in the document. User-defined styles can be applied by setting the StyleRule property of a Web item to the user-defined style name that forms the selector of a style definition.

Note: If the StylesFile property is not set, you can specify the style definitions using the Styles (see page 5716) property instead.

53.1.1.6 TBaseInetXPageProducer Events

The events of the TBaseInetXPageProducer class are listed here.

Public Events

	Name	Description
	OnAfterGetContent (see page 5718)	Occurs after the page producer generates its HTML document.
	OnAfterGetXMLData (see page 5718)	Occurs after the page producer translates fetches an XML data packet from an XML broker.
	OnBeforeGetContent (see page 5719)	Occurs when the Content method is called.
	OnBeforeGetXMLData (see page 5719)	Occurs before the page producer fetches an XML data packet from an XML broker.

53.1.1.6.1 TBaseInetXPageProducer.OnAfterGetContent Event

Occurs after the page producer generates its HTML document.

Pascal

```
property OnAfterGetContent: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnAfterGetContent;
```

Description

Write an OnAfterGetContent event handler to take specific action immediately after the page producer generates an HTML document. This event occurs immediately before the Content method returns the generated document. Typically it is used in applications where the page producer automatically responds to messages as the Provider (see page 6441) property of an action item or the Response producer property of an XML broker.

See Also

OnBeforeGetContent (see page 5719)

Content (see page 3466)

Producer (see page 3342)

53.1.1.6.2 TBaseInetXPageProducer.OnAfterGetXMLData Event

Occurs after the page producer translates fetches an XML data packet from an XML broker.

Pascal

```
property OnAfterGetXMLData: TXMLDataEvent;
```

C++

```
__property TXMLDataEvent OnAfterGetXMLData;
```

Description

Write an OnAfterGetXMLData event handler to take specific action immediately after the page producer obtains an XML data packet from an XML broker. Typically, the OnAfterGetXMLData event handler responds to any values returned by the provider on the application server as the OwnerData parameter.

When the page producer generates its HTML document (that is, when the Content method executes), it adds code to define the XML data packets manipulated in the document. To fetch these XML data packets, the page producer calls an XML broker's RequestRecords method. OnAfterGetXMLData occurs after the page producer has returned an XML data packet but before it is assigned as part of the emerging content.

See Also

OnBeforeGetXMLData (see page 5719)

GetXMLData (see page 5712)

OnHTMLTag (see page 3472)

Content (see page 3466)

53.1.1.6.3 TBaseInetXPageProducer.OnBeforeGetContent Event

Occurs when the Content method is called.

Pascal

```
property OnBeforeGetContent: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnBeforeGetContent;
```

Description

Write an OnBeforeGetContent event handler to take specific action immediately before the page producer generates an HTML document. This event occurs when the Content method is called before the page producer starts assembling its HTML document. Typically it is used in applications where the page producer automatically responds to messages as the Provider (see page 6441) property of an action item or the Response producer property of an XML broker.

See Also

OnAfterGetContent (see page 5718)

Content (see page 3466)

Producer (see page 3342)

53.1.1.6.4 TBaseInetXPageProducer.OnBeforeGetXMLData Event

Occurs before the page producer fetches an XML data packet from an XML broker.

Pascal

```
property OnBeforeGetXMLData: TXMLDataEvent;
```

C++

```
__property TXMLDataEvent OnBeforeGetXMLData;
```

Description

Write an OnBeforeGetXMLData event handler to take specific action immediately before the page producer requests an XML data packet from an XML broker. Typically, the OnBeforeGetXMLData event handler encodes any values for the provider on the application server as the OwnerData parameter or initializes properties on the XML broker that affect the data packet.

When the page producer generates its HTML document (that is, when the Content method executes), it adds code to define the XML data packets manipulated in the document. To fetch these XML data packets, the page producer calls an XML broker's RequestRecords method. OnBeforeGetXMLData occurs immediately before the page producer requests an XML data packet. Any value assigned to the OwnerData parameter is passed to the XML broker's OnRequestRecords event handler, and from there to the provider's OnBeforeGetRecords event handler.

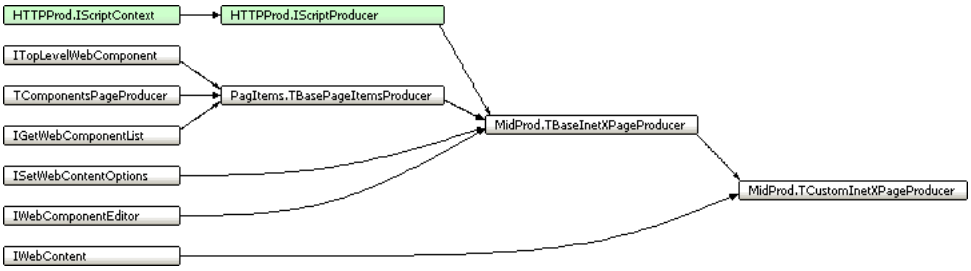
53.1.2 TCustomInetXPageProducer Class

TCustomInetXPageProducer is the base class for page producers that display live database information in an InternetExpress application.

Class Hierarchy



Pascal

```
TCustomInetXPageProducer = class(TBaseInetXPageProducer, IWebContent);
```

C++

```
class TCustomInetXPageProducer : public TBaseInetXPageProducer, public IWebContent;
```

File

MidProd

Description

Use TCustomInetXPageProducer as a base class for components that create Web pages in an InternetExpress Web application. These pages display database information from an application server and include data packets encoded in XML and javascript that lets Web browsers navigate that data, post changes, and apply updates back to the application server.

The InetX page producer creates its HTML document from a template. The InetX page producer has a default template that coordinates several top-level declarations for the HTML document with content produced by other components. The other components that generate HTML content for the InetX page producer can be added at design time using the Web Page editor.

Do not instantiate TCustomInetXPageProducer. To create a producer that generates HTML pages with javascript database functions and XML data packets, use a descendant class such as TInetXPageProducer (see page 5730).

53.1.2.1 TCustomInetXPageProducer Members

The following tables list the members exposed by TCustomInetXPageProducer.

Protected Methods

	Name	Description
	AddIncludes (see page 5705)	This is AddIncludes, a member of class TBaseInetXPageProducer.
	AddScriptComponents (see page 5705)	This is AddScriptComponents, a member of class TBaseInetXPageProducer.
	CanAddClass (see page 5705)	Indicates whether a specified class can be used as a child Web item.
	CreatePageElements (see page 5706)	This is CreatePageElements, a member of class TBaseInetXPageProducer.
	CreateScriptManager (see page 5707)	This is CreateScriptManager, a member of class TBaseInetXPageProducer.
	DeclareFunctions (see page 5707)	This is DeclareFunctions, a member of class TBaseInetXPageProducer.
	DeclareIncludes (see page 5707)	This is DeclareIncludes, a member of class TBaseInetXPageProducer.
	DeclareRowSets (see page 5707)	This is DeclareRowSets, a member of class TBaseInetXPageProducer.
	DeclareScript (see page 5708)	This is DeclareScript, a member of class TBaseInetXPageProducer.
	DeclareStyles (see page 5708)	This is DeclareStyles, a member of class TBaseInetXPageProducer.
	DeclareWarnings (see page 5708)	This is DeclareWarnings, a member of class TBaseInetXPageProducer.
	DeclareXMLDocuments (see page 5708)	This is DeclareXMLDocuments, a member of class TBaseInetXPageProducer.
	DeclareXMLIslands (see page 5708)	This is DeclareXMLIslands, a member of class TBaseInetXPageProducer.
	DoAfterGetContent (see page 5709)	This is DoAfterGetContent, a member of class TBaseInetXPageProducer.
	DoAfterGetXMLData (see page 5709)	This is DoAfterGetXMLData, a member of class TBaseInetXPageProducer.
	DoBeforeGetContent (see page 5709)	This is DoBeforeGetContent, a member of class TBaseInetXPageProducer.
	DoBeforeGetXMLData (see page 5709)	This is DoBeforeGetXMLData, a member of class TBaseInetXPageProducer.
	DoTagEvent (see page 5710)	This is DoTagEvent, a member of class TBaseInetXPageProducer.
	GeneratePageElements (see page 5711)	This is GeneratePageElements, a member of class TBaseInetXPageProducer.
	GetChildren (see page 6392)	This is GetChildren, a member of class TBasePageItemsProducer.
	GetComponentList (see page 6392)	This is GetComponentList, a member of class TBasePageItemsProducer.
	GetContentOptions (see page 5711)	This is GetContentOptions, a member of class TBaseInetXPageProducer.
	GetDefaultComponentList (see page 6392)	This is GetDefaultComponentList, a member of class TBasePageItemsProducer.
	GetDefaultTemplate (see page 5711)	This is GetDefaultTemplate, a member of class TBaseInetXPageProducer.
	GetScriptManager (see page 5712)	This is GetScriptManager, a member of class TBaseInetXPageProducer.
	GetTemplateFileName (see page 5725)	This is GetTemplateFileName, a member of class TCustomInetXPageProducer.
	GetTemplateStream (see page 5725)	This is GetTemplateStream, a member of class TCustomInetXPageProducer.
	GetUseXMLIslands (see page 5712)	This is GetUseXMLIslands, a member of class TBaseInetXPageProducer.
	GetXMLDelta (see page 5713)	This is GetXMLDelta, a member of class TBaseInetXPageProducer.
	GetXMLErrors (see page 5713)	This is GetXMLErrors, a member of class TBaseInetXPageProducer.
	ImplCanAddClass (see page 5713)	This is ImplCanAddClass, a member of class TBaseInetXPageProducer.
	SetChildOrder (see page 6393)	This is SetChildOrder, a member of class TBasePageItemsProducer.
	SetWebContentOptions (see page 5714)	This is SetWebContentOptions, a member of class TBaseInetXPageProducer.
	WebContent (see page 5725)	This is WebContent, a member of class TCustomInetXPageProducer.

Protected Properties

	Name	Description
	PageElements (see page 5716)	This is PageElements, a member of class TBaseInetXPageProducer.
	ScriptManager (see page 5716)	This is ScriptManager, a member of class TBaseInetXPageProducer.

Public Events

	Name	Description
	OnAfterGetContent (see page 5718)	Occurs after the page producer generates its HTML document.
	OnAfterGetXMLData (see page 5718)	Occurs after the page producer translates fetches an XML data packet from an XML broker.
	OnBeforeGetContent (see page 5719)	Occurs when the Content method is called.
	OnBeforeGetXMLData (see page 5719)	Occurs before the page producer fetches an XML data packet from an XML broker.

Public Methods

	Name	Description
	Content (see page 5723)	Returns the HTML document assembled by the InternetExpress page producer.

	ContentFromStream (see page 5706)	Returns the content produced in response to input read from a stream.
	Create (see page 5722)	Creates and initializes an instance of TCustomInetXPageProducer (see page 5720).
	Destroy (see page 5723)	Frees an instance of TCustomInetXPageProducer (see page 5720).
	Evaluate (see page 3509)	This is Evaluate, a member of class IScriptProducer.
	FindXMLBroker (see page 5710)	Returns the XML broker that supplies the data packet specified by a DATAPACKET tag.
	FindXMLBrokerName (see page 5710)	Returns the name of an XML broker given the parameters in a DATAPACKET tag..
	GetContent (see page 3509)	This is GetContent, a member of class IScriptProducer.
	GetErrors (see page 3509)	This is GetErrors, a member of class IScriptProducer.
	GetHTMLBlock (see page 3510)	This is GetHTMLBlock, a member of class IScriptProducer.
	GetHTMLBlockCount (see page 3510)	This is GetHTMLBlockCount, a member of class IScriptProducer.
	GetRequiredTags (see page 5711)	Returns the default set of HTML-transparent tags for an InternetExpress page producer.
	GetWebModuleContext (see page 3507)	This is GetWebModuleContext, a member of class IScriptContext.
	GetXMLData (see page 5712)	Obtains an XML data packet from a specified XML broker.
	HandleScriptError (see page 3510)	This is HandleScriptError, a member of class IScriptProducer.
	ParseStream (see page 3510)	This is ParseStream, a member of class IScriptProducer.
	ParseString (see page 3510)	This is ParseString, a member of class IScriptProducer.
	ReplaceTags (see page 3511)	This is ReplaceTags, a member of class IScriptProducer.
	SetContent (see page 3511)	This is SetContent, a member of class IScriptProducer.
	SetIncludePathURL (see page 5713)	Assigns a value to the IncludePathURL (see page 5715) property.
	SetStyles (see page 5714)	Assigns a value to the Styles (see page 5716) property.
	SetStylesFile (see page 5714)	Assigns a value to the StylesFile (see page 5717) property.
	Write (see page 3511)	This is the overview for the Write method overload.
	WriteItem (see page 3512)	This is WriteItem, a member of class IScriptProducer.

Public Properties

	Name	Description
	EnableXMLIslands (see page 5715)	Specifies whether XML data packets should be declared using XML islands if the requesting browser supports them.
R	Errors (see page 3512)	This is Errors, a member of class IScriptProducer.
R	HTMLBlockCount (see page 3513)	This is HTMLBlockCount, a member of class IScriptProducer.
R	HTMLBlocks (see page 3513)	This is HTMLBlocks, a member of class IScriptProducer.
	HTMLDoc (see page 5726)	Specifies the HTML template used to generate the value returned by the Content (see page 5723) method.
	HTMLFile (see page 5726)	Specifies the name of a file that contains the HTML template used to generate the value returned by the Content (see page 5723) method.
	IncludePathURL (see page 5715)	Indicates the URL where the javascript libraries are installed.
	Styles (see page 5716)	Defines the styles that can be used by the page producer and its Web items.
	StylesFile (see page 5717)	Specifies a file containing the individual styles for the page producer's style sheet.
R	WebModuleContext (see page 3507)	This is WebModuleContext, a member of class IScriptContext.
R	WebPageItems (see page 6393)	Maintains a list of components that generate HTML content for the producer.

53.1.2.2 TCustomInetXPageProducer.Create Constructor

Creates and initializes an instance of TCustomInetXPageProducer (see page 5720).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomInetXPageProducer(TComponent * AOwner);
```

Description

Call Create to instantiate an InternetExpress page producer at runtime. InternetExpress page producers placed in a Web module at design time are instantiated automatically.

AOwner is a component, typically a Web module, that becomes the value of the Owner property. The Owner is responsible for freeing the TCustomInetXPageProducer (see page 5720) instance.

See Also

Owner

53.1.2.3 TCustomInetXPageProducer.Destroy Destructor

Frees an instance of TCustomInetXPageProducer (see page 5720).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomInetXPageProducer();
```

Description

Do not call Destroy directly. Instead, call the Free method, which checks whether the reference to the producer is not nil before calling Destroy.

See Also

System::TObject::Free

53.1.2.4 TCustomInetXPageProducer Methods

The methods of the TCustomInetXPageProducer class are listed here.

Protected Methods

	Name	Description
	GetTemplateFileName (see page 5725)	This is GetTemplateFileName, a member of class TCustomInetXPageProducer.
	GetTemplateStream (see page 5725)	This is GetTemplateStream, a member of class TCustomInetXPageProducer.
	WebContent (see page 5725)	This is WebContent, a member of class TCustomInetXPageProducer.

Public Methods

	Name	Description
	Content (see page 5723)	Returns the HTML document assembled by the InternetExpress page producer.

53.1.2.4.1 TCustomInetXPageProducer.Content Method

Returns the HTML document assembled by the InternetExpress page producer.

Pascal

```
function Content: string; override;
```

C++

```
virtual __fastcall UnicodeString Content();
```

Description

Call Content to get the HTML document produced by TCustomInetXPageProducer (see page 5720). This document contains a mixture of HTML, XML, and javascript. It allows Web browsers to view and edit data from an application server.

The InternetExpress page producer creates its content by replacing HTML-transparent tags in the template specified by HTMLDoc (see page 5726) or HTMLFile (see page 5726).

By default, this template has the form

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<#INCLUDES> <#STYLES> <#WARNINGS> <#FORMS> <#SCRIPT>
</BODY>
</HTML>
```

Although the template can be changed to include any combination of these tags with tags of the following forms

```
<#COMPONENT Name=WebItemName>
<#DATAPACKET XMLBroker=BrokerName>
```

which are also translated automatically. The template can replace the default HTML-transparent tags with the tag

```
<#BODYELEMENTS>
```

Finally, the template can include any tags translated by the OnHTMLTag event handler.

The Content method translates the tags listed above as follows:

<#INCLUDES> generates the statements that include the javascript libraries at the location specified by IncludePathURL (see page 5715).

<#STYLES> generates the statements that defines a style sheet from the definitions listed in the Styles (see page 5716) or StylesFile (see page 5717) property.

<#WARNINGS> generates nothing at runtime. At design time, it adds warning messages for problems detected while generating the HTML document. You can see these messages in the Web page editor.

<#FORMS> generates the HTML produced by the components listed in the WebPageItems property. The HTML from each component is listed in the order it appears in WebPageItems.

<#SCRIPT> generates a block of javascript declarations that are used by the components listed in WebPageItems.

<#BODYELEMENTS> generates the same HTML as results from the 5 tags in the default template. It is useful when generating a template in an HTML editor when you want to use the default layout but add additional elements (such as style sheets) using the editor.

<#COMPONENT> is replaced with the content produced by the specified component. Typically, this is a component listed in the WebPageItems property, but it can be any component that supports the IWebContent interface and has the same Owner as the INETX page producer.

<#DATAPACKET> is replaced with the XML data packet obtained from the specified XML broker.

The string returned by Content can be used as the Content property of the response to an HTTP request message.

Customizing the InternetExpress Page Producer Template

53.1.2.4.2 TCustomInetXPageProducer.GetTemplateFileName Method

Pascal

```
function GetTemplateFileName: string; override;
```

C++

```
virtual __fastcall UnicodeString GetTemplateFileName();
```

Description

This is GetTemplateFileName, a member of class TCustomInetXPageProducer.

53.1.2.4.3 TCustomInetXPageProducer.GetTemplateStream Method

Pascal

```
function GetTemplateStream(out AOwned: Boolean): TStream; override;
```

C++

```
virtual __fastcall TStream GetTemplateStream(Boolean AOwned);
```

Description

This is GetTemplateStream, a member of class TCustomInetXPageProducer.

53.1.2.4.4 TCustomInetXPageProducer.WebContent Method

Pascal

```
function WebContent(Options: TWebContentOptions; Layout: TLayout): string;
```

C++

```
__fastcall UnicodeString WebContent(TWebContentOptions Options, TLayout Layout);
```

Description

This is WebContent, a member of class TCustomInetXPageProducer.

53.1.2.5 TCustomInetXPageProducer Properties

The properties of the TCustomInetXPageProducer class are listed here.

Public Properties

	Name	Description
	HTMLDoc (see page 5726)	Specifies the HTML template used to generate the value returned by the Content (see page 5723) method.
	HTMLFile (see page 5726)	Specifies the name of a file that contains the HTML template used to generate the value returned by the Content (see page 5723) method.

53.1.2.5.1 TCustomInetXPageProducer.HTMLDoc Property

Specifies the HTML template used to generate the value returned by the Content (see page 5723) method.

Pascal

```
property HTMLDoc: TStrings;
```

C++

```
__property TStrings HTMLDoc;
```

Description

Set HTMLDoc to a set of strings that make up the HTML template. By default, HTMLDoc is initialized to the following template:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<#INCLUDES> <#STYLES> <#WARNINGS> <#FORMS> <#SCRIPT>
</BODY>
</HTML>
```

Each string is a sequence of one or more HTML commands or HTML-transparent tags. An HTML-transparent tag has the form

```
<#TagName Param1=Value1 Param2=Value2 ...>
```

A pound sign (#) immediately follows the opening angle bracket (<) with no spaces separating it from the angle bracket. The pound sign identifies the string to the page producer as an HTML-transparent tag. The tag name immediately follows the pound sign with no spaces separating it from the pound sign. Following the tag name, the HTML-transparent tag can optionally include parameters that specify details of the conversion to be performed. Each parameter is of the form ParamName=Value, where there is no space between the parameter name, the equals symbol (=) and the value. Each parameter is delimited by white space.

The angle brackets (< >) make the tag transparent to HTML browsers that do not recognize the #TagName construct.

The page producer converts the entire HTML-transparent tag into true HTML commands based on the value of the tag name. TCustomInetXPageProducer (see page 5720) automatically handles the conversion of the HTML-transparent tags in the default template, as well as the tags described in the help for the Content (see page 5723) method. If you set HTMLDoc to include other HTML-transparent tags, you must translate these in an OnHTMLTag event handler.

Note: Setting HTMLDoc clears the HTMLFile (see page 5726) property.

Creating Web Pages with an InternetExpress Page Producer

Customizing the InternetExpress Page Producer Template

53.1.2.5.2 TCustomInetXPageProducer.HTMLFile Property

Specifies the name of a file that contains the HTML template used to generate the value returned by the Content (see page 5723) method.

Pascal

```
property HTMLFile: TFileName;
```

C++

```
__property TFileName HTMLFile;
```

Description

Set HTMLFile to the name of the file that contains an HTML template. The HTML template is a sequence of HTML commands and HTML-transparent tags. An HTML-transparent tag has the form

```
<#TagName Param1=Value1 Param2=Value2 ...>
```

A pound sign (#) immediately follows the opening angle bracket (<) with no spaces separating it from the angle bracket. The pound sign identifies the string to the page producer as an HTML-transparent tag. The tag name immediately follows the pound sign with no spaces separating it from the pound sign. The page producer converts the entire HTML-transparent tag into true HTML commands based on the value of the tag name. Following the tag name, the HTML-transparent tag can optionally include parameters that specify details of the conversion to be performed. Each parameter is of the form ParamName=Value, where there is no space between the parameter name, the equals symbol (=) and the value. Each parameter is delimited by white space.

The angle brackets (< >) make the tag transparent to HTML browsers that do not recognize the #TagName construct.

Note: Setting HTMLFile clears the HTMLDoc (see page 5726) property.

Note: When distributing applications that contain page producers which use the HTMLFile property, be sure to distribute the file along with the application. Also, be sure that the value of HTMLFile does not include a hard-coded path name that will not be available on the user's disk.

TInetXPageElements = class(TObject);
```

C++

```
class TInetXPageElements : public TObject;
```

File

MidProd

Description

This is class MidProd.TInetXPageElements.

53.1.3.1 TInetXPageElements Members

The following tables list the members exposed by TInetXPageElements.

Public Fields

	Name	Description
	FormsContent (see page 5728)	This is FormsContent, a member of class TInetXPageElements.
	IncludesContent (see page 5728)	This is IncludesContent, a member of class TInetXPageElements.
	ScriptContent (see page 5729)	This is ScriptContent, a member of class TInetXPageElements.
	StylesContent (see page 5729)	This is StylesContent, a member of class TInetXPageElements.
	WarningsContent (see page 5729)	This is WarningsContent, a member of class TInetXPageElements.

Public Methods

	Name	Description
	BodyContent (see page 5729)	This is BodyContent, a member of class TInetXPageElements.

53.1.3.2 TInetXPageElements Fields

The fields of the TInetXPageElements class are listed here.

Public Fields

	Name	Description
	FormsContent (see page 5728)	This is FormsContent, a member of class TInetXPageElements.
	IncludesContent (see page 5728)	This is IncludesContent, a member of class TInetXPageElements.
	ScriptContent (see page 5729)	This is ScriptContent, a member of class TInetXPageElements.
	StylesContent (see page 5729)	This is StylesContent, a member of class TInetXPageElements.
	WarningsContent (see page 5729)	This is WarningsContent, a member of class TInetXPageElements.

53.1.3.2.1 TInetXPageElements.FormsContent Field

Pascal

```
FormsContent: string;
```

C++

```
UnicodeString FormsContent;
```

Description

This is FormsContent, a member of class TInetXPageElements.

53.1.3.2.2 TInetXPageElements.IncludesContent Field

Pascal

```
IncludesContent: string;
```

C++

```
UnicodeString IncludesContent;
```

Description

This is IncludesContent, a member of class TInetXPageElements.

53.1.3.2.3 TInetXPageElements.ScriptContent Field

Pascal

```
ScriptContent: string;
```

C++

```
UnicodeString ScriptContent;
```

Description

This is ScriptContent, a member of class TInetXPageElements.

53.1.3.2.4 TInetXPageElements.StylesContent Field

Pascal

```
StylesContent: string;
```

C++

```
UnicodeString StylesContent;
```

Description

This is StylesContent, a member of class TInetXPageElements.

53.1.3.2.5 TInetXPageElements.WarningsContent Field

Pascal

```
WarningsContent: string;
```

C++

```
UnicodeString WarningsContent;
```

Description

This is WarningsContent, a member of class TInetXPageElements.

53.1.3.3 TInetXPageElements Methods

The methods of the TInetXPageElements class are listed here.

Public Methods

	Name	Description
	BodyContent (see page 5729)	This is BodyContent, a member of class TInetXPageElements.

53.1.3.3.1 TInetXPageElements.BodyContent Method

Pascal

```
function BodyContent: string; virtual;
```

C++

```
virtual __fastcall UnicodeString BodyContent();
```

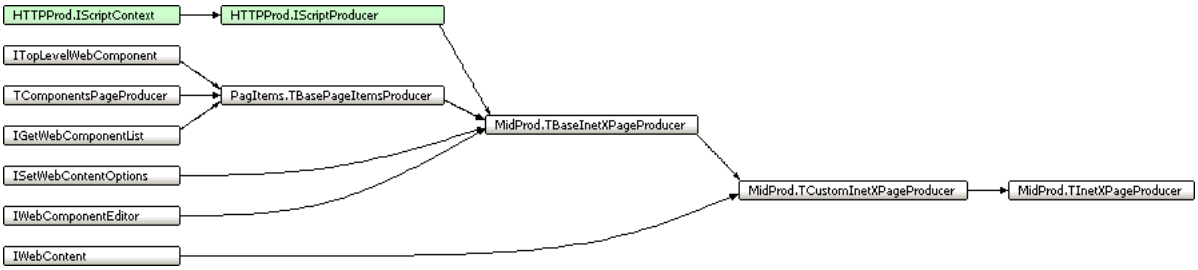
Description

This is BodyContent, a member of class TInetXPageElements.

53.1.4 TInetXPageProducer Class

TInetXPageProducer assembles an HTML document that represents live database information from an application server.

Class Hierarchy



Pascal

```
TInetXPageProducer = class(TCustomInetXPageProducer);
```

C++

```
class TInetXPageProducer : public TCustomInetXPageProducer;
```

File

MidProd

Description

Use TInetXPageProducer to create Web pages for an InternetExpress application. These pages display database information from an application server and include data packets encoded in XML and javascript that lets Web browsers navigate that data, post changes, and apply updates back to the application server.

The InetX page producer is assigned as the Producer property of a Web action item or called from an OnAction event handler.

The InetX page producer creates its HTML document from a template. Unlike other page producers, the InetX page producer has a default template that coordinates several top-level declarations for the HTML document with content produced by other components. The other components that generate HTML content for the InetX page producer can be added at design time using the Web Page editor.

53.1.4.1 TInetXPageProducer Members

The following tables list the members exposed by TInetXPageProducer.

Protected Methods

	Name	Description
	AddIncludes (see page 5705)	This is AddIncludes, a member of class TBaseInetXPageProducer.
	AddScriptComponents (see page 5705)	This is AddScriptComponents, a member of class TBaseInetXPageProducer.
	CanAddClass (see page 5705)	Indicates whether a specified class can be used as a child Web item.
	CreatePageElements (see page 5706)	This is CreatePageElements, a member of class TBaseInetXPageProducer.
	CreateScriptManager (see page 5707)	This is CreateScriptManager, a member of class TBaseInetXPageProducer.
	DeclareFunctions (see page 5707)	This is DeclareFunctions, a member of class TBaseInetXPageProducer.
	DeclareIncludes (see page 5707)	This is DeclareIncludes, a member of class TBaseInetXPageProducer.
	DeclareRowSets (see page 5707)	This is DeclareRowSets, a member of class TBaseInetXPageProducer.
	DeclareScript (see page 5708)	This is DeclareScript, a member of class TBaseInetXPageProducer.
	DeclareStyles (see page 5708)	This is DeclareStyles, a member of class TBaseInetXPageProducer.
	DeclareWarnings (see page 5708)	This is DeclareWarnings, a member of class TBaseInetXPageProducer.
	DeclareXMLDocuments (see page 5708)	This is DeclareXMLDocuments, a member of class TBaseInetXPageProducer.
	DeclareXMLIslands (see page 5708)	This is DeclareXMLIslands, a member of class TBaseInetXPageProducer.
	DoAfterGetContent (see page 5709)	This is DoAfterGetContent, a member of class TBaseInetXPageProducer.
	DoAfterGetXMLData (see page 5709)	This is DoAfterGetXMLData, a member of class TBaseInetXPageProducer.
	DoBeforeGetContent (see page 5709)	This is DoBeforeGetContent, a member of class TBaseInetXPageProducer.
	DoBeforeGetXMLData (see page 5709)	This is DoBeforeGetXMLData, a member of class TBaseInetXPageProducer.
	DoTagEvent (see page 5710)	This is DoTagEvent, a member of class TBaseInetXPageProducer.
	GeneratePageElements (see page 5711)	This is GeneratePageElements, a member of class TBaseInetXPageProducer.
	GetChildren (see page 6392)	This is GetChildren, a member of class TBasePageItemsProducer.
	GetComponentList (see page 6392)	This is GetComponentList, a member of class TBasePageItemsProducer.
	GetContentOptions (see page 5711)	This is GetContentOptions, a member of class TBaseInetXPageProducer.
	GetDefaultComponentList (see page 6392)	This is GetDefaultComponentList, a member of class TBasePageItemsProducer.
	GetDefaultTemplate (see page 5711)	This is GetDefaultTemplate, a member of class TBaseInetXPageProducer.
	GetScriptManager (see page 5712)	This is GetScriptManager, a member of class TBaseInetXPageProducer.
	GetTemplateFileName (see page 5725)	This is GetTemplateFileName, a member of class TCustomInetXPageProducer.
	GetTemplateStream (see page 5725)	This is GetTemplateStream, a member of class TCustomInetXPageProducer.
	GetUseXMLIslands (see page 5712)	This is GetUseXMLIslands, a member of class TBaseInetXPageProducer.
	GetXMLDelta (see page 5713)	This is GetXMLDelta, a member of class TBaseInetXPageProducer.
	GetXMLErrors (see page 5713)	This is GetXMLErrors, a member of class TBaseInetXPageProducer.
	ImplCanAddClass (see page 5713)	This is ImplCanAddClass, a member of class TBaseInetXPageProducer.
	SetChildOrder (see page 6393)	This is SetChildOrder, a member of class TBasePageItemsProducer.
	SetWebContentOptions (see page 5714)	This is SetWebContentOptions, a member of class TBaseInetXPageProducer.
	WebContent (see page 5725)	This is WebContent, a member of class TCustomInetXPageProducer.

Protected Properties

	Name	Description
	PageElements (see page 5716)	This is PageElements, a member of class TBaseInetXPageProducer.
	ScriptManager (see page 5716)	This is ScriptManager, a member of class TBaseInetXPageProducer.

Public Methods

	Name	Description
	Content (see page 5723)	Returns the HTML document assembled by the InternetExpress page producer.
	ContentFromStream (see page 5706)	Returns the content produced in response to input read from a stream.
	Create (see page 5703)	Creates an instance of a TBaseInetXPageProducer (see page 5701).
	Create (see page 5722)	Creates and initializes an instance of TCustomInetXPageProducer (see page 5720).
	Create (see page 6391)	Creates an instance of a TBasePageItemsProducer (see page 6390).
	Destroy (see page 5704)	Destroys the instance of the TBasePageItemsProducer.
	Destroy (see page 5723)	Frees an instance of TCustomInetXPageProducer (see page 5720).
	Destroy (see page 6391)	Destroys the instance of the TBasePageItemsProducer (see page 6390).
	Evaluate (see page 3509)	This is Evaluate, a member of class IScriptProducer.

	FindXMLBroker (see page 5710)	Returns the XML broker that supplies the data packet specified by a DATAPACKET tag.
	FindXMLBrokerName (see page 5710)	Returns the name of an XML broker given the parameters in a DATAPACKET tag..
	GetContent (see page 3509)	This is GetContent, a member of class IScriptProducer.
	GetErrors (see page 3509)	This is GetErrors, a member of class IScriptProducer.
	GetHTMLBlock (see page 3510)	This is GetHTMLBlock, a member of class IScriptProducer.
	GetHTMLBlockCount (see page 3510)	This is GetHTMLBlockCount, a member of class IScriptProducer.
	GetRequiredTags (see page 5711)	Returns the default set of HTML-transparent tags for an InternetExpress page producer.
	GetWebModuleContext (see page 3507)	This is GetWebModuleContext, a member of class IScriptContext.
	GetXMLData (see page 5712)	Obtains an XML data packet from a specified XML broker.
	HandleScriptError (see page 3510)	This is HandleScriptError, a member of class IScriptProducer.
	ParseStream (see page 3510)	This is ParseStream, a member of class IScriptProducer.
	ParseString (see page 3510)	This is ParseString, a member of class IScriptProducer.
	ReplaceTags (see page 3511)	This is ReplaceTags, a member of class IScriptProducer.
	SetContent (see page 3511)	This is SetContent, a member of class IScriptProducer.
	SetIncludePathURL (see page 5713)	Assigns a value to the IncludePathURL (see page 5715) property.
	SetStyles (see page 5714)	Assigns a value to the Styles (see page 5716) property.
	SetStylesFile (see page 5714)	Assigns a value to the StylesFile (see page 5717) property.
	Write (see page 3511)	This is the overview for the Write method overload.
	WriteItem (see page 3512)	This is WriteItem, a member of class IScriptProducer.

Public Properties

	Name	Description
	Content (see page 3512)	This is Content, a member of class IScriptProducer.
R	Errors (see page 3512)	This is Errors, a member of class IScriptProducer.
R	HTMLBlockCount (see page 3513)	This is HTMLBlockCount, a member of class IScriptProducer.
R	HTMLBlocks (see page 3513)	This is HTMLBlocks, a member of class IScriptProducer.
R	WebModuleContext (see page 3507)	This is WebModuleContext, a member of class IScriptContext.

Published Events

	Name	Description
	OnAfterGetContent (see page 5738)	Occurs after the page producer generates its HTML document.
	OnAfterGetXMLData (see page 5738)	Occurs after the page producer translates fetches an XML data packet from an XML broker.
	OnBeforeGetContent (see page 5739)	Occurs when the Content method is called.
	OnBeforeGetXMLData (see page 5739)	Occurs before the page producer fetches an XML data packet from an XML broker.

Published Properties

	Name	Description
	EnableXMLIslands (see page 5733)	Specifies whether XML data packets should be declared using XML islands if the requesting browser supports them.
	HTMLDoc (see page 5733)	Specifies the HTML template used to generate the value returned by the Content method.
	HTMLFile (see page 5734)	Specifies the name of a file that contains the HTML template used to generate the value returned by the Content method.
	IncludePathURL (see page 5735)	Indicates the URL where the javascript libraries are installed.
	ScriptEngine (see page 5735)	Names the script engine that generates or interprets script embedded in the documents that this producer creates.
	Styles (see page 5736)	Defines the styles that can be used by the page producer and its Web items.
	StylesFile (see page 5736)	Specifies a file containing the individual styles for the page producer's style sheet.
	WebPageItems (see page 5737)	Maintains a list of components that generate HTML content for the producer.

53.1.4.2 TInetXPageProducer Properties

The properties of the TInetXPageProducer class are listed here.

Published Properties

	Name	Description
	EnableXMLIslands (see page 5733)	Specifies whether XML data packets should be declared using XML islands if the requesting browser supports them.
	HTMLDoc (see page 5733)	Specifies the HTML template used to generate the value returned by the Content method.
	HTMLFile (see page 5734)	Specifies the name of a file that contains the HTML template used to generate the value returned by the Content method.
	IncludePathURL (see page 5735)	Indicates the URL where the javascript libraries are installed.
	ScriptEngine (see page 5735)	Names the script engine that generates or interprets script embedded in the documents that this producer creates.
	Styles (see page 5736)	Defines the styles that can be used by the page producer and its Web items.
	StylesFile (see page 5736)	Specifies a file containing the individual styles for the page producer's style sheet.
	WebPageItems (see page 5737)	Maintains a list of components that generate HTML content for the producer.

53.1.4.2.1 TInetXPageProducer.EnableXMLIslands Property

Specifies whether XML data packets should be declared using XML islands if the requesting browser supports them.

Pascal

```
property EnableXMLIslands: Boolean;
```

C++

```
__property Boolean EnableXMLIslands;
```

Description

Set EnableXMLIslands to indicate whether the XML in the generated HTML document should be declared using XML islands. XML islands are only used if the document is created in response to a request message whose headers indicate that the browser supports XML islands.

Set EnableXMLIslands to false to prevent the page producer from declaring XML islands even if the requesting browser supports them.

See Also

GetXMLData (see page 5712)

Content (see page 3466)

53.1.4.2.2 TInetXPageProducer.HTMLDoc Property

Specifies the HTML template used to generate the value returned by the Content method.

Pascal

```
property HTMLDoc: TStrings;
```

C++

```
__property TStrings HTMLDoc;
```

Description

Set HTMLDoc to a set of strings that make up the HTML template. By default, HTMLDoc is initialized to the following template:

```
<HTML>
<HEAD>
</HEAD>
<BODY>
<#INCLUDES> <#STYLES> <#WARNINGS> <#FORMS> <#SCRIPT>
</BODY>
</HTML>
```

Each string is a sequence of one or more HTML commands or HTML-transparent tags. An HTML-transparent tag has the form

```
<#TagName Param1=Value1 Param2=Value2 ...>
```

A pound sign (#) immediately follows the opening angle bracket (<) with no spaces separating it from the angle bracket. The pound sign identifies the string to the page producer as an HTML-transparent tag. The tag name immediately follows the pound sign with no spaces separating it from the pound sign. Following the tag name, the HTML-transparent tag can optionally include parameters that specify details of the conversion to be performed. Each parameter is of the form ParamName=Value, where there is no space between the parameter name, the equals symbol (=) and the value. Each parameter is delimited by white space.

The angle brackets (< >) make the tag transparent to HTML browsers that do not recognize the #TagName construct.

The page producer converts the entire HTML-transparent tag into true HTML commands based on the value of the tag name. TCustomInetXPageProducer automatically handles the conversion of the HTML-transparent tags in the default template, as well as the tags described in the help for the Content method. If you set HTMLDoc to include other HTML-transparent tags, you must translate these in an OnHTMLTag event handler.

Note: Setting HTMLDoc clears the HTMLFile property.

Creating Web Pages with an InternetExpress Page Producer

Customizing the InternetExpress Page Producer Template

53.1.4.2.3 TInetXPageProducer.HTMLFile Property

Specifies the name of a file that contains the HTML template used to generate the value returned by the Content method.

Pascal

```
property HTMLFile: TFileName;
```

C++

```
__property TFileName HTMLFile;
```

Description

Set HTMLFile to the name of the file that contains an HTML template. The HTML template is a sequence of HTML commands and HTML-transparent tags. An HTML-transparent tag has the form

```
<#TagName Param1=Value1 Param2=Value2 ...>
```

A pound sign (#) immediately follows the opening angle bracket (<) with no spaces separating it from the angle bracket. The pound sign identifies the string to the page producer as an HTML-transparent tag. The tag name immediately follows the pound sign with no spaces separating it from the pound sign. The page producer converts the entire HTML-transparent tag into true HTML commands based on the value of the tag name. Following the tag name, the HTML-transparent tag can optionally include parameters that specify details of the conversion to be performed. Each parameter is of the form ParamName=Value, where

there is no space between the parameter name, the equals symbol (=) and the value. Each parameter is delimited by white space.

The angle brackets (< >) make the tag transparent to HTML browsers that do not recognize the #TagName construct.

Note: Setting HTMLFile clears the HTMLDoc property.

Note: When distributing applications that contain page producers which use the HTMLFile property, be sure to distribute the file along with the application. Also, be sure that the value of HTMLFile does not include a hard-coded path name that will not be available on the user's disk.

See Also

Content (see page 5723)

HTMLDoc (see page 5726)

Customizing the InternetExpress Page Producer Template

53.1.4.2.4 TInetXPageProducer.IncludePathURL Property

Indicates the URL where the javascript libraries are installed.

Pascal

```
property IncludePathURL: string;
```

C++

```
__property UnicodeString IncludePathURL;
```

Description

Set IncludePathURL to indicate where the javascript libraries are installed. The page producer uses this value to create HTML statements that include the libraries in the generated HTML document. These statements have the form

```
<SCRIPT language=Javascript type="text/javascript" SRC="IncludePathURL/xmldb.js"> </SCRIPT>
```

The javascript libraries define classes and methods that allow the HTML document to interpret XML data packets if the Web browser is not XML-enabled, and that enable controls in the document to navigate the data, post changes, and apply updates.

See Also

SetIncludePathURL (see page 5713)

Content (see page 3466)

Creating Web Pages with an InternetExpress Page Producer

53.1.4.2.5 TInetXPageProducer.ScriptEngine Property

Names the script engine that generates or interprets script embedded in the documents that this producer creates.

Pascal

```
property ScriptEngine;
```

C++

```
__property ScriptEngine;
```

Description

ScriptEngine indicates the scripting language that the producer uses in its generated documents. For example, if the producer

generates code that includes jscript, the value of ScriptEngine is 'JSCRIPT'.

When ScriptEngine is defined, the page producer generates its content using a special script-producer component. When ScriptEngine is not defined, the page producer uses only the OnHTMLTag event, plus any other built-in translations provided by a descendant class.

See Also

OnHTMLTag (see page 3472)

53.1.4.2.6 TInetXPageProducer.Styles Property

Defines the styles that can be used by the page producer and its Web items.

Pascal

```
property Styles: TStrings;
```

C++

```
__property TStrings Styles;
```

Description

Use Styles to define a style sheet for the HTML document produced by TBaseInetXPageProducer. Each string in the TStrings object specifies a specific style by giving a style selector followed by a set of attributes in curly braces. These definitions can define styles for standard HTML elements such as

```
H2 B  {color: red}
```

or they can define styles that you name, such as

```
.MyStyle  {font-family: arial; font-weight: bold; font-size: 18px }
```

Note that user-defined style names must begin with a dot.

Styles for standard elements are applied automatically to HTML that uses the tag or tags that form the style selector. User-defined styles can be applied by setting the StyleRule property of a Web item to the user-defined style name that forms the selector.

Note: If you are sharing a set of styles between multiple page producers or multiple applications, you can define the styles in a file. To define the styles in a file, use the StylesFile property instead. If StylesFile is defined, it takes precedence over the Styles property.

See Also

SetStyles (see page 5714)

StylesFile (see page 5717)

Content (see page 3466)

Customizing the InternetExpress Page Producer Template

Setting Web Item Properties

53.1.4.2.7 TInetXPageProducer.StylesFile Property

Specifies a file containing the individual styles for the page producer's style sheet.

Pascal

```
property StylesFile: TFileName;
```

C++

```
__property TFileName StylesFile;
```

Description

Set StylesFile to the name of a file containing the style definitions used by the page producer. The page producer uses these style definitions to declare a style sheet in the HTML document it generates.

Styles for standard elements are applied automatically to HTML in the document. User-defined styles can be applied by setting the StyleRule property of a Web item to the user-defined style name that forms the selector of a style definition.

Note: If the StylesFile property is not set, you can specify the style definitions using the Styles property instead.

Customizing the InternetExpress Page Producer Template

Setting Web Item Properties

53.1.4.2.8 TInetXPageProducer.WebPageItems Property

Maintains a list of components that generate HTML content for the producer.

Pascal

```
property WebPageItems: TWebComponentList;
```

C++

```
__property TWebComponentList WebPageItems;
```

Description

WebPageItems lists the components that generate content for the page items producer. Each of these components supports the IWebContent interface, and can contain its own list of Web items that help it generate its content.

The type of items that can be added to the WebPageItems list are restricted by a protected method that is abstract or, in C++ terminology, pure virtual in TBasePageItemsProducer. Descendant classes implement this protected method to indicate what types of items can be added to the list.

At design time, use the Web page editor to add components to the WebPageItems property.

Note: Typically, WebPageItems lists all the components that generate content for the page items producer, in the order that the generated content appears in the final HTML document. However, the page items producer can transform COMPONENT tags in its template using components that are not in this list, as long as they have the same owner as the page items producer..

Creating Web Pages with an InternetExpress Page Producer

53.1.4.3 TInetXPageProducer Events

The events of the TInetXPageProducer class are listed here.

Published Events

	Name	Description
	OnAfterGetContent (see page 5738)	Occurs after the page producer generates its HTML document.
	OnAfterGetXMLData (see page 5738)	Occurs after the page producer translates fetches an XML data packet from an XML broker.
	OnBeforeGetContent (see page 5739)	Occurs when the Content method is called.
	OnBeforeGetXMLData (see page 5739)	Occurs before the page producer fetches an XML data packet from an XML broker.

53.1.4.3.1 TInetXPageProducer.OnAfterGetContent Event

Occurs after the page producer generates its HTML document.

Pascal

```
property OnAfterGetContent: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnAfterGetContent;
```

Description

Write an OnAfterGetContent event handler to take specific action immediately after the page producer generates an HTML document. This event occurs immediately before the Content method returns the generated document. Typically it is used in applications where the page producer automatically responds to messages as the Provider property of an action item or the Response producer property of an XML broker.

See Also

OnBeforeGetContent (see page 5719)

Content (see page 3466)

Producer (see page 3342)

53.1.4.3.2 TInetXPageProducer.OnAfterGetXMLData Event

Occurs after the page producer translates fetches an XML data packet from an XML broker.

Pascal

```
property OnAfterGetXMLData: TXMLDataEvent;
```

C++

```
__property TXMLDataEvent OnAfterGetXMLData;
```

Description

Write an OnAfterGetXMLData event handler to take specific action immediately after the page producer obtains an XML data packet from an XML broker. Typically, the OnAfterGetXMLData event handler responds to any values returned by the provider on the application server as the OwnerData parameter.

When the page producer generates its HTML document (that is, when the Content method executes), it adds code to define the XML data packets manipulated in the document. To fetch these XML data packets, the page producer calls an XML broker's RequestRecords method. OnAfterGetXMLData occurs after the page producer has returned an XML data packet but before it is assigned as part of the emerging content.

See Also

OnBeforeGetXMLData (see page 5719)

GetXMLData (see page 5712)

OnHTMLTag (see page 3472)

Content (see page 3466)

53.1.4.3.3 TInetXPageProducer.OnBeforeGetContent Event

Occurs when the Content method is called.

Pascal

```
property OnBeforeGetContent: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnBeforeGetContent;
```

Description

Write an OnBeforeGetContent event handler to take specific action immediately before the page producer generates an HTML document. This event occurs when the Content method is called before the page producer starts assembling its HTML document. Typically it is used in applications where the page producer automatically responds to messages as the Provider property of an action item or the Response producer property of an XML broker.

See Also

OnAfterGetContent (see page 5718)

Content (see page 3466)

Producer (see page 3342)

53.1.4.3.4 TInetXPageProducer.OnBeforeGetXMLData Event

Occurs before the page producer fetches an XML data packet from an XML broker.

Pascal

```
property OnBeforeGetXMLData: TXMLDataEvent;
```

C++

```
__property TXMLDataEvent OnBeforeGetXMLData;
```

Description

Write an OnBeforeGetXMLData event handler to take specific action immediately before the page producer requests an XML data packet from an XML broker. Typically, the OnBeforeGetXMLData event handler encodes any values for the provider on the application server as the OwnerData parameter or initializes properties on the XML broker that affect the data packet.

When the page producer generates its HTML document (that is, when the Content method executes), it adds code to define the XML data packets manipulated in the document. To fetch these XML data packets, the page producer calls an XML broker's RequestRecords method. OnBeforeGetXMLData occurs immediately before the page producer requests an XML data packet. Any value assigned to the OwnerData parameter is passed to the XML broker's OnRequestRecords event handler, and from there to the provider's OnBeforeGetRecords event handler.

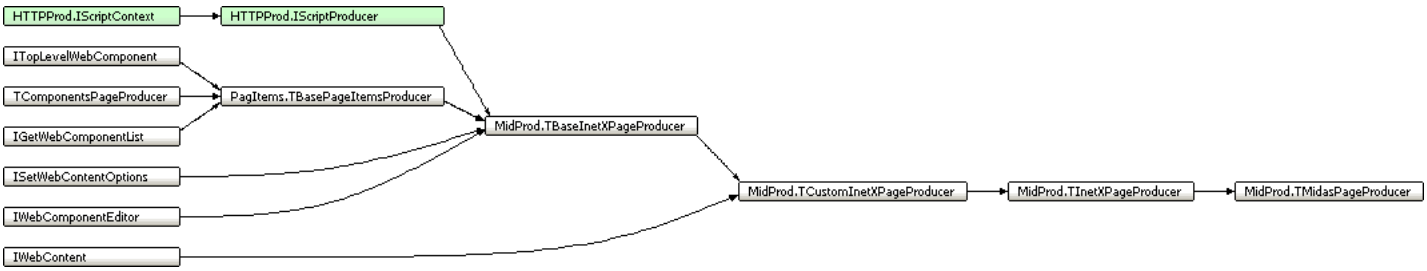
53.1.5 TMidasPageProducer Class

TMidasPageProducer assembles an HTML document that represents live database information from an application server.

Class Hierarchy



Pascal

```
TMidasPageProducer = class(TInetXPageProducer);
```

C++

```
class TMidasPageProducer : public TInetXPageProducer;
```

File

MidProd

Description

Do not use TMidasPageProducer. It is included only for backward compatibility. To add a page producer that assembles Web pages in an InternetExpress application, use TInetXPageProducer (see page 5730) instead.

53.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	AddStdIncludes (see page 5741)	This is function MidProd.AddStdIncludes.
	PathInfoToRelativePath (see page 5741)	This is function MidProd.PathInfoToRelativePath.

53.2.1 MidProd.AddStdIncludes Function

Pascal

```
procedure AddStdIncludes(StdIncludes: TStdIncludes; AddIntf: IAddScriptElements);
```

C++

```
AddStdIncludes(TStdIncludes StdIncludes, IAddScriptElements AddIntf);
```

File

MidProd

Description

This is function MidProd.AddStdIncludes.

53.2.2 MidProd.PathInfoToRelativePath Function

Pascal

```
function PathInfoToRelativePath(const PathInfo: string): string;
```

C++

```
UnicodeString PathInfoToRelativePath(const UnicodeString PathInfo);
```

File

MidProd

Description

This is function MidProd.PathInfoToRelativePath.

53.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TStdInclude (see page 5742)	This is record MidProd.TStdInclude.

53.3.1 MidProd.TStdInclude Enumeration

Pascal

```
TStdInclude = (
  jsDom,
  jsDB,
  jsDisp,
  jsBind,
  jsErrDisp,
  jsShow
);
```

C++

```
enum TStdInclude {
  jsDom,
  jsDB,
  jsDisp,
  jsBind,
  jsErrDisp,
  jsShow
};
```

File

MidProd

Description

This is record MidProd.TStdInclude.

53.4 Types

The following table lists types in this documentation.

Types

Name	Description
TBaseMidasPageProducer (see page 5743)	This is type MidProd.TBaseMidasPageProducer.
TCustomMidasPageProducer (see page 5743)	This is type MidProd.TCustomMidasPageProducer.
TMidasPageElements (see page 5744)	This is type MidProd.TMidasPageElements.
TStdIncludes (see page 5744)	This is type MidProd.TStdIncludes.
TXMLDataEvent (see page 5744)	This is type MidProd.TXMLDataEvent.

53.4.1 MidProd.TBaseMidasPageProducer Type

Pascal

```
TBaseMidasPageProducer = TBaseInetXPageProducer;
```

C++

```
TBaseInetXPageProducer TBaseMidasPageProducer;
```

File

MidProd

Description

This is type MidProd.TBaseMidasPageProducer.

53.4.2 MidProd.TCustomMidasPageProducer Type

Pascal

```
TCustomMidasPageProducer = TCustomInetXPageProducer;
```

C++

```
TCustomInetXPageProducer TCustomMidasPageProducer;
```

File

MidProd

Description

This is type MidProd.TCustomMidasPageProducer.

53.4.3 MidProd.TMidasPageElements Type

Pascal

```
TMidasPageElements = TInetXPageElements;
```

C++

```
TInetXPageElements TMidasPageElements;
```

File

MidProd

Description

This is type MidProd.TMidasPageElements.

53.4.4 MidProd.TStdIncludes Type

Pascal

```
TStdIncludes = set of TStdInclude;
```

C++

```
TStdInclude TStdIncludes;
```

File

MidProd

Description

This is type MidProd.TStdIncludes.

53.4.5 MidProd.TXMLDataEvent Type

Pascal

```
TXMLDataEvent = procedure (Sender: TObject; Request: TWebRequest; XMLBroker: TXMLBroker; var
OwnerData: OleVariant) of object;
```

C++

```
(Sender: TObject; Request: TWebRequest; XMLBroker: TXMLBroker; var OwnerData: OleVariant) (
TXMLDataEvent)();
```

File

MidProd

Description

This is type MidProd.TXMLDataEvent.

53.5 Constants

The following table lists constants in this documentation.

Constants

Name	Description
sXMLBroker (see page 5745)	This is constant MidProd.sXMLBroker.
sXMLReadyVar (see page 5745)	This is constant MidProd.sXMLReadyVar.

53.5.1 MidProd.sXMLBroker Constant

Pascal

```
sXMLBroker = 'XMLBROKER';
```

C++

```
sXMLBroker = 'XMLBROKER';
```

File

MidProd

Description

This is constant MidProd.sXMLBroker.

53.5.2 MidProd.sXMLReadyVar Constant

Pascal

```
sXMLReadyVar = 'xml_ready';
```

C++

```
sXMLReadyVar = 'xml_ready';
```

File

MidProd

Description

This is constant MidProd.sXMLReadyVar.

54 MPlayer Namespace

This is namespace MPlayer.

Topics

Name	Description
Classes (see page 5749)	The following table lists classes in this documentation.
Structs, Records, Enums (see page 5819)	The following table lists structs, records, enums in this documentation.
Types (see page 5827)	The following table lists types in this documentation.

Classes

	Name	Description
	EMCIDeviceError (see page 5749)	EMCIDeviceError is the exception class for devices that provide a Media Control Interface (MCI) driver.
	TMediaPlayer (see page 5749)	TMediaPlayer controls devices that provide a Media Control Interface (MCI) driver.

Structs, Records, Enums

	Name	Description
	TMPBtnType (see page 5819)	TMPBtnType defines the possible buttons in a TMediaPlayer (see page 5749) component and TButtonSet (see page 5828) represents a set of those buttons.
	TMPButton (see page 5820)	This is record MPlayer.TMPButton.
	TMPDevCaps (see page 5821)	TMPDevCaps defines the capabilities of a TMediaPlayer (see page 5749) component and TMPDevCapsSet (see page 5828) represents a set of those capabilities.
	TMPDeviceTypes (see page 5821)	TMPDeviceTypes identifies a multimedia device.
	TMPGlyph (see page 5823)	This is record MPlayer.TMPGlyph.
	TMPModes (see page 5823)	TMPModes identifies the state of a TMediaPlayer (see page 5749) component.
	TMPNotifyValues (see page 5824)	TMPNotifyValues identifies the types of notifications a media device can give a TMediaPlayer (see page 5749) component.
	TMPTimeFormats (see page 5825)	TMPTimeFormats indicates the format a media player uses to indicate position.

Types

Name	Description
EMPNotify (see page 5827)	EMPNotify is the type of event handlers that respond when the user interacts with a TMediaPlayer (see page 5749) component.
EMPPostNotify (see page 5827)	EMPPostNotify is the type of a media player's OnPostClick event handler.
TButtonSet (see page 5828)	TButtonSet is a set of TMPBtnType (see page 5819) values.

TMediaDevice (see page 5828)	This is type MPlayer.TMediaDevice.
TMPDevCapsSet (see page 5828)	This is type MPlayer.TMPDevCapsSet.

54.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EMCIDeviceError (see page 5749)	EMCIDeviceError is the exception class for devices that provide a Media Control Interface (MCI) driver.
	TMediaPlayer (see page 5749)	TMediaPlayer controls devices that provide a Media Control Interface (MCI) driver.

54.1.1 EMCIDeviceError Class

EMCIDeviceError is the exception class for devices that provide a Media Control Interface (MCI) driver.

Class Hierarchy

Pascal

```
EMCIDeviceError = class(Exception);
```

C++

```
class EMCIDeviceError : public Exception;
```

File

MPlayer

Description

EMCIDeviceError is raised if an error occurs when accessing a multimedia device. The most common cause for the exception is trying to access a multimedia device before it has been opened with the Open method of TMediaPlayer (see page 5749).

See Also

TMediaPlayer (see page 5749)

TMediaPlayer (see page 5749)

54.1.2 TMediaPlayer Class

TMediaPlayer controls devices that provide a Media Control Interface (MCI) driver.

Class Hierarchy

Pascal

```
TMediaPlayer = class(TCustomControl);
```

C++

```
class TMediaPlayer : public TCustomControl;
```

File

MPlayer

Description

The TMediaPlayer component includes a set of buttons (Play (see page 5767), Stop (see page 5774), Eject (see page 5759), and so on) that control a multimedia device such as a CD-ROM drive, MIDI sequencer, or VCR. A multimedia device may be hardware or software.

The media player component contains of multiple buttons. These buttons can be clicked with the mouse, but are not separate objects or button components.

ButtonValueAction

Button	Value	Action
Play (see page 5767)	btPlay	Plays the media player
Pause (see page 5766)	btPause	Pauses playing or recording. If already paused when clicked, resumes playing or recording.
Stop (see page 5774)	btStop	Stops playing or recording
Next (see page 5762)	btNext	Skips to the next track, or to the end if the medium doesn't use tracks
Prev	btPrev	Skips to the previous track, or to the beginning if the medium doesn't use tracks
Step (see page 5774)	btStep	Moves forward a number of frames
Back (see page 5757)	btBack	Moves backward a number of frames
Record	btRecord	Starts recording
Eject (see page 5759)	btEject	Ejects the medium

The multimedia device is played, paused, stopped, and so on when the user clicks the corresponding button on the TMediaPlayer component. The device can also be controlled by the control methods that correspond to the buttons (Play (see page 5767), Pause (see page 5766), Stop (see page 5774), Next (see page 5762), Previous (see page 5771), Step (see page 5774), Back (see page 5757), StartRecording (see page 5773), and Eject (see page 5759)).

The type of multimedia device (such as dtWaveAudio or dtVideodisc) is specified by the DeviceType (see page 5783) property. If the device stores its media in a file, the name of the media file is specified by the FileName (see page 5791) property. If DeviceType (see page 5783) is dtAutoSelect, the media player attempts to determine the type of device from the extension of the file specified by FileName (see page 5791).

To have the media player attempt to open the device specified by DeviceType (see page 5783) automatically when the media player component is created at runtime, set the AutoOpen (see page 5780) property to true.

C++ Examples:

```
//
//This example demonstrates the use of TMediaPlayer component. Assuming 2 buttons
//for Open and Stop are present on the form.
//Note: AutoEnable must be set to false to be able to control
//the buttons manually.
```

```
//
void __fastcall TForm2::btOpenClick(TObject *Sender)
{
    TOpenDialog* OpenMediaDialog;

    OpenMediaDialog = new TOpenDialog(this);
    OpenMediaDialog->Filter = "All Video Files (*.avi)|*.avi";
  // There are avi files in
  // C:\Documents and Settings\All Users\Documents\RAD
Studio\6.0\Demos\DelphiWin32\VCLWin32\CoolStuff
    if (OpenMediaDialog->Execute())
    {
        /* Assign a file to the media player */
        MediaPlayer1->FileName = OpenMediaDialog->FileName;

        /* Check if the file exists and is not a directory */
        if ((FileExists(OpenMediaDialog->FileName)) &&
           (!DirectoryExists(OpenMediaDialog->FileName)))
        {
            /* Open the files */
            MediaPlayer1->Wait = true;
            MediaPlayer1->Open();
            MediaPlayer1->Play();

            /* Override automatic button controlling */
            MediaPlayer1->EnabledButtons =
                TButtonSet() <<
                TMPBtnType::btPause <<
                TMPBtnType::btStop <<
                TMPBtnType::btPlay;

            /* Enable  the stop button */
            btStop->Enabled = true;
            btOpen->Enabled = false;
        }
    }

    delete OpenMediaDialog;
}

void __fastcall TForm2::btStopClick(TObject *Sender)
{
    /* Stop and close the media */
    MediaPlayer1->Stop();
    MediaPlayer1->Close();

    MediaPlayer1->EnabledButtons = TButtonSet();

    /* Enable open button again */
    btOpen->Enabled = true;
}

void __fastcall TForm2::FormCreate(TObject *Sender)
{
    /* Disable all buttons */
    MediaPlayer1->AutoEnable = false;
    MediaPlayer1->EnabledButtons = TButtonSet();
}

void __fastcall TForm2::MediaPlayer1PostClick(TObject *Sender,
          TMPBtnType Button)
{
    if (Button == TMPBtnType::btStop)
        btStop->Click();
}
```

Delphi Examples:

```
{
This example demonstrates the use of TMediaPlayer component. Assuming 2 buttons
for Open and Stop are present on the form.
Note: AutoEnable must be set to false to be able to control
the buttons manually.
}

procedure TForm2.btOpenClick(Sender: TObject);
var
  OpenMediaDialog : TOpenDialog;
begin
  OpenMediaDialog := TOpenDialog.Create(Self);
  OpenMediaDialog.Filter := 'All Video Files (*.avi)|*.avi';
  // There are avi files in
  // C:\Documents and Settings\All Users\Documents\RAD
Studio\6.0\Demos\DelphiWin32\VCLWin32\CoolStuff
  if OpenMediaDialog.Execute() then
  begin
    { Assign a file to the media player }
    MediaPlayer1.FileName := OpenMediaDialog.FileName;

    { Check if the file exists and is not a directory }
    if (FileExists(OpenMediaDialog.FileName)) and
       (not DirectoryExists(OpenMediaDialog.FileName)) then
    begin
      { Open the files }
      MediaPlayer1.Wait := true;
      MediaPlayer1.Open;
      MediaPlayer1.Play;

      { Override automatic button controlling }
      MediaPlayer1.EnabledButtons :=
        [TMPBtnType.btPause, TMPBtnType.btStop, TMPBtnType.btPlay];

      { Enable  the stop button }
      btStop.Enabled := true;
      btOpen.Enabled := false;
    end;
  end;

  OpenMediaDialog.Free;
end;

procedure TForm2.btStopClick(Sender: TObject);
begin
  { Stop and close the media }
  MediaPlayer1.Stop;
  MediaPlayer1.Close;

  MediaPlayer1.EnabledButtons := [];

  { Enable open button again }
  btOpen.Enabled := true;
end;

procedure TForm2.FormCreate(Sender: TObject);
begin
  { Disable all buttons }
  MediaPlayer1.AutoEnable := false;
  MediaPlayer1.EnabledButtons := [];
end;

procedure TForm2.MediaPlayer1PostClick(Sender: TObject;
  Button: TMPBtnType);
```

```
begin
  if Button = TMPBtnType.btStop then
     btStop.Click;
end;
```

54.1.2.1 TMediaPlayer Members

The following tables list the members exposed by TMediaPlayer.

Protected Methods

	Name	Description
	AutoButtonSet (see page 5756)	Enables or Disables the media player's buttons.
	Click (see page 5757)	Generates an OnClick (see page 5810) event.
	DoNotify (see page 5759)	Generates an OnNotify (see page 5817) event.
V	KeyDown (see page 5761)	Provides responses when the user types arrow keys or the space bar.
V	Loaded (see page 5761)	Initializes the media player after it is loaded from a stream.
	MMNotify (see page 5762)	Responds to a notification that the MCI device has completed an operation.
V	Notification (see page 5763)	Responds when components are about to be inserted or removed.
V	Paint (see page 5766)	Renders the image of the media player.
	PostClick (see page 5770)	Determines the action that takes place when an OnPostClick (see page 5818) event occurs.
V	Updated (see page 5775)	Signals that the media player has finished updating.

Public Methods

	Name	Description
	Back (see page 5757)	Steps backward a number of frames (determined by the value of the Frames (see page 5793) property) in the currently loaded medium.
	Close (see page 5758)	Closes the open multimedia device.
V	Create (see page 5755)	Creates a media player object.
V	Destroy (see page 5755)	Destroys an instance of the media player.
	Eject (see page 5759)	Releases the loaded medium from the open multimedia device.
	Next (see page 5762)	Moves to the beginning of the next track of the currently loaded medium.
	Open (see page 5763)	Opens a multimedia device.
	Pause (see page 5766)	Toggles the open multimedia device on or off.
	PauseOnly (see page 5767)	Pauses the open multimedia device.
	Play (see page 5767)	Plays the media loaded in the open multimedia device.
	Previous (see page 5771)	Sets the current position to the beginning of the previous track if the position was at the beginning of a track when Previous was called.
	Resume (see page 5771)	Resumes playing or recording the currently paused multimedia device.
	Rewind (see page 5772)	Sets the current position to the beginning of the the medium, which is stored in the Start (see page 5804) property.
	Save (see page 5772)	Saves the currently loaded medium to the file specified in the FileName (see page 5791) property.
	StartRecording (see page 5773)	Begins recording from the current Position (see page 5801) or from the position specified in StartPos (see page 5804).
	Step (see page 5774)	Moves forward a number of frames (determined by the Frames (see page 5793) property) in the currently loaded medium.
	Stop (see page 5774)	Halts playing or recording.

Public Properties

	Name	Description
R	Capabilities (see page 5781)	Determines the capabilities of the open multimedia device.
R	DeviceID (see page 5782)	Specifies the device ID for the currently open multimedia device.

	DisplayRect (see page 5784)	Specifies a rectangular area in the control specified by the Display (see page 5783) property that is used to display output from a multimedia device.
	EndPos (see page 5789)	Specifies the position within the currently loaded medium at which to stop playing or recording.
R	Error (see page 5789)	Specifies the MCI error code returned by the media control method.
R	ErrorMessage (see page 5790)	Describes the error code stored in the Error (see page 5789) property.
	Frames (see page 5793)	Specifies the number of frames moved forward or backward.
R	Length (see page 5794)	Specifies the length of the medium in the open multimedia device.
R	Mode (see page 5794)	Indicates the state of the currently open multimedia device.
	Notify (see page 5794)	Determines whether an OnNotify (see page 5817) event is generated.
R	NotifyValue (see page 5795)	Indicates the result of the last media control method that requested a notification.
	Position (see page 5801)	Specifies the current position within the currently loaded medium.
R	Start (see page 5804)	Specifies the starting position within the currently loaded medium.
	StartPos (see page 5804)	Specifies the position within the currently loaded medium from which to begin playing or recording.
	TimeFormat (see page 5805)	Determines the format used to specify position information.
R	TrackLength (see page 5806)	Reports the length of the track.
R	TrackPosition (see page 5806)	Reports the starting position of the track.
R	Tracks (see page 5807)	Specifies the number of playable tracks on the open multimedia device.
	Wait (see page 5809)	Determines whether a media control method returns control to the application only after it has been completed.

Published Events

	Name	Description
	OnClick (see page 5810)	Occurs when the user presses and releases the mouse button while the mouse pointer is over one of the control buttons, or when the user presses Spacebar while the media player control has focus.
	OnContextPopup (see page 5811)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnEnter (see page 5811)	Occurs when a control receives the input focus.
	OnExit (see page 5814)	Occurs when the input focus shifts away from one control to another.
	OnMouseEnter (see page 5817)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5817)	Occurs when the user moves the mouse outside of a control.
	OnNotify (see page 5817)	Occurs upon the completion of a media control method.
	OnPostClick (see page 5818)	Occurs after the OnClick (see page 5810) event handler is called.

Published Properties

	Name	Description
	Anchors (see page 5776)	Specifies how the control is anchored to its parent.
	AutoEnable (see page 5777)	Determines whether the media player automatically enables and disables individual buttons in the component.
	AutoOpen (see page 5780)	Determines if the media player is opened automatically when the application is run.
	AutoRewind (see page 5781)	Determines if the media player control rewinds before playing or recording.
	ColoredButtons (see page 5781)	Determines which buttons on the media player control have color.
	Constraints (see page 5782)	Specifies the size constraints for the control.
	DeviceType (see page 5783)	Specifies a multimedia device type to open the media player.
	Display (see page 5783)	Specifies the display window for a multimedia device that uses a window for output.
	DoubleBuffered (see page 5784)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	Enabled (see page 5786)	Controls whether the control responds to mouse, keyboard, and timer events.
	EnabledButtons (see page 5786)	Determines which buttons on the media player are usable.
	FileName (see page 5791)	Specifies the opened or saved media file.
	ParentDoubleBuffered (see page 5795)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentShowHint (see page 5796)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 5796)	Identifies the pop-up menu associated with the control.

	Shareable (see page 5802)	Determines whether more than one application can share a multimedia device.
	ShowHint (see page 5802)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 5804)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 5805)	Determines if the user can tab to a control.
	Visible (see page 5807)	Determines whether the component appears onscreen.
	VisibleButtons (see page 5809)	Indicates which of the buttons on the media player are visible.

54.1.2.2 TMediaPlayer.Create Constructor

Creates a media player object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TMediaPlayer(TComponent * AOwner);
```

Description

Call Create to instantiate a media player at runtime. For media players created at design time, Create is called automatically.

Create allocates memory for a media player and calls the inherited Create. Then it loads the bitmaps for the media player's buttons and initializes its properties, setting AutoEnable (see page 5777), AutoRewind (see page 5781), Colored, Enabled (see page 5786), and Visible (see page 5807) to true, AutoOpen (see page 5780) to false, and DeviceType (see page 5783) to dtAutoSelect.

See Also

Create

ParentWindow

54.1.2.3 TMediaPlayer.Destroy Destructor

Destroys an instance of the media player.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TMediaPlayer();
```

Description

Do not call Destroy directly in an application. Call Free instead. Free checks that the TMediaPlayer (see page 5749) reference is not nil before it calls Destroy.

Destroy first verifies that no device is open, then destroys the bitmaps used for the media player's buttons and calls the inherited Destroy.

Destroy

System::TObject::Free

54.1.2.4 TMediaPlayer Methods

The methods of the TMediaPlayer class are listed here.

Protected Methods

	Name	Description
	AutoButtonSet (see page 5756)	Enables or Disables the media player's buttons.
	Click (see page 5757)	Generates an OnClick (see page 5810) event.
	DoNotify (see page 5759)	Generates an OnNotify (see page 5817) event.
V	KeyDown (see page 5761)	Provides responses when the user types arrow keys or the space bar.
V	Loaded (see page 5761)	Initializes the media player after it is loaded from a stream.
	MMNotify (see page 5762)	Responds to a notification that the MCI device has completed an operation.
V	Notification (see page 5763)	Responds when components are about to be inserted or removed.
V	Paint (see page 5766)	Renders the image of the media player.
	PostClick (see page 5770)	Determines the action that takes place when an OnPostClick (see page 5818) event occurs.
V	Updated (see page 5775)	Signals that the media player has finished updating.

Public Methods

	Name	Description
	Back (see page 5757)	Steps backward a number of frames (determined by the value of the Frames (see page 5793) property) in the currently loaded medium.
	Close (see page 5758)	Closes the open multimedia device.
	Eject (see page 5759)	Releases the loaded medium from the open multimedia device.
	Next (see page 5762)	Moves to the beginning of the next track of the currently loaded medium.
	Open (see page 5763)	Opens a multimedia device.
	Pause (see page 5766)	Toggles the open multimedia device on or off.
	PauseOnly (see page 5767)	Pauses the open multimedia device.
	Play (see page 5767)	Plays the media loaded in the open multimedia device.
	Previous (see page 5771)	Sets the current position to the beginning of the previous track if the position was at the beginning of a track when Previous was called.
	Resume (see page 5771)	Resumes playing or recording the currently paused multimedia device.
	Rewind (see page 5772)	Sets the current position to the beginning of the the medium, which is stored in the Start (see page 5804) property.
	Save (see page 5772)	Saves the currently loaded medium to the file specified in the FileName (see page 5791) property.
	StartRecording (see page 5773)	Begins recording from the current Position (see page 5801) or from the position specified in StartPos (see page 5804).
	Step (see page 5774)	Moves forward a number of frames (determined by the Frames (see page 5793) property) in the currently loaded medium.
	Stop (see page 5774)	Halts playing or recording.

54.1.2.4.1 TMediaPlayer.AutoButtonSet Method

Enables or Disables the media player's buttons.

Pascal

```
procedure AutoButtonSet(Btn: TMPBtnType); dynamic;
```

C++

```
__fastcall AutoButtonSet(TMPBtnType Btn);
```

Description

AutoButtonSet implements the automatic enabling and disabling of the media player's buttons when the AutoEnable (see page 5777) property is true. The Btn parameter indicates which of the media player's buttons the user pressed.

See Also

AutoEnable (see page 5777)

EnabledButtons (see page 5786)

54.1.2.4.2 TMediaPlayer.Back Method

Steps backward a number of frames (determined by the value of the Frames (see page 5793) property) in the currently loaded medium.

Pascal

```
procedure Back;
```

C++

```
__fastcall Back();
```

Description

Back is called when the Back button on the media player control is clicked at runtime.

Upon completion, Back stores a numerical error code in the Error (see page 5789) property and the corresponding error message in the ErrorMessage (see page 5790) property.

The Wait (see page 5809) property determines whether control is returned to the application before the Back method has been completed. The Notify (see page 5794) property determines whether Back generates an OnNotify (see page 5817) event.

See Also

Error (see page 5789)

ErrorMessage (see page 5790)

Notify (see page 5794)

OnNotify (see page 5817)

Wait (see page 5809)

Adding Audio and/or Video Clips to an Application

54.1.2.4.3 TMediaPlayer.Click Method

Generates an OnClick (see page 5810) event.

Pascal

```
procedure Click(Button: TMPBtnType; var DoDefault: Boolean); dynamic; reintroduce;
```

C++

```
__fastcall Click(TMPBtnType Button, Boolean DoDefault);
```

Description

Click for media-player components is the implementation method for the OnClick (see page 5810) event. By default, Click does nothing other than call any event handler attached to the media player's OnClick (see page 5810) event. Click can be overridden in descendant classes to customize responses to clicks.

See Also

OnClick (see page 5810)

54.1.2.4.4 TMediaPlayer.Close Method

Closes the open multimedia device.

Pascal

```
procedure Close;
```

C++

```
__fastcall Close();
```

Description

Upon completion, Close stores a numerical error code in the Error (see page 5789) property, and the corresponding error message in the ErrorMessage (see page 5790) property.

The Wait (see page 5809) property determines whether control is returned to the application before the Close method is completed. The Notify (see page 5794) property determines whether Close generates an OnNotify (see page 5817) event.

Close is called automatically when the application is terminated.

C++ Examples:

```
/*
This code ejects the CD from the CD-ROM player and shuts
down the media player after 10 seconds. For the code to run
correctly, you must have your CD audio device installed
correctly, and the device must have software-ejecting
capabilities.
*/

Word TimeOver;

void __fastcall TForm1::FormClick(TObject *Sender)
{
  MediaPlayer1->DeviceType = dtCDAudio;
  MediaPlayer1->Open();
  MediaPlayer1->Play();
  Timer1->Enabled = true;
  TimeOver = 0;
}

void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  if (TimeOver == 10)
  {
    MediaPlayer1->Eject();
    MediaPlayer1->Close();
    // disable the timer, as we are done
    Timer1->Enabled = false;
  }
  else
    TimeOver++;
}
```

Delphi Examples:

```
{
This code ejects the CD from the CD-ROM player and shuts
down the media player after 10 seconds. For the code to run
correctly, you must have your CD audio device installed
correctly, and the device must have software-ejecting
capabilities.
}
var
```

```
    TimerOver: Word;

  procedure TForm1.FormClick(Sender: TObject);
  begin
    MediaPlayer1.DeviceType := dtCDAudio;
    MediaPlayer1.Open;
    MediaPlayer1.Play;
  end;

  procedure TForm1.Timer1Timer(Sender: TObject);
  begin
    if TimeOver = 10 then
    begin
      MediaPlayer1.Eject;
      MediaPlayer1.Close;
      { disable the timer, as we are done }
      Timer1.Enabled := False;
    end
    else
      if (MediaPlayer1.Mode = mpOpen) then
       Inc(TimeOver);
  end;
```

See Also

Error (see page 5789)

ErrorMessage (see page 5790)

Notify (see page 5794)

OnNotify (see page 5817)

Wait (see page 5809)

54.1.2.4.5 TMediaPlayer.DoNotify Method

Generates an OnNotify (see page 5817) event.

Pascal

```
procedure DoNotify; dynamic;
```

C++

```
__fastcall DoNotify();
```

Description

DoNotify is the implementation method for a media-player component's OnNotify (see page 5817) event. The media player's MMNotify (see page 5762) method calls DoNotify after correcting the enabling and disabling of buttons and setting internal flags from the values passed in the notification message parameters.

By default, DoNotify does nothing except call any event handler attached to the media player's OnNotify (see page 5817) event. DoNotify can be overridden to provide other responses in addition to the inherited event-handler call.

See Also

MMNotify (see page 5762)

OnNotify (see page 5817)

54.1.2.4.6 TMediaPlayer.Eject Method

Releases the loaded medium from the open multimedia device.

Pascal

```
procedure Eject;
```

C++

```
__fastcall Eject();
```

Description

Eject is called when the Eject button on the media player control is clicked at runtime. It ejects the loaded medium from the open multimedia device.

Upon completion, Eject stores a numerical error code in the Error (see page 5789) property, and the corresponding error message in the ErrorMessage (see page 5790) property.

The Wait (see page 5809) property determines whether control is returned to the application before the Eject method has been completed. The Notify (see page 5794) property determines whether Eject generates an OnNotify (see page 5817) event.

C++ Examples:

```
/*
This code ejects the CD from the CD-ROM player and shuts
down the media player after 10 seconds. For the code to run
correctly, you must have your CD audio device installed
correctly, and the device must have software-ejecting
capabilities.
*/

Word TimeOver;

void __fastcall TForm1::FormClick(TObject *Sender)
{
  MediaPlayer1->DeviceType = dtCDAudio;
  MediaPlayer1->Open();
  MediaPlayer1->Play();
  Timer1->Enabled = true;
  TimeOver = 0;
}

void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  if (TimeOver == 10)
  {
    MediaPlayer1->Eject();
    MediaPlayer1->Close();
    // disable the timer, as we are done
    Timer1->Enabled = false;
  }
  else
    TimeOver++;
}
```

Delphi Examples:

```
{
This code ejects the CD from the CD-ROM player and shuts
down the media player after 10 seconds. For the code to run
correctly, you must have your CD audio device installed
correctly, and the device must have software-ejecting
capabilities.
}
var
  TimerOver: Word;

procedure TForm1.FormClick(Sender: TObject);
begin
```

```
    MediaPlayer1.DeviceType := dtCDAudio;
    MediaPlayer1.Open;
    MediaPlayer1.Play;
  end;

  procedure TForm1.Timer1Timer(Sender: TObject);
  begin
    if TimeOver = 10 then
    begin
      MediaPlayer1.Eject;
      MediaPlayer1.Close;
      { disable the timer, as we are done }
      Timer1.Enabled := False;
    end
    else
      if (MediaPlayer1.Mode = mpOpen) then
       Inc(TimeOver);
  end;
```

See Also

Error (see page 5789)

ErrorMessage (see page 5790)

Notify (see page 5794)

OnNotify (see page 5817)

Wait (see page 5809)

Adding Audio and/or Video Clips to an Application

54.1.2.4.7 TMediaPlayer.KeyDown Method

Provides responses when the user types arrow keys or the space bar.

Pascal

```
procedure KeyDown(var Key: Word; Shift: TShiftState); override;
```

C++

```
virtual __fastcall KeyDown(Word Key, TShiftState Shift);
```

Description

KeyDown overrides the inherited method to implement the media player's response to certain keystrokes. It changes the current button when the user types the left or right arrow keys. When the user presses the space bar, KeyDown simulates a click on the current button.

See Also

EnabledButtons (see page 5786)

KeyDown

54.1.2.4.8 TMediaPlayer.Loaded Method

Initializes the media player after it is loaded from a stream.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Loaded provides an opportunity for a component to initialize itself after all its parts have loaded from a stream. TMediaPlayer (see page 5749) overrides the inherited method to implement the AutoOpen (see page 5780) property.

See Also

Create (see page 5755)

AutoOpen (see page 5780)

54.1.2.4.9 TMediaPlayer.MMNotify Method

Responds to a notification that the MCI device has completed an operation.

Pascal

```
procedure MMNotify(var Message: TMessage); message MM_MCINOTIFY;
```

C++

```
__fastcall MMNotify(TMessage Message);
```

Description

MMNotify responds to a notification message from Windows that a multimedia command completed by updating button states if the AutoEnable (see page 5777) property is true, setting internal flags to reflect the outcome of the command, then calling the DoNotify (see page 5759) method to trigger the OnNotify (see page 5817) event and any other special responses.

See Also

AutoEnable (see page 5777)

DoNotify (see page 5759)

OnNotify (see page 5817)

54.1.2.4.10 TMediaPlayer.Next Method

Moves to the beginning of the next track of the currently loaded medium.

Pascal

```
procedure Next;
```

C++

```
__fastcall Next();
```

Description

If the current position is at the last track when Next is called, Next makes the current position the beginning of the last track. If the multimedia device doesn't use tracks, Next goes to the end of the medium. Next is called when the Next button on the media player control is clicked at runtime.

Upon completion, Next stores a numerical error code in the Error (see page 5789) property, and the corresponding error message in the ErrorMessage (see page 5790) property.

The Wait (see page 5809) property determines whether control is returned to the application before the Next method has completed. The Notify (see page 5794) property determines whether Next generates an OnNotify (see page 5817) event.

See Also

Error (see page 5789)

ErrorMessage (see page 5790)

Notify (see page 5794)

OnNotify (see page 5817)

Wait (see page 5809)

Adding Audio and/or Video Clips to an Application

54.1.2.4.11 TMediaPlayer.Notification Method

Responds when components are about to be inserted or removed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

By default, components pass along the notification to their owned components, if any. Notification calls the inherited Notification and then, if the Display (see page 5783) window is deleted at runtime, it sets the video display back to original window.

See Also

Notification

Display (see page 5783)

54.1.2.4.12 TMediaPlayer.Open Method

Opens a multimedia device.

Pascal

```
procedure Open;
```

C++

```
__fastcall Open();
```

Description

Use Open to open a multimedia device. The multimedia device type must be specified in the DeviceType (see page 5783) property before a device can be opened.

Upon completion, Open stores a numerical error code in the Error (see page 5789) property, and the corresponding error message in the ErrorMessage (see page 5790) property.

The Wait (see page 5809) property determines whether control is returned to the application before the Open method is completed. The Notify (see page 5794) property determines whether Open generates an OnNotify (see page 5817) event.

C++ Examples:

```
//
//This example demonstrates the use of TMediaPlayer component. Assuming 2 buttons
//for Open and Stop are present on the form.
//Note: AutoEnable must be set to false to be able to control
```

```
//the buttons manually.
//
void __fastcall TForm2::btOpenClick(TObject *Sender)
{
    TOpenDialog* OpenMediaDialog;

    OpenMediaDialog = new TOpenDialog(this);
    OpenMediaDialog->Filter = "All Video Files (*.avi)|*.avi";
  // There are avi files in
  // C:\Documents and Settings\All Users\Documents\RAD
Studio\6.0\Demos\DelphiWin32\VCLWin32\CoolStuff
    if (OpenMediaDialog->Execute())
    {
        /* Assign a file to the media player */
        MediaPlayer1->FileName = OpenMediaDialog->FileName;

        /* Check if the file exists and is not a directory */
        if ((FileExists(OpenMediaDialog->FileName)) &&
           (!DirectoryExists(OpenMediaDialog->FileName)))
        {
            /* Open the files */
            MediaPlayer1->Wait = true;
            MediaPlayer1->Open();
            MediaPlayer1->Play();

            /* Override automatic button controlling */
            MediaPlayer1->EnabledButtons =
                TButtonSet() <<
                TMPBtnType::btPause <<
                TMPBtnType::btStop <<
                TMPBtnType::btPlay;

            /* Enable  the stop button */
            btStop->Enabled = true;
            btOpen->Enabled = false;
        }
    }

    delete OpenMediaDialog;
}

void __fastcall TForm2::btStopClick(TObject *Sender)
{
    /* Stop and close the media */
    MediaPlayer1->Stop();
    MediaPlayer1->Close();

    MediaPlayer1->EnabledButtons = TButtonSet();

    /* Enable open button again */
    btOpen->Enabled = true;
}

void __fastcall TForm2::FormCreate(TObject *Sender)
{
    /* Disable all buttons */
    MediaPlayer1->AutoEnable = false;
    MediaPlayer1->EnabledButtons = TButtonSet();
}

void __fastcall TForm2::MediaPlayer1PostClick(TObject *Sender,
          TMPBtnType Button)
{
    if (Button == TMPBtnType::btStop)
        btStop->Click();
```

```
}
```

Delphi Examples:

```
{
This example demonstrates the use of TMediaPlayer component. Assuming 2 buttons
for Open and Stop are present on the form.
Note: AutoEnable must be set to false to be able to control
the buttons manually.
}

procedure TForm2.btOpenClick(Sender: TObject);
var
  OpenMediaDialog : TOpenDialog;
begin
  OpenMediaDialog := TOpenDialog.Create(Self);
  OpenMediaDialog.Filter := 'All Video Files (*.avi)|*.avi';
  // There are avi files in
  // C:\Documents and Settings\All Users\Documents\RAD
Studio\6.0\Demos\DelphiWin32\VCLWin32\CoolStuff
  if OpenMediaDialog.Execute() then
  begin
    { Assign a file to the media player }
    MediaPlayer1.FileName := OpenMediaDialog.FileName;

    { Check if the file exists and is not a directory }
    if (FileExists(OpenMediaDialog.FileName)) and
       (not DirectoryExists(OpenMediaDialog.FileName)) then
    begin
      { Open the files }
      MediaPlayer1.Wait := true;
      MediaPlayer1.Open;
      MediaPlayer1.Play;

      { Override automatic button controlling }
      MediaPlayer1.EnabledButtons :=
        [TMPBtnType.btPause, TMPBtnType.btStop, TMPBtnType.btPlay];

      { Enable  the stop button }
      btStop.Enabled := true;
      btOpen.Enabled := false;
    end;
  end;

  OpenMediaDialog.Free;
end;

procedure TForm2.btStopClick(Sender: TObject);
begin
  { Stop and close the media }
  MediaPlayer1.Stop;
  MediaPlayer1.Close;

  MediaPlayer1.EnabledButtons := [];

  { Enable open button again }
  btOpen.Enabled := true;
end;

procedure TForm2.FormCreate(Sender: TObject);
begin
  { Disable all buttons }
  MediaPlayer1.AutoEnable := false;
  MediaPlayer1.EnabledButtons := [];
end;

procedure TForm2.MediaPlayer1PostClick(Sender: TObject;
```

```
  Button: TMPBtnType);
begin
  if Button = TMPBtnType.btStop then
     btStop.Click;
end;
```

54.1.2.4.13 TMediaPlayer.Paint Method

Renders the image of the media player.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

When the media player component receives a WM_PAINT (see page 5198) message, like other custom controls, it responds by initializing the control's canvas and calling Paint. Paint draws the frame and all visible buttons.

When creating a descendant media player class, Paint can be overridden to draw the image of the corresponding media player object.

See Also

VisibleButtons (see page 5809)

54.1.2.4.14 TMediaPlayer.Pause Method

Toggles the open multimedia device on or off.

Pascal

```
procedure Pause;
```

C++

```
__fastcall Pause();
```

Description

If the device is already paused when Pause is called, the device resumes playing or recording by calling the Resume (see page 5771) method. Pause is called when the Pause button on the media player control is clicked at runtime.

Upon completion, Pause stores a numerical error code in the Error (see page 5789) property and the corresponding error message in the ErrorMessage (see page 5790) property.

The Wait (see page 5809) property determines whether control is returned to the application before the Pause method has completed. The Notify (see page 5794) property determines whether Pause generates an OnNotify (see page 5817) event.

See Also

Error (see page 5789)

ErrorMessage (see page 5790)

Notify (see page 5794)

OnNotify (see page 5817)

Resume (see page 5771)

Adding Audio and/or Video Clips to an Application

54.1.2.4.15 TMediaPlayer.PauseOnly Method

Pauses the open multimedia device.

Pascal

```
procedure PauseOnly;
```

C++

```
__fastcall PauseOnly();
```

Description

If the device is already paused when PauseOnly is called, the device will remain paused.

Upon completion, PauseOnly stores a numerical error code in the Error (see page 5789) property and the corresponding error message in the ErrorMessage (see page 5790) property.

The Wait (see page 5809) property determines whether control is returned to the application before the PauseOnly method has completed. The Notify (see page 5794) property determines whether PauseOnly generates an OnNotify (see page 5817) event.

See Also

Error (see page 5789)

ErrorMessage (see page 5790)

Notify (see page 5794)

OnNotify (see page 5817)

Wait (see page 5809)

54.1.2.4.16 TMediaPlayer.Play Method

Plays the media loaded in the open multimedia device.

Pascal

```
procedure Play;
```

C++

```
__fastcall Play();
```

Description

Play is called when the Play button on the media player control is clicked at runtime.

Upon completion, Play stores a numerical error code in the Error (see page 5789) property and the corresponding error message in the ErrorMessage (see page 5790) property.

The Wait (see page 5809) property determines whether control is returned to the application before the Play method has completed. The Notify (see page 5794) property determines whether Play generates an OnNotify (see page 5817) event.

If the StartPos (see page 5804) property is set, playing starts at the position specified in StartPos (see page 5804). Otherwise, playing starts at the current position, specified in the Position (see page 5801) property. Similarly, if the EndPos (see page 5789) property is set, playing stops at the position specified in EndPos (see page 5789). Otherwise, playing stops at the end of the medium.

Whether the medium (specified in the Position (see page 5801) property) is rewound before playing starts depends on the AutoRewind (see page 5781) property.

C++ Examples:

```
//
//This example demonstrates the use of TMediaPlayer component. Assuming 2 buttons
//for Open and Stop are present on the form.
//Note: AutoEnable must be set to false to be able to control
//the buttons manually.
//
void __fastcall TForm2::btOpenClick(TObject *Sender)
{
    TOpenDialog* OpenMediaDialog;

    OpenMediaDialog = new TOpenDialog(this);
    OpenMediaDialog->Filter = "All Video Files (*.avi)|*.avi";
  // There are avi files in
  // C:\Documents and Settings\All Users\Documents\RAD
Studio\6.0\Demos\DelphiWin32\VCLWin32\CoolStuff
    if (OpenMediaDialog->Execute())
    {
        /* Assign a file to the media player */
        MediaPlayer1->FileName = OpenMediaDialog->FileName;

        /* Check if the file exists and is not a directory */
        if ((FileExists(OpenMediaDialog->FileName)) &&
           (!DirectoryExists(OpenMediaDialog->FileName)))
        {
            /* Open the files */
            MediaPlayer1->Wait = true;
            MediaPlayer1->Open();
            MediaPlayer1->Play();

            /* Override automatic button controlling */
            MediaPlayer1->EnabledButtons =
                TButtonSet() <<
                TMPBtnType::btPause <<
                TMPBtnType::btStop <<
                TMPBtnType::btPlay;

            /* Enable  the stop button */
            btStop->Enabled = true;
            btOpen->Enabled = false;
        }
    }

    delete OpenMediaDialog;
}

void __fastcall TForm2::btStopClick(TObject *Sender)
{
    /* Stop and close the media */
```

```
    MediaPlayer1->Stop();
    MediaPlayer1->Close();

    MediaPlayer1->EnabledButtons = TButtonSet();

    /* Enable open button again */
    btOpen->Enabled = true;
}

void __fastcall TForm2::FormCreate(TObject *Sender)
{
    /* Disable all buttons */
    MediaPlayer1->AutoEnable = false;
    MediaPlayer1->EnabledButtons = TButtonSet();
}

void __fastcall TForm2::MediaPlayer1PostClick(TObject *Sender,
          TMPBtnType Button)
{
    if (Button == TMPBtnType::btStop)
        btStop->Click();
}
```

Delphi Examples:

```
{
This example demonstrates the use of TMediaPlayer component. Assuming 2 buttons
for Open and Stop are present on the form.
Note: AutoEnable must be set to false to be able to control
the buttons manually.
}

procedure TForm2.btOpenClick(Sender: TObject);
var
  OpenMediaDialog : TOpenDialog;
begin
  OpenMediaDialog := TOpenDialog.Create(Self);
  OpenMediaDialog.Filter := 'All Video Files (*.avi)|*.avi';
  // There are avi files in
  // C:\Documents and Settings\All Users\Documents\RAD
Studio\6.0\Demos\DelphiWin32\VCLWin32\CoolStuff
  if OpenMediaDialog.Execute() then
  begin
    { Assign a file to the media player }
    MediaPlayer1.FileName := OpenMediaDialog.FileName;

    { Check if the file exists and is not a directory }
    if (FileExists(OpenMediaDialog.FileName)) and
       (not DirectoryExists(OpenMediaDialog.FileName)) then
    begin
      { Open the files }
      MediaPlayer1.Wait := true;
      MediaPlayer1.Open;
      MediaPlayer1.Play;

      { Override automatic button controlling }
      MediaPlayer1.EnabledButtons :=
        [TMPBtnType.btPause, TMPBtnType.btStop, TMPBtnType.btPlay];

      { Enable  the stop button }
      btStop.Enabled := true;
      btOpen.Enabled := false;
    end;
  end;

  OpenMediaDialog.Free;
end;
```

```
procedure TForm2.btStopClick(Sender: TObject);
begin
  { Stop and close the media }
  MediaPlayer1.Stop;
  MediaPlayer1.Close;

  MediaPlayer1.EnabledButtons := [];

  { Enable open button again }
  btOpen.Enabled := true;
end;

procedure TForm2.FormCreate(Sender: TObject);
begin
  { Disable all buttons }
  MediaPlayer1.AutoEnable := false;
  MediaPlayer1.EnabledButtons := [];
end;

procedure TForm2.MediaPlayer1PostClick(Sender: TObject;
  Button: TMPBtnType);
begin
  if Button = TMPBtnType.btStop then
     btStop.Click;
end;
```

54.1.2.4.17 TMediaPlayer.PostClick Method

Determines the action that takes place when an OnPostClick (see page 5818) event occurs.

Pascal

```
procedure PostClick(Button: TMPBtnType); dynamic;
```

C++

```
__fastcall PostClick(TMPBtnType Button);
```

Description

PostClick is the implementation method for the OnPostClick (see page 5818) event. By default, PostClick does nothing other than call any event handler attached to the media player's OnPostClick (see page 5818) event. PostClick can be overridden in

descendant types to customize responses to clicks.

See Also

OnPostClick (see page 5818)

54.1.2.4.18 TMediaPlayer.Previous Method

Sets the current position to the beginning of the previous track if the position was at the beginning of a track when Previous was called.

Pascal

```
procedure Previous;
```

C++

```
__fastcall Previous();
```

Description

If the position is at the first track or somewhere other than the beginning of a track when Previous was called, Previous sets the current position to the beginning of the current track. If the device doesn't use tracks, Previous sets the current position to the beginning of the medium, which is specified in the Start (see page 5804) property. Previous is called when the Previous button on the media player control is clicked at runtime.

Upon completion, Previous stores a numerical error code in the Error (see page 5789) property and the corresponding error message in the ErrorMessage (see page 5790) property.

The Wait (see page 5809) property determines whether control is returned to the application before the Previous method has completed. The Notify (see page 5794) property determines whether Previous generates an OnNotify (see page 5817) event.

Adding Audio and/or Video Clips to an Application

54.1.2.4.19 TMediaPlayer.Resume Method

Resumes playing or recording the currently paused multimedia device.

Pascal

```
procedure Resume;
```

C++

```
__fastcall Resume();
```

Description

Resume is called when the Pause (see page 5766) button on the media player control is clicked at runtime, when the device is paused.

Upon completion, Resume stores a numerical error code in the Error (see page 5789) property, and the corresponding error message in the ErrorMessage (see page 5790) property.

The Wait (see page 5809) property determines whether control is returned to the application before the Resume method has completed. The Notify (see page 5794) property determines whether Resume generates an OnNotify (see page 5817) event.

See Also

Error (see page 5789)

ErrorMessage (see page 5790)

Notify (see page 5794)

OnNotify (see page 5817)

Wait (see page 5809)

54.1.2.4.20 TMediaPlayer.Rewind Method

Sets the current position to the beginning of the the medium, which is stored in the Start (see page 5804) property.

Pascal

```
procedure Rewind;
```

C++

```
__fastcall Rewind();
```

Description

Upon completion, Rewind stores a numerical error code in the Error (see page 5789) property, and the corresponding error message in the ErrorMessage (see page 5790) property.

The Wait (see page 5809) property determines whether control is returned to the application before the Rewind method has completed. The Notify (see page 5794) property determines whether Rewind generates an OnNotify (see page 5817) event.

See Also

Error (see page 5789)

ErrorMessage (see page 5790)

Notify (see page 5794)

OnNotify (see page 5817)

Start (see page 5804)

54.1.2.4.21 TMediaPlayer.Save Method

Saves the currently loaded medium to the file specified in the FileName (see page 5791) property.

Pascal

```
procedure Save;
```

C++

```
__fastcall Save();
```

Description

Save is ignored for devices that don't use media stored in files (videodiscs, for example).

Upon completion, Save stores a numerical error code in the Error (see page 5789) property, and the corresponding error message in the ErrorMessage (see page 5790) property.

The Wait (see page 5809) property determines whether control is returned to the application before the Save method has completed. The Notify (see page 5794) property determines whether Save generates an OnNotify (see page 5817) event.

See Also

Error (see page 5789)

ErrorMessage (see page 5790)

FileName (see page 5791)

Notify (see page 5794)

OnNotify (see page 5817)

54.1.2.4.22 TMediaPlayer.StartRecording Method

Begins recording from the current Position (see page 5801) or from the position specified in StartPos (see page 5804).

Pascal

```
procedure StartRecording;
```

C++

```
__fastcall StartRecording();
```

Description

StartRecording is called when the Record button on the media player control is clicked at runtime.

Upon completion, StartRecording stores a numerical error code in the Error (see page 5789) property and the corresponding error message in the ErrorMessage (see page 5790) property.

The Wait (see page 5809) property determines whether control is returned to the application before the StartRecording method has completed. The Notify (see page 5794) property determines whether StartRecording generates an OnNotify (see page 5817) event.

By default, the Notify (see page 5794) property becomes true, and the Wait (see page 5809) property becomes false upon completion of the StartRecording method. However, if these properties have been set to specific values prior to calling StartRecording, they remain unchanged.

Wait (see page 5809)

54.1.2.4.23 TMediaPlayer.Step Method

Moves forward a number of frames (determined by the Frames (see page 5793) property) in the currently loaded medium.

Pascal

```
procedure Step;
```

C++

```
__fastcall Step();
```

Description

Step is called when the Step button on the media player control is clicked at runtime.

Upon completion, Step stores a numerical error code in the Error (see page 5789) property and the corresponding error message in the ErrorMessage (see page 5790) property.

The Wait (see page 5809) property determines whether control is returned to the application before the Step method has completed. The Notify (see page 5794) property determines whether Step generates an OnNotify (see page 5817) event.

Adding Audio and/or Video Clips to an Application

54.1.2.4.24 TMediaPlayer.Stop Method

Halts playing or recording.

Pascal

```
procedure Stop;
```

C++

```
__fastcall Stop();
```

Description

Stop is called when the Stop button on the media player control is clicked at runtime.

Upon completion, Stop stores a numerical error code in the Error (see page 5789) property, and the corresponding error message in the ErrorMessage (see page 5790) property.

The Wait (see page 5809) property determines whether control is returned to the application before the Stop method has completed. The Notify (see page 5794) property determines whether Stop generates an OnNotify (see page 5817) event.

54.1.2.4.25 TMediaPlayer.Updated Method

Signals that the media player has finished updating.

Pascal

```
procedure Updated; override;
```

C++

```
virtual __fastcall Updated();
```

Description

Updated calls the inherited Updated before it modifies the layout of the media player buttons and forces a repaint.

Updated

54.1.2.5 TMediaPlayer Properties

The properties of the TMediaPlayer class are listed here.

Public Properties

	Name	Description
R	Capabilities (see page 5781)	Determines the capabilities of the open multimedia device.
R	DeviceID (see page 5782)	Specifies the device ID for the currently open multimedia device.
	DisplayRect (see page 5784)	Specifies a rectangular area in the control specified by the Display (see page 5783) property that is used to display output from a multimedia device.
	EndPos (see page 5789)	Specifies the position within the currently loaded medium at which to stop playing or recording.
R	Error (see page 5789)	Specifies the MCI error code returned by the media control method.
R	ErrorMessage (see page 5790)	Describes the error code stored in the Error (see page 5789) property.
	Frames (see page 5793)	Specifies the number of frames moved forward or backward.
R	Length (see page 5794)	Specifies the length of the medium in the open multimedia device.
R	Mode (see page 5794)	Indicates the state of the currently open multimedia device.
	Notify (see page 5794)	Determines whether an OnNotify (see page 5817) event is generated.
R	NotifyValue (see page 5795)	Indicates the result of the last media control method that requested a notification.
	Position (see page 5801)	Specifies the current position within the currently loaded medium.
R	Start (see page 5804)	Specifies the starting position within the currently loaded medium.
	StartPos (see page 5804)	Specifies the position within the currently loaded medium from which to begin playing or recording.
	TimeFormat (see page 5805)	Determines the format used to specify position information.
R	TrackLength (see page 5806)	Reports the length of the track.
R	TrackPosition (see page 5806)	Reports the starting position of the track.
R	Tracks (see page 5807)	Specifies the number of playable tracks on the open multimedia device.
	Wait (see page 5809)	Determines whether a media control method returns control to the application only after it has been completed.

Published Properties

	Name	Description
	Anchors (see page 5776)	Specifies how the control is anchored to its parent.
	AutoEnable (see page 5777)	Determines whether the media player automatically enables and disables individual buttons in the component.
	AutoOpen (see page 5780)	Determines if the media player is opened automatically when the application is run.
	AutoRewind (see page 5781)	Determines if the media player control rewinds before playing or recording.
	ColoredButtons (see page 5781)	Determines which buttons on the media player control have color.
	Constraints (see page 5782)	Specifies the size constraints for the control.
	DeviceType (see page 5783)	Specifies a multimedia device type to open the media player.
	Display (see page 5783)	Specifies the display window for a multimedia device that uses a window for output.
	DoubleBuffered (see page 5784)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	Enabled (see page 5786)	Controls whether the control responds to mouse, keyboard, and timer events.
	EnabledButtons (see page 5786)	Determines which buttons on the media player are usable.
	FileName (see page 5791)	Specifies the opened or saved media file.
	ParentDoubleBuffered (see page 5795)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentShowHint (see page 5796)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 5796)	Identifies the pop-up menu associated with the control.
	Shareable (see page 5802)	Determines whether more than one application can share a multimedia device.
	ShowHint (see page 5802)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 5804)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 5805)	Determines if the user can tab to a control.
	Visible (see page 5807)	Determines whether the component appears onscreen.
	VisibleButtons (see page 5809)	Indicates which of the buttons on the media player are visible.

54.1.2.5.1 TMediaPlayer.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

54.1.2.5.2 TMediaPlayer.AutoEnable Property

Determines whether the media player automatically enables and disables individual buttons in the component.

Pascal

```
property AutoEnable: Boolean;
```

C++

```
__property Boolean AutoEnable;
```

Description

Use AutoEnable to automatically enable or disable the control buttons on the media player. If AutoEnable is true, the media player automatically enables or disables its control buttons. The media player determines which buttons to enable or disable by the current mode specified in the Mode (see page 5794) property, and the current multimedia device type specified in the DeviceType (see page 5783) property.

AutoEnable overrides the EnabledButtons (see page 5786) property. The buttons enabled or disabled automatically by the media player supersede any buttons enabled or disabled with EnabledButtons (see page 5786).

If AutoEnable is false, the media player does not enable or disable buttons. The buttons must enabled or disabled with the EnabledButtons (see page 5786) property.

The following table shows whether buttons are automatically enabled or disabled for each device mode:

Button	Play (see page 5767)	Record	Pause (see page 5766)	Stop (see page 5774)	Not Open (see page 5763)
Back (see page 5757)	Enabled (see page 5786)	Enabled (see page 5786)	Enabled (see page 5786)	Enabled (see page 5786)	Disabled
Eject (see page 5759)	Enabled (see page 5786)	Enabled (see page 5786)	Enabled (see page 5786)	Enabled (see page 5786)	Disabled
Next (see page 5762)	Enabled (see page 5786)	Enabled (see page 5786)	Enabled (see page 5786)	Enabled (see page 5786)	Disabled
Pause (see page 5766)	Enabled (see page 5786)	Enabled (see page 5786)	Enabled (see page 5786)	Disabled	Disabled
Play (see page 5767)	Disabled	Disabled	Enabled (see page 5786)	Enabled (see page 5786)	Disabled
Prev	Enabled (see page 5786)	Enabled (see page 5786)	Enabled (see page 5786)	Enabled (see page 5786)	Disabled
Record	Disabled	Disabled	Enabled (see page 5786)	Enabled (see page 5786)	Disabled
Step (see page 5774)	Enabled (see page 5786)	Enabled (see page 5786)	Enabled (see page 5786)	Enabled (see page 5786)	Disabled
Stop (see page 5774)	Enabled (see page 5786)	Enabled (see page 5786)	Disabled	Disabled	Disabled

C++ Examples:

```
//
```

```
//This example demonstrates the use of TMediaPlayer component. Assuming 2 buttons
//for Open and Stop are present on the form.
//Note: AutoEnable must be set to false to be able to control
//the buttons manually.
//

54.1.2.5.3 TMediaPlayer.AutoOpen Property

Determines if the media player is opened automatically when the application is run.

Pascal

```
property AutoOpen: Boolean;
```

C++

```
__property Boolean AutoOpen;
```

Description

Use AutoOpen to have the media player automatically open at runtime.

If AutoOpen is true, the media player attempts to open the multimedia device specified by the DeviceType (see page 5783) property (or FileName (see page 5791) if DeviceType (see page 5783) is dtAutoSelect) when the form containing the media player component is created at runtime.

If AutoOpen is false, the device must be opened with a call to the Open (see page 5763) method.

If an error occurs when opening the device, an exception of type EMCIDeviceError (see page 5749) exception is raised that contains the error message. Upon completion, a numerical error code is stored in the Error (see page 5789) property, and the corresponding error message is stored in the ErrorMessage (see page 5790) property.

The Wait (see page 5809) property determines whether control is returned to the application before opening the multimedia device. The Notify (see page 5794) property determines whether opening the device generates an OnNotify (see page 5817) event.

Adding Audio and/or Video Clips to an Application

54.1.2.5.4 TMediaPlayer.AutoRewind Property

Determines if the media player control rewinds before playing or recording.

Pascal

```
property AutoRewind: Boolean;
```

C++

```
__property Boolean AutoRewind;
```

Description

If AutoRewind is true and the current position is at the end of the medium, Play (see page 5767) or StartRecording (see page 5773) moves the current position to the beginning of the medium before playing or recording. If AutoRewind is false, the user must click the Prev button or write code to call Previous (see page 5771) to move to the beginning.

If values have been assigned to StartPos (see page 5804) or EndPos (see page 5789) or if the multimedia device uses tracks, AutoRewind has no effect on playing or recording. When calling Play (see page 5767) or StartRecording (see page 5773), the current position remains at the end of the medium.

See Also

Previous (see page 5771)

54.1.2.5.5 TMediaPlayer.Capabilities Property

Determines the capabilities of the open multimedia device.

Pascal

```
property Capabilities: TMPDevCapsSet;
```

C++

```
__property TMPDevCapsSet Capabilities;
```

Description

The various capabilities specified in Capabilities are determined when the device is opened with the Open (see page 5763) method.

Note: Currently, there is no way to check whether a device can step forward or backward. Capabilities includes mpCanStep only if the device type (specified in the DeviceType (see page 5783) property) is Animation, AVI Video, Digital Video, Overlay, or VCR.

See Also

DeviceType (see page 5783)

Open (see page 5763)

54.1.2.5.6 TMediaPlayer.ColoredButtons Property

Determines which buttons on the media player control have color.

Pascal

```
property ColoredButtons: TButtonSet;
```

C++

```
__property TButtonSet ColoredButtons;
```

Description

ColoredButtons controls which buttons on the media player are colored.

If a button is not colored with ColoredButtons, it appears in black-and-white when visible. All media player control buttons are colored by default.

See Also

EnabledButtons (see page 5786)

VisibleButtons (see page 5809)

54.1.2.5.7 TMediaPlayer.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

AutoSize

Align

Anchors

OnConstrainedResize

OnCanResize

54.1.2.5.8 TMediaPlayer.DeviceID Property

Specifies the device ID for the currently open multimedia device.

Pascal

```
property DeviceID: Word;
```

C++

```
__property Word DeviceID;
```

Description

The value of DeviceID is determined when a device is opened with the Open (see page 5763) method. If no device is open, DeviceID is 0.

See Also

Open (see page 5763)

54.1.2.5.9 TMediaPlayer.DeviceType Property

Specifies a multimedia device type to open the media player.

Pascal

```
property DeviceType: TMPDeviceTypes;
```

C++

```
__property TMPDeviceTypes DeviceType;
```

Description

DeviceType specifies a multimedia device type to open with the Open (see page 5763) method. The default is dtAutoSelect.

If DeviceType is dtAutoSelect, the device type is determined by the file extension specified in the FileName (see page 5791) property. If no device type is associated with the extension, the correct device type must be explicitly specified by setting DeviceType to a value other than dtAutoSelect.

A multimedia device is typically associated with an appropriate file name extension when the device is installed. Associations are specified in the registry or SYSTEM.INI file. See the documentation for the specific device for instructions about how to associate file name extensions with the device.

See Also

FileName (see page 5791)

Open (see page 5763)

Adding Audio and/or Video Clips to an Application

54.1.2.5.10 TMediaPlayer.Display Property

Specifies the display window for a multimedia device that uses a window for output.

Pascal

```
property Display: TWinControl;
```

C++

```
__property TWinControl * Display;
```

Description

To use Display, assign the name of a windowed control such as a form or panel to Display to display output in that control.

The default value of Display is nil (Delphi) or NULL (C++), meaning that the device creates its own window to display output.

Also, by freeing the control assigned to Display after the device has been opened, video output will be in its own default window.

Examples of multimedia devices that use a window to display output are Animation, AVI Video, Digital Video, Overlay, and VCR.

See Also

DisplayRect (see page 5784)

Adding Audio and/or Video Clips to an Application

54.1.2.5.11 TMediaPlayer.DisplayRect Property

Specifies a rectangular area in the control specified by the Display (see page 5783) property that is used to display output from a multimedia device.

Pascal

```
property DisplayRect: TRect;
```

C++

```
__property TRect DisplayRect;
```

Description

To display output in a specific rectangle area on a form assign a TRect record to DisplayRect. The Rect function can be used to create a TRect record.

Media that use a rectangle to display output usually perform best if the default DisplayRect size is used. To set DisplayRect to the default size, position the rectangle in the upper left corner and use 0, 0 for the lower right corner.

DisplayRect is ignored if Display (see page 5783) is nil (Delphi) or NULL (C++).

Examples of multimedia devices that use a window to display output are Animation, AVI Video, Digital Video, Overlay, and VCR.

Note: DisplayRect can be set only after the media device is opened.

See Also

Display (see page 5783)

Open (see page 5763)

54.1.2.5.12 TMediaPlayer.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:
```

```
procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

54.1.2.5.13 TMediaPlayer.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

DisableControls

EnableControls

Enabling Mouse

54.1.2.5.14 TMediaPlayer.EnabledButtons Property

Determines which buttons on the media player are usable.

Pascal

```
property EnabledButtons: TButtonSet;
```

C++

```
__property TButtonSet EnabledButtons;
```

Description

EnabledButtons controls which buttons on the media player are enabled and usable.

An enabled button is colored and usable. A disabled button is dimmed and not usable. If a button is not enabled with EnabledButtons, it is disabled. By default, all buttons are enabled.

If the AutoEnable (see page 5777) property is true, AutoEnable (see page 5777) supersedes EnabledButtons. The buttons automatically enabled or disabled by the media player override any buttons enabled or disabled with the EnabledButtons property.

C++ Examples:

```
//
//This example demonstrates the use of TMediaPlayer component. Assuming 2 buttons
//for Open and Stop are present on the form.
//Note: AutoEnable must be set to false to be able to control
//the buttons manually.
//
void __fastcall TForm2::btOpenClick(TObject *Sender)
{
    TOpenDialog* OpenMediaDialog;

    OpenMediaDialog = new TOpenDialog(this);
    OpenMediaDialog->Filter = "All Video Files (*.avi)|*.avi";
  // There are avi files in
  // C:\Documents and Settings\All Users\Documents\RAD
Studio\6.0\Demos\DelphiWin32\VCLWin32\CoolStuff
    if (OpenMediaDialog->Execute())
    {
        /* Assign a file to the media player */
        MediaPlayer1->FileName = OpenMediaDialog->FileName;

        /* Check if the file exists and is not a directory */
        if ((FileExists(OpenMediaDialog->FileName)) &&
           (!DirectoryExists(OpenMediaDialog->FileName)))
        {
            /* Open the files */
            MediaPlayer1->Wait = true;
            MediaPlayer1->Open();
            MediaPlayer1->Play();

            /* Override automatic button controlling */
            MediaPlayer1->EnabledButtons =
                TButtonSet() <<
                TMPBtnType::btPause <<
                TMPBtnType::btStop <<
                TMPBtnType::btPlay;

            /* Enable  the stop button */
            btStop->Enabled = true;
            btOpen->Enabled = false;
        }
    }

    delete OpenMediaDialog;
}

void __fastcall TForm2::btStopClick(TObject *Sender)
{
    /* Stop and close the media */
```

```
    MediaPlayer1->Stop();
    MediaPlayer1->Close();

    MediaPlayer1->EnabledButtons = TButtonSet();

    /* Enable open button again */
    btOpen->Enabled = true;
}

Adding Audio and/or Video Clips to an Application

54.1.2.5.15 TMediaPlayer.EndPos Property

Specifies the position within the currently loaded medium at which to stop playing or recording.

Pascal

```
property EndPos: Longint;
```

C++

```
__property Longint EndPos;
```

Description

EndPos is specified using the current time format, which is specified in the TimeFormat (see page 5805) property.

The EndPos property affects only the next Play (see page 5767) or StartRecording (see page 5773) method called after setting EndPos. Reset EndPos to affect any subsequent calls to Play (see page 5767) or StartRecording (see page 5773).

See Also

Play (see page 5767)

StartRecording (see page 5773)

TimeFormat (see page 5805)

54.1.2.5.16 TMediaPlayer.Error Property

Specifies the MCI error code returned by the media control method.

Pascal

```
property Error: Longint;
```

C++

```
__property Longint Error;
```

Description

Error specifies the MCI error code returned by the most recent media control method (Back (see page 5757), Close (see page 5758), Eject (see page 5759), Next (see page 5762), Open (see page 5763), Pause (see page 5766), PauseOnly (see page 5767), Play (see page 5767), Previous (see page 5771), StartRecording (see page 5773), Resume (see page 5771), Rewind (see page 5772), Step (see page 5774), or Stop (see page 5774)). The ErrorMessage (see page 5790) property describes the Error.

The error code returned by media control methods are the same error code returned by the mciSendCommand function. The message describing the error code is stored in the ErrorMessage (see page 5790) property.

The value of Error is zero if the most recent media control method didn't cause an error. If a method results in an error, a value other than zero is stored in Error. If the error occurs during the opening of the device, an EMCIDeviceError (see page 5749) exception occurs.

See Also

EMCIDeviceError (see page 5749)

ErrorMessage (see page 5790)

Play (see page 5767)

StartRecording (see page 5773)

TimeFormat (see page 5805)

54.1.2.5.17 TMediaPlayer.ErrorMessage Property

Describes the error code stored in the Error (see page 5789) property.

Pascal

```
property ErrorMessage: string;
```

C++

```
__property UnicodeString ErrorMessage;
```

Description

ErrorMessage specifies the error message that describes the error code returned from the most recent media control method (Back (see page 5757), Close (see page 5758), Eject (see page 5759), Next (see page 5762), Open (see page 5763), Pause (see page 5766), PauseOnly (see page 5767), Play (see page 5767), Previous (see page 5771), StartRecording (see page 5773), Resume (see page 5771), Rewind (see page 5772), Step (see page 5774), or Stop (see page 5774)).

The error code described by the message is stored in the Error (see page 5789) property.

See Also

Error (see page 5789)

54.1.2.5.18 TMediaPlayer.FileName Property

Specifies the opened or saved media file.

Pascal

```
property FileName: string;
```

C++

```
__property UnicodeString FileName;
```

Description

FileName specifies the media file to be opened by the Open (see page 5763) method, or the file to save by the Save (see page 5772) method.

At design time, use a file open dialog box to specify the FileName property by clicking the ellipsis button (...) in the Object Inspector.

C++ Examples:

```
//
//This example demonstrates the use of TMediaPlayer component. Assuming 2 buttons
//for Open and Stop are present on the form.
//Note: AutoEnable must be set to false to be able to control
//the buttons manually.
//
void __fastcall TForm2::btOpenClick(TObject *Sender)
{
    TOpenDialog* OpenMediaDialog;

    OpenMediaDialog = new TOpenDialog(this);
    OpenMediaDialog->Filter = "All Video Files (*.avi)|*.avi";
  // There are avi files in
  // C:\Documents and Settings\All Users\Documents\RAD
Studio\6.0\Demos\DelphiWin32\VCLWin32\CoolStuff
    if (OpenMediaDialog->Execute())
    {
        /* Assign a file to the media player */
        MediaPlayer1->FileName = OpenMediaDialog->FileName;

        /* Check if the file exists and is not a directory */
        if ((FileExists(OpenMediaDialog->FileName)) &&
           (!DirectoryExists(OpenMediaDialog->FileName)))
        {
            /* Open the files */
            MediaPlayer1->Wait = true;
            MediaPlayer1->Open();
            MediaPlayer1->Play();

            /* Override automatic button controlling */
            MediaPlayer1->EnabledButtons =
                TButtonSet() <<
                TMPBtnType::btPause <<
                TMPBtnType::btStop <<
                TMPBtnType::btPlay;

            /* Enable  the stop button */
            btStop->Enabled = true;
            btOpen->Enabled = false;
        }
    }

    delete OpenMediaDialog;
```

```
}

void __fastcall TForm2::btStopClick(TObject *Sender)
{
    /* Stop and close the media */
    MediaPlayer1->Stop();
    MediaPlayer1->Close();

    MediaPlayer1->EnabledButtons = TButtonSet();

    /* Enable open button again */
    btOpen->Enabled = true;
}

void __fastcall TForm2::FormCreate(TObject *Sender)
{
    /* Disable all buttons */

}
```

Delphi Examples:

```
{
This example demonstrates the use of TMediaPlayer component. Assuming 2 buttons
for Open and Stop are present on the form.
Note: AutoEnable must be set to false to be able to control
the buttons manually.
}

procedure TForm2.btOpenClick(Sender: TObject);
var
  OpenMediaDialog : TOpenDialog;
begin
  OpenMediaDialog := TOpenDialog.Create(Self);
  OpenMediaDialog.Filter := 'All Video Files (*.avi)|*.avi';
  // There are avi files in
  // C:\Documents and Settings\All Users\Documents\RAD
Studio\6.0\Demos\DelphiWin32\VCLWin32\CoolStuff
  if OpenMediaDialog.Execute() then
  begin
    { Assign a file to the media player }
    MediaPlayer1.FileName := OpenMediaDialog.FileName;

    { Check if the file exists and is not a directory }
    if (FileExists(OpenMediaDialog.FileName)) and
       (not DirectoryExists(OpenMediaDialog.FileName)) then
    begin
      { Open the files }
      MediaPlayer1.Wait := true;
      MediaPlayer1.Open;
      MediaPlayer1.Play;

      { Override automatic button controlling }
      MediaPlayer1.EnabledButtons :=
        [TMPBtnType.btPause, TMPBtnType.btStop, TMPBtnType.btPlay];

      { Enable  the stop button }
      btStop.Enabled := true;
      btOpen.Enabled := false;
```

```
    end;
  end;

  OpenMediaDialog.Free;
end;

procedure TForm2.btStopClick(Sender: TObject);
begin
  { Stop and close the media }
  MediaPlayer1.Stop;
  MediaPlayer1.Close;

  MediaPlayer1.EnabledButtons := [];

  { Enable open button again }
  btOpen.Enabled := true;
end;

procedure TForm2.FormCreate(Sender: TObject);
begin
  { Disable all buttons }
  MediaPlayer1.AutoEnable := false;
  MediaPlayer1.EnabledButtons := [];
end;

procedure TForm2.MediaPlayer1PostClick(Sender: TObject;
  Button: TMPBtnType);
begin
  if Button = TMPBtnType.btStop then

54.1.2.5.19 TMediaPlayer.Frames Property

Specifies the number of frames moved forward or backward.

Pascal

```
property Frames: Longint;
```

C++

```
__property Longint Frames;
```

Description

Frames specifies the number of frames the Step (see page 5774) method steps forward or the Back (see page 5757) method steps backward. Frames defaults to ten percent of the length of the currently loaded medium, which is specified by the Length (see page 5794) property.

The definition of a frame varies by multimedia device. For display media, a frame is one still image.

See Also

Back (see page 5757)

Length (see page 5794)

Step (see page 5774)

54.1.2.5.20 TMediaPlayer.Length Property

Specifies the length of the medium in the open multimedia device.

Pascal

```
property Length: Longint;
```

C++

```
__property Longint Length;
```

Description

Length is specified using the current time format, which is specified by the TimeFormat (see page 5805) property.

See Also

TimeFormat (see page 5805)

54.1.2.5.21 TMediaPlayer.Mode Property

Indicates the state of the currently open multimedia device.

Pascal

```
property Mode: TMPModes;
```

C++

```
__property TMPModes Mode;
```

Description

Mode specifies the current state or mode of the currently open multimedia device.

The TMPModes (see page 5823) type defines the modes for a multimedia device used with a TMediaPlayer (see page 5749).

See Also

OnNotify (see page 5817)

54.1.2.5.22 TMediaPlayer.Notify Property

Determines whether an OnNotify (see page 5817) event is generated.

Pascal

```
property Notify: Boolean;
```

C++

```
__property Boolean Notify;
```

Description

Notify determines whether the next call to a media control method (Back (see page 5757), Close (see page 5758), Eject (see page 5759), Next (see page 5762), Open (see page 5763), Pause (see page 5766), PauseOnly (see page 5767), Play (see page 5767), Previous (see page 5771), StartRecording (see page 5773), Resume (see page 5771), Rewind (see page 5772), Step (see page 5774), or Stop (see page 5774)) generates an OnNotify (see page 5817) event when the method has completed.

If Notify is true, the next media control method generates OnNotify (see page 5817) event upon completion and stores the notification message in the NotifyValue (see page 5795) property. If Notify is false, the method does not generate an OnNotify

(see page 5817) event and NotifyValue (see page 5795) remains unchanged.

Notify affects only the next call to a media control method. After an OnNotify (see page 5817) event, Notify must be reset to affect any subsequent media control methods.

By default, Play (see page 5767) and StartRecording (see page 5773) function as if Notify is true. Set Notify to false before calling Play (see page 5767) or StartRecording (see page 5773) to prevent an OnNotify (see page 5817) event from being generated when playing or recording has finished. By default, all other media control methods function as if Notify is false.

Tip: Set Notify to true if the next media control is expected to take a long time, so the application is notified when the media control method has completed. If Notify is set to true, it is recommended to set Wait (see page 5809) to false so that control returns to the application before the media control method is finished.

Note: When trying to resume a device that doesn't support Resume (see page 5771), the device is resumed as if the Play (see page 5767) method was called. If Notify was assigned true before calling Resume (see page 5771) (or any other media control method), Notify doesn't affect the call to Resume (see page 5771). Resume (see page 5771) does not generate an OnNotify (see page 5817) event upon completion, and NotifyValue (see page 5795) remains unchanged.

OnNotify (see page 5817)

Resume (see page 5771)

Wait (see page 5809)

54.1.2.5.23 TMediaPlayer.NotifyValue Property

Indicates the result of the last media control method that requested a notification.

Pascal

```
property NotifyValue: TMPNotifyValues;
```

C++

```
__property TMPNotifyValues NotifyValue;
```

Description

NotifyValue reports the result of the last media control method (Back (see page 5757), Close (see page 5758), Eject (see page 5759), Next (see page 5762), Open (see page 5763), Pause (see page 5766), PauseOnly (see page 5767), Play (see page 5767), Previous (see page 5771), StartRecording (see page 5773), Resume (see page 5771), Rewind (see page 5772), Step (see page 5774), or Stop (see page 5774)) that requested a notification.

To request notification, set Notify (see page 5794) to true before calling a media control method.

See Also

OnNotify (see page 5817)

Notify (see page 5794)

54.1.2.5.24 TMediaPlayer.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

54.1.2.5.25 TMediaPlayer.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

54.1.2.5.26 TMediaPlayer.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup

property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
```

```
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}
```

```
void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
```

```
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

OnContextPopup

54.1.2.5.27 TMediaPlayer.Position Property

Specifies the current position within the currently loaded medium.

Pascal

```
property Position: Longint;
```

C++

```
__property Longint Position;
```

Description

The value of Position is specified according to the current time format, which is specified in the TimeFormat (see page 5805) property.

Position defaults to the beginning of the medium. If the medium supports multiple tracks, Position defaults to the beginning of the first track.

See Also

TimeFormat (see page 5805)

54.1.2.5.28 TMediaPlayer.Shareable Property

Determines whether more than one application can share a multimedia device.

Pascal

```
property Shareable: Boolean;
```

C++

```
__property Boolean Shareable;
```

Description

If Shareable is false, no other components or applications can access the device. If Shareable is true, more than one component or application can access the device. Shareable defaults to false.

Be sure to set Shareable before opening a device.

Some devices are not shareable. If Shareable is set to true for a device that isn't shareable, the Open (see page 5763) method fails and the error code is returned to the Error (see page 5789) property.

See Also

Error (see page 5789)

Open (see page 5763)

54.1.2.5.29 TMediaPlayer.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
```

```
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

54.1.2.5.30 TMediaPlayer.Start Property

Specifies the starting position within the currently loaded medium.

Pascal

```
property Start: Longint;
```

C++

```
__property Longint Start;
```

Description

Start is the beginning of the medium for devices that don't use tracks, or the beginning of the first track for devices that use tracks. Start is defined when a multimedia device is opened with the Open (see page 5763) method. Start is specified according to the current time format, which is stored in the TimeFormat (see page 5805) property. Start is read-only at runtime and is unavailable at design time.

See Also

Open (see page 5763)

TimeFormat (see page 5805)

54.1.2.5.31 TMediaPlayer.StartPos Property

Specifies the position within the currently loaded medium from which to begin playing or recording.

Pascal

```
property StartPos: Longint;
```

C++

```
__property Longint StartPos;
```

Description

StartPos is specified using the current time format, which is specified in the TimeFormat (see page 5805) property.

The StartPos property affects only the next Play (see page 5767) or StartRecording (see page 5773) method called after setting StartPos. Reset must be set to StartPos to affect any subsequent calls to Play (see page 5767) or StartRecording (see page 5773).

StartPos does not affect the current position of the medium (specified in the Position (see page 5801) property) until the next Play (see page 5767) or StartRecording (see page 5773) method is called.

See Also

Play (see page 5767)

StartRecording (see page 5773)

TimeFormat (see page 5805)

54.1.2.5.32 TMediaPlayer.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

54.1.2.5.33 TMediaPlayer.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

54.1.2.5.34 TMediaPlayer.TimeFormat Property

Determines the format used to specify position information.

Pascal

```
property TimeFormat: TMPTimeFormats;
```

C++

```
__property TMPTimeFormats TimeFormat;
```

Description

TimeFormat determines how the StartPos (see page 5804), Length (see page 5794), Position (see page 5801), Start (see page 5804), and EndPos (see page 5789) properties are interpreted. For example, if Position (see page 5801) is 180 and TimeFormat is tfMilliseconds, the current position is 180 milliseconds into the medium. If Position (see page 5801) is 180 and TimeFormat is tfMSF, the current position is 180 minutes into the medium.

Not all formats are supported by every device. When trying to set an unsupported format, the assignment is ignored.

The current timing information is always passed in a 4-byte integer. In some formats, the timing information returned is not really one integer, but single bytes of information packed in the long integer.

See Also

EndPos (see page 5789)

Length (see page 5794)

Position (see page 5801)

Start (see page 5804)

StartPos (see page 5804)

54.1.2.5.35 TMediaPlayer.TrackLength Property

Reports the length of the track.

Pascal

```
property TrackLength [TrackNum: Integer]: Longint;
```

C++

```
__property Longint TrackLength[int TrackNum];
```

Description

TrackLength reports the length of the track specified by the TrackNum index.

The value of TrackLength is specified according to the current time format, which is specified in the TimeFormat (see page 5805) property.

See Also

TimeFormat (see page 5805)

Tracks (see page 5807)

54.1.2.5.36 TMediaPlayer.TrackPosition Property

Reports the starting position of the track.

Pascal

```
property TrackPosition [TrackNum: Integer]: Longint;
```

C++

```
__property Longint TrackPosition[int TrackNum];
```

Description

TrackPosition reports the starting position of the track specified by the TrackNum index.

The value of TrackPosition is specified according to the current time format, which is specified in the TimeFormat (see page 5805) property.

See Also

TimeFormat (see page 5805)

Tracks (see page 5807)

54.1.2.5.37 TMediaPlayer.Tracks Property

Specifies the number of playable tracks on the open multimedia device.

Pascal

```
property Tracks: Longint;
```

C++

```
__property Longint Tracks;
```

Description

Tracks indicates how many of playable tracks are available on the open multimedia device.

Tracks is undefined for devices that don't use tracks.

See Also

TrackLength (see page 5806)

TrackPosition (see page 5806)

Adding Audio and/or Video Clips to an Application

54.1.2.5.38 TMediaPlayer.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
```

```
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

VisibleChanging

54.1.2.5.39 TMediaPlayer.VisibleButtons Property

Indicates which of the buttons on the media player are visible.

Pascal

```
property VisibleButtons: TButtonSet;
```

C++

```
__property TButtonSet VisibleButtons;
```

Description

VisibleButtons determines which buttons on the media player that are visible. If a button is not made visible with VisibleButtons, it does not appear on the media player control. By default, all buttons are visible when a media player component is added to a form.

ColoredButtons (see page 5781)

EnabledButtons (see page 5786)

54.1.2.5.40 TMediaPlayer.Wait Property

Determines whether a media control method returns control to the application only after it has been completed.

Pascal

```
property Wait: Boolean;
```

C++

```
__property Boolean Wait;
```

Description

Wait determines whether a media control method (Back (see page 5757), Close (see page 5758), Eject (see page 5759), Next (see page 5762), Open (see page 5763), Pause (see page 5766), PauseOnly (see page 5767), Play (see page 5767), Previous (see page 5771), StartRecording (see page 5773), Resume (see page 5771), Rewind (see page 5772), Step (see page 5774), or Stop (see page 5774)) returns control to the application only after it has been completed.

Wait is unavailable at design time.

If Wait is true, the media player component waits until the next media control method has completed before returning control to the application. If Wait is false, the application won't wait for the next media control method to finish before continuing.

Wait affects only the next media control method called after setting Wait. Wait must be reset to affect any subsequent call to a media control method.

By default, Play (see page 5767) and StartRecording (see page 5773) function as if Wait is false. Wait must be set to true before calling Play (see page 5767) or StartRecording (see page 5773) to prevent control from returning to the application before playing or recording has finished. By default, all other media control methods function as if Wait is true.

Note: Wait is usually set to false only if the next media control is expected to take a long time, so that the application can execute other code before the media control method has completed. If Wait is set to false, you should set Notify (see page 5794) to true so the application is notified when the media control method completes.

Notify (see page 5794)

54.1.2.6 TMediaPlayer Events

The events of the TMediaPlayer class are listed here.

Published Events

	Name	Description
	OnClick (see page 5810)	Occurs when the user presses and releases the mouse button while the mouse pointer is over one of the control buttons, or when the user presses Spacebar while the media player control has focus.
	OnContextPopup (see page 5811)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnEnter (see page 5811)	Occurs when a control receives the input focus.
	OnExit (see page 5814)	Occurs when the input focus shifts away from one control to another.
	OnMouseEnter (see page 5817)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5817)	Occurs when the user moves the mouse outside of a control.
	OnNotify (see page 5817)	Occurs upon the completion of a media control method.
	OnPostClick (see page 5818)	Occurs after the OnClick (see page 5810) event handler is called.

54.1.2.6.1 TMediaPlayer.OnClick Event

Occurs when the user presses and releases the mouse button while the mouse pointer is over one of the control buttons, or when the user presses Spacebar while the media player control has focus.

Pascal

```
property OnClick: EMPNotify;
```

C++

```
__property EMPNotify OnClick;
```

Description

When the media player control has focus and the Spacebar is pressed, the user can use the Left Arrow or Right Arrow keys to select which control button to click.

The EMPNotify (see page 5827) type is a method pointer that is called when an OnClick event for a TMediaPlayer (see page 5749) components occurs. The Button argument can be one of the following values: btBack, btEject, btNext, btPause, btPlay, btPrev, btRecord, btStep, or btStop.

The default value of the event handler's DoDefault argument is true. If DoDefault is true, the media player control calls the method that corresponds to the clicked button. For example, if the user clicks the Play (see page 5767) button (btPlay), the Play (see page 5767) method is called.

If DoDefault is false, the user must write code that executes when a media player control button is clicked in the OnClick event handler. The following table lists the default methods corresponding to the media player control buttons:

Control button	Button value	Method called
Play (see page 5767)	btPlay	Play (see page 5767)
Record	btRecord	StartRecording (see page 5773)
Stop (see page 5774)	btStop	Stop (see page 5774)
Next (see page 5762)	btNext	Next (see page 5762)

Prev	btPrev	Previous (see page 5771)
Step (see page 5774)	btStep	Step (see page 5774)
Back (see page 5757)	btBack	Back (see page 5757)
Pause (see page 5766)	btPause	Pause (see page 5766)
Eject (see page 5759)	btEject	Eject (see page 5759)

See Also

Click (see page 5757)

54.1.2.6.2 TMediaPlayer.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

PopupMenu

AutoPopup (see page 4942)

54.1.2.6.3 TMediaPlayer.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   (dynamic_cast<TEdit *>(myActiveControl))->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    (dynamic_cast<TRichEdit *>(myActiveControl))->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
```

```
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;
```

```
procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

54.1.2.6.4 TMediaPlayer.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
```

```
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

procedure TForm1.MaskEdit2Exit(Sender: TObject);
var
  net1, net2, host1, host2,
  netmask1, netmask2, hostmask1, hostmask2,
```

```
    sub_net1, sub_net2, sub_host1, sub_host2: Integer;

    IP, mask: String;

  begin
    // extract the net and host address from the IP
    IP := MaskEdit1.Text;
    net1 := StrToInt(TrimRight(Copy(IP, 0, 3)));
    net2 := StrToInt(TrimRight(Copy(IP, 5, 3)));
    host1 := StrToInt(TrimRight(Copy(IP, 9, 3)));
    host2 := StrToInt(TrimRight(Copy(IP, 13, 3)));

    // a range test that you cannot validate through edit masks
    if ((net1 < 0) Or (net1 > 255) Or
        (net2 < 0) Or (net2 > 255) Or
        (host1 < 0) Or (host1 > 255) Or
        (host2 < 0) Or (host2 > 255)) then
      raise EArgumentException.Create('Not a valid IP address.');

    // extract the net and host mask from the subnet mask
    mask := MaskEdit2.Text;
    netmask1 := StrToInt(TrimRight(Copy(mask, 0, 3)));
    netmask2 := StrToInt(TrimRight(Copy(mask, 5, 3)));
    hostmask1 := StrToInt(TrimRight(Copy(mask, 9, 3)));
    hostmask2 := StrToInt(TrimRight(Copy(mask, 13, 3)));

    // a range test that you cannot validate through edit masks
    if ((netmask1 < 0) Or (netmask1 > 255) Or
        (netmask2 < 0) Or (netmask2 > 255) Or
        (hostmask1 < 0) Or (hostmask1 > 255) Or
        (hostmask2 < 0) Or (hostmask2 > 255)) then
      raise EArgumentException.Create('Not a valid subnet mask.');

    // compute the subnet address using bit-wise AND
    sub_net1 := net1 And netmask1;
    sub_net2 := net2 And netmask2;
    sub_host1 := host1 And hostmask1;
    sub_host2 := host2 And hostmask2;

    // display the subnet address
    MaskEdit3.Text :=
      IntToStr(sub_net1) + '.' + IntToStr(sub_net2) + '.' +
      IntToStr(sub_host1) + '.' + IntToStr(sub_host2);
  end;
  {
  This example uses an edit box and a memo control on a form.
  When either the edit box or the memo is the active control,
  it is colored yellow. When the active control becomes
  inactive, the color of the control returns to the Windows
  system color for a window.  These event handlers could also
  be shared.
  }
  procedure TForm1.Edit1Enter(Sender: TObject);
  begin
    Edit1.Color := clYellow;
  end;

  procedure TForm1.Edit1Exit(Sender: TObject);
  begin
    Edit1.Color := clWindow;
  end;

  procedure TForm1.Memo1Enter(Sender: TObject);
  begin
    Memo1.Color := clYellow;
  end;
```

```
procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

OnEnter

ActiveControl (see page 2145)

54.1.2.6.5 TMediaPlayer.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

54.1.2.6.6 TMediaPlayer.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

54.1.2.6.7 TMediaPlayer.OnNotify Event

Occurs upon the completion of a media control method.

Pascal

```
property OnNotify: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnNotify;
```

Description

OnNotify occurs upon the completion of a media control method (Back (see page 5757), Close (see page 5758), Eject (see page 5759), Next (see page 5762), Open (see page 5763), Pause (see page 5766), PauseOnly (see page 5767), Play (see page 5767), Previous (see page 5771), Resume (see page 5771), Rewind (see page 5772), StartRecording (see page 5773), Step (see page 5774), or Stop (see page 5774)) when the Notify (see page 5794) property is set to true before the call to the media control method. After an OnNotify event, the Notify (see page 5794) property must be reset to

true for the next OnNotify event to occur.

See Also

DoNotify (see page 5759)

MMNotify (see page 5762)

Notify (see page 5794)

54.1.2.6.8 TMediaPlayer.OnPostClick Event

Occurs after the OnClick (see page 5810) event handler is called.

Pascal

```
property OnPostClick: EMPPostNotify;
```

C++

```
__property EMPPostNotify OnPostClick;
```

Description

OnPostClick is generated after the code of the OnClick (see page 5810) event handler has been called. If Wait (see page 5809) is true when the media player was clicked, OnPostClick won't be called until the completion of the OnClick (see page 5810) code. If Wait (see page 5809) is false, control can return to the application before completion of the OnClick (see page 5810) code; therefore, the OnPostClick event may occur before the actions initiated by the OnClick (see page 5810) event have completed.

For example, if the user clicks the Play (see page 5767) button and the DoDefault parameter of the OnClick (see page 5810) event handler for the media player is true, the media is played. If the media is long enough, it will still be playing when the OnPostClick event is generated if Wait (see page 5809) is true. If Wait (see page 5809) is false, however, OnPostClick won't occur until the media has finished playing.

54.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TMPBtnType (see page 5819)	TMPBtnType defines the possible buttons in a TMediaPlayer (see page 5749) component and TButtonSet (see page 5828) represents a set of those buttons.
	TMPDevCaps (see page 5821)	TMPDevCaps defines the capabilities of a TMediaPlayer (see page 5749) component and TMPDevCapsSet (see page 5828) represents a set of those capabilities.
	TMPDeviceTypes (see page 5821)	TMPDeviceTypes identifies a multimedia device.
	TMPGlyph (see page 5823)	This is record MPlayer.TMPGlyph.
	TMPModes (see page 5823)	TMPModes identifies the state of a TMediaPlayer (see page 5749) component.
	TMPNotifyValues (see page 5824)	TMPNotifyValues identifies the types of notifications a media device can give a TMediaPlayer (see page 5749) component.
	TMPTimeFormats (see page 5825)	TMPTimeFormats indicates the format a media player uses to indicate position.

Records

	Name	Description
	TMPButton (see page 5820)	This is record MPlayer.TMPButton.

54.2.1 MPlayer.TMPBtnType Enumeration

TMPBtnType defines the possible buttons in a TMediaPlayer (see page 5749) component and TButtonSet (see page 5828) represents a set of those buttons.

Pascal

```
TMPBtnType = (
  btPlay,
  btPause,
  btStop,
  btNext,
  btPrev,
  btStep,
  btBack,
  btRecord,
  btEject
);
```

C++

```
enum TMPBtnType {
  btPlay,
  btPause,
  btStop,
  btNext,
  btPrev,
  btStep,
  btBack,
  btRecord,
  btEject
};
```

File

MPlayer

Description

TMPBtnType represents the type of a media player button. TButtonSet (see page 5828) is a set of button types for the media player.

Each button type has an associated action on the media player. The following table lists the button types and their associated actions:

Value	Action
btPlay	Plays the media player.
btRecord	Starts recording.
btStop	Stops playing or recording.
btNext	Skips to the next track, or to the end if the medium doesn't use tracks.
btPrev	Skips to the previous track, or to the beginning if the medium doesn't use tracks.
btStep	Moves forward a number of frames.
btBack	Moves backward a number of frames.
btPause	Pauses playing or recording. If already paused when clicked, resumes playing or recording.
btEject	Ejects the medium.

54.2.2 MPlayer.TMPButton Record

Pascal

```
TMPButton = record
  Visible: Boolean;
  Enabled: Boolean;
  Colored: Boolean;
  Auto: Boolean;
  Bitmaps: array[TMPGlyph] of TBitmap;
end;
```

C++

```
struct TMPButton {
  Boolean Visible;
  Boolean Enabled;
  Boolean Colored;
  Boolean Auto;
  array[TMPGlyph] of TBitmap Bitmaps;
};
```

File

MPlayer

Description

This is record MPlayer.TMPButton.

54.2.3 MPlayer.TMPDevCaps Enumeration

TMPDevCaps defines the capabilities of a TMediaPlayer (see page 5749) component and TMPDevCapsSet (see page 5828) represents a set of those capabilities.

Pascal

```
TMPDevCaps = (
  mpCanStep,
  mpCanEject,
  mpCanPlay,
  mpCanRecord,
  mpUsesWindow
);
```

C++

```
enum TMPDevCaps {
  mpCanStep,
  mpCanEject,
  mpCanPlay,
  mpCanRecord,
  mpUsesWindow
};
```

File

MPlayer

Description

TMPDevCaps represents the capabilities of a media player control. TMPDevCapsSet (see page 5828) is a set of TMPDevCaps values.

The following table lists the possible TMPDevCaps values:

Value	Capability
mpCanEject	Can eject media
mpCanPlay	Can play media
mpCanRecord	Can record media
mpCanStep	Can step forward or backward within media
mpUsesWindow	Uses a window for displaying output

TMediaPlayer

54.2.4 MPlayer.TMPDeviceTypes Enumeration

TMPDeviceTypes identifies a multimedia device.

Pascal

```
TMPDeviceTypes = (
  dtAutoSelect,
  dtAVIVideo,
  dtCDAudio,
  dtDAT,
  dtDigitalVideo,
  dtMMMovie,
  dtOther,
  dtOverlay,
  dtScanner,
  dtSequencer,
  dtVCR,
  dtVideodisc,
  dtWaveAudio
);
```

C++

```
enum TMPDeviceTypes {
  dtAutoSelect,
  dtAVIVideo,
  dtCDAudio,
  dtDAT,
  dtDigitalVideo,
  dtMMMovie,
  dtOther,
  dtOverlay,
  dtScanner,
  dtSequencer,
  dtVCR,
  dtVideodisc,
  dtWaveAudio
};
```

File

MPlayer

Description

TMPDeviceTypes type identifies the multimedia device types that can be opened by a TMediaPlayer (see page 5749) component.

The following table lists the possible values:

Value	Meaning
dtAutoSelect	the device type is determined by the file extension.
dtAVIVideo	AVI clip
dtCDAudio	Audio CD recording
dtDAT	DAT file
dtDigitalVideo	Digital video recording
dtMMMovie	MM recording
dtOther	media type not identified by other categories
dtOverlay	Overlay
dtScanner	scanner
dtSequencer	sequencer
dtVCR	VCR

dtVideodisc	Videodisc
dtWaveAudio	.wav file

54.2.5 MPlayer.TMPGlyph Enumeration

Pascal

```
TMPGlyph = (
  mgEnabled,
  mgDisabled,
  mgColored
);
```

C++

```
enum TMPGlyph {
  mgEnabled,
  mgDisabled,
  mgColored
};
```

File

MPlayer

Description

This is record MPlayer.TMPGlyph.

54.2.6 MPlayer.TMPModes Enumeration

TMPModes identifies the state of a TMediaPlayer (see page 5749) component.

Pascal

```
TMPModes = (
  mpNotReady,
  mpStopped,
  mpPlaying,
  mpRecording,
  mpSeeking,
  mpPaused,
  mpOpen
);
```

C++

```
enum TMPModes {
  mpNotReady,
  mpStopped,
  mpPlaying,
  mpRecording,
  mpSeeking,
  mpPaused,
  mpOpen
```

```
};
```

File

MPlayer

Description

TMPModes type identifies the state of a media player. The following table lists the possible values:

Value	Mode
mpNotReady	Not ready
mpStopped	Stopped
mpPlaying	Playing
mpRecording	Recording
mpSeeking	Seeking
mpPaused	Paused
mpOpen	Open

TMediaPlayer

54.2.7 MPlayer.TMPNotifyValues Enumeration

TMPNotifyValues identifies the types of notifications a media device can give a TMediaPlayer (see page 5749) component.

Pascal

```
TMPNotifyValues = (
  nvSuccessful,
  nvSuperseded,
  nvAborted,
  nvFailure
);
```

C++

```
enum TMPNotifyValues {
  nvSuccessful,
  nvSuperseded,
  nvAborted,
  nvFailure
};
```

File

MPlayer

Description

The TMPNotifyValues type defines the notification values for a multimedia device used with a TMediaPlayer (see page 5749). The possible values for the TMPNotifyValues type are as follows.

Value	Meaning
nvSuccessful	Command completed successfully
nvSuperseded	Command was superseded by another command

nvAborted	Command was aborted by the user
nvFailure	Command failed

TMediaPlayer

54.2.8 MPlayer.TMPTimeFormats Enumeration

TMPTimeFormats indicates the format a media player uses to indicate position.

Pascal

```
TMPTimeFormats = (
  tfMilliseconds,
  tfHMS,
  tfMSF,
  tfFrames,
  tfSMPTE24,
  tfSMPTE25,
  tfSMPTE30,
  tfSMPTE30Drop,
  tfBytes,
  tfSamples,
  tfTMSF
);
```

C++

```
enum TMPTimeFormats {
  tfMilliseconds,
  tfHMS,
  tfMSF,
  tfFrames,
  tfSMPTE24,
  tfSMPTE25,
  tfSMPTE30,
  tfSMPTE30Drop,
  tfBytes,
  tfSamples,
  tfTMSF
};
```

File

MPlayer

Description

The TMPTimeFormats type defines the time formats for a multimedia device used with a TMediaPlayer (see page 5749). The following table lists the possible values for the TMPTimeFormats type:

Value	Time format
tfMilliseconds	Milliseconds are stored as a 4-byte integer variable.
tfHMS	Hours, minutes, and seconds packed into a 4-byte integer. From least significant to most significant byte, the data values are
Hours (least significant byte)	
Minutes	

Seconds	
Unused (most significant byte)	
tfMSF	Minutes, seconds, and frames packed into a 4-byte integer. From least significant to most significant byte, the data values are
Minutes (least significant byte)	
Seconds	
Frames	
Unused (most significant byte)	
tfFrames	Frames are stored as a 4-byte integer variable.
tfSMPTE24	24-frame SMPTE packs values in a 4-byte variable. From least significant to most significant byte, the data values are
Hours (least significant byte)	
Minutes	
Seconds	
Frames (most significant byte)	
SMPTE (Society of Motion Picture and Television Engineers) time is an absolute time format expressed in hours, minutes, seconds, and frames. The standard SMPTE division types are 24, 25, and 30 frames per second.	
tfSMPTE25	25-frame SMPTE packs data into a 4-byte variable in the same order as 24-frame SMPTE.
tfSMPTE30	30-frame SMPTE packs data into the 4-byte variable in the same order as 24-frame SMPTE.
tfSMPTE30Drop	30-drop-frame SMPTE packs data into the 4-byte variable in the same order as 24-frame SMPTE.
tfBytes	Bytes are stored as a 4-byte integer variable.
tfSamples	Samples are stored as a 4-byte integer variable.
tfTMSF	Tracks, minutes, seconds, and frames are packed in the 4-byte variable. From least significant to most significant byte, the data values are
Tracks (least significant byte)	
Minutes	
Seconds	
Frames (most significant byte)	

Note that MCI uses continuous track numbering.

Note: Functions provided with MCI to help decoding the 4-byte integer specified in a given time format are documented under MCI Macros for Encoding and Decoding Time Data in the MMSYSTEM.HLP Help file.

TMediaPlayer

54.3 Types

The following table lists types in this documentation.

Types

Name	Description
EMPNotify (see page 5827)	EMPNotify is the type of event handlers that respond when the user interacts with a TMediaPlayer (see page 5749) component.
EMPPostNotify (see page 5827)	EMPPostNotify is the type of a media player's OnPostClick event handler.
TButtonSet (see page 5828)	TButtonSet is a set of TMPBtnType (see page 5819) values.
TMediaDevice (see page 5828)	This is type MPlayer.TMediaDevice.
TMPDevCapsSet (see page 5828)	This is type MPlayer.TMPDevCapsSet.

54.3.1 MPlayer.EMPNotify Type

EMPNotify is the type of event handlers that respond when the user interacts with a TMediaPlayer (see page 5749) component.

Pascal

```
EMPNotify = procedure (Sender: TObject; Button: TMPBtnType; var DoDefault: Boolean) of object;
```

C++

```
(Sender: TObject; Button: TMPBtnType; var DoDefault: Boolean) ( EMPNotify)();
```

File

MPlayer

Description

Sender is the TMediaPlayer (see page 5749) component whose button was clicked.

Button indicates the button that was clicked. It can be one of the following values: btBack, btEject, btNext, btPause, btPlay, btPrev, btRecord, btStep, or btStop.

DoDefault returns an indication of whether the media player should make its default response after the event handler exits.

See Also

TMediaPlayer

54.3.2 MPlayer.EMPPostNotify Type

EMPPostNotify is the type of a media player's OnPostClick event handler.

Pascal

```
EMPPostNotify = procedure (Sender: TObject; Button: TMPBtnType) of object;
```

C++

```
(Sender: TObject; Button: TMPBtnType) ( EMPPostNotify)();
```

File

MPlayer

Description

Sender is the TMediaPlayer (see page 5749) component whose button was clicked.

Button indicates the button that was clicked. It can be one of the following values: btBack, btEject, btNext, btPause, btPlay, btPrev, btRecord, btStep, or btStop.

See Also

TMediaPlayer (see page 5749)

54.3.3 MPlayer.TButtonSet Type

TButtonSet is a set of TMPBtnType (see page 5819) values.

Pascal

```
TButtonSet = set of TMPBtnType;
```

C++

```
TMPBtnType TButtonSet;
```

File

MPlayer

Description

TButtonSet represents a set of zero or more of the buttons that can appear on a TMPDeviceType control.

54.3.4 MPlayer.TMediaDevice Type

Pascal

```
TMediaDevice = Word;
```

C++

```
Word TMediaDevice;
```

File

MPlayer

Description

This is type MPlayer.TMediaDevice.

54.3.5 MPlayer.TMPDevCapsSet Type

Pascal

```
TMPDevCapsSet = set of TMPDevCaps;
```

C++

```
TMPDevCaps TMPDevCapsSet;
```

File

MPlayer

Description

This is type MPlayer.TMPDevCapsSet.

55 Mtsobj Namespace

This is namespace Mtsobj.

Topics

Name	Description
Classes (see page 5832)	The following table lists classes in this documentation.

Classes

	Name	Description
	TMtsAutoObject (see page 5832)	TMtsAutoObject encapsulates the objects and interfaces of the MTS application server.

55.1 Classes

The following table lists classes in this documentation.

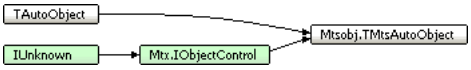
Classes

	Name	Description
	TMtsAutoObject (see page 5832)	TMtsAutoObject encapsulates the objects and interfaces of the MTS application server.

55.1.1 TMtsAutoObject Class

TMtsAutoObject encapsulates the objects and interfaces of the MTS application server.

Class Hierarchy



Pascal

```
TMtsAutoObject = class(TAutoObject, IObjectControl);
```

C++

```
class TMtsAutoObject : public TAutoObject, public IObjectControl;
```

File

Mtsobj

Description

Use a TMtsAutoObject object as the central repository for all objects in an MTS-enabled application server.

MTS Automation objects are dual-interface Automation servers that implement the IObjectControl (see page 5866) interface. MTS Automation objects are like any Automation server with additional features that encapsulate MTS services such as transaction support and security.

55.1.1.1 TMtsAutoObject Members

The following tables list the members exposed by TMtsAutoObject.

Protected Methods

	Name	Description
	Activate (see page 5833)	This is Activate, a member of class TMtsAutoObject.
	CanBePooled (see page 5834)	This is CanBePooled, a member of class TMtsAutoObject.
	Deactivate (see page 5834)	This is Deactivate, a member of class TMtsAutoObject.

	OnActivate (see page 5836)	This is OnActivate, a member of class TMtsAutoObject.
	OnDeactivate (see page 5837)	This is OnDeactivate, a member of class TMtsAutoObject.

Protected Properties

	Name	Description
	ObjectContext (see page 5838)	This is ObjectContext, a member of class TMtsAutoObject.

Public Methods

	Name	Description
	DisableCommit (see page 5834)	Prevents clients from completing transactions.
	EnableCommit (see page 5835)	Allows clients to complete transactions without releasing state information.
	IsCallerInRole (see page 5835)	Indicates whether the current client matches a particular security role.
	IsInTransaction (see page 5836)	Indicates whether the MTS Automation object is running in a transaction.
	IsSecurityEnabled (see page 5836)	This is IsSecurityEnabled, a member of class TMtsAutoObject.
	SetAbort (see page 5837)	Allows the MTS Automation object to be deactivated and aborts any current transactions.
	SetComplete (see page 5837)	Indicates that the MTS Automation object has successfully completed its current task.

Public Properties

	Name	Description
	Pooled (see page 5838)	Indicates whether the object can be pooled when installed under COM+.

55.1.1.2 TMtsAutoObject Methods

The methods of the TMtsAutoObject class are listed here.

Protected Methods

	Name	Description
	Activate (see page 5833)	This is Activate, a member of class TMtsAutoObject.
	CanBePooled (see page 5834)	This is CanBePooled, a member of class TMtsAutoObject.
	Deactivate (see page 5834)	This is Deactivate, a member of class TMtsAutoObject.
	OnActivate (see page 5836)	This is OnActivate, a member of class TMtsAutoObject.
	OnDeactivate (see page 5837)	This is OnDeactivate, a member of class TMtsAutoObject.

Public Methods

	Name	Description
	DisableCommit (see page 5834)	Prevents clients from completing transactions.
	EnableCommit (see page 5835)	Allows clients to complete transactions without releasing state information.
	IsCallerInRole (see page 5835)	Indicates whether the current client matches a particular security role.
	IsInTransaction (see page 5836)	Indicates whether the MTS Automation object is running in a transaction.
	IsSecurityEnabled (see page 5836)	This is IsSecurityEnabled, a member of class TMtsAutoObject.
	SetAbort (see page 5837)	Allows the MTS Automation object to be deactivated and aborts any current transactions.
	SetComplete (see page 5837)	Indicates that the MTS Automation object has successfully completed its current task.

55.1.1.2.1 TMtsAutoObject.Activate Method

Pascal

```
procedure Activate; safecall;
```

C++

```
__fastcall Activate();
```

Description

This is Activate, a member of class TMtsAutoObject.

55.1.1.2.2 TMtsAutoObject.CanBePooled Method

Pascal

```
function CanBePooled: Bool; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall Bool CanBePooled();
```

Description

This is CanBePooled, a member of class TMtsAutoObject.

55.1.1.2.3 TMtsAutoObject.Deactivate Method

Pascal

```
procedure Deactivate; stdcall;
```

C++

```
__fastcall __stdcall Deactivate();
```

Description

This is Deactivate, a member of class TMtsAutoObject.

55.1.1.2.4 TMtsAutoObject.DisableCommit Method

Prevents clients from completing transactions.

Pascal

```
procedure DisableCommit;
```

C++

```
__fastcall DisableCommit();
```

Description

Call DisableCommit to indicate that the MTS Automation object cannot complete its current transaction or release state information until it receives further method invocations from the client. After calling DisableCommit, the current transaction (if any) cannot be completed until the MTS Automation object calls EnableCommit (see page 5835) or SetComplete (see page 5837).

With transactions that are started automatically when the MTS Automation object's interface is called, DisableCommit is not necessary. These transactions are not committed until the MTS Automation object calls SetComplete (see page 5837). However, when the MTS Automation object is enlisted in a transaction that was started previously, the client controls the transaction and can attempt to commit it before the MTS Automation object has completed its part. Calling DisableCommit prevents the client from prematurely committing a transaction. If a client tries to commit a transaction after the MTS Automation object has called DisableCommit, the transaction aborts.

Tip: Call DisableCommit at the beginning of a method to protect your MTS Automation object from committing prematurely in the event of an unexpected return. If the method call finishes normally, calling EnableCommit (see page 5835) or SetComplete (see page 5837) reverses this affect and allows the transaction to complete.

See Also

EnableCommit (see page 5835)

SetAbort (see page 5837)

SetComplete (see page 5837)

IsInTransaction (see page 5836)

55.1.1.2.5 TMtsAutoObject.EnableCommit Method

Allows clients to complete transactions without releasing state information.

Pascal

```
procedure EnableCommit;
```

C++

```
__fastcall EnableCommit();
```

Description

Call EnableCommit to indicate that the MTS Automation object can complete its current transaction without releasing state information. Unlike the SetComplete (see page 5837) method (which also signals that the current transaction can be committed), EnableCommit does not allow MTS to deactivate the MTS Automation object. This lets the MTS Automation object preserve state information over multiple interface calls, while still allowing clients that have enlisted the object in a transaction to commit.

By default, transactions can be completed when an interface call ends, unless the DisableCommit (see page 5834) method is called. There is no need to call EnableCommit unless the MTS Automation object has previously called DisableCommit (see page 5834).

Note: Although EnableCommit permits the current transaction to be completed, it does not automatically commit the transaction. The client that enlisted the MTS Automation object must still explicitly commit that transaction. If MTS started the transaction automatically (because the MTS Automation object requires a transaction for its interface calls), the transaction is not committed until the data module calls SetComplete (see page 5837).

See Also

DisableCommit (see page 5834)

SetComplete (see page 5837)

SetAbort (see page 5837)

IsInTransaction (see page 5836)

55.1.1.2.6 TMtsAutoObject.IsCallerInRole Method

Indicates whether the current client matches a particular security role.

Pascal

```
function IsCallerInRole(const Role: WideString): Bool;
```

C++

```
__fastcall Bool IsCallerInRole(const BSTR Role);
```

Description

MTS provides role-based security. Each level of access to your application server can be assigned a role. Using the MTS

Explorer, administrators can prevent clients from using an interface based on their role. (This is called declarative security.) In addition, however, programs can provide more fine-grained security programmatically. To do this, use IsCallerInRole to provide access to blocks of code based on the caller's security role.

IsCallerInRole checks whether the current client is part of the role named by the Role parameter. It returns true if the client matches the named role, and False otherwise. Use IsCallerInRole to prevent clients from invoking certain blocks of code if they do not have the appropriate security role.

Note: MTS security is not available on servers running Windows95. If the MTS application is running on Windows95, IsCallerInRole always returns true . In addition, IsCallerInRole always returns True if the application is part of an MTS Library package (which runs in the client's process space).

55.1.1.2.7 TMtsAutoObject.IsInTransaction Method

Indicates whether the MTS Automation object is running in a transaction.

Pascal

```
function IsInTransaction: Bool;
```

C++

```
__fastcall Bool IsInTransaction();
```

Description

Call IsInTransaction to determine whether the MTS Automation object is currently running in a transaction. For example, if the MTS Automation object requires a transaction, use IsInTransaction to check that this requirement has not been turned off by an administrator using the MTS Explorer, and to raise an exception if it has.

Note: If IsInTransaction returns False, the EnableCommit (see page 5835) and DisableCommit (see page 5834) methods have no effect.

See Also

EnableCommit (see page 5835)

DisableCommit (see page 5834)

55.1.1.2.8 TMtsAutoObject.IsSecurityEnabled Method

Pascal

```
function IsSecurityEnabled: Bool;
```

C++

```
__fastcall Bool IsSecurityEnabled();
```

Description

This is IsSecurityEnabled, a member of class TMtsAutoObject.

55.1.1.2.9 TMtsAutoObject.OnActivate Method

Pascal

```
procedure OnActivate; virtual;
```

C++

```
virtual __fastcall OnActivate();
```

Description

This is OnActivate, a member of class TMtsAutoObject.

55.1.1.2.10 TMtsAutoObject.OnDeactivate Method

Pascal

```
procedure OnDeactivate; virtual;
```

C++

```
virtual __fastcall OnDeactivate();
```

Description

This is OnDeactivate, a member of class TMtsAutoObject.

55.1.1.2.11 TMtsAutoObject.SetAbort Method

Allows the MTS Automation object to be deactivated and aborts any current transactions.

Pascal

```
procedure SetAbort;
```

C++

```
__fastcall SetAbort();
```

Description

Call SetAbort to indicate that any current transaction that includes the MTS Automation object to abort. If MTS started a transaction automatically, the transaction aborts when the current method call exits. If the MTS Automation object was enlisted in a pre-existing transaction, the client transaction will eventually fail. Usually, SetAbort is called in the except block of a try...except statement.

In addition to aborting any current transaction, SetAbort indicates that the MTS Automation object can be deactivated when the current interface call exits. This means that state information is not preserved for the next time and the client calls the Automation object's interface. To prevent transactions from committing successfully without losing state information, use the DisableCommit (see page 5834) method instead.

Tip: Call SetAbort at the beginning of a method to protect your MTS data module from committing prematurely in the event of an unexpected return. If the method call finishes normally, calling SetComplete (see page 5837) reverses this affect and allows the transaction to complete.

55.1.1.2.12 TMtsAutoObject.SetComplete Method

Indicates that the MTS Automation object has successfully completed its current task.

Pascal

```
procedure SetComplete;
```

C++

```
__fastcall SetComplete();
```

Description

Call SetComplete to indicate that the MTS Automation object no longer needs to maintain state information. After calling SetComplete, the MTS Automation object is deactivated when the current method call exits.

If the MTS Automation object is part of a transaction, SetComplete indicates that this part of the transaction can commit. If MTS started the transaction automatically when the client called the MTS Automation object's methods, MTS tries to commit the transaction when the current method exits.

Note: This transaction may still fail if the current transaction included another MTS object that called SetAbort (see page 5837) or DisableCommit (see page 5834).

See Also

EnableCommit (see page 5849)

55.1.1.3 TMtsAutoObject Properties

The properties of the TMtsAutoObject class are listed here.

Protected Properties

	Name	Description
	ObjectContext (see page 5838)	This is ObjectContext, a member of class TMtsAutoObject.

Public Properties

	Name	Description
	Pooled (see page 5838)	Indicates whether the object can be pooled when installed under COM+.

55.1.1.3.1 TMtsAutoObject.ObjectContext Property

Pascal

```
property ObjectContext: IObjectContext;
```

C++

```
__property IObjectContext ObjectContext;
```

Description

This is ObjectContext, a member of class TMtsAutoObject.

55.1.1.3.2 TMtsAutoObject.Pooled Property

Indicates whether the object can be pooled when installed under COM+.

Pascal

```
property Pooled: Boolean;
```

C++

```
__property Boolean Pooled;
```

Description

Set Pooled to indicate whether instances of the MTS Automation object can be pooled when installed under COM+. The MTS Automation object uses the Pooled property when implementing the IObjectControl (see page 5866) method CanBePooled (see page 5834). This instructs COM+ that the object can be moved to an object pool when deactivated, so that the single instance is shared by all clients.

Warning: Do not set Pooled to True unless the MTS Automation object is stateless.

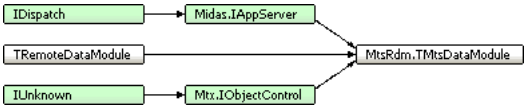
56.1.1 TMtsDataModule Class

TMtsDataModule encapsulates the objects and interfaces of a transactional application server.

Class Hierarchy



Pascal

```
TMtsDataModule = class(TRemoteDataModule, IAppServer, IObjectControl);
```

C++

```
class TMtsDataModule : public TRemoteDataModule, public IAppServer, public IObjectControl;
```

File

MtsRdm

Description

Use a TMtsDataModule object as the central repository for all objects in a transactional application server that is written in Delphi. MTS data modules can contain any nonvisual components. . Typically these are data access components, such as datasets and the provider components that handle communication between these datasets and client applications. MTS data modules can also contain other nonvisual components, such as TTimer, or TImageList.

MTS data modules are dual-interface Automation servers that implement the IAppServer (see page 5222) interface. Connection components on client applications are designed to look for this interface. The methods in this interface, however, do not call the SetComplete (see page 5852) method, so the MTS data module is not transactional. You may want to expand the MTS data module's interface to provide alternate versions of these methods that use the MTS data module's transaction.

The default interaction between a client dataset and an MTS data module does not rely on state information, so it is safe to use the MTS data module with just-in-time activation. However, you may need to provide a mechanism for communicating persistent state information to take advantage of some features such as incremental fetches.

To create an MTS data module at design time, choose File|New|Other, and select Transactional Data Module from the multitier page of the new items dialog. If you are writing the application server in Delphi, the Transactional Data Module Wizard then creates a new descendant of TMtsDataModule that supports an interface that descends from IAppServer (see page 5222).

56.1.1.1 TMtsDataModule Members

The following tables list the members exposed by TMtsDataModule.

Protected Methods

	Name	Description
	Activate (see page 5842)	This is Activate, a member of class TMtsDataModule.
	AS_ApplyUpdates (see page 5843)	Applies updates received from a client dataset using a specified provider.
	AS_DataRequest (see page 5843)	Generates an OnAS_DataRequest event on the specified provider component.
	AS_Execute (see page 5844)	AS_Executes the query or stored procedure bound to a specified provider.
	AS_GetParams (see page 5845)	Fetches current parameter values from the dataset bound to a specified provider.
	AS_GetProviderNames (see page 5846)	Returns a list of all the available providers on the remote data module.
	AS_GetRecords (see page 5846)	Returns a data packet that contains the specified data.
	AS_RowRequest (see page 5847)	Returns information from a specified record of the provider's dataset.
V	CallComplete (see page 5848)	This is CallComplete, a member of class TMtsDataModule.
V	CanBePooled (see page 5848)	This is CanBePooled, a member of class TMtsDataModule.
	Deactivate (see page 5848)	This is Deactivate, a member of class TMtsDataModule.

Protected Properties

	Name	Description
R	ObjectContext (see page 5853)	This is ObjectContext, a member of class TMtsDataModule.

Public Methods

	Name	Description
V	Create (see page 5841)	Creates an MTS data module instance.
	DisableCommit (see page 5849)	Prevents clients from completing transactions.
	EnableCommit (see page 5849)	Allows clients to complete transactions without releasing state information.
	IsCallerInRole (see page 5850)	Indicates whether the current client fits into a particular security role.
	IsInTransaction (see page 5850)	Indicates whether the MTS data module is running in a transaction.
	IsSecurityEnabled (see page 5851)	This is IsSecurityEnabled, a member of class TMtsDataModule.
	SetAbort (see page 5851)	Allows the MTS data module to be deactivated and aborts any current transactions.
	SetComplete (see page 5852)	Indicates that the MTS data module has successfully completed its current task.

Published Events

	Name	Description
	OnActivate (see page 5854)	Occurs when an instance of TMtsDataModule (see page 5840) is activated.
	OnDeactivate (see page 5854)	Occurs when an instance of TMtsDataModule (see page 5840) is deactivated.

Published Properties

	Name	Description
	AutoComplete (see page 5853)	Specifies whether the IAppServer (see page 5222) methods are transactional.
	Pooled (see page 5853)	Indicates whether the data module can be pooled when installed under COM+.

56.1.1.2 TMtsDataModule.Create Constructor

Creates an MTS data module instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TMtsDataModule(TComponent * AOwner);
```

Description

Most applications do not need to call the constructor for TMtsDataModule (see page 5840). Instead, add a remote data module to a server application using the transactional data module wizard on the multi-tier page of the new items dialog.

AOwner specifies the component that is responsible for freeing the remote data module (typically the application).

Create

56.1.1.3 TMtsDataModule Methods

The methods of the TMtsDataModule class are listed here.

Protected Methods

	Name	Description
	Activate (see page 5842)	This is Activate, a member of class TMtsDataModule.
	AS_ApplyUpdates (see page 5843)	Applies updates received from a client dataset using a specified provider.
	AS_DataRequest (see page 5843)	Generates an OnAS_DataRequest event on the specified provider component.
	AS_Execute (see page 5844)	AS_Executes the query or stored procedure bound to a specified provider.
	AS_GetParams (see page 5845)	Fetches current parameter values from the dataset bound to a specified provider.
	AS_GetProviderNames (see page 5846)	Returns a list of all the available providers on the remote data module.
	AS_GetRecords (see page 5846)	Returns a data packet that contains the specified data.
	AS_RowRequest (see page 5847)	Returns information from a specified record of the provider's dataset.
	CallComplete (see page 5848)	This is CallComplete, a member of class TMtsDataModule.
	CanBePooled (see page 5848)	This is CanBePooled, a member of class TMtsDataModule.
	Deactivate (see page 5848)	This is Deactivate, a member of class TMtsDataModule.

Public Methods

	Name	Description
	DisableCommit (see page 5849)	Prevents clients from completing transactions.
	EnableCommit (see page 5849)	Allows clients to complete transactions without releasing state information.
	IsCallerInRole (see page 5850)	Indicates whether the current client fits into a particular security role.
	IsInTransaction (see page 5850)	Indicates whether the MTS data module is running in a transaction.
	IsSecurityEnabled (see page 5851)	This is IsSecurityEnabled, a member of class TMtsDataModule.
	SetAbort (see page 5851)	Allows the MTS data module to be deactivated and aborts any current transactions.
	SetComplete (see page 5852)	Indicates that the MTS data module has successfully completed its current task.

56.1.1.3.1 TMtsDataModule.Activate Method

Pascal

```
procedure Activate; safecall;
```

C++

```
__fastcall Activate();
```

Description

This is Activate, a member of class TMtsDataModule.

56.1.1.3.2 TMtsDataModule.AS_ApplyUpdates Method

Applies updates received from a client dataset using a specified provider.

Pascal

```
function AS_ApplyUpdates(const ProviderName: WideString; Delta: OleVariant; MaxErrors:
Integer; out ErrorCount: Integer; var OwnerData: OleVariant): OleVariant; safecall;
```

C++

```
__fastcall OleVariant AS_ApplyUpdates(const BSTR ProviderName, OleVariant Delta, int
MaxErrors, int ErrorCount, OleVariant OwnerData);
```

Description

AS_AS_ApplyUpdates writes client updates to a dataset or database server. ProviderName specifies the name of the provider component that manages the update operation. Delta is a Variant containing the updated, inserted, and deleted records to write to the database. MaxErrors indicates the maximum number of errors to permit before rolling back the update operation; ErrorCount returns the actual number of errors encountered during the update operation. OwnerData is information supplied by the client application in a BeforeAS_ApplyUpdates event handler and returned to the client application in an AfterAS_ApplyUpdates event handler. It is passed to the provider's BeforeAS_ApplyUpdates event handler and returned from the provider's AfterAS_ApplyUpdates event handler.

AS_AS_ApplyUpdates The AS_ApplyUpdates_result parameter returns a Variant that is a data packet containing all records that could not be applied.

Note: Applications can only call the protected AS_AS_ApplyUpdates method using the IAppServer interface. To apply updates directly in code from the application server, use the provider component's AS_ApplyUpdates method.

AfterApplyUpdates

providers

IAppServer (see page 5222)

56.1.1.3.3 TMtsDataModule.AS_DataRequest Method

Generates an OnAS_DataRequest event on the specified provider component.

Pascal

```
function AS_DataRequest(const ProviderName: WideString; Data: OleVariant): OleVariant;
safecall;
```

C++

```
__fastcall OleVariant AS_DataRequest(const BSTR ProviderName, OleVariant Data);
```

Description

Use AS_AS_DataRequest to invoke an OnAS_DataRequest event handler of the provider named by ProviderName. This

method is provided to allow application developers to customize the communication between a client application and a provider component. There is no predefined meaning for the Data parameter or the return value AS_DataRequest_result parameter, which is returned to the caller.

Note: Applications can only call the protected AS_AS_DataRequest method using the IAppServer interface.

See Also

OnDataRequest (see page 6490)

providers

DataRequest

IAppServer (see page 5222)

56.1.1.3.4 TMtsDataModule.AS_Execute Method

AS_Executes the query or stored procedure bound to a specified provider.

Pascal

```
procedure AS_Execute(const ProviderName: WideString; const CommandText: WideString; var
Params: OleVariant; var OwnerData: OleVariant); safecall;
```

C++

```
__fastcall AS_Execute(const BSTR ProviderName, const BSTR CommandText, OleVariant Params,
OleVariant OwnerData);
```

Description

Use AS_AS_Execute to pass an execute command to a remote provider, using a specified set of parameters. AS_AS_Execute calls the AS_Execute method of the specified provider after assigning any parameters. Output parameters that result from executing a query or stored procedure are returned in the Params parameter.

The provider's AS_Execute method generates a BeforeAS_Execute event, passes the command on to its associated dataset, and generates an AfterAS_Execute event. The dataset must represent a query or stored procedure that does not return a cursor.

The ProviderName parameter specifies the name of the provider component associated with the query or stored procedure.

CommandText specifies an optional SQL statement that replaces the SQL of the query, or the name of a stored procedure that replaces the dataset's stored procedure. This parameter is ignored if the provider's Options property does not include poAllowCommandText.

The Params parameter encodes any parameters expected by the query or stored procedure and returns any output parameters. To create a properly encoded value for Params from a TParams object, use the PackageParams routine. To decode Params into a TParams object, use the Unpackparams routine.

The OwnerData parameter contains custom information that appears as an argument to the provider's BeforeAS_Execute and AfterAS_Execute event handlers. This information originates in a client dataset's BeforeAS_Execute event handler. The value returned in OwnerData is passed to the client dataset's AfterAS_Execute event handler.

UnpackParams

Communicating with the Client Dataset

56.1.1.3.5 TMtsDataModule.AS_GetParams Method

Fetches current parameter values from the dataset bound to a specified provider.

Pascal

```
function AS_GetParams(const ProviderName: WideString; var OwnerData: OleVariant): OleVariant;
safecall;
```

C++

```
__fastcall OleVariant AS_GetParams(const BSTR ProviderName, OleVariant OwnerData);
```

Description

Use AS_AS_GetParams to retrieve the current parameter values from the dataset associated with a provider.

The ProviderName parameter specifies the name of the provider component whose dataset has the parameters.

The OwnerData represents custom information that originates in a client dataset's BeforeAS_GetParams event handler and returns information that is passed to the client dataset's AfterAS_GetParams event handler.

AS_GetParams_result (C++) or AS_AS_GetParams (Delphi) returns the parameters, encoded as a Variant array, where each element is a 2-element Variant array containing a parameter name and a parameter value. These parameters can be converted to a TParams object using the UnpackParams procedure. If the dataset has no parameters, or if the provider does not support parameter fetching, AS_GetParams_result (C++) or AS_AS_GetParams (Delphi) returns a Null Variant.

Note: AS_AS_GetParams should not be used to retrieve output parameters from stateless application servers, because parameter values may be changed by other applications. When writing a stateless application server, retrieve parameter values using the AS_Execute method instead.

UnpackParams

Communicating with the Client Dataset

56.1.1.3.6 TMtsDataModule.AS_GetProviderNames Method

Returns a list of all the available providers on the remote data module.

Pascal

```
function AS_GetProviderNames: OleVariant; safecall;
```

C++

```
__fastcall OleVariant AS_GetProviderNames();
```

Description

Call AS_AS_GetProviderNames for a list of all registered providers available from a remote data module. These values indicate the possible values for the ProviderName property of a client dataset that connects to the remote data module. When calling any of the remote data modules through the IAppServer interface, pass one of these names to indicate the provider that is the target of the method call.

AS_AS_GetProviderNames returns the names of the providers in a Variant array. Client datasets are associated with a provider by setting their ProviderName property to one of these names.

Note: Applications can only call the protected AS_AS_GetProviderNames method using the IAppServer interface.

See Also

ProviderName

providers

IAppServer (see page 5222)

Exported (see page 6482)

56.1.1.3.7 TMtsDataModule.AS_GetRecords Method

Returns a data packet that contains the specified data.

Pascal

```
function AS_GetRecords(const ProviderName: WideString; Count: Integer; out RecsOut: Integer;
Options: Integer; const CommandText: WideString; var Params: OleVariant; var OwnerData:
OleVariant): OleVariant; safecall;
```

C++

```
__fastcall OleVariant AS_GetRecords(const BSTR ProviderName, int Count, int RecsOut, int
Options, const BSTR CommandText, OleVariant Params, OleVariant OwnerData);
```

Description

Call AS_AS_GetRecords to retrieve a specified number of records. AS_AS_GetRecords returns the requested records, starting with the current record of the provider's dataset. When working with a stateless remote data module, you may need to reposition the cursor or re-execute a query or stored procedure in the provider's BeforeAS_GetRecords event handler.

ProviderName gives the name of the provider component that provides the records.

Count indicates the number or type of records to retrieve. If Count is -1, all records are retrieved. If Count is 0, only metadata is retrieved. If Count is greater than 0, only Count records are retrieved.

RecsOut returns the actual number of records retrieved.

Options indicates what information should be added to the data packet in addition to data. It is a combination of the GetRecordOption constants. For example, the following value requests metadata along with a data packet encoded in XML:

```
MetaDataOption + XMLOption
MetaDataOption || XMLOption
```

CommandText specifies an optional SQL statement that replaces the SQL of the provider's query, or the name of a table or stored procedure that replaces the provider's underlying database table or stored procedure. This parameter is ignored if the provider's Options property does not include poAllowCommandText.

Params is a Variant containing any parameters that should be passed to the provider's dataset before it executes to generate the requested data. It returns any output parameters.

OwnerData contains custom information that is supplied by a client dataset's BeforeAS_GetRecords event handler. This information is passed to the provider's BeforeAS_GetRecords event handler. OwnerData returns information supplied by the provider's AfterAS_GetRecords event handler.

Records are returned as a data packet in a Variant parameter, AS_GetRecords_result.

Note: Applications can only call the protected AS_AS_GetRecords method using the IAppServer interface. To fetch records directly in code from the application server, use the provider component's AS_GetRecords method.

56.1.1.3.8 TMtsDataModule.AS_RowRequest Method

Returns information from a specified record of the provider's dataset.

Pascal

```
function AS_RowRequest(const ProviderName: WideString; Row: OleVariant; RequestType: Integer;
var OwnerData: OleVariant): OleVariant; safecall;
```

C++

```
__fastcall OleVariant AS_RowRequest(const BSTR ProviderName, OleVariant Row, int RequestType,
OleVariant OwnerData);
```

Description

Client datasets call AS_AS_RowRequest automatically to implement their FetchBlobs, FetchDetails , or RefreshRecord method.

The ProviderName parameter indicates the provider associated with the dataset from which information should be fetched.

The Row parameter is an OleVariant that describes the current record on the client dataset.

The RequestType parameter indicates the type of information required. It is an integer version of the TFetchOptions type. (An integer because the value may be marshaled to a remote application server). To create a value for RequestType, take the corresponding TFetchOptions value, cast it to a Byte, and cast the result to an Integer:

```
Integer(Byte([foBlobs, foDetails]));
(int) (Byte) (TFetchOptions() << foBlobs << foDetails);
```

OwnerData contains custom information that is supplied by a client dataset's BeforeAS_RowRequest event handler. This information is passed to the provider's BeforeAS_RowRequest event handler. OwnerData returns custom information supplied by the provider's AfterAS_RowRequest event handler.

The requested data is returned as a delta packet.

Note: Applications can only call the protected AS_AS_RowRequest method using the IAppServer interface.

56.1.1.3.9 TMtsDataModule.CallComplete Method

Pascal

```
procedure CallComplete(Complete: Boolean); virtual;
```

C++

```
virtual __fastcall CallComplete(Boolean Complete);
```

Description

This is CallComplete, a member of class TMtsDataModule.

56.1.1.3.10 TMtsDataModule.CanBePooled Method

Pascal

```
function CanBePooled: Bool; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall Bool CanBePooled();
```

Description

This is CanBePooled, a member of class TMtsDataModule.

56.1.1.3.11 TMtsDataModule.Deactivate Method

Pascal

```
procedure Deactivate; stdcall;
```

C++

```
__fastcall __stdcall Deactivate();
```

Description

This is Deactivate, a member of class TMtsDataModule.

56.1.1.3.12 TMtsDataModule.DisableCommit Method

Prevents clients from completing transactions.

Pascal

```
procedure DisableCommit;
```

C++

```
__fastcall DisableCommit();
```

Description

Call DisableCommit to indicate that the MTS data module can't complete its current transaction or release state information (properties) until it receives further method invocations from the client. After calling DisableCommit, the current transaction (if any) can't be completed until the MTS data module calls EnableCommit (see page 5849) or SetComplete (see page 5852).

With transactions that are started automatically when the MTS data module's interface is called, DisableCommit is not necessary. These automatically generated transactions are not committed until the MTS data module calls SetComplete (see page 5852). However, when the MTS data module is enlisted in a transaction that was started previously, the client controls the transaction and can attempt to commit it before the MTS data module has completed its part. Calling DisableCommit prevents the client from prematurely committing a transaction. If a client tries to commit a transaction after the MTS data module has called DisableCommit, the transaction aborts.

Tip: Call DisableCommit at the beginning of a method to protect your MTS data module from committing prematurely in the event of an unexpected return. If the method call finishes normally, calling EnableCommit (see page 5849) or SetComplete (see page 5852) reverses this affect and allows the transaction to complete.

See Also

EnableCommit (see page 5849)

SetComplete (see page 5852)

SetAbort (see page 5851)

IsInTransaction (see page 5850)

56.1.1.3.13 TMtsDataModule.EnableCommit Method

Allows clients to complete transactions without releasing state information.

Pascal

```
procedure EnableCommit;
```

C++

```
__fastcall EnableCommit();
```

Description

Call EnableCommit to indicate that the MTS data module can complete its current transaction without releasing state information (properties). Unlike the SetComplete (see page 5852) method (which also signals that the current transaction can be committed), EnableCommit does not allow the data module to be deactivated. This lets the MTS data module preserve state information over multiple interface calls, while still allowing clients that have enlisted the data module in a transaction to commit.

By default, transactions can be completed when interface calls finish, unless the DisableCommit (see page 5849) method is

called. There is no need to call EnableCommit unless the MTS data module has previously called DisableCommit (see page 5849).

Note: Although EnableCommit permits the current transaction to be completed, it does not automatically commit the transaction. The client that enlisted the MTS data module in a transaction must still explicitly commit that transaction. If the transaction was started automatically (because the MTS data module requires a transaction for its interface calls), the transaction is not committed until the data module calls SetComplete (see page 5852).

See Also

DisableCommit (see page 5849)

SetComplete (see page 5852)

SetAbort (see page 5851)

IsInTransaction (see page 5850)

56.1.1.3.14 TMtsDataModule.IsCallerInRole Method

Indicates whether the current client fits into a particular security role.

Pascal

```
function IsCallerInRole(const Role: WideString): Bool;
```

C++

```
__fastcall Bool IsCallerInRole(const BSTR Role);
```

Description

MTS provides role-based security. Each level of access to the application server can be assigned a name, called a role. Using the MTS Explorer or COM+ administrator, administrators can prevent clients from using an interface based on their role. (This is called declarative security.) In addition, however, programs can provide more fine-grained security programmatically. To do this, use IsCallerInRole to provide access to blocks of code based on the caller's security role.

IsCallerInRole checks whether the current client is part of the role named by the Role parameter. It returns true if the client fits the named role, and false otherwise. Use IsCallerInRole to prevent clients that do not have the appropriate security roles from invoking certain blocks of code.

Note: MTS security is not available on servers running Windows95. If the application server is running on Windows95, IsCallerInRole always returns true. In addition, IsCallerInRole always returns true if the application server is part of an MTS Library package (which runs in the client's process space).

See Also

issecurityenabled (see page 5851)

Using Transactional Data Modules

56.1.1.3.15 TMtsDataModule.IsInTransaction Method

Indicates whether the MTS data module is running in a transaction.

Pascal

```
function IsInTransaction: Bool;
```

C++

```
__fastcall Bool IsInTransaction();
```

Description

Call IsInTransaction to determine whether the MTS data module is currently running in a transaction. For example, if the MTS data module requires a transaction, use IsInTransaction to check that this requirement has not been turned off using the MTS Explorer or COM+ administrator, and to raise an exception if it has.

Note: If IsInTransaction returns false, the EnableCommit (see page 5849) and DisableCommit (see page 5849) methods have no effect.

See Also

EnableCommit (see page 5849)

DisableCommit (see page 5849)

SetComplete (see page 5852)

SetAbort (see page 5851)

56.1.1.3.16 TMtsDataModule.IsSecurityEnabled Method

Pascal

```
function IsSecurityEnabled: Bool;
```

C++

```
__fastcall Bool IsSecurityEnabled();
```

Description

This is IsSecurityEnabled, a member of class TMtsDataModule.

56.1.1.3.17 TMtsDataModule.SetAbort Method

Allows the MTS data module to be deactivated and aborts any current transactions.

Pascal

```
procedure SetAbort;
```

C++

```
__fastcall SetAbort();
```

Description

Call SetAbort to indicate that any current transaction that includes the MTS data module should abort. If MTS or COM+ started a transaction automatically (because the data module requires one), that transaction aborts when the current method call exits. If the MTS data module was enlisted in a pre-existing transaction, the client transaction will eventually fail. Usually, SetAbort is called in the except block of a try..exceptstatement.

In addition to aborting any current transaction, SetAbort indicates that the MTS data module can be deactivated when the current interface call exits. This means that state information is not preserved for the next time the client calls the data module's interface. To prevent transactions from committing successfully without losing state information, use the DisableCommit (see page 5849) method instead.

Tip: Call SetAbort at the beginning of a method to protect your MTS data module from committing prematurely in the event of an unexpected return. If the method call finishes normally, calling SetComplete (see page 5852) reverses this affect and allows the transaction to complete.

See Also

SetComplete (see page 5852)

DisableCommit (see page 5849)

EnableCommit (see page 5849)

IsInTransaction (see page 5850)

56.1.1.3.18 TMtsDataModule.SetComplete Method

Indicates that the MTS data module has successfully completed its current task.

Pascal

```
procedure SetComplete;
```

C++

```
__fastcall SetComplete();
```

Description

Call SetComplete to indicate that the MTS data module no longer needs to maintain state information. After calling SetComplete, the MTS data module is deactivated when the current method call exits.

If the MTS data module is part of a transaction, SetComplete indicates that this part of the transaction can commit. If MTS or COM+ started the transaction automatically when the client called the MTS data module's method (because the MTS data module requires a transaction), it tries to commit the transaction when the current method exits.

Note: This transaction may still fail if the current transaction included another MTS or COM+ object that called SetAbort (see page 5851) or DisableCommit (see page 5849).

See Also

SetAbort (see page 5851)

DisableCommit (see page 5849)

EnableCommit (see page 5849)

IsInTransaction (see page 5850)

Extending the Interface of the Application Server

56.1.1.4 TMtsDataModule Properties

The properties of the TMtsDataModule class are listed here.

Protected Properties

	Name	Description
	ObjectContext (see page 5853)	This is ObjectContext, a member of class TMtsDataModule.

Published Properties

	Name	Description
	AutoComplete (see page 5853)	Specifies whether the IAppServer (see page 5222) methods are transactional.
	Pooled (see page 5853)	Indicates whether the data module can be pooled when installed under COM+.

56.1.1.4.1 TMtsDataModule.AutoComplete Property

Specifies whether the IAppServer (see page 5222) methods are transactional.

Pascal

```
property AutoComplete: Boolean;
```

C++

```
__property Boolean AutoComplete;
```

Description

AutoComplete controls whether calls made using the IAppServer (see page 5222) interface end in a call to SetComplete (see page 5852) or SetAbort (see page 5851). By calling SetComplete (see page 5852) or SetAbort (see page 5851), the MTS data module indicates that no state information needs to be preserved when the call exits. This allows any MTS transactions to complete (or roll back) and allows COM+ or the MTS proxy to deactivate the MTS data module.

When AutoComplete is true, all IAppServer (see page 5222) methods call SetComplete (see page 5852) when they are done with two exceptions:

AS_ApplyUpdates (see page 5843) calls SetAbort (see page 5851) if an exception is raised or if the error count exceeds the specified maximum.

AS_DataRequest (see page 5843) doesn't call either SetComplete (see page 5852) or SetAbort (see page 5851). You must add the appropriate call to the OnDataRequest event handler.

Set AutoComplete to false if the MTS data module needs to preserve state information (such as the current record in a dataset) after an IAppServer (see page 5222) call exits. When AutoComplete is false, you must add your own interface methods that call SetComplete (see page 5852) or SetAbort (see page 5851) when the MTS data module can be safely deactivated.

See Also

IAppServer (see page 5222)

SetComplete (see page 5852)

SetAbort (see page 5851)

56.1.1.4.2 TMtsDataModule.ObjectContext Property

Pascal

```
property ObjectContext: IObjectContext;
```

C++

```
__property IObjectContext ObjectContext;
```

Description

This is ObjectContext, a member of class TMtsDataModule.

56.1.1.4.3 TMtsDataModule.Pooled Property

Indicates whether the data module can be pooled when installed under COM+.

Pascal

```
property Pooled: Boolean;
```

C++

```
__property Boolean Pooled;
```

Description

Set Pooled to indicate whether instances of the MTS data module can be pooled when installed under COM+. The MTS remote data module uses the Pooled property when implementing the IObjectControl (see page 5866) method CanBePooled (see page 5848). This instructs COM+ that the object can be moved to an object pool when deactivated, so that the single instance is shared by all clients.

Warning: Do not set Pooled to True unless the MTS data module is stateless.

56.1.1.5 TMtsDataModule Events

The events of the TMtsDataModule class are listed here.

Published Events

	Name	Description
	OnActivate (see page 5854)	Occurs when an instance of TMtsDataModule (see page 5840) is activated.
	OnDeactivate (see page 5854)	Occurs when an instance of TMtsDataModule (see page 5840) is deactivated.

56.1.1.5.1 TMtsDataModule.OnActivate Event

Occurs when an instance of TMtsDataModule (see page 5840) is activated.

Pascal

```
property OnActivate: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnActivate;
```

Description

Write an OnActivate event handler to take specific action when COMN+ or the MTS proxy activates the MTS data module. This is the point when any database connections should be established. Database connections must not opened before the MTS data module is activated.

Note: In traditional MTS or COM+ programming, objects acquire their context object when they are activated. However, TMtsDataModule (see page 5840) handles this task automatically.

See Also

OnDeactivate (see page 5854)

56.1.1.5.2 TMtsDataModule.OnDeactivate Event

Occurs when an instance of TMtsDataModule (see page 5840) is deactivated.

Pascal

```
property OnDeactivate: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDeactivate;
```

Description

Write an OnDeactivate event handler to take specific action when COM+ or the MTS proxy releases an instance of the MTS data

module. Use this method to close any database connections that were opened when the MTS data module was activated. Database connections must not be left open after the MTS data module is deactivated.

Note: In traditional COM+ and MTS programming, objects release their context object when they are deactivated. However, TMtsDataModule (see page 5840) handles this task automatically.

See Also

OnActivate (see page 5854)

Name	Description
CLASS_SharedPropertyGroupManager (see page 5884)	This is constant Mtx.CLASS_SharedPropertyGroupManager.
CLASS_TransactionContext (see page 5884)	This is constant Mtx.CLASS_TransactionContext.
CLASS_TransactionContextEx (see page 5885)	This is constant Mtx.CLASS_TransactionContextEx.
LockMethod (see page 5885)	This is constant Mtx.LockMethod.
LockSetGet (see page 5885)	This is constant Mtx.LockSetGet.
mtsErrCtxAborted (see page 5886)	This is constant Mtx.mtsErrCtxAborted.
mtsErrCtxAborting (see page 5886)	This is constant Mtx.mtsErrCtxAborting.
mtsErrCtxActivityTimeout (see page 5886)	This is constant Mtx.mtsErrCtxActivityTimeout.
mtsErrCtxNoContext (see page 5887)	This is constant Mtx.mtsErrCtxNoContext.
mtsErrCtxNoSecurity (see page 5887)	This is constant Mtx.mtsErrCtxNoSecurity.
mtsErrCtxNotRegistered (see page 5887)	This is constant Mtx.mtsErrCtxNotRegistered.
mtsErrCtxOldReference (see page 5888)	This is constant Mtx.mtsErrCtxOldReference.
mtsErrCtxRoleNotFound (see page 5888)	This is constant Mtx.mtsErrCtxRoleNotFound.
mtsErrCtxTMNotAvailable (see page 5888)	This is constant Mtx.mtsErrCtxTMNotAvailable.
mtsErrCtxWrongThread (see page 5889)	This is constant Mtx.mtsErrCtxWrongThread.
Process (see page 5889)	This is constant Mtx.Process.
Standard (see page 5889)	This is constant Mtx.Standard.

Functions

	Name	Description
	CreateSharedPropertyGroup (see page 5879)	Returns the interface for a SharedPropertyGroup that allows MTS objects within a server process to share state.
	CreateSharedPropertyGroupManager (see page 5880)	Returns an interface for a new shared property group manager that creates and coordinates shared properties of MTS objects.
	CreateTransactionContext (see page 5880)	Starts an MTS transaction.

	CreateTransactionContextEx (see page 5881)	Instantiates a TransactionContextEx object, which marks the beginning of a transaction.
	GetObjectContext (see page 5882)	Fetches the IObjectContext (see page 5862) interface for the current thread.
	SafeRef (see page 5882)	Returns a reference to a transactional object that is safe to pass outside its context.

Interfaces

	Name	Description
	IEnumNames (see page 5859)	This is class Mtx.IEnumNames.
	IGetContextProperties (see page 5861)	This is class Mtx.IGetContextProperties.
	IObjectContext (see page 5862)	This is class Mtx.IObjectContext.
	IObjectContextActivity (see page 5865)	This is class Mtx.IObjectContextActivity.
	IObjectControl (see page 5866)	This is class Mtx.IObjectControl.
	ISecurityProperty (see page 5867)	This is class Mtx.ISecurityProperty.
	ISharedProperty (see page 5869)	This is class Mtx.ISharedProperty.
	ISharedPropertyGroup (see page 5871)	This is class Mtx.ISharedPropertyGroup.
	ISharedPropertyGroupManager (see page 5873)	This is class Mtx.ISharedPropertyGroupManager.
	ITransactionContext (see page 5875)	This is class Mtx.ITransactionContext.
	ITransactionContextEx (see page 5877)	This is class Mtx.ITransactionContextEx.

57.1 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IEnumNames (see page 5859)	This is class Mtx.IEnumNames.
	IGetContextProperties (see page 5861)	This is class Mtx.IGetContextProperties.
	IObjectContext (see page 5862)	This is class Mtx.IObjectContext.
	IObjectContextActivity (see page 5865)	This is class Mtx.IObjectContextActivity.
	IObjectControl (see page 5866)	This is class Mtx.IObjectControl.
	ISecurityProperty (see page 5867)	This is class Mtx.ISecurityProperty.
	ISharedProperty (see page 5869)	This is class Mtx.ISharedProperty.
	ISharedPropertyGroup (see page 5871)	This is class Mtx.ISharedPropertyGroup.
	ISharedPropertyGroupManager (see page 5873)	This is class Mtx.ISharedPropertyGroupManager.
	ITransactionContext (see page 5875)	This is class Mtx.ITransactionContext.
	ITransactionContextEx (see page 5877)	This is class Mtx.ITransactionContextEx.

57.1.1 IEnumNames Interface

Class Hierarchy

Pascal

```
IEnumNames = interface(IUnknown);
```

C++

```
__interface IEnumNames : public IUnknown;
```

File

Mtx

Description

This is class Mtx.IEnumNames.

57.1.1.1 IEnumNames Members

The following tables list the members exposed by IEnumNames.

Public Methods

	Name	Description
	Clone (see page 5860)	This is Clone, a member of class IEnumNames.
	Next (see page 5860)	This is Next, a member of class IEnumNames.
	Reset (see page 5860)	This is Reset, a member of class IEnumNames.
	Skip (see page 5860)	This is Skip, a member of class IEnumNames.

57.1.1.2 IEnumNames Methods

The methods of the IEnumNames class are listed here.

Public Methods

	Name	Description
	Clone (see page 5860)	This is Clone, a member of class IEnumNames.
	Next (see page 5860)	This is Next, a member of class IEnumNames.
	Reset (see page 5860)	This is Reset, a member of class IEnumNames.
	Skip (see page 5860)	This is Skip, a member of class IEnumNames.

57.1.1.2.1 IEnumNames.Clone Method

Pascal

```
function Clone(out enm: IEnumNames): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT Clone(IEnumNames enm);
```

Description

This is Clone, a member of class IEnumNames.

57.1.1.2.2 IEnumNames.Next Method

Pascal

```
function Next(celt: UINT; out rgname: WideString; out pceltFetched: UINT): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT Next(UINT celt, BSTR rgname, UINT pceltFetched);
```

Description

This is Next, a member of class IEnumNames.

57.1.1.2.3 IEnumNames.Reset Method

Pascal

```
function Reset: HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT Reset();
```

Description

This is Reset, a member of class IEnumNames.

57.1.1.2.4 IEnumNames.Skip Method

Pascal

```
function Skip(celt: UINT): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT Skip(UINT celt);
```

Description

This is Skip, a member of class IEnumNames.

57.1.2 IGetContextProperties Interface

Class Hierarchy

Pascal

```
IGetContextProperties = interface(IUnknown);
```

C++

```
__interface IGetContextProperties : public IUnknown;
```

File

Mtx

Description

This is class Mtx.IGetContextProperties.

57.1.2.1 IGetContextProperties Members

The following tables list the members exposed by IGetContextProperties.

Public Methods

	Name	Description
	Count (see page 5861)	This is Count, a member of class IGetContextProperties.
	EnumNames (see page 5862)	This is EnumNames, a member of class IGetContextProperties.
	GetProperty (see page 5862)	This is GetProperty, a member of class IGetContextProperties.

57.1.2.2 IGetContextProperties Methods

The methods of the IGetContextProperties class are listed here.

Public Methods

	Name	Description
	Count (see page 5861)	This is Count, a member of class IGetContextProperties.
	EnumNames (see page 5862)	This is EnumNames, a member of class IGetContextProperties.
	GetProperty (see page 5862)	This is GetProperty, a member of class IGetContextProperties.

57.1.2.2.1 IGetContextProperties.Count Method

Pascal

```
function Count: Integer; safecall;
```

C++

```
__fastcall int Count();
```

Description

This is Count, a member of class IGetContextProperties.

57.1.2.2.2 IGetContextProperties.EnumNames Method

Pascal

```
function EnumNames: IEnumNames; safecall;
```

C++

```
__fastcall IEnumNames EnumNames();
```

Description

This is EnumNames, a member of class IGetContextProperties.

57.1.2.2.3 IGetContextProperties.GetProperty Method

Pascal

```
function GetProperty(const name: WideString): OleVariant; safecall;
```

C++

```
__fastcall OleVariant GetProperty(const BSTR name);
```

Description

This is GetProperty, a member of class IGetContextProperties.

57.1.3 IObjectContext Interface

Class Hierarchy

Pascal

```
IObjectContext = interface(IUnknown);
```

C++

```
__interface IObjectContext : public IUnknown;
```

File

Mtx

Description

This is class Mtx.IObjectContext.

57.1.3.1 IObjectContext Members

The following tables list the members exposed by IObjectContext.

Public Methods

	Name	Description
	CreateInstance (see page 5863)	This is CreateInstance, a member of class IObjectContext.
	DisableCommit (see page 5863)	This is DisableCommit, a member of class IObjectContext.
	EnableCommit (see page 5864)	This is EnableCommit, a member of class IObjectContext.
	IsCallerInRole (see page 5864)	This is IsCallerInRole, a member of class IObjectContext.
	IsInTransaction (see page 5864)	This is IsInTransaction, a member of class IObjectContext.
	IsSecurityEnabled (see page 5864)	This is IsSecurityEnabled, a member of class IObjectContext.
	SetAbort (see page 5864)	This is SetAbort, a member of class IObjectContext.
	SetComplete (see page 5865)	This is SetComplete, a member of class IObjectContext.

57.1.3.2 IObjectContext Methods

The methods of the IObjectContext class are listed here.

Public Methods

	Name	Description
	CreateInstance (see page 5863)	This is CreateInstance, a member of class IObjectContext.
	DisableCommit (see page 5863)	This is DisableCommit, a member of class IObjectContext.
	EnableCommit (see page 5864)	This is EnableCommit, a member of class IObjectContext.
	IsCallerInRole (see page 5864)	This is IsCallerInRole, a member of class IObjectContext.
	IsInTransaction (see page 5864)	This is IsInTransaction, a member of class IObjectContext.
	IsSecurityEnabled (see page 5864)	This is IsSecurityEnabled, a member of class IObjectContext.
	SetAbort (see page 5864)	This is SetAbort, a member of class IObjectContext.
	SetComplete (see page 5865)	This is SetComplete, a member of class IObjectContext.

57.1.3.2.1 IObjectContext.CreateInstance Method

Pascal

```
function CreateInstance(const cid: TGUID; const rid: TGUID; out pv): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT CreateInstance(const TGUID cid, const TGUID rid,  pv);
```

Description

This is CreateInstance, a member of class IObjectContext.

57.1.3.2.2 IObjectContext.DisableCommit Method

Pascal

```
procedure DisableCommit; safecall;
```

C++

```
__fastcall DisableCommit();
```

Description

This is DisableCommit, a member of class IObjectContext.

57.1.3.2.3 IObjectContext.EnableCommit Method

Pascal

```
procedure EnableCommit; safecall;
```

C++

```
__fastcall EnableCommit();
```

Description

This is EnableCommit, a member of class IObjectContext.

57.1.3.2.4 IObjectContext.IsCallerInRole Method

Pascal

```
function IsCallerInRole(const bstrRole: WideString): Bool; safecall;
```

C++

```
__fastcall Bool IsCallerInRole(const BSTR bstrRole);
```

Description

This is IsCallerInRole, a member of class IObjectContext.

57.1.3.2.5 IObjectContext.IsInTransaction Method

Pascal

```
function IsInTransaction: Bool; stdcall;
```

C++

```
__fastcall __stdcall Bool IsInTransaction();
```

Description

This is IsInTransaction, a member of class IObjectContext.

57.1.3.2.6 IObjectContext.IsSecurityEnabled Method

Pascal

```
function IsSecurityEnabled: Bool; stdcall;
```

C++

```
__fastcall __stdcall Bool IsSecurityEnabled();
```

Description

This is IsSecurityEnabled, a member of class IObjectContext.

57.1.3.2.7 IObjectContext.SetAbort Method

Pascal

```
procedure SetAbort; safecall;
```

C++

```
__fastcall SetAbort();
```

Description

This is SetAbort, a member of class IObjectContext.

57.1.3.2.8 IObjectContext.SetComplete Method

Pascal

```
procedure SetComplete; safecall;
```

C++

```
__fastcall SetComplete();
```

Description

This is SetComplete, a member of class IObjectContext.

57.1.4 IObjectContextActivity Interface

Class Hierarchy

Pascal

```
IObjectContextActivity = interface(IUnknown);
```

C++

```
__interface IObjectContextActivity : public IUnknown;
```

File

Mtx

Description

This is class Mtx.IObjectContextActivity.

57.1.4.1 IObjectContextActivity Members

The following tables list the members exposed by IObjectContextActivity.

Public Methods

	Name	Description
	GetActivityId (see page 5866)	This is GetActivityId, a member of class IObjectContextActivity.

57.1.4.2 IObjectContextActivity Methods

The methods of the IObjectContextActivity class are listed here.

Public Methods

	Name	Description
	GetActivityId (see page 5866)	This is GetActivityId, a member of class IObjectContextActivity.

57.1.4.2.1 IObjectContextActivity.GetActivityId Method

Pascal

```
function GetActivityId: TGuid; safecall;
```

C++

```
__fastcall TGuid GetActivityId();
```

Description

This is GetActivityId, a member of class IObjectContextActivity.

57.1.5 IObjectControl Interface

Class Hierarchy

Pascal

```
IObjectControl = interface(IUnknown);
```

C++

```
__interface IObjectControl : public IUnknown;
```

File

Mtx

Description

This is class Mtx.IObjectControl.

57.1.5.1 IObjectControl Members

The following tables list the members exposed by IObjectControl.

Public Methods

	Name	Description
	Activate (see page 5867)	This is Activate, a member of class IObjectControl.
	CanBePooled (see page 5867)	This is CanBePooled, a member of class IObjectControl.
	Deactivate (see page 5867)	This is Deactivate, a member of class IObjectControl.

57.1.5.2 IObjectControl Methods

The methods of the IObjectControl class are listed here.

Public Methods

	Name	Description
	Activate (see page 5867)	This is Activate, a member of class IObjectControl.
	CanBePooled (see page 5867)	This is CanBePooled, a member of class IObjectControl.
	Deactivate (see page 5867)	This is Deactivate, a member of class IObjectControl.

57.1.5.2.1 IObjectControl.Activate Method

Pascal

```
procedure Activate; safecall;
```

C++

```
__fastcall Activate();
```

Description

This is Activate, a member of class IObjectControl.

57.1.5.2.2 IObjectControl.CanBePooled Method

Pascal

```
function CanBePooled: Bool; stdcall;
```

C++

```
__fastcall __stdcall Bool CanBePooled();
```

Description

This is CanBePooled, a member of class IObjectControl.

57.1.5.2.3 IObjectControl.Deactivate Method

Pascal

```
procedure Deactivate; stdcall;
```

C++

```
__fastcall __stdcall Deactivate();
```

Description

This is Deactivate, a member of class IObjectControl.

57.1.6 ISecurityProperty Interface

Class Hierarchy

Pascal

```
ISecurityProperty = interface(IUnknown);
```

C++

```
__interface ISecurityProperty : public IUnknown;
```

File

Mtx

Description

This is class Mtx.ISecurityProperty.

57.1.6.1 ISecurityProperty Members

The following tables list the members exposed by ISecurityProperty.

Public Methods

	Name	Description
	GetDirectCallerSID (see page 5868)	This is GetDirectCallerSID, a member of class ISecurityProperty.
	GetDirectCreatorSID (see page 5868)	This is GetDirectCreatorSID, a member of class ISecurityProperty.
	GetOriginalCallerSID (see page 5868)	This is GetOriginalCallerSID, a member of class ISecurityProperty.
	GetOriginalCreatorSID (see page 5869)	This is GetOriginalCreatorSID, a member of class ISecurityProperty.
	ReleaseSID (see page 5869)	This is ReleaseSID, a member of class ISecurityProperty.

57.1.6.2 ISecurityProperty Methods

The methods of the ISecurityProperty class are listed here.

Public Methods

	Name	Description
	GetDirectCallerSID (see page 5868)	This is GetDirectCallerSID, a member of class ISecurityProperty.
	GetDirectCreatorSID (see page 5868)	This is GetDirectCreatorSID, a member of class ISecurityProperty.
	GetOriginalCallerSID (see page 5868)	This is GetOriginalCallerSID, a member of class ISecurityProperty.
	GetOriginalCreatorSID (see page 5869)	This is GetOriginalCreatorSID, a member of class ISecurityProperty.
	ReleaseSID (see page 5869)	This is ReleaseSID, a member of class ISecurityProperty.

57.1.6.2.1 ISecurityProperty.GetDirectCallerSID Method

Pascal

```
function GetDirectCallerSID(out sid: PSID): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetDirectCallerSID(PSID sid);
```

Description

This is GetDirectCallerSID, a member of class ISecurityProperty.

57.1.6.2.2 ISecurityProperty.GetDirectCreatorSID Method

Pascal

```
function GetDirectCreatorSID(out sid: PSID): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetDirectCreatorSID(PSID sid);
```

Description

This is GetDirectCreatorSID, a member of class ISecurityProperty.

57.1.6.2.3 ISecurityProperty.GetOriginalCallerSID Method

Pascal

```
function GetOriginalCallerSID(out sid: PSID): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetOriginalCallerSID(PSID sid);
```

Description

This is GetOriginalCallerSID, a member of class ISecurityProperty.

57.1.6.2.4 ISecurityProperty.GetOriginalCreatorSID Method

Pascal

```
function GetOriginalCreatorSID(out sid: PSID): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetOriginalCreatorSID(PSID sid);
```

Description

This is GetOriginalCreatorSID, a member of class ISecurityProperty.

57.1.6.2.5 ISecurityProperty.ReleaseSID Method

Pascal

```
function ReleaseSID(sid: PSID): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT ReleaseSID(PSID sid);
```

Description

This is ReleaseSID, a member of class ISecurityProperty.

57.1.7 ISharedProperty Interface

Class Hierarchy

Pascal

```
ISharedProperty = interface(IDispatch);
```

C++

```
__interface ISharedProperty : public IDispatch;
```

File

Mtx

Description

This is class Mtx.ISharedProperty.

57.1.7.1 ISharedProperty Members

The following tables list the members exposed by ISharedProperty.

Public Methods

	Name	Description
	Get_Value (see page 5870)	This is Get_Value, a member of class ISharedProperty.
	Set_Value (see page 5870)	This is Set_Value, a member of class ISharedProperty.

Public Properties

	Name	Description
	Value (see page 5871)	This is Value, a member of class ISharedProperty.

57.1.7.2 ISharedProperty Methods

The methods of the ISharedProperty class are listed here.

Public Methods

	Name	Description
	Get_Value (see page 5870)	This is Get_Value, a member of class ISharedProperty.
	Set_Value (see page 5870)	This is Set_Value, a member of class ISharedProperty.

57.1.7.2.1 ISharedProperty.Get_Value Method

Pascal

```
function Get_Value: OleVariant; safecall;
```

C++

```
__fastcall OleVariant Get_Value();
```

Description

This is Get_Value, a member of class ISharedProperty.

57.1.7.2.2 ISharedProperty.Set_Value Method

Pascal

```
procedure Set_Value(pVal: OleVariant); safecall;
```

C++

```
__fastcall Set_Value(OleVariant pVal);
```

Description

This is Set_Value, a member of class ISharedProperty.

57.1.7.3 ISharedProperty Properties

The properties of the ISharedProperty class are listed here.

Public Properties

	Name	Description
	Value (see page 5871)	This is Value, a member of class ISharedProperty.

57.1.7.3.1 ISharedProperty.Value Property

Pascal

```
property Value: OleVariant;
```

C++

```
__property OleVariant Value;
```

Description

This is Value, a member of class ISharedProperty.

57.1.8 ISharedPropertyGroup Interface

Class Hierarchy

Pascal

```
ISharedPropertyGroup = interface(IDispatch);
```

C++

```
__interface ISharedPropertyGroup : public IDispatch;
```

File

Mtx

Description

This is class Mtx.ISharedPropertyGroup.

57.1.8.1 ISharedPropertyGroup Members

The following tables list the members exposed by ISharedPropertyGroup.

Public Methods

	Name	Description
	CreateProperty (see page 5872)	This is CreateProperty, a member of class ISharedPropertyGroup.
	CreatePropertyByPosition (see page 5872)	This is CreatePropertyByPosition, a member of class ISharedPropertyGroup.
	Get_PropertyByName (see page 5872)	This is Get_PropertyByName, a member of class ISharedPropertyGroup.
	Get_PropertyByPosition (see page 5872)	This is Get_PropertyByPosition, a member of class ISharedPropertyGroup.

Public Properties

	Name	Description
R	PropertyByName (see page 5873)	This is PropertyByName, a member of class ISharedPropertyGroup.
R	PropertyByPosition (see page 5873)	This is PropertyByPosition, a member of class ISharedPropertyGroup.

57.1.8.2 ISharedPropertyGroup Methods

The methods of the ISharedPropertyGroup class are listed here.

Public Methods

	Name	Description
	CreateProperty (see page 5872)	This is CreateProperty, a member of class ISharedPropertyGroup.
	CreatePropertyByPosition (see page 5872)	This is CreatePropertyByPosition, a member of class ISharedPropertyGroup.
	Get_PropertyByName (see page 5872)	This is Get_PropertyByName, a member of class ISharedPropertyGroup.
	Get_PropertyByPosition (see page 5872)	This is Get_PropertyByPosition, a member of class ISharedPropertyGroup.

57.1.8.2.1 ISharedPropertyGroup.CreateProperty Method

Pascal

```
function CreateProperty(const Name: WideString; out fExists: WordBool): ISharedProperty;
safecall;
```

C++

```
__fastcall ISharedProperty CreateProperty(const BSTR Name, WordBool fExists);
```

Description

This is CreateProperty, a member of class ISharedPropertyGroup.

57.1.8.2.2 ISharedPropertyGroup.CreatePropertyByPosition Method

Pascal

```
function CreatePropertyByPosition(Index: Integer; out fExists: WordBool): ISharedProperty;
safecall;
```

C++

```
__fastcall ISharedProperty CreatePropertyByPosition(int Index, WordBool fExists);
```

Description

This is CreatePropertyByPosition, a member of class ISharedPropertyGroup.

57.1.8.2.3 ISharedPropertyGroup.Get_PropertyByName Method

Pascal

```
function Get_PropertyByName(const Name: WideString): ISharedProperty; safecall;
```

C++

```
__fastcall ISharedProperty Get_PropertyByName(const BSTR Name);
```

Description

This is Get_PropertyByName, a member of class ISharedPropertyGroup.

57.1.8.2.4 ISharedPropertyGroup.Get_PropertyByPosition Method

Pascal

```
function Get_PropertyByPosition(Index: Integer): ISharedProperty; safecall;
```

C++

```
__fastcall ISharedProperty Get_PropertyByPosition(int Index);
```

Description

This is Get_PropertyByPosition, a member of class ISharedPropertyGroup.

57.1.8.3 ISharedPropertyGroup Properties

The properties of the ISharedPropertyGroup class are listed here.

Public Properties

	Name	Description
	PropertyByName (see page 5873)	This is PropertyByName, a member of class ISharedPropertyGroup.
	PropertyByPosition (see page 5873)	This is PropertyByPosition, a member of class ISharedPropertyGroup.

57.1.8.3.1 ISharedPropertyGroup.PropertyByName Property

Pascal

```
property PropertyByName [const Name: WideString]: ISharedProperty;
```

C++

```
__property ISharedProperty PropertyByName[BSTR const Name];
```

Description

This is PropertyByName, a member of class ISharedPropertyGroup.

57.1.8.3.2 ISharedPropertyGroup.PropertyByPosition Property

Pascal

```
property PropertyByPosition [Index: Integer]: ISharedProperty;
```

C++

```
__property ISharedProperty PropertyByPosition[int Index];
```

Description

This is PropertyByPosition, a member of class ISharedPropertyGroup.

57.1.9 ISharedPropertyGroupManager Interface

Class Hierarchy

Pascal

```
ISharedPropertyGroupManager = interface(IDispatch);
```

C++

```
__interface ISharedPropertyGroupManager : public IDispatch;
```

File

Mtx

Description

This is class Mtx.ISharedPropertyGroupManager.

57.1.9.1 ISharedPropertyGroupManager Members

The following tables list the members exposed by ISharedPropertyGroupManager.

Public Methods

	Name	Description
	CreatePropertyGroup (see page 5874)	This is CreatePropertyGroup, a member of class ISharedPropertyGroupManager.
	Get__NewEnum (see page 5874)	This is Get__NewEnum, a member of class ISharedPropertyGroupManager.
	Get_Group (see page 5875)	This is Get_Group, a member of class ISharedPropertyGroupManager.

Public Properties

	Name	Description
R	_NewEnum (see page 5875)	This is _NewEnum, a member of class ISharedPropertyGroupManager.
R	Group (see page 5875)	This is Group, a member of class ISharedPropertyGroupManager.

57.1.9.2 ISharedPropertyGroupManager Methods

The methods of the ISharedPropertyGroupManager class are listed here.

Public Methods

	Name	Description
	CreatePropertyGroup (see page 5874)	This is CreatePropertyGroup, a member of class ISharedPropertyGroupManager.
	Get__NewEnum (see page 5874)	This is Get__NewEnum, a member of class ISharedPropertyGroupManager.
	Get_Group (see page 5875)	This is Get_Group, a member of class ISharedPropertyGroupManager.

57.1.9.2.1 ISharedPropertyGroupManager.CreatePropertyGroup Method

Pascal

```
function CreatePropertyGroup(const Name: WideString; var LockMode: Integer; var RelMode:
Integer; out fExists: WordBool): ISharedPropertyGroup; safecall;
```

C++

```
__fastcall ISharedPropertyGroup CreatePropertyGroup(const BSTR Name, int LockMode, int
RelMode, WordBool fExists);
```

Description

This is CreatePropertyGroup, a member of class ISharedPropertyGroupManager.

57.1.9.2.2 ISharedPropertyGroupManager.Get__NewEnum Method

Pascal

```
function Get__NewEnum: IUnknown; safecall;
```

C++

```
__fastcall IUnknown Get__NewEnum();
```

Description

This is Get__NewEnum, a member of class ISharedPropertyGroupManager.

57.1.9.2.3 ISharedPropertyGroupManager.Get_Group Method

Pascal

```
function Get_Group(const Name: WideString): ISharedPropertyGroup; safecall;
```

C++

```
__fastcall ISharedPropertyGroup Get_Group(const BSTR Name);
```

Description

This is Get_Group, a member of class ISharedPropertyGroupManager.

57.1.9.3 ISharedPropertyGroupManager Properties

The properties of the ISharedPropertyGroupManager class are listed here.

Public Properties

	Name	Description
	_NewEnum (see page 5875)	This is _NewEnum, a member of class ISharedPropertyGroupManager.
	Group (see page 5875)	This is Group, a member of class ISharedPropertyGroupManager.

57.1.9.3.1 ISharedPropertyGroupManager._NewEnum Property

Pascal

```
property _NewEnum: IUnknown;
```

C++

```
__property IUnknown _NewEnum;
```

Description

This is _NewEnum, a member of class ISharedPropertyGroupManager.

57.1.9.3.2 ISharedPropertyGroupManager.Group Property

Pascal

```
property Group [const Name: WideString]: ISharedPropertyGroup;
```

C++

```
__property ISharedPropertyGroup Group[BSTR const Name];
```

Description

This is Group, a member of class ISharedPropertyGroupManager.

57.1.10 ITransactionContext Interface

Class Hierarchy

Pascal

```
ITransactionContext = interface(IDispatch);
```

C++

```
__interface ITransactionContext : public IDispatch;
```

File

Mtx

Description

This is class Mtx.ITransactionContext.

57.1.10.1 ITransactionContext Members

The following tables list the members exposed by ITransactionContext.

Public Methods

	Name	Description
	Abort (see page 5876)	This is Abort, a member of class ITransactionContext.
	Commit (see page 5876)	This is Commit, a member of class ITransactionContext.
	CreateInstance (see page 5877)	This is CreateInstance, a member of class ITransactionContext.

57.1.10.2 ITransactionContext Methods

The methods of the ITransactionContext class are listed here.

Public Methods

	Name	Description
	Abort (see page 5876)	This is Abort, a member of class ITransactionContext.
	Commit (see page 5876)	This is Commit, a member of class ITransactionContext.
	CreateInstance (see page 5877)	This is CreateInstance, a member of class ITransactionContext.

57.1.10.2.1 ITransactionContext.Abort Method

Pascal

```
procedure Abort; safecall;
```

C++

```
__fastcall Abort();
```

Description

This is Abort, a member of class ITransactionContext.

57.1.10.2.2 ITransactionContext.Commit Method

Pascal

```
procedure Commit; safecall;
```

C++

```
__fastcall Commit();
```

Description

This is Commit, a member of class ITransactionContext.

57.1.10.2.3 ITransactionContext.CreateInstance Method

Pascal

```
function CreateInstance(const pszProgId: WideString): OleVariant; safecall;
```

C++

```
__fastcall OleVariant CreateInstance(const BSTR pszProgId);
```

Description

This is CreateInstance, a member of class ITransactionContext.

57.1.11 ITransactionContextEx Interface

Class Hierarchy

Pascal

```
ITransactionContextEx = interface(IUnknown);
```

C++

```
__interface ITransactionContextEx : public IUnknown;
```

File

Mtx

Description

This is class Mtx.ITransactionContextEx.

57.1.11.1 ITransactionContextEx Members

The following tables list the members exposed by ITransactionContextEx.

Public Methods

	Name	Description
	Abort (see page 5878)	This is Abort, a member of class ITransactionContextEx.
	Commit (see page 5878)	This is Commit, a member of class ITransactionContextEx.
	CreateInstance (see page 5878)	This is CreateInstance, a member of class ITransactionContextEx.

57.1.11.2 ITransactionContextEx Methods

The methods of the ITransactionContextEx class are listed here.

Public Methods

	Name	Description
	Abort (see page 5878)	This is Abort, a member of class ITransactionContextEx.
	Commit (see page 5878)	This is Commit, a member of class ITransactionContextEx.
	CreateInstance (see page 5878)	This is CreateInstance, a member of class ITransactionContextEx.

57.1.11.2.1 ITransactionContextEx.Abort Method

Pascal

```
function Abort: HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT Abort();
```

Description

This is Abort, a member of class ITransactionContextEx.

57.1.11.2.2 ITransactionContextEx.Commit Method

Pascal

```
function Commit: HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT Commit();
```

Description

This is Commit, a member of class ITransactionContextEx.

57.1.11.2.3 ITransactionContextEx.CreateInstance Method

Pascal

```
function CreateInstance(const cid: TGUID; const rid: TGUID; out pv): HRESULT; stdcall;
```

C++

```
__fastcall __stdcall HRESULT CreateInstance(const TGUID cid, const TGUID rid,  pv);
```

Description

This is CreateInstance, a member of class ITransactionContextEx.

57.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	CreateSharedPropertyGroup (see page 5879)	Returns the interface for a SharedPropertyGroup that allows MTS objects within a server process to share state.
	CreateSharedPropertyGroupManager (see page 5880)	Returns an interface for a new shared property group manager that creates and coordinates shared properties of MTS objects.
	CreateTransactionContext (see page 5880)	Starts an MTS transaction.
	CreateTransactionContextEx (see page 5881)	Instantiates a TransactionContextEx object, which marks the beginning of a transaction.
	GetObjectContext (see page 5882)	Fetches the IObjectContext (see page 5862) interface for the current thread.
	SafeRef (see page 5882)	Returns a reference to a transactional object that is safe to pass outside its context.

57.2.1 Mtx.CreateSharedPropertyGroup Function

Returns the interface for a SharedPropertyGroup that allows MTS objects within a server process to share state.

Pascal

```
function CreateSharedPropertyGroup(const Name: WideString): ISharedPropertyGroup;
```

C++

```
ISharedPropertyGroup CreateSharedPropertyGroup(const BSTR Name);
```

File

Mtx

Description

CreateSharedPropertyGroup returns an interface to a new shared property group. If a property group of the specified name exists, it returns a reference to the existing shared property group. Use this function to create and access the shared properties of a shared property group.

CreateSharedPropertyGroup sets up a SharedPropertyGroup with the default values of LockSetGet (see page 5885) for locking (isolation) mode, and Process (see page 5889) for release mode. LockSetGet (see page 5885) locks a property during every get or set operation on a shared property, making each operation atomic. This ensures that two clients cannot read or write to the same property at the same time, but it does not prevent other clients from concurrently accessing other properties in the same group. The Process (see page 5889) release mode ensures that the property group is not destroyed until the process in which it was created has terminated. (Objects that hold references on a property group must still call Release on their references).

To override these defaults, call CreateSharedPropertyGroupManager (see page 5880) and use the resulting interface to create a property group.

ISharedPropertyGroup (see page 5871) has several methods that can be used to share state among multiple objects in a server process. See ISharedPropertyGroup (see page 5871) in the MTS documentation for a list of methods.

By using shared property groups, you eliminate name collisions because they establish unique name spaces for the shared

properties they contain. The Shared Property Manager also implements locks and semaphores to protect shared properties from simultaneous access, which could result in lost updates and could leave the properties in an unpredictable state.

Note: Only objects running in the same process can share properties. If you want instances of different components to share properties, you have to install the components in the same MTS package. Because there is a risk that administrators will move components from one package to another, it's safest to limit the use of a shared property group to instances of components that are defined in the same DLL.

See Also

CreateSharedPropertyGroupManager

57.2.2 Mtx.CreateSharedPropertyGroupManager Function

Returns an interface for a new shared property group manager that creates and coordinates shared properties of MTS objects.

Pascal

```
function CreateSharedPropertyGroupManager: ISharedPropertyGroupManager;
```

C++

```
ISharedPropertyGroupManager CreateSharedPropertyGroupManager();
```

File

Mtx

Description

Call CreateSharedPropertyGroupManager before creating shared property groups if you are not using the CreateSharedPropertyGroup (see page 5879) function. The ISharedPropertyGroupManager (see page 5873) interface lets you create and access shared properties with more control that is provided by CreateSharedPropertyGroup (see page 5879).

By using shared property groups, you eliminate name collisions because they establish unique name spaces for the shared properties they contain. The Shared Property Manager also implements locks and semaphores to protect shared properties from simultaneous access, which could result in lost updates and could leave the properties in an unpredictable state.

For more information about the ISharedPropertyGroupManager (see page 5873) interface, see the MTS documentation.

CreateSharedPropertyGroup

57.2.3 Mtx.CreateTransactionContext Function

Starts an MTS transaction.

Pascal

```
function CreateTransactionContext: ITransactionContext;
```

C++

```
ITransactionContext CreateTransactionContext();
```

File

Mtx

Description

CreateTransactionContext allows client applications to control MTS transactions. CreateTransactionContext returns an interface to the new transaction context. Use this interface to enlist MTS server objects in the transaction, and to commit or roll back the transaction when done.

See Also

CreateTransactionContextEx

TMtsAutoObject

TMtsAutoObject

TMtsDataModule

TMtsDataModule

57.2.4 Mtx.CreateTransactionContextEx Function

Instantiates a TransactionContextEx object, which marks the beginning of a transaction.

Pascal

```
function CreateTransactionContextEx: ITransactionContextEx;
```

C++

```
ITransactionContextEx CreateTransactionContextEx();
```

File

Mtx

Description

MTS base clients use CreateTransactionEx to combine the work of one or more MTS objects into an atomic transaction and to commit or abort the transaction. Clients initiate a transaction by instantiating a CreateTransactionEx object. Clients end a transaction by calling Complete or Abort on the object.

Method	Description
Abort	Aborts the work of all MTS objects participating in the current transaction. The transaction is completed on return from this method.
Commit	Attempts to commit the work of all MTS objects participating in the current transaction. If any of the MTS objects participating in the transaction call SetAbort or DisableCommit, or if a system error occurs, the transaction is aborted. Otherwise, the transaction is committed. In either case, the transaction is completed on return from this method.
CreateInstance	Instantiates another MTS object. If the component that provides the object is configured to support or require a transaction, then the new object runs under the transaction of the TransactionContextEx object.

TMtsDataModule

57.2.5 Mtx.GetObjectContext Function

Fetches the IObjectContext (see page 5862) interface for the current thread.

Pascal

```
function GetObjectContext: IObjectContext;
```

C++

```
IObjectContext GetObjectContext();
```

File

Mtx

Description

When a COM object is created as part of the MTS environment or of a COM+ package (that is, a transactional object), a corresponding context object is also created. This context object exists for the entire lifetime of its transactional object, across one or more reactivation cycles. The object context keeps track of the object during deactivation. Call GetObjectContext to obtain an IObjectContext (see page 5862) interface pointer for the context object associated with the current thread.

Pass a pointer that receives the IObjectContext (see page 5862) interface pointer as ppInstanceContext.

GetObjectContext returns S_OK if it returns a pointer to the context object. Otherwise, it returns an error code.

Note: C++Builder automatically fetches the IObjectContext (see page 5862) interface when a transactional object is activated. The interface pointer is stored as the m_spObjectContext member of the transactional object's class.

Warning: When writing a transactional object that uses VCL classes, use the Get_ObjectContext method of TMtsDll instead. ComSvcs.h defines GetObjectContext using a macro so that it calls COM+ or MTS, depending on the system you use to build the transactional object. This macro interferes with the GetObjectContext method of some VCL classes, and so it is undefined when you include the VCL headers.

See Also

TMtsDll

57.2.6 Mtx.SafeRef Function

Returns a reference to a transactional object that is safe to pass outside its context.

Pascal

```
function SafeRef(const rid: TGUID; Unk: IUnknown): Pointer;
```

C++

```
void * SafeRef(const TGUID rid, IUnknown Unk);
```

File

Mtx

Description

SafeRef encapsulates the SafeRef MTS function that passes in

a reference to the interface ID of the interface (rid) that the current object wants to pass to another object or client

and

a reference to an interface on the current object (pUnk).

SafeRef returns a pointer to the interface specified in the rid parameter that is safe to pass outside the current object's context.

When using COM+, it is always safe to pass a self-reference to a client or other object. Thus, when you call SafeRef in an application that is running under a version of Windows that implemnts COM+, SafeRef simply returns the pointer passed as pUnk. Thus, it is not necessary to call SafeRef for COM+ applications. It will, however, do no harm in an application that is used under both MTS and COM+.

Under MTS, and should always call SafeRef before passing a self-reference to a client or other object and then pass the reference returned by this call. Under MTS, it is not safe for an object to pass a self pointer (Delphi) or this pointer (C++), or a self-reference obtained through an internal call to QueryInterface, to a client or to any other object. Once such a reference is passed outside the object's context, it is no longer a valid reference.

Calling SafeRef on a reference that is already safe returns the safe reference unchanged, except that the reference count on the interface is incremented.

When a client calls QueryInterface on a reference that is safe, MTS automatically ensures that the reference returned to the client is also a safe reference.

An object that obtains a safe reference must release the safe reference when it is finished with it.

Under MTS, safe references have different pointer values than their unsafe counterparts. For example, self or this and the safe version of self or this do not have the same value. It is important to be aware of this when testing whether two pointers refer to the same object. Calling QueryInterface for IID_IUnknown on each of the pointers and comparing the value of the returned pointers may result in the wrong conclusion. It is possible that both pointers refer to the same object, but that one is a safe reference and the other is not. If both references are safe references, they can be compared in the usual way. This is only a consideration for MTS objects, because clients should never have access to unsafe references.

Note: When writing a transactional object that may be installed under either MTS or COM+, use the SafeRef method of TMtsDll instead. TMtsDll automatically checks the current environment and returns the appropriate reference.

57.3 Constants

The following table lists constants in this documentation.

Constants

Name	Description
CLASS_SharedPropertyGroupManager (see page 5884)	This is constant Mtx.CLASS_SharedPropertyGroupManager.
CLASS_TransactionContext (see page 5884)	This is constant Mtx.CLASS_TransactionContext.
CLASS_TransactionContextEx (see page 5885)	This is constant Mtx.CLASS_TransactionContextEx.
LockMethod (see page 5885)	This is constant Mtx.LockMethod.
LockSetGet (see page 5885)	This is constant Mtx.LockSetGet.
mtsErrCtxAborted (see page 5886)	This is constant Mtx.mtsErrCtxAborted.
mtsErrCtxAborting (see page 5886)	This is constant Mtx.mtsErrCtxAborting.
mtsErrCtxActivityTimeout (see page 5886)	This is constant Mtx.mtsErrCtxActivityTimeout.
mtsErrCtxNoContext (see page 5887)	This is constant Mtx.mtsErrCtxNoContext.
mtsErrCtxNoSecurity (see page 5887)	This is constant Mtx.mtsErrCtxNoSecurity.
mtsErrCtxNotRegistered (see page 5887)	This is constant Mtx.mtsErrCtxNotRegistered.
mtsErrCtxOldReference (see page 5888)	This is constant Mtx.mtsErrCtxOldReference.
mtsErrCtxRoleNotFound (see page 5888)	This is constant Mtx.mtsErrCtxRoleNotFound.
mtsErrCtxTMNotAvailable (see page 5888)	This is constant Mtx.mtsErrCtxTMNotAvailable.
mtsErrCtxWrongThread (see page 5889)	This is constant Mtx.mtsErrCtxWrongThread.
Process (see page 5889)	This is constant Mtx.Process.
Standard (see page 5889)	This is constant Mtx.Standard.

57.3.1 Mtx.CLASS_SharedPropertyGroupManager Constant

Pascal

```
CLASS_SharedPropertyGroupManager: TGUID = '{2A005C11-A5DE-11CF-9E66-00AA00A3F464}';
```

C++

```
TGUID CLASS_SharedPropertyGroupManager = '{2A005C11-A5DE-11CF-9E66-00AA00A3F464}';
```

File

Mtx

Description

This is constant Mtx.CLASS_SharedPropertyGroupManager.

57.3.2 Mtx.CLASS_TransactionContext Constant

Pascal

```
CLASS_TransactionContext: TGUID = '{7999FC25-D3C6-11CF-ACAB-00A024A55AEF}';
```

C++

```
TGUID CLASS_TransactionContext = '{7999FC25-D3C6-11CF-ACAB-00A024A55AEF}';
```

File

Mtx

Description

This is constant Mtx.CLASS_TransactionContext.

57.3.3 Mtx.CLASS_TransactionContextEx Constant

Pascal

```
CLASS_TransactionContextEx: TGUID = '{5CB66670-D3D4-11CF-ACAB-00A024A55AEF}';
```

C++

```
TGUID CLASS_TransactionContextEx = '{5CB66670-D3D4-11CF-ACAB-00A024A55AEF}';
```

File

Mtx

Description

This is constant Mtx.CLASS_TransactionContextEx.

57.3.4 Mtx.LockMethod Constant

Pascal

```
LockMethod = $00000001;
```

C++

```
LockMethod = 0x00000001;
```

File

Mtx

Description

This is constant Mtx.LockMethod.

57.3.5 Mtx.LockSetGet Constant

Pascal

```
LockSetGet = $00000000;
```

C++

```
LockSetGet = 0x00000000;
```

File

Mtx

Description

This is constant Mtx.LockSetGet.

57.3.6 Mtx.mtsErrCtxAborted Constant

Pascal

```
mtsErrCtxAborted = $8004E002;
```

C++

```
mtsErrCtxAborted = 0x8004E002;
```

File

Mtx

Description

This is constant Mtx.mtsErrCtxAborted.

57.3.7 Mtx.mtsErrCtxAborting Constant

Pascal

```
mtsErrCtxAborting = $8004E003;
```

C++

```
mtsErrCtxAborting = 0x8004E003;
```

File

Mtx

Description

This is constant Mtx.mtsErrCtxAborting.

57.3.8 Mtx.mtsErrCtxActivityTimeout Constant

Pascal

```
mtsErrCtxActivityTimeout = $8004E006;
```

C++

```
mtsErrCtxActivityTimeout = 0x8004E006;
```

File

Mtx

Description

This is constant Mtx.mtsErrCtxActivityTimeout.

57.3.9 Mtx.mtsErrCtxNoContext Constant

Pascal

```
mtsErrCtxNoContext = $8004E004;
```

C++

```
mtsErrCtxNoContext = 0x8004E004;
```

File

Mtx

Description

This is constant Mtx.mtsErrCtxNoContext.

57.3.10 Mtx.mtsErrCtxNoSecurity Constant

Pascal

```
mtsErrCtxNoSecurity = $8004E00D;
```

C++

```
mtsErrCtxNoSecurity = 0x8004E00D;
```

File

Mtx

Description

This is constant Mtx.mtsErrCtxNoSecurity.

57.3.11 Mtx.mtsErrCtxNotRegistered Constant

Pascal

```
mtsErrCtxNotRegistered = $8004E005;
```

C++

```
mtsErrCtxNotRegistered = 0x8004E005;
```

File

Mtx

Description

This is constant Mtx.mtsErrCtxNotRegistered.

57.3.12 Mtx.mtsErrCtxOldReference Constant

Pascal

```
mtsErrCtxOldReference = $8004E007;
```

C++

```
mtsErrCtxOldReference = 0x8004E007;
```

File

Mtx

Description

This is constant Mtx.mtsErrCtxOldReference.

57.3.13 Mtx.mtsErrCtxRoleNotFound Constant

Pascal

```
mtsErrCtxRoleNotFound = $8004E00C;
```

C++

```
mtsErrCtxRoleNotFound = 0x8004E00C;
```

File

Mtx

Description

This is constant Mtx.mtsErrCtxRoleNotFound.

57.3.14 Mtx.mtsErrCtxTMNotAvailable Constant

Pascal

```
mtsErrCtxTMNotAvailable = $8004E00F;
```

C++

```
mtsErrCtxTMNotAvailable = 0x8004E00F;
```

File

Mtx

Description

This is constant Mtx.mtsErrCtxTMNotAvailable.

57.3.15 Mtx.mtsErrCtxWrongThread Constant

Pascal

```
mtsErrCtxWrongThread = $8004E00E;
```

C++

```
mtsErrCtxWrongThread = 0x8004E00E;
```

File

Mtx

Description

This is constant Mtx.mtsErrCtxWrongThread.

57.3.16 Mtx.Process Constant

Pascal

```
Process = $00000001;
```

C++

```
Process = 0x00000001;
```

File

Mtx

Description

This is constant Mtx.Process.

57.3.17 Mtx.Standard Constant

Pascal

```
Standard = $00000000;
```

C++

```
Standard = 0x00000000;
```

File

Mtx

Description

This is constant Mtx.Standard.

58 ObjAuto Namespace

This is namespace ObjAuto.

Topics

Name	Description
Interfaces (see page 5893)	The following table lists interfaces in this documentation.
Functions (see page 5895)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 5898)	The following table lists structs, records, enums in this documentation.
Types (see page 5901)	The following table lists types in this documentation.
Constants (see page 5905)	The following table lists constants in this documentation.

Constants

Name	Description
paEAX (see page 5905)	This is constant ObjAuto.paEAX.
paECX (see page 5905)	This is constant ObjAuto.paECX.
paEDX (see page 5906)	This is constant ObjAuto.paEDX.
paStack (see page 5906)	This is constant ObjAuto.paStack.

Functions

	Name	Description
	CreateMethodPointer (see page 5895)	This is function ObjAuto.CreateMethodPointer.
	CreateMethodPointer (see page 5895)	This is function ObjAuto.CreateMethodPointer.
	GetInvokeInstance (see page 5896)	This is function ObjAuto.GetInvokeInstance.
	GetMethodInfo (see page 5896)	This is function ObjAuto.GetMethodInfo.
	GetMethods (see page 5896)	This is function ObjAuto.GetMethods.
	ObjectInvoke (see page 5897)	This is function ObjAuto.ObjectInvoke.
	ReleaseMethodPointer (see page 5897)	This is function ObjAuto.ReleaseMethodPointer.

Interfaces

	Name	Description
	IMethodHandler (see page 5893)	This is class ObjAuto.IMethodHandler.

Structs, Records, Enums

	Name	Description
	TCallingConvention (see page 5898)	This is record ObjAuto.TCallingConvention.
	TMethodInfoHeader (see page 5898)	This is record ObjAuto.TMethodInfoHeader.

	TParameters (see page 5899)	This is record ObjAuto.TParameters.
	TParamInfo (see page 5899)	This is record ObjAuto.TParamInfo.
	TReturnInfo (see page 5900)	This is record ObjAuto.TReturnInfo.

Types

Name	Description
PMethodInfoHeader (see page 5901)	This is type ObjAuto.PMethodInfoHeader.
PParameters (see page 5901)	This is type ObjAuto.PParameters.
PParamInfo (see page 5902)	This is type ObjAuto.PParamInfo.
PPointer (see page 5902)	This is type ObjAuto.PPointer.
PReturnInfo (see page 5902)	This is type ObjAuto.PReturnInfo.
PWord (see page 5903)	This is type ObjAuto.PWord.
TDynamicInvokeEvent (see page 5903)	This is type ObjAuto.TDynamicInvokeEvent.
TMethodInfoArray (see page 5903)	This is type ObjAuto.TMethodInfoArray.
TParamFlags (see page 5904)	This is type ObjAuto.TParamFlags.

58.1 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IMethodHandler (see page 5893)	This is class ObjAuto.IMethodHandler.

58.1.1 IMethodHandler Interface

Class Hierarchy

ObjAuto.IMethodHandler

Pascal

```
IMethodHandler = interface;
```

C++

```
__interface IMethodHandler;
```

File

ObjAuto

Description

This is class ObjAuto.IMethodHandler.

58.1.1.1 IMethodHandler Members

The following tables list the members exposed by IMethodHandler.

Public Methods

	Name	Description
	Execute (see page 5894)	This is Execute, a member of class IMethodHandler.
	InstanceToVariant (see page 5894)	This is InstanceToVariant, a member of class IMethodHandler.

58.1.1.2 IMethodHandler Methods

The methods of the IMethodHandler class are listed here.

Public Methods

	Name	Description
	Execute (see page 5894)	This is Execute, a member of class IMethodHandler.
	InstanceToVariant (see page 5894)	This is InstanceToVariant, a member of class IMethodHandler.

58.1.1.2.1 IMethodHandler.Execute Method

Pascal

```
function Execute(const Args: array of Variant): Variant;
```

C++

```
__fastcall Variant Execute(const array of Variant Args);
```

Description

This is Execute, a member of class IMethodHandler.

58.1.1.2.2 IMethodHandler.InstanceToVariant Method

Pascal

```
function InstanceToVariant(Instance: TObject): Variant;
```

C++

```
__fastcall Variant InstanceToVariant(TObject * Instance);
```

Description

This is InstanceToVariant, a member of class IMethodHandler.

58.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	CreateMethodPointer (see page 5895)	This is function ObjAuto.CreateMethodPointer.
	CreateMethodPointer (see page 5895)	This is function ObjAuto.CreateMethodPointer.
	GetInvokeInstance (see page 5896)	This is function ObjAuto.GetInvokeInstance.
	GetMethodInfo (see page 5896)	This is function ObjAuto.GetMethodInfo.
	GetMethods (see page 5896)	This is function ObjAuto.GetMethods.
	ObjectInvoke (see page 5897)	This is function ObjAuto.ObjectInvoke.
	ReleaseMethodPointer (see page 5897)	This is function ObjAuto.ReleaseMethodPointer.

58.2.1 ObjAuto.CreateMethodPointer Function

Pascal

```
function CreateMethodPointer(const MethodHandler: IMethodHandler; TypeData: PTypeData):
TMethod; overload;
```

C++

```
TMethod CreateMethodPointer(const IMethodHandler MethodHandler, PTypeData TypeData);
```

File

ObjAuto

Description

This is function ObjAuto.CreateMethodPointer.

58.2.2 ObjAuto.CreateMethodPointer Function

Pascal

```
function CreateMethodPointer(const ADynamicInvokeEvent: TDynamicInvokeEvent; TypeData:
PTypeData): TMethod; overload;
```

C++

```
TMethod CreateMethodPointer(const TDynamicInvokeEvent ADynamicInvokeEvent, PTypeData TypeData);
```

File

ObjAuto

Description

This is function ObjAuto.CreateMethodPointer.

58.2.3 ObjAuto.GetInvokeInstance Function

Pascal

```
function GetInvokeInstance(MethodPointer: TMethod): TObject;
```

C++

```
TObject * GetInvokeInstance(TMethod MethodPointer);
```

File

ObjAuto

Description

This is function ObjAuto.GetInvokeInstance.

58.2.4 ObjAuto.GetMethodInfo Function

Pascal

```
function GetMethodInfo(Instance: TObject; const MethodName: ShortString): PMethodInfoHeader;
```

C++

```
PMethodInfoHeader GetMethodInfo(TObject * Instance, const ShortString MethodName);
```

File

ObjAuto

Description

This is function ObjAuto.GetMethodInfo.

58.2.5 ObjAuto.GetMethods Function

Pascal

```
function GetMethods(ClassType: TClass): TMethodInfoArray;
```

C++

```
TMethodInfoArray GetMethods(TClass ClassType);
```

File

ObjAuto

Description

This is function ObjAuto.GetMethods.

58.2.6 ObjAuto.ObjectInvoke Function

Pascal

```
function ObjectInvoke(Instance: TObject; MethodHeader: PMethodInfoHeader; const ParamIndexes:
array of Integer; const Params: array of Variant): Variant;
```

C++

```
Variant ObjectInvoke(TObject * Instance, PMethodInfoHeader MethodHeader, const array of
Integer ParamIndexes, const array of Variant Params);
```

File

ObjAuto

Description

This is function ObjAuto.ObjectInvoke.

58.2.7 ObjAuto.ReleaseMethodPointer Function

Pascal

```
procedure ReleaseMethodPointer(MethodPointer: TMethod);
```

C++

```
ReleaseMethodPointer(TMethod MethodPointer);
```

File

ObjAuto

Description

This is function ObjAuto.ReleaseMethodPointer.

58.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TCallingConvention (see page 5898)	This is record ObjAuto.TCallingConvention.

Records

	Name	Description
	TMethodInfoHeader (see page 5898)	This is record ObjAuto.TMethodInfoHeader.
	TParameters (see page 5899)	This is record ObjAuto.TParameters.
	TParamInfo (see page 5899)	This is record ObjAuto.TParamInfo.
	TReturnInfo (see page 5900)	This is record ObjAuto.TReturnInfo.

58.3.1 ObjAuto.TCallingConvention Enumeration

Pascal

```
TCallingConvention = (
  ccRegister,
  ccCdecl,
  ccPascal,
  ccStdCall,
  ccSafeCall
);
```

C++

```
enum TCallingConvention {
  ccRegister,
  ccCdecl,
  ccPascal,
  ccStdCall,
  ccSafeCall
};
```

File

ObjAuto

Description

This is record ObjAuto.TCallingConvention.

58.3.2 ObjAuto.TMethodInfoHeader Record

Pascal

```
TMethodInfoHeader = packed record
  Len: Word;
  Addr: Pointer;
```

```
    Name: ShortString;
  end;
```

C++

```
  struct TMethodInfoHeader {
    Word Len;
    void * Addr;
    ShortString Name;
  };
```

File

ObjAuto

Description

This is record ObjAuto.TMethodInfoHeader.

58.3.3 ObjAuto.TParameters Record

Pascal

```
  TParameters = packed record
    Registers: array[paEDX..paECX] of Cardinal;
    Stack: array[0..1023] of Byte;
  end;
```

C++

```
  struct TParameters {
    array[paEDX..paECX] of Cardinal Registers;
    array[0..1023] of Byte Stack;
  };
```

File

ObjAuto

Description

This is record ObjAuto.TParameters.

58.3.4 ObjAuto.TParamInfo Record

Pascal

```
  TParamInfo = packed record
    Flags: TParamFlags;
    ParamType: ^PTypeInfo;
    Access: Word;
    Name: ShortString;
  end;
```

C++

```
  struct TParamInfo {
    TParamFlags Flags;
    ^PTypeInfo ParamType;
    Word Access;
    ShortString Name;
  };
```

File

ObjAuto

Description

This is record ObjAuto.TParamInfo.

58.3.5 ObjAuto.TReturnInfo Record

Pascal

```
TReturnInfo = packed record
  Version: Byte;
  CallingConvention: TCallingConvention;
  ReturnType: ^PTypeInfo;
  ParamSize: Word;
end;
```

C++

```
struct TReturnInfo {
  Byte Version;
  TCallingConvention CallingConvention;
  ^PTypeInfo ReturnType;
  Word ParamSize;
};
```

File

ObjAuto

Description

This is record ObjAuto.TReturnInfo.

58.4 Types

The following table lists types in this documentation.

Types

Name	Description
PMethodInfoHeader (see page 5901)	This is type ObjAuto.PMethodInfoHeader.
PParameters (see page 5901)	This is type ObjAuto.PParameters.
PParamInfo (see page 5902)	This is type ObjAuto.PParamInfo.
PPointer (see page 5902)	This is type ObjAuto.PPointer.
PReturnInfo (see page 5902)	This is type ObjAuto.PReturnInfo.
PWord (see page 5903)	This is type ObjAuto.PWord.
TDynamicInvokeEvent (see page 5903)	This is type ObjAuto.TDynamicInvokeEvent.
TMethodInfoArray (see page 5903)	This is type ObjAuto.TMethodInfoArray.
TParamFlags (see page 5904)	This is type ObjAuto.TParamFlags.

58.4.1 ObjAuto.PMethodInfoHeader Type

Pascal

```
PMethodInfoHeader = ^TMethodInfoHeader;
```

C++

```
^TMethodInfoHeader PMethodInfoHeader;
```

File

ObjAuto

Description

This is type ObjAuto.PMethodInfoHeader.

58.4.2 ObjAuto.PParameters Type

Pascal

```
PParameters = ^TParameters;
```

C++

```
^TParameters PParameters;
```

File

ObjAuto

Description

This is type ObjAuto.PParameters.

58.4.3 ObjAuto.PParamInfo Type

Pascal

```
PParamInfo = ^TParamInfo;
```

C++

```
^TParamInfo PParamInfo;
```

File

ObjAuto

Description

This is type ObjAuto.PParamInfo.

58.4.4 ObjAuto.PPointer Type

Pascal

```
PPointer = ^Pointer;
```

C++

```
^Pointer PPointer;
```

File

ObjAuto

Description

This is type ObjAuto.PPointer.

58.4.5 ObjAuto.PReturnInfo Type

Pascal

```
PReturnInfo = ^TReturnInfo;
```

C++

```
^TReturnInfo PReturnInfo;
```

File

ObjAuto

Description

This is type ObjAuto.PReturnInfo.

58.4.6 ObjAuto.PWord Type

Pascal

```
PWord = ^Word;
```

C++

```
^Word PWord;
```

File

ObjAuto

Description

This is type ObjAuto.PWord.

58.4.7 ObjAuto.TDynamicInvokeEvent Type

Pascal

```
TDynamicInvokeEvent = procedure (Params: PParameters; StackSize: Integer) of object;
```

C++

```
(Params: PParameters; StackSize: Integer) ( TDynamicInvokeEvent)();
```

File

ObjAuto

Description

This is type ObjAuto.TDynamicInvokeEvent.

58.4.8 ObjAuto.TMethodInfoArray Type

Pascal

```
TMethodInfoArray = array of PMethodInfoHeader;
```

C++

```
array of PMethodInfoHeader TMethodInfoArray;
```

File

ObjAuto

Description

This is type ObjAuto.TMethodInfoArray.

58.4.9 ObjAuto.TParamFlags Type

Pascal

```
TParamFlags = set of (pfVar, pfConst, pfArray, pfAddress, pfReference, pfOut, pfResult);
```

C++

```
(pfVar, pfConst, pfArray, pfAddress, pfReference, pfOut, pfResult) TParamFlags;
```

File

ObjAuto

Description

This is type ObjAuto.TParamFlags.

58.5 Constants

The following table lists constants in this documentation.

Constants

Name	Description
paEAX (see page 5905)	This is constant ObjAuto.paEAX.
paECX (see page 5905)	This is constant ObjAuto.paECX.
paEDX (see page 5906)	This is constant ObjAuto.paEDX.
paStack (see page 5906)	This is constant ObjAuto.paStack.

58.5.1 ObjAuto.paEAX Constant

Pascal

```
paEAX = Word(0);
```

C++

```
paEAX = Word(0);
```

File

ObjAuto

Description

This is constant ObjAuto.paEAX.

58.5.2 ObjAuto.paECX Constant

Pascal

```
paECX = Word(2);
```

C++

```
paECX = Word(2);
```

File

ObjAuto

Description

This is constant ObjAuto.paECX.

58.5.3 ObjAuto.paEDX Constant

Pascal

```
paEDX = Word(1);
```

C++

```
paEDX = Word(1);
```

File

ObjAuto

Description

This is constant ObjAuto.paEDX.

58.5.4 ObjAuto.paStack Constant

Pascal

```
paStack = Word(3);
```

C++

```
paStack = Word(3);
```

File

ObjAuto

Description

This is constant ObjAuto.paStack.

59 ObjBrkr Namespace

This is namespace ObjBrkr.

Topics

Name	Description
Classes (see page 5908)	The following table lists classes in this documentation.

Classes

	Name	Description
	EBrokerException (see page 5908)	EBrokerException is the exception raised by simple object brokers when they can't locate an available server.
	TServerCollection (see page 5908)	TServerCollection is a collection of TServerItem (see page 5912) objects.
	TServerItem (see page 5912)	TServerItem describes an application server for a simple object broker.
	TSimpleObjectBroker (see page 5916)	TSimpleObjectBroker maintains a list of available application servers for a connection component.

59.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EBrokerException (see page 5908)	EBrokerException is the exception raised by simple object brokers when they can't locate an available server.
	TServerCollection (see page 5908)	TServerCollection is a collection of TServerItem (see page 5912) objects.
	TServerItem (see page 5912)	TServerItem describes an application server for a simple object broker.
	TSimpleObjectBroker (see page 5916)	TSimpleObjectBroker maintains a list of available application servers for a connection component.

59.1.1 EBrokerException Class

EBrokerException is the exception raised by simple object brokers when they can't locate an available server.

Class Hierarchy

Pascal

```
EBrokerException = class(Exception);
```

C++

```
class EBrokerException : public Exception;
```

File

ObjBrkr

Description

EBrokerException is raised when a simple object broker can't locate an available server.

See Also

TSimpleObjectBroker (see page 5916)

TServerCollection (see page 5908)

59.1.2 TServerCollection Class

TServerCollection is a collection of TServerItem (see page 5912) objects.

Class Hierarchy

Pascal

```
TServerCollection = class(TOwnedCollection);
```

C++

```
class TServerCollection : public TOwnedCollection;
```

File

ObjBrkr

Description

TSimpleObjectBroker (see page 5916) uses TServerCollection to represent the set of available application servers to which a client application can connect. Use the properties and methods of TServerCollection to manage the set of servers. For example, you can add items as new server systems come on line, disable server items when the corresponding system is temporarily out of commission, and so on.

See Also

TServerItem (see page 5912)

TSimpleObjectBroker (see page 5916)

59.1.2.1 TServerCollection Members

The following tables list the members exposed by TServerCollection.

Public Methods

	Name	Description
	Create (see page 5909)	Creates and initializes a TServerCollection (see page 5908) object.
	FindServer (see page 5910)	Returns the server from the Items (see page 5911) property array that has a specified computer name.
	GetBalancedName (see page 5910)	Returns the ComputerName property of a randomly chosen server from the Items (see page 5911) property array.
	GetNextName (see page 5911)	This is GetNextName, a member of class TServerCollection.

Public Properties

	Name	Description
	Items (see page 5911)	Lists the TServerItem (see page 5912) objects in the collection.

59.1.2.2 TServerCollection.Create Constructor

Creates and initializes a TServerCollection (see page 5908) object.

Pascal

```
constructor Create(AOwner: TComponent);
```

C++

```
__fastcall TServerCollection(TComponent * AOwner);
```

Description

Applications should not need to instantiate TServerCollection (see page 5908). The simple object broker that uses TServerCollection (see page 5908) to manage its list of available servers creates this object from its own constructor.

See Also

Servers (see page 5923)

59.1.2.3 TServerCollection Methods

The methods of the TServerCollection class are listed here.

Public Methods

	Name	Description
	FindServer (see page 5910)	Returns the server from the Items (see page 5911) property array that has a specified computer name.
	GetBalancedName (see page 5910)	Returns the ComputerName property of a randomly chosen server from the Items (see page 5911) property array.
	GetNextName (see page 5911)	This is GetNextName, a member of class TServerCollection.

59.1.2.3.1 TServerCollection.FindServer Method

Returns the server from the Items (see page 5911) property array that has a specified computer name.

Pascal

```
function FindServer(const ComputerName: string): TServerItem;
```

C++

```
__fastcall TServerItem FindServer(const UnicodeString ComputerName);
```

Description

Call FindServer to locate a server in the items property array given its ComputerName property. The ComputerName parameter specifies this computer name. Usually, this value is obtained by a previous call to GetBalancedName (see page 5910) or GetNextName (see page 5911).

Note: FindServer returns the first item it finds with the given ComputerName property. Unlike the GetBalancedName (see page 5910) and GetNextName (see page 5911) methods, it does not ignore servers that have failed or been disabled (HasFailed is true, or Enabled is false).

See Also

GetBalancedName (see page 5910)

getnextname (see page 5911)

ComputerName (see page 5914)

Items (see page 5911)

Enabled (see page 5915)

HasFailed (see page 5915)

59.1.2.3.2 TServerCollection.GetBalancedName Method

Returns the ComputerName property of a randomly chosen server from the Items (see page 5911) property array.

Pascal

```
function GetBalancedName: string;
```

C++

```
__fastcall UnicodeString GetBalancedName();
```

Description

Call GetBalancedName to get the name of an available server. Servers in the Items (see page 5911) property array are considered available when no connection attempts have failed (HasFailed is false) and their Enabled property has not been set to false. GetBalancedName selects an available TServerItem (see page 5912) at random from the Items (see page 5911) property array and returns its ComputerName property.

See Also

Items (see page 5911)

LoadBalanced (see page 5922)

ComputerName (see page 5914)

HasFailed (see page 5915)

Enabled (see page 5915)

getnextname (see page 5911)

59.1.2.3.3 TServerCollection.GetNextName Method

Pascal

```
function GetNextName: string;
```

C++

```
__fastcall UnicodeString GetNextName();
```

Description

This is GetNextName, a member of class TServerCollection.

59.1.2.4 TServerCollection Properties

The properties of the TServerCollection class are listed here.

Public Properties

	Name	Description
	Items (see page 5911)	Lists the TServerItem (see page 5912) objects in the collection.

59.1.2.4.1 TServerCollection.Items Property

Lists the TServerItem (see page 5912) objects in the collection.

Pascal

```
property Items [Index: Integer]: TServerItem;
```

C++

```
__property TServerItem Items[int Index];
```

Description

Use Items to access individual TServerItem (see page 5912) objects maintained by TServerCollection (see page 5908).

Note: In Delphi, Items is the default property of TServerCollection (see page 5908), so the name of the Items property can be left off when using this property. Thus the line

```
TSimpleObjectBroker1.Servers.Items[I].Enabled := False;
```

can be written

```
TSimpleObjectBroker1.Servers[I].Enabled := False;
```

Note: In C++, Items can be accessed using the [] operator, to achieve an affect similar to the default property in Delphi.

See Also

Enabled (see page 5915)

GetBalancedName (see page 5910)

getnextname (see page 5911)

FindServer (see page 5910)

operator_[]

59.1.3 TServerItem Class

TServerItem describes an application server for a simple object broker.

Class Hierarchy

Pascal

```
TServerItem = class(TCollectionItem);
```

C++

```
class TServerItem : public TCollectionItem;
```

File

ObjBrkr

Description

Use TServerItem to describe an application server to which client applications can connect. TSimpleObjectBroker (see page 5916) maintains a list of these descriptions. Then, when a connection component needs to open a connection, it can use the information stored in a server item to identify an available application server.

See Also

TSimpleObjectBroker (see page 5916)

TRemoteDataModule

TDispatchConnection (see page 4796)

59.1.3.1 TServerItem Members

The following tables list the members exposed by TServerItem.

Protected Methods

	Name	Description
	GetDisplayName (see page 5914)	Returns the name of the collection item as it appears in the collection editor.

Public Methods

	Name	Description
	Create (see page 5913)	Creates and initializes a TServerItem (see page 5912) instance.

Public Properties

	Name	Description
	HasFailed (see page 5915)	Indicates whether a connection attempt to the associated server machine has failed.

Published Properties

	Name	Description
	ComputerName (see page 5914)	Identifies the machine where the application server resides.
	Enabled (see page 5915)	Enables or disables the server item.
	Port (see page 5916)	Specifies the port number for the associated server application.

59.1.3.2 TServerItem.Create Constructor

Creates and initializes a TServerItem (see page 5912) instance.

Pascal

```
constructor Create(AOwner: TCollection); override;
```

C++

```
virtual __fastcall TServerItem(TCollection AOwner);
```

Description

Do not call Create directly to add a new server item to a server collection. Instead, use the Add or Insert method of the TServerCollection (see page 5908) object.

The AOwner parameter specifies the server collection that manages the newly created server item.

After calling the inherited constructor, Create initializes the Enabled (see page 5915) property to true, the HasFailed (see page 5915) property to false, and the Port (see page 5916) property to 211.

See Also

Add

Insert

Port (see page 5916)

HasFailed (see page 5915)

Enabled (see page 5915)

59.1.3.3 TServerItem Methods

The methods of the TServerItem class are listed here.

Protected Methods

	Name	Description
	GetDisplayName (see page 5914)	Returns the name of the collection item as it appears in the collection editor.

59.1.3.3.1 TServerItem.GetDisplayName Method

Returns the name of the collection item as it appears in the collection editor.

Pascal

```
function GetDisplayName: string; override;
```

C++

```
virtual __fastcall UnicodeString GetDisplayName();
```

Description

GetDisplayName is the protected read implementation of the DisplayName property.

See Also

DisplayName

GetNamePath

59.1.3.4 TServerItem Properties

The properties of the TServerItem class are listed here.

Public Properties

	Name	Description
	HasFailed (see page 5915)	Indicates whether a connection attempt to the associated server machine has failed.

Published Properties

	Name	Description
	ComputerName (see page 5914)	Identifies the machine where the application server resides.
	Enabled (see page 5915)	Enables or disables the server item.
	Port (see page 5916)	Specifies the port number for the associated server application.

59.1.3.4.1 TServerItem.ComputerName Property

Identifies the machine where the application server resides.

Pascal

```
property ComputerName: string;
```

C++

```
__property UnicodeString ComputerName;
```

Description

Set ComputerName to a string that identifies the machine where the application server resides. The value of this string depends on the type of connection component that requests this value from its object broker.

If the connection component is a TDCOMConnection (see page 4790) object, ComputerName is the Windows computer name. (This value can be found in the Control panel under network settings.)

If the connection component is a TSocketConnection object, ComputerName is either the host name or IP address of the system running the application server. Socket connection components parse this string to determine which it is.

If the connection component is a TWebConnection or TSoapConnection object, ComputerName is the URL of the dispatcher (httpsrvr.dll or soapsrvr.dll (running on the system with the application server.

See Also

GetBalancedName (see page 5910)

getnextname (see page 5911)

Port (see page 5916)

computername (see page 4793)

Address

Host

ObjectBroker (see page 4806)

59.1.3.4.2 TServerItem.Enabled Property

Enables or disables the server item.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Set Enabled to indicate whether the server should made available in the simple object broker. When Enabled is true, the ComputerName (see page 5914) property can be supplied to connection components by the object broker's GetComputerForGUID or GetComputerForProgID methods. When Enabled is false, the server item is not returned.

Note: Even when the server item is disabled, it is still returned by TServerCollection (see page 5908)'s FindServer method.

See Also

GetComputerForGUID (see page 5919)

GetComputerForProgID (see page 5919)

HasFailed (see page 5915)

FindServer (see page 5910)

59.1.3.4.3 TServerItem.HasFailed Property

Indicates whether a connection attempt to the associated server machine has failed.

Pascal

```
property HasFailed: Boolean;
```

C++

```
__property Boolean HasFailed;
```

Description

When connection components can't successfully open a connection to an application server, they inform the object broker by calling SetConnectStatus. The simple object broker, in turn, records this fact by setting the HasFailed property to true.

When HasFailed is false, the ComputerName (see page 5914) property can be supplied to connection components by the object broker's GetComputerForGUID or GetComputerForProgID methods. When HasFailed is true, the server item is not returned.

Once a server has failed it is presumed to be down until the application explicitly resets the HasFailed property to false.

Do not use HasFailed to disable server items. Instead, use the Enabled (see page 5915) property to disable servers for any reason other than a failed connection.

Note: Even when HasFailed is true, the server item is still returned by TServerCollection (see page 5908)'s FindServer method.

See Also

SetConnectStatus (see page 5921)

Enabled (see page 5915)

GetComputerForGUID (see page 5919)

GetComputerForProgID (see page 5919)

FindServer (see page 5910)

59.1.3.4.4 TServerItem.Port Property

Specifies the port number for the associated server application.

Pascal

```
property Port: Integer;
```

C++

```
__property int Port;
```

Description

Read Port to obtain a port number when using the server item to supply information for connecting using TCP/IP. This value is returned by the GetPortForComputer method of the simple object broker.

By default, the value of Port is 211, which is the default port number for the socket dispatcher application ScktSrvr.exe. If the server listens on a different port, change this property to indicate the listening port.

Note: Server items that supply a Port number should specify the server system's IP address or host name as the value of ComputerName (see page 5914).

See Also

ComputerName (see page 5914)

59.1.4 TSimpleObjectBroker Class

TSimpleObjectBroker maintains a list of available application servers for a connection component.

Class Hierarchy

Pascal

```
TSimpleObjectBroker = class(TCustomObjectBroker);
```

C++

```
class TSimpleObjectBroker : public TCustomObjectBroker;
```

File

ObjBrkr

Description

TSimpleObjectBroker maintains a list of servers, all of which run the application server for a multi-tiered application. When a connection component requests a server, the simple object broker passes the name of one of the available servers in the list. This process allows client applications to locate server systems dynamically at runtime. If there are redundant server systems, this allows client applications to continue functioning when a server goes down.

TSimpleObjectBroker can randomize the selection of servers from among the currently available servers in its list to provide a simple system of load balancing.

See Also

TDispatchConnection (see page 4796)

TServerCollection (see page 5908)

59.1.4.1 TSimpleObjectBroker Members

The following tables list the members exposed by TSimpleObjectBroker.

Public Methods

	Name	Description
	Create (see page 5918)	Creates and initializes a simple object broker.
	Destroy (see page 5918)	Destroys an instance of TSimpleObjectBroker (see page 5916).
	GetComputerForGUID (see page 5919)	Returns a string that identifies an available server machine.
	GetComputerForProgID (see page 5919)	Returns a string that identifies an available server machine.
	GetPortForComputer (see page 5920)	Returns a port number for connecting to a specified remote server.
	LoadFromStream (see page 5920)	Sets the value of the Servers (see page 5923) property from a stream.
	SaveToStream (see page 5921)	Saves the value of the Servers (see page 5923) property to a stream.
	SetConnectStatus (see page 5921)	Records whether a connection was established to a specified server.

Public Properties

	Name	Description
	ServerData (see page 5922)	Encapsulates the list of servers as an OleVariant.

Published Properties

	Name	Description
	LoadBalanced (see page 5922)	Specifies how the simple object broker picks a server from its list.
	Servers (see page 5923)	Maintains the list of servers that can be provided to connection components.

59.1.4.2 TSimpleObjectBroker.Create Constructor

Creates and initializes a simple object broker.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TSimpleObjectBroker(TComponent * AOwner);
```

Description

Call Create to instantiate a simple object broker at runtime.

After calling the inherited constructor, Create initializes the LoadBalanced (see page 5922) property to false and creates the TServerCollection (see page 5908) that implements the Servers (see page 5923) property.

See Also

Create

Servers (see page 5923)

LoadBalanced (see page 5922)

59.1.4.3 TSimpleObjectBroker.Destroy Destructor

Destroys an instance of TSimpleObjectBroker (see page 5916).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TSimpleObjectBroker();
```

Description

Do not call Destroy directly. Instead, call Free, which verifies that the simple object broker is not nil, and only then calls Destroy.

See Also

System::TObject::Free

59.1.4.4 TSimpleObjectBroker Methods

The methods of the TSimpleObjectBroker class are listed here.

Public Methods

	Name	Description
	GetComputerForGUID (see page 5919)	Returns a string that identifies an available server machine.
	GetComputerForProgID (see page 5919)	Returns a string that identifies an available server machine.
	GetPortForComputer (see page 5920)	Returns a port number for connecting to a specified remote server.
	LoadFromStream (see page 5920)	Sets the value of the Servers (see page 5923) property from a stream.
	SaveToStream (see page 5921)	Saves the value of the Servers (see page 5923) property to a stream.
	SetConnectStatus (see page 5921)	Records whether a connection was established to a specified server.

59.1.4.4.1 TSimpleObjectBroker.GetComputerForGUID Method

Returns a string that identifies an available server machine.

Pascal

```
function GetComputerForGUID(GUID: TGUID): string; override;
```

C++

```
virtual __fastcall UnicodeString GetComputerForGUID(TGUID GUID);
```

Description

Call GetComputerForGUID to obtain the name of an available server machine. The GUID parameter (which specifies the global unique identifier of the desired server interface) is ignored.

GetComputerForGUID returns the ComputerName property of an available server from the Servers (see page 5923) property. If the LoadBalanced (see page 5922) property is true, this server is chosen at random from available servers. If the LoadBalanced (see page 5922) property is false, this server is the first available server listed in the Servers (see page 5923) property. If no servers are available, GetComputerForGUID raises an EBrokerException (see page 5908) exception.

A server is considered available if its Enabled property is true and its HasFailed property is false. The broker automatically sets HasFailed to false when it is notified of a connection failure for that server.

See Also

GetComputerForProgID (see page 5919)

ComputerName (see page 5914)

LoadBalanced (see page 5922)

EBrokerException (see page 5908)

Enabled (see page 5915)

HasFailed (see page 5915)

SetConnectStatus (see page 5921)

59.1.4.4.2 TSimpleObjectBroker.GetComputerForProgID Method

Returns a string that identifies an available server machine.

Pascal

```
function GetComputerForProgID(const ProgID): string; override;
```

C++

```
virtual __fastcall UnicodeString GetComputerForProgID(const  ProgID);
```

Description

Call GetComputerForProgID to obtain the name of an available server machine. The ProgID parameter (which specifies the desired server interface) is ignored.

TSimpleObjectBroker (see page 5916) returns the ComputerName property of an available server from the Servers (see page 5923) property. If the LoadBalanced (see page 5922) property is true, this server is chosen at random from available servers. If the LoadBalanced (see page 5922) property is false, this server is the first available server listed in the Servers (see page 5923) property. If no servers are available, GetComputerForGUID (see page 5919) raises an EBrokerException (see page 5908) exception.

A server is considered available if its Enabled property is true and its HasFailed property is false. The broker automatically sets HasFailed to false when it is notified of a connection failure for that server.

See Also

GetComputerForGUID (see page 5919)

ComputerName (see page 5914)

LoadBalanced (see page 5922)

EBrokerException (see page 5908)

Enabled (see page 5915)

HasFailed (see page 5915)

SetConnectStatus (see page 5921)

59.1.4.4.3 TSimpleObjectBroker.GetPortForComputer Method

Returns a port number for connecting to a specified remote server.

Pascal

```
function GetPortForComputer(const ComputerName: string): Integer; override;
```

C++

```
virtual __fastcall int GetPortForComputer(const UnicodeString ComputerName);
```

Description

Socket connection components call GetPortForComputer to get a value for their Port property. The ComputerName parameter specifies a Host name or IP address that was returned by GetComputerForGUID (see page 5919) or GetComputerForProgID (see page 5919). This value is used to identify a server in the list maintained by the Servers (see page 5923) property.

There are no connection components that explicitly use a Port number except on the Windows product. GetPortForComputer is included in TCustomObjectBroker (see page 4787) to allow for the possibility of connection components that use an explicit Port number. The ComputerName parameter is a Host name or IP address that is returned by the GetComputerForGUID (see page 5919) or GetComputerForProgID (see page 5919) method. This value is used to identify a server in the list maintained by the Servers (see page 5923) property.

See Also

GetComputerForProgID (see page 5919)

GetComputerForGUID (see page 5919)

Port

ComputerName (see page 5914)

Port (see page 5916)

59.1.4.4.4 TSimpleObjectBroker.LoadFromStream Method

Sets the value of the Servers (see page 5923) property from a stream.

Pascal

```
procedure LoadFromStream(Stream: TStream);
```

C++

```
__fastcall LoadFromStream(TStream Stream);
```

Description

Call LoadFromStream to load a list of available servers that has been previously saved using the SaveToStream (see page 5921) method.

See Also

SaveToStream (see page 5921)

ServerData (see page 5922)

59.1.4.4.5 TSimpleObjectBroker.SaveToStream Method

Saves the value of the Servers (see page 5923) property to a stream.

Pascal

```
procedure SaveToStream(Stream: TStream);
```

C++

```
__fastcall SaveToStream(TStream Stream);
```

Description

Call SaveToStream to save the list of available servers. The servers can be restored later by calling the LoadFromStream (see page 5920) method.

See Also

LoadFromStream (see page 5920)

ServerData (see page 5922)

59.1.4.4.6 TSimpleObjectBroker.SetConnectStatus Method

Records whether a connection was established to a specified server.

Pascal

```
procedure SetConnectStatus(ComputerName: string; Success: Boolean); override;
```

C++

```
virtual __fastcall SetConnectStatus(UnicodeString ComputerName, Boolean Success);
```

Description

After calling GetComputerForGUID (see page 5919) or GetComputerForProgID (see page 5919), connection components use the returned value to open a connection to the identified server. They then call SetConnectStatus to inform the broker of whether the connection was successfully opened.

SetConnectStatus sets the HasFailed property of the corresponding server to true if the connection was unsuccessful. It sets the HasFailed property to false if the connection was successful.

When the HasFailed property of a server is true, that server is ignored when the GetComputerForGUID (see page 5919) or GetComputerForProgID (see page 5919) method looks for available connections.

See Also

GetComputerForGUID (see page 5919)

GetComputerForProgID (see page 5919)

59.1.4.5 TSimpleObjectBroker Properties

The properties of the TSimpleObjectBroker class are listed here.

Public Properties

	Name	Description
	ServerData (see page 5922)	Encapsulates the list of servers as an OleVariant.

Published Properties

	Name	Description
	LoadBalanced (see page 5922)	Specifies how the simple object broker picks a server from its list.
	Servers (see page 5923)	Maintains the list of servers that can be provided to connection components.

59.1.4.5.1 TSimpleObjectBroker.LoadBalanced Property

Specifies how the simple object broker picks a server from its list.

Pascal

```
property LoadBalanced: Boolean;
```

C++

```
__property Boolean LoadBalanced;
```

Description

Set LoadBalanced to true to indicate that the simple object broker should supply computer names randomly from the available servers listed in the Servers (see page 5923) property. When LoadBalanced is false, GetComputerForGUID (see page 5919) and GetComputerForProgID (see page 5919) always return the first available server.

If the simple object broker is used by multiple connection components in the client application, it is preferable to set LoadBalanced to true in order to distribute the work among available servers.

When there is only a single connection component, there is no need to randomize the selection of servers, because only one connection will be used at a time. However, when deploying client applications, you may want to reorder the Servers (see page 5923) list in the simple object broker for each client, so that different clients give preference to different servers.

See Also

Servers (see page 5923)

GetComputerForGUID (see page 5919)

GetComputerForProgID (see page 5919)

59.1.4.5.2 TSimpleObjectBroker.ServerData Property

Encapsulates the list of servers as an OleVariant.

Pascal

```
property ServerData: OleVariant;
```

C++

```
__property OleVariant ServerData;
```

Description

Reading ServerData returns the value of the Servers (see page 5923) property stored in the internal component format. Writing ServerData sets the value of the Servers (see page 5923) property from an OleVariant that was saved previously.

Use the ServerData property to provide a mechanism for loading and saving the list of servers represented by the Servers (see page 5923) property. For example, An application can write the value of ServerData to an .ini file or the system registry. Later, it can read the value it saved as an OleVariant, and set ServerData to restore the Servers (see page 5923) property to the value that was saved.

Note: The implementation of ServerData uses the SaveToStream (see page 5921) method to encode the Servers (see page 5923) property as an OleVariant and the LoadFromStream (see page 5920) method to decode that OleVariant and restore the Servers (see page 5923) property.

See Also

Servers (see page 5923)

LoadFromStream (see page 5920)

SaveToStream (see page 5921)

59.1.4.5.3 TSimpleObjectBroker.Servers Property

Maintains the list of servers that can be provided to connection components.

Pascal

```
property Servers: TServerCollection;
```

C++

```
__property TServerCollection Servers;
```

Description

Use Servers to specify the list of servers that the simple object broker can return from the GetComputerForProgID (see page 5919) and GetComputerForGUID (see page 5919) methods.

Each item in the collection keeps track of whether the last connection attempt to that server was successful, and if not, the simple object broker ignores that server. In addition, individual servers in the collection can be disabled so that the simple object broker ignores them until they are re-enabled.

See Also

ServerData (see page 5922)

GetComputerForProgID (see page 5919)

GetComputerForGUID (see page 5919)

TServerItem (see page 5912)

60 ObjComAuto Namespace

This is namespace ObjComAuto.

Topics

Name	Description

60.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TObjectDispatch (see page 5926)	This is class ObjComAuto.TObjectDispatch.

60.1.1 TObjectDispatch Class

Class Hierarchy

Pascal

```
TObjectDispatch = class(TInterfacedObject, IDispatch);
```

C++

```
class TObjectDispatch : public TInterfacedObject, public IDispatch;
```

File

ObjComAuto

Description

This is class ObjComAuto.TObjectDispatch.

60.1.1.1 TObjectDispatch Members

The following tables list the members exposed by TObjectDispatch.

Protected Methods

	Name	Description
V	GetMethodInfo (see page 5928)	This is GetMethodInfo, a member of class TObjectDispatch.
V	GetObjectDispatch (see page 5928)	This is GetObjectDispatch, a member of class TObjectDispatch.
V	GetPropInfo (see page 5929)	This is GetPropInfo, a member of class TObjectDispatch.

Protected Properties

	Name	Description
R	Instance (see page 5930)	This is Instance, a member of class TObjectDispatch.

Public Methods

	Name	Description
	Create (see page 5927)	This is Create, a member of class TObjectDispatch.
V	Destroy (see page 5927)	Disposes of an object instance.
V	GetIDsOfNames (see page 5928)	This is GetIDsOfNames, a member of class TObjectDispatch.
	GetTypeInfo (see page 5929)	This is GetTypeInfo, a member of class TObjectDispatch.

	GetTypeInfoCount (see page 5929)	This is GetTypeInfoCount, a member of class TObjectDispatch.
	Invoke (see page 5929)	This is Invoke, a member of class TObjectDispatch.

60.1.1.2 TObjectDispatch.Create Constructor

Pascal

```
constructor Create(Instance: TObject; Owned: Boolean = True);
```

C++

```
__fastcall TObjectDispatch(TObject * Instance, Boolean Owned = True);
```

Description

This is Create, a member of class TObjectDispatch.

60.1.1.3 TObjectDispatch.Destroy Destructor

Disposes of an object instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TObjectDispatch();
```

Description

Do not call System::TObject::Destroy directly. Call System::TObject::Free instead. Free verifies that the object reference is not nil before calling System::TObject::Destroy.

The System::TObject::Destroy method defined by System::TObject::TObject deallocates memory. Descendant objects usually define a destructor that is customized for that particular kind of object.

When declaring a System::TObject::Destroy method in a descendant, always add the override directive to the declaration and call the inherited System::TObject::Destroy as the last statement in the overriding method. Since System::TObject::Destroy is a virtual method, overriding it ensures that the proper inherited behavior occurs.

Note: If an exception escapes from the constructor, the destructor is called to destroy the partially constructed object instance that failed to initialize completely. Therefore, destructors should check that allocated resources, such as handles, were actually allocated before trying to release them, since their value might be zero.

System::TObject::Destroy should be implemented so that it calls System::TObject::Free on all subobjects created within the object's constructor (that is, allocated by the constructor). Unlike System::TObject::Destroy, System::TObject::Free provides a safeguard when destroying objects that are nil.

See Also

System::TObject::Free

60.1.1.4 TObjectDispatch Methods

The methods of the TObjectDispatch class are listed here.

Protected Methods

	Name	Description
	GetMethodInfo (see page 5928)	This is GetMethodInfo, a member of class TObjectDispatch.
	GetObjectDispatch (see page 5928)	This is GetObjectDispatch, a member of class TObjectDispatch.
	GetPropInfo (see page 5929)	This is GetPropInfo, a member of class TObjectDispatch.

Public Methods

	Name	Description
	GetIDsOfNames (see page 5928)	This is GetIDsOfNames, a member of class TObjectDispatch.
	GetTypeInfo (see page 5929)	This is GetTypeInfo, a member of class TObjectDispatch.
	GetTypeInfoCount (see page 5929)	This is GetTypeInfoCount, a member of class TObjectDispatch.
	Invoke (see page 5929)	This is Invoke, a member of class TObjectDispatch.

60.1.1.4.1 TObjectDispatch.GetIDsOfNames Method

Pascal

```
function GetIDsOfNames(const IID: TGUID; Names: Pointer; NameCount: Integer; LocaleID:
Integer; DispIDs: Pointer): HRESULT; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT GetIDsOfNames(const TGUID IID, void * Names, int
NameCount, int LocaleID, void * DispIDs);
```

Description

This is GetIDsOfNames, a member of class TObjectDispatch.

60.1.1.4.2 TObjectDispatch.GetMethodInfo Method

Pascal

```
function GetMethodInfo(const AName: ShortString; var AInstance: TObject): PMethodInfoHeader;
virtual;
```

C++

```
virtual __fastcall PMethodInfoHeader GetMethodInfo(const ShortString AName, TObject *
AInstance);
```

Description

This is GetMethodInfo, a member of class TObjectDispatch.

60.1.1.4.3 TObjectDispatch.GetObjectDispatch Method

Pascal

```
function GetObjectDispatch(Obj: TObject): TObjectDispatch; virtual;
```

C++

```
virtual __fastcall TObjectDispatch GetObjectDispatch(TObject * Obj);
```

Description

This is GetObjectDispatch, a member of class TObjectDispatch.

60.1.1.4.4 TObjectDispatch.GetPropInfo Method

Pascal

```
function GetPropInfo(const AName: string; var AInstance: TObject; var CompIndex: Integer):
PPropInfo; virtual;
```

C++

```
virtual __fastcall PPropInfo GetPropInfo(const UnicodeString AName, TObject * AInstance, int
CompIndex);
```

Description

This is GetPropInfo, a member of class TObjectDispatch.

60.1.1.4.5 TObjectDispatch.GetTypeInfo Method

Pascal

```
function GetTypeInfo(Index: Integer; LocaleID: Integer; out TypeInfo): HRESULT; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetTypeInfo(int Index, int LocaleID,  TypeInfo);
```

Description

This is GetTypeInfo, a member of class TObjectDispatch.

60.1.1.4.6 TObjectDispatch.GetTypeInfoCount Method

Pascal

```
function GetTypeInfoCount(out Count: Integer): HRESULT; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetTypeInfoCount(int Count);
```

Description

This is GetTypeInfoCount, a member of class TObjectDispatch.

60.1.1.4.7 TObjectDispatch.Invoke Method

Pascal

```
function Invoke(DispID: Integer; const IID: TGUID; LocaleID: Integer; Flags: Word; var Params;
VarResult: Pointer; ExcepInfo: Pointer; ArgErr: Pointer): HRESULT; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT Invoke(int DispID, const TGUID IID, int LocaleID, Word
Flags,  Params, void * VarResult, void * ExcepInfo, void * ArgErr);
```

Description

This is Invoke, a member of class TObjectDispatch.

60.1.1.5 TObjectDispatch Properties

The properties of the TObjectDispatch class are listed here.

Protected Properties

	Name	Description
	Instance (see page 5930)	This is Instance, a member of class TObjectDispatch.

60.1.1.5.1 TObjectDispatch.Instance Property

Pascal

```
property Instance: TObject;
```

C++

```
__property TObject * Instance;
```

Description

This is Instance, a member of class TObjectDispatch.

60.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	CreateMethodPointer (see page 5931)	This is function ObjComAuto.CreateMethodPointer.
	CreateMethodPointer (see page 5931)	This is function ObjComAuto.CreateMethodPointer.
	ReleaseMethodPointer (see page 5932)	This is function ObjComAuto.ReleaseMethodPointer.

60.2.1 ObjComAuto.CreateMethodPointer Function

Pascal

```
function CreateMethodPointer(const Instance: IDispatch; DispID: Integer; TypeInfo: PTypeInfo):
TMethod; overload;
```

C++

```
TMethod CreateMethodPointer(const IDispatch Instance, int DispID, PTypeInfo TypeInfo);
```

File

ObjComAuto

Description

This is function ObjComAuto.CreateMethodPointer.

60.2.2 ObjComAuto.CreateMethodPointer Function

Pascal

```
function CreateMethodPointer(const Instance: IDispatch; const MethodName: string; TypeInfo:
PTypeInfo): TMethod; overload;
```

C++

```
TMethod CreateMethodPointer(const IDispatch Instance, const UnicodeString MethodName,
PTypeInfo TypeInfo);
```

File

ObjComAuto

Description

This is function ObjComAuto.CreateMethodPointer.

60.2.3 ObjComAuto.ReleaseMethodPointer Function

Pascal

```
procedure ReleaseMethodPointer(MethodPointer: TMethod);
```

C++

```
ReleaseMethodPointer(TMethod MethodPointer);
```

File

ObjComAuto

Description

This is function ObjComAuto.ReleaseMethodPointer.

60.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TDispatchKind (see page 5933)	This is record ObjComAuto.TDispatchKind.

Records

	Name	Description
	TDispatchInfo (see page 5933)	This is record ObjComAuto.TDispatchInfo.

60.3.1 ObjComAuto.TDispatchInfo Record

Pascal

```
TDispatchInfo = record
  Instance: TObject;
  Kind: TDispatchKind;
  case TDispatchKind of
    dkMethod: (MethodInfo: PMethodInfoHeader;);
    dkProperty: (PropInfo: PPropInfo;);
    dkSubComponent: (Index: Integer;);
end;
```

C++

```
struct TDispatchInfo {
  TObject * Instance;
  TDispatchKind Kind;
  PMethodInfoHeader MethodInfo;
  PPropInfo PropInfo;
  int Index;
};
```

File

ObjComAuto

Description

This is record ObjComAuto.TDispatchInfo.

60.3.2 ObjComAuto.TDispatchKind Enumeration

Pascal

```
TDispatchKind = (
  dkMethod,
  dkProperty,
  dkSubComponent
);
```

C++

```
enum TDispatchKind {
  dkMethod,
  dkProperty,
  dkSubComponent
};
```

File

ObjComAuto

Description

This is record ObjComAuto.TDispatchKind.

60.4 Types

The following table lists types in this documentation.

Types

Name	Description
TDispatchInfos (see page 5935)	This is type ObjComAuto.TDispatchInfos.

60.4.1 ObjComAuto.TDispatchInfos Type

Pascal

```
TDispatchInfos = array of TDispatchInfo;
```

C++

```
array of TDispatchInfo TDispatchInfos;
```

File

ObjComAuto

Description

This is type ObjComAuto.TDispatchInfos.

61 OleAuto Namespace

This is namespace OleAuto.

Topics

Name	Description
Classes (see page 5939)	The following table lists classes in this documentation.
Functions (see page 5955)	The following table lists functions in this documentation.

	OleError (see page 5959)	This is function OleAuto.OleError.
	ProgIDToClassID (see page 5959)	This is function OleAuto.ProgIDToClassID.
	StringToClassID (see page 5959)	This is function OleAuto.StringToClassID.
	VarFromInterface (see page 5960)	This is function OleAuto.VarFromInterface.
	VarToAutoObject (see page 5960)	This is function OleAuto.VarToAutoObject.
	VarToInterface (see page 5960)	This is function OleAuto.VarToInterface.

Structs, Records, Enums

	Name	Description
	TAutoClassInfo (see page 5961)	This is record OleAuto.TAutoClassInfo.
	TAutoClassInstancing (see page 5961)	This is record OleAuto.TAutoClassInstancing.
	TStartMode (see page 5962)	This is record OleAuto.TStartMode.

Types

Name	Description
TAutoClass (see page 5963)	This is type OleAuto.TAutoClass.
TLastReleaseEvent (see page 5963)	This is type OleAuto.TLastReleaseEvent.

Variables

Name	Description
Automation (see page 5964)	This is variable OleAuto.Automation.

61.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EOleError (see page 5939)	This is class OleAuto.EOleError.
	EOleException (see page 5939)	This is class OleAuto.EOleException.
	EOleSysError (see page 5941)	This is class OleAuto.EOleSysError.
	TAutoDispatch (see page 5942)	This is class OleAuto.TAutoDispatch.
	TAutomation (see page 5946)	This is class OleAuto.TAutomation.
	TAutoObject (see page 5949)	This is class OleAuto.TAutoObject.
	TRegistryClass (see page 5953)	This is class OleAuto.TRegistryClass.

61.1.1 EOleError Class

Class Hierarchy

Pascal

```
EOleError = class(Exception);
```

C++

```
class EOleError : public Exception;
```

File

OleAuto

Description

This is class OleAuto.EOleError.

61.1.2 EOleException Class

Class Hierarchy

Pascal

```
EOleException = class(EOleError);
```

C++

```
class EOleException : public EOleError;
```

File

OleAuto

Description

This is class OleAuto.EOleException.

61.1.2.1 EOleException Members

The following tables list the members exposed by EOleException.

Public Methods

	Name	Description
	Create (see page 5940)	This is Create, a member of class EOleException.

Public Properties

	Name	Description
R	ErrorCode (see page 5940)	This is ErrorCode, a member of class EOleException.
R	HelpFile (see page 5941)	This is HelpFile, a member of class EOleException.
R	Source (see page 5941)	This is Source, a member of class EOleException.

61.1.2.2 EOleException.Create Constructor

Pascal

```
constructor Create(const ExcepInfo: TExcepInfo);
```

C++

```
__fastcall EOleException(const TExcepInfo ExcepInfo);
```

Description

This is Create, a member of class EOleException.

61.1.2.3 EOleException Properties

The properties of the EOleException class are listed here.

Public Properties

	Name	Description
R	ErrorCode (see page 5940)	This is ErrorCode, a member of class EOleException.
R	HelpFile (see page 5941)	This is HelpFile, a member of class EOleException.
R	Source (see page 5941)	This is Source, a member of class EOleException.

61.1.2.3.1 EOleException.ErrorCode Property

Pascal

```
property ErrorCode: Integer;
```

C++

```
__property int ErrorCode;
```

Description

This is ErrorCode, a member of class EOleException.

61.1.2.3.2 EOleException.HelpFile Property

Pascal

```
property HelpFile: string;
```

C++

```
__property UnicodeString HelpFile;
```

Description

This is HelpFile, a member of class EOleException.

61.1.2.3.3 EOleException.Source Property

Pascal

```
property Source: string;
```

C++

```
__property UnicodeString Source;
```

Description

This is Source, a member of class EOleException.

61.1.3 EOleSysError Class

Class Hierarchy

Pascal

```
EOleSysError = class(EOleError);
```

C++

```
class EOleSysError : public EOleError;
```

File

OleAuto

Description

This is class OleAuto.EOleSysError.

61.1.3.1 EOleSysError Members

The following tables list the members exposed by EOleSysError.

Public Methods

	Name	Description
	Create (see page 5942)	This is Create, a member of class EOleSysError.

Public Properties

	Name	Description
	ErrorCode (see page 5942)	This is ErrorCode, a member of class EOleSysError.

61.1.3.2 EOleSysError.Create Constructor

Pascal

```
constructor Create(ErrorCode: Integer);
```

C++

```
__fastcall EOleSysError(int ErrorCode);
```

Description

This is Create, a member of class EOleSysError.

61.1.3.3 EOleSysError Properties

The properties of the EOleSysError class are listed here.

Public Properties

	Name	Description
	ErrorCode (see page 5942)	This is ErrorCode, a member of class EOleSysError.

61.1.3.3.1 EOleSysError.ErrorCode Property

Pascal

```
property ErrorCode: Integer;
```

C++

```
__property int ErrorCode;
```

Description

This is ErrorCode, a member of class EOleSysError.

61.1.4 TAutoDispatch Class

Class Hierarchy

Pascal

```
TAutoDispatch = class(IDispatch);
```

C++

```
class TAutoDispatch : public IDispatch;
```

File

OleAuto

Description

This is class OleAuto.TAutoDispatch.

61.1.4.1 TAutoDispatch Members

The following tables list the members exposed by TAutoDispatch.

Public Methods

	Name	Description
	AddRef (see page 5944)	This is AddRef, a member of class TAutoDispatch.
	Create (see page 5943)	This is Create, a member of class TAutoDispatch.
	GetAutoObject (see page 5944)	This is GetAutoObject, a member of class TAutoDispatch.
	GetIDsOfNames (see page 5944)	This is GetIDsOfNames, a member of class TAutoDispatch.
	GetTypeInfo (see page 5944)	This is GetTypeInfo, a member of class TAutoDispatch.
	GetTypeInfoCount (see page 5944)	This is GetTypeInfoCount, a member of class TAutoDispatch.
	Invoke (see page 5945)	This is Invoke, a member of class TAutoDispatch.
	QueryInterface (see page 5945)	This is QueryInterface, a member of class TAutoDispatch.
	Release (see page 5945)	This is Release, a member of class TAutoDispatch.

Public Properties

	Name	Description
	AutoObject (see page 5946)	This is AutoObject, a member of class TAutoDispatch.

61.1.4.2 TAutoDispatch.Create Constructor

Pascal

```
constructor Create(AutoObject: TAutoObject);
```

C++

```
__fastcall TAutoDispatch(TAutoObject AutoObject);
```

Description

This is Create, a member of class TAutoDispatch.

61.1.4.3 TAutoDispatch Methods

The methods of the TAutoDispatch class are listed here.

Public Methods

	Name	Description
	AddRef (see page 5944)	This is AddRef, a member of class TAutoDispatch.
	GetAutoObject (see page 5944)	This is GetAutoObject, a member of class TAutoDispatch.
	GetIDsOfNames (see page 5944)	This is GetIDsOfNames, a member of class TAutoDispatch.
	GetTypeInfo (see page 5944)	This is GetTypeInfo, a member of class TAutoDispatch.
	GetTypeInfoCount (see page 5944)	This is GetTypeInfoCount, a member of class TAutoDispatch.
	Invoke (see page 5945)	This is Invoke, a member of class TAutoDispatch.
	QueryInterface (see page 5945)	This is QueryInterface, a member of class TAutoDispatch.
	Release (see page 5945)	This is Release, a member of class TAutoDispatch.

61.1.4.3.1 TAutoDispatch.AddRef Method

Pascal

```
function AddRef: Longint; override;
```

C++

```
virtual __fastcall Longint AddRef();
```

Description

This is AddRef, a member of class TAutoDispatch.

61.1.4.3.2 TAutoDispatch.GetAutoObject Method

Pascal

```
function GetAutoObject: TAutoObject; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall TAutoObject GetAutoObject();
```

Description

This is GetAutoObject, a member of class TAutoDispatch.

61.1.4.3.3 TAutoDispatch.GetIDsOfNames Method

Pascal

```
function GetIDsOfNames(const iid: TIID; rgszNames: POleStrList; cNames: Integer; lcid: TLCID;
rgdispid: PDispIDList): HResult; override;
```

C++

```
virtual __fastcall HRESULT GetIDsOfNames(const TIID iid, POleStrList rgszNames, int cNames,
TLCID lcid, PDispIDList rgdispid);
```

Description

This is GetIDsOfNames, a member of class TAutoDispatch.

61.1.4.3.4 TAutoDispatch.GetTypeInfo Method

Pascal

```
function GetTypeInfo(itinfo: Integer; lcid: TLCID; var tinfo: ITypeInfo): HResult; override;
```

C++

```
virtual __fastcall HRESULT GetTypeInfo(int itinfo, TLCID lcid, ITypeInfo tinfo);
```

Description

This is GetTypeInfo, a member of class TAutoDispatch.

61.1.4.3.5 TAutoDispatch.GetTypeInfoCount Method

Pascal

```
function GetTypeInfoCount(var ctinfo: Integer): HResult; override;
```

C++

```
virtual __fastcall HRESULT GetTypeInfoCount(int ctinfo);
```

Description

This is GetTypeInfoCount, a member of class TAutoDispatch.

61.1.4.3.6 TAutoDispatch.Invoke Method

Pascal

```
function Invoke(dispIDMember: TDispID; const iid: TIID; lcid: TLCID; flags: Word; var
dispParams: TDispParams; varResult: PVariant; excepInfo: PExcepInfo; argErr: PInteger):
HResult; override;
```

C++

```
virtual __fastcall HRESULT Invoke(TDispID dispIDMember, const TIID iid, TLCID lcid, Word
flags, TDispParams dispParams, PVariant varResult, PExcepInfo excepInfo, PInteger argErr);
```

Description

This is Invoke, a member of class TAutoDispatch.

61.1.4.3.7 TAutoDispatch.QueryInterface Method

Pascal

```
function QueryInterface(const iid: TIID; var obj): HResult; override;
```

C++

```
virtual __fastcall HRESULT QueryInterface(const TIID iid,  obj);
```

Description

This is QueryInterface, a member of class TAutoDispatch.

61.1.4.3.8 TAutoDispatch.Release Method

Pascal

```
function Release: Longint; override;
```

C++

```
virtual __fastcall Longint Release();
```

Description

This is Release, a member of class TAutoDispatch.

61.1.4.4 TAutoDispatch Properties

The properties of the TAutoDispatch class are listed here.

Public Properties

	Name	Description
	AutoObject (see page 5946)	This is AutoObject, a member of class TAutoDispatch.

61.1.4.4.1 TAutoDispatch.AutoObject Property

Pascal

```
property AutoObject: TAutoObject;
```

C++

```
__property TAutoObject AutoObject;
```

Description

This is AutoObject, a member of class TAutoDispatch.

61.1.5 TAutomation Class

Class Hierarchy

Pascal

```
TAutomation = class;
```

C++

```
class TAutomation;
```

File

OleAuto

Description

This is class OleAuto.TAutomation.

61.1.5.1 TAutomation Members

The following tables list the members exposed by TAutomation.

Public Events

	Name	Description
	OnLastRelease (see page 5949)	This is OnLastRelease, a member of class TAutomation.

Public Methods

	Name	Description
	Create (see page 5947)	This is Create, a member of class TAutomation.
V	Destroy (see page 5947)	This is Destroy, a member of class TAutomation.
	RegisterClass (see page 5947)	This is RegisterClass, a member of class TAutomation.
	UpdateRegistry (see page 5947)	This is UpdateRegistry, a member of class TAutomation.

Public Properties

	Name	Description
R	AutoObjectCount (see page 5948)	This is AutoObjectCount, a member of class TAutomation.
	IsInprocServer (see page 5948)	This is IsInprocServer, a member of class TAutomation.
R	StartMode (see page 5948)	This is StartMode, a member of class TAutomation.

61.1.5.2 TAutomation.Create Constructor

Pascal

```
constructor Create;
```

C++

```
__fastcall TAutomation();
```

Description

This is Create, a member of class TAutomation.

61.1.5.3 TAutomation.Destroy Destructor

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TAutomation();
```

Description

This is Destroy, a member of class TAutomation.

61.1.5.4 TAutomation Methods

The methods of the TAutomation class are listed here.

Public Methods

	Name	Description
	RegisterClass (see page 5947)	This is RegisterClass, a member of class TAutomation.
	UpdateRegistry (see page 5947)	This is UpdateRegistry, a member of class TAutomation.

61.1.5.4.1 TAutomation.RegisterClass Method

Pascal

```
procedure RegisterClass(const AutoClassInfo: TAutoClassInfo);
```

C++

```
__fastcall RegisterClass(const TAutoClassInfo AutoClassInfo);
```

Description

This is RegisterClass, a member of class TAutomation.

61.1.5.4.2 TAutomation.UpdateRegistry Method

Pascal

```
procedure UpdateRegistry(Register: Boolean);
```

C++

```
__fastcall UpdateRegistry(Boolean Register);
```

Description

This is UpdateRegistry, a member of class TAutomation.

61.1.5.5 TAutomation Properties

The properties of the TAutomation class are listed here.

Public Properties

	Name	Description
	AutoObjectCount (see page 5948)	This is AutoObjectCount, a member of class TAutomation.
	IsInprocServer (see page 5948)	This is IsInprocServer, a member of class TAutomation.
	StartMode (see page 5948)	This is StartMode, a member of class TAutomation.

61.1.5.5.1 TAutomation.AutoObjectCount Property

Pascal

```
property AutoObjectCount: Integer;
```

C++

```
__property int AutoObjectCount;
```

Description

This is AutoObjectCount, a member of class TAutomation.

61.1.5.5.2 TAutomation.IsInprocServer Property

Pascal

```
property IsInprocServer: Boolean;
```

C++

```
__property Boolean IsInprocServer;
```

Description

This is IsInprocServer, a member of class TAutomation.

61.1.5.5.3 TAutomation.StartMode Property

Pascal

```
property StartMode: TStartMode;
```

C++

```
__property TStartMode StartMode;
```

Description

This is StartMode, a member of class TAutomation.

61.1.5.6 TAutomation Events

The events of the TAutomation class are listed here.

Public Events

	Name	Description
	OnLastRelease (see page 5949)	This is OnLastRelease, a member of class TAutomation.

61.1.5.6.1 TAutomation.OnLastRelease Event

Pascal

```
property OnLastRelease: TLastReleaseEvent;
```

C++

```
__property TLastReleaseEvent OnLastRelease;
```

Description

This is OnLastRelease, a member of class TAutomation.

61.1.6 TAutoObject Class

Class Hierarchy

Pascal

```
TAutoObject = class(TObject);
```

C++

```
class TAutoObject : public TObject;
```

File

OleAuto

Description

This is class OleAuto.TAutoObject.

61.1.6.1 TAutoObject Members

The following tables list the members exposed by TAutoObject.

Protected Methods

	Name	Description
	CreateAutoDispatch (see page 5951)	This is CreateAutoDispatch, a member of class TAutoObject.
	GetExceptionInfo (see page 5951)	This is GetExceptionInfo, a member of class TAutoObject.

Public Methods

	Name	Description
	AddRef (see page 5951)	This is AddRef, a member of class TAutoObject.
	Create (see page 5950)	Constructs an object and initializes its data before the object is first used.
	Destroy (see page 5950)	Disposes of an object instance.
	Release (see page 5952)	This is Release, a member of class TAutoObject.

Public Properties

	Name	Description
	AutoDispatch (see page 5952)	This is AutoDispatch, a member of class TAutoObject.
	OleObject (see page 5952)	This is OleObject, a member of class TAutoObject.
	RefCount (see page 5952)	This is RefCount, a member of class TAutoObject.

61.1.6.2 TAutoObject.Create Constructor

Constructs an object and initializes its data before the object is first used.

Pascal

```
constructor Create; virtual;
```

C++

```
virtual __fastcall TAutoObject();
```

Description

System::TObject::Create constructs an object. The purpose, size, and behavior of objects differ greatly. The System::TObject::Create constructor defined by System::TObject::TObject allocates memory but does not initialize data.

Descendant objects usually define a constructor that creates the particular kind of object and initializes its data.

Note: If an exception escapes from a constructor, the object's destructor is called to clean up the failed instance.

See Also

System::TObject::Destroy

System::TObject::Free

61.1.6.3 TAutoObject.Destroy Destructor

Disposes of an object instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TAutoObject();
```

Description

Do not call System::TObject::Destroy directly. Call System::TObject::Free instead. Free verifies that the object reference is not nil before calling System::TObject::Destroy.

The System::TObject::Destroy method defined by System::TObject::TObject deallocates memory. Descendant objects usually define a destructor that is customized for that particular kind of object.

When declaring a System::TObject::Destroy method in a descendant, always add the override directive to the declaration and call the inherited System::TObject::Destroy as the last statement in the overriding method. Since System::TObject::Destroy is a virtual method, overriding it ensures that the proper inherited behavior occurs.

Note: If an exception escapes from the constructor, the destructor is called to destroy the partially constructed object instance that failed to initialize completely. Therefore, destructors should check that allocated resources, such as handles, were actually allocated before trying to release them, since their value might be zero.

System::TObject::Destroy should be implemented so that it calls System::TObject::Free on all subobjects created within the

object's constructor (that is, allocated by the constructor). Unlike System::TObject::Destroy, System::TObject::Free provides a safeguard when destroying objects that are nil.

See Also

System::TObject::Free

61.1.6.4 TAutoObject Methods

The methods of the TAutoObject class are listed here.

Protected Methods

	Name	Description
	CreateAutoDispatch (see page 5951)	This is CreateAutoDispatch, a member of class TAutoObject.
	GetExceptionInfo (see page 5951)	This is GetExceptionInfo, a member of class TAutoObject.

Public Methods

	Name	Description
	AddRef (see page 5951)	This is AddRef, a member of class TAutoObject.
	Release (see page 5952)	This is Release, a member of class TAutoObject.

61.1.6.4.1 TAutoObject.AddRef Method

Pascal

```
function AddRef: Integer;
```

C++

```
__fastcall int AddRef();
```

Description

This is AddRef, a member of class TAutoObject.

61.1.6.4.2 TAutoObject.CreateAutoDispatch Method

Pascal

```
function CreateAutoDispatch: TAutoDispatch; virtual;
```

C++

```
virtual __fastcall TAutoDispatch CreateAutoDispatch();
```

Description

This is CreateAutoDispatch, a member of class TAutoObject.

61.1.6.4.3 TAutoObject.GetExceptionInfo Method

Pascal

```
procedure GetExceptionInfo(ExceptObject: TObject; var ExcepInfo: TExcepInfo); virtual;
```

C++

```
virtual __fastcall GetExceptionInfo(TObject * ExceptObject, TExcepInfo ExcepInfo);
```

Description

This is GetExceptionInfo, a member of class TAutoObject.

61.1.6.4.4 TAutoObject.Release Method

Pascal

```
function Release: Integer;
```

C++

```
__fastcall int Release();
```

Description

This is Release, a member of class TAutoObject.

61.1.6.5 TAutoObject Properties

The properties of the TAutoObject class are listed here.

Public Properties

	Name	Description
	AutoDispatch (see page 5952)	This is AutoDispatch, a member of class TAutoObject.
	OleObject (see page 5952)	This is OleObject, a member of class TAutoObject.
	RefCount (see page 5952)	This is RefCount, a member of class TAutoObject.

61.1.6.5.1 TAutoObject.AutoDispatch Property

Pascal

```
property AutoDispatch: TAutoDispatch;
```

C++

```
__property TAutoDispatch AutoDispatch;
```

Description

This is AutoDispatch, a member of class TAutoObject.

61.1.6.5.2 TAutoObject.OleObject Property

Pascal

```
property OleObject: Variant;
```

C++

```
__property Variant OleObject;
```

Description

This is OleObject, a member of class TAutoObject.

61.1.6.5.3 TAutoObject.RefCount Property

Pascal

```
property RefCount: Integer;
```

C++

```
__property int RefCount;
```

Description

This is RefCount, a member of class TAutoObject.

61.1.7 TRegistryClass Class

Class Hierarchy

Pascal

```
TRegistryClass = class;
```

C++

```
class TRegistryClass;
```

File

OleAuto

Description

This is class OleAuto.TRegistryClass.

61.1.7.1 TRegistryClass Members

The following tables list the members exposed by TRegistryClass.

Public Methods

	Name	Description
	Create (see page 5953)	This is Create, a member of class TRegistryClass.
	Destroy (see page 5953)	This is Destroy, a member of class TRegistryClass.
	UpdateRegistry (see page 5954)	This is UpdateRegistry, a member of class TRegistryClass.

61.1.7.2 TRegistryClass.Create Constructor

Pascal

```
constructor Create(const AutoClassInfo: TAutoClassInfo);
```

C++

```
__fastcall TRegistryClass(const TAutoClassInfo AutoClassInfo);
```

Description

This is Create, a member of class TRegistryClass.

61.1.7.3 TRegistryClass.Destroy Destructor

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TRegistryClass();
```

Description

This is Destroy, a member of class TRegistryClass.

61.1.7.4 TRegistryClass Methods

The methods of the TRegistryClass class are listed here.

Public Methods

	Name	Description
	UpdateRegistry (see page 5954)	This is UpdateRegistry, a member of class TRegistryClass.

61.1.7.4.1 TRegistryClass.UpdateRegistry Method

Pascal

```
procedure UpdateRegistry(Register: Boolean);
```

C++

```
__fastcall UpdateRegistry(Boolean Register);
```

Description

This is UpdateRegistry, a member of class TRegistryClass.

61.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	ClassIDToProgID (see page 5955)	This is function OleAuto.ClassIDToProgID.
	ClassIDToString (see page 5955)	This is function OleAuto.ClassIDToString.
	CreateOleObject (see page 5956)	This is function OleAuto.CreateOleObject.
	DispInvoke (see page 5956)	This is function OleAuto.DispInvoke.
	DispInvokeError (see page 5956)	This is function OleAuto.DispInvokeError.
	DllCanUnloadNow (see page 5957)	This is function OleAuto.DllCanUnloadNow.
	DllGetClassObject (see page 5957)	This is function OleAuto.DllGetClassObject.
	DllRegisterServer (see page 5957)	This is function OleAuto.DllRegisterServer.
	DllUnregisterServer (see page 5958)	This is function OleAuto.DllUnregisterServer.
	GetActiveOleObject (see page 5958)	This is function OleAuto.GetActiveOleObject.
	OleCheck (see page 5958)	This is function OleAuto.OleCheck.
	OleError (see page 5959)	This is function OleAuto.OleError.
	ProgIDToClassID (see page 5959)	This is function OleAuto.ProgIDToClassID.
	StringToClassID (see page 5959)	This is function OleAuto.StringToClassID.
	VarFromInterface (see page 5960)	This is function OleAuto.VarFromInterface.
	VarToAutoObject (see page 5960)	This is function OleAuto.VarToAutoObject.
	VarToInterface (see page 5960)	This is function OleAuto.VarToInterface.

61.2.1 OleAuto.ClassIDToProgID Function

Pascal

```
function ClassIDToProgID(const ClassID: TCLSID): string;
```

C++

```
UnicodeString ClassIDToProgID(const TCLSID ClassID);
```

File

OleAuto

Description

This is function OleAuto.ClassIDToProgID.

61.2.2 OleAuto.ClassIDToString Function

Pascal

```
function ClassIDToString(const ClassID: TCLSID): string;
```

C++

```
UnicodeString ClassIDToString(const TCLSID ClassID);
```

File

OleAuto

Description

This is function OleAuto.ClassIDToString.

61.2.3 OleAuto.CreateOleObject Function

Pascal

```
function CreateOleObject(const ClassName: string): Variant;
```

C++

```
Variant CreateOleObject(const UnicodeString ClassName);
```

File

OleAuto

Description

This is function OleAuto.CreateOleObject.

61.2.4 OleAuto.DispInvoke Function

Pascal

```
procedure DispInvoke(Dispatch: IDispatch; CallDesc: PCallDesc; DispIDs: PDispIDList; Params:
Pointer; Result: PVariant);
```

C++

```
DispInvoke(IDispatch Dispatch, PCallDesc CallDesc, PDispIDList DispIDs, void * Params,
PVariant Result);
```

File

OleAuto

Description

This is function OleAuto.DispInvoke.

61.2.5 OleAuto.DispInvokeError Function

Pascal

```
procedure DispInvokeError(Status: HResult; const ExcepInfo: TExcepInfo);
```

C++

```
DispInvokeError(HRESULT Status, const TExcepInfo ExcepInfo);
```

File

OleAuto

Description

This is function OleAuto.DispInvokeError.

61.2.6 OleAuto.DllCanUnloadNow Function

Pascal

```
function DllCanUnloadNow: HResult; stdcall;
```

C++

```
__stdcall HRESULT DllCanUnloadNow();
```

File

OleAuto

Description

This is function OleAuto.DllCanUnloadNow.

61.2.7 OleAuto.DllGetClassObject Function

Pascal

```
function DllGetClassObject(const CLSID: TCLSID; const IID: TIID; var Obj): HResult; stdcall;
```

C++

```
__stdcall HRESULT DllGetClassObject(const TCLSID CLSID, const TIID IID,  Obj);
```

File

OleAuto

Description

This is function OleAuto.DllGetClassObject.

61.2.8 OleAuto.DllRegisterServer Function

Pascal

```
function DllRegisterServer: HResult; stdcall;
```

C++

```
__stdcall HRESULT DllRegisterServer();
```

File

OleAuto

Description

This is function OleAuto.DllRegisterServer.

61.2.9 OleAuto.DllUnregisterServer Function

Pascal

```
function DllUnregisterServer: HResult; stdcall;
```

C++

```
__stdcall HRESULT DllUnregisterServer();
```

File

OleAuto

Description

This is function OleAuto.DllUnregisterServer.

61.2.10 OleAuto.GetActiveOleObject Function

Pascal

```
function GetActiveOleObject(const ClassName: string): Variant;
```

C++

```
Variant GetActiveOleObject(const UnicodeString ClassName);
```

File

OleAuto

Description

This is function OleAuto.GetActiveOleObject.

61.2.11 OleAuto.OleCheck Function

Pascal

```
procedure OleCheck(Result: HResult);
```

C++

```
OleCheck(HRESULT Result);
```

File

OleAuto

Description

This is function OleAuto.OleCheck.

61.2.12 OleAuto.OleError Function

Pascal

```
procedure OleError(ErrorCode: HResult);
```

C++

```
OleError(HRESULT ErrorCode);
```

File

OleAuto

Description

This is function OleAuto.OleError.

61.2.13 OleAuto.ProgIDToClassID Function

Pascal

```
function ProgIDToClassID(const ProgID: string): TCLSID;
```

C++

```
TCLSID ProgIDToClassID(const UnicodeString ProgID);
```

File

OleAuto

Description

This is function OleAuto.ProgIDToClassID.

61.2.14 OleAuto.StringToClassID Function

Pascal

```
function StringToClassID(const S: string): TCLSID;
```

C++

```
TCLSID StringToClassID(const UnicodeString S);
```

File

OleAuto

Description

This is function OleAuto.StringToClassID.

61.2.15 OleAuto.VarFromInterface Function

Pascal

```
function VarFromInterface(Unknown: IUnknown): Variant;
```

C++

```
Variant VarFromInterface(IUnknown Unknown);
```

File

OleAuto

Description

This is function OleAuto.VarFromInterface.

61.2.16 OleAuto.VarToAutoObject Function

Pascal

```
function VarToAutoObject(const V: Variant): TAutoObject;
```

C++

```
TAutoObject VarToAutoObject(const Variant V);
```

File

OleAuto

Description

This is function OleAuto.VarToAutoObject.

61.2.17 OleAuto.VarToInterface Function

Pascal

```
function VarToInterface(const V: Variant): IDispatch;
```

C++

```
IDispatch VarToInterface(const Variant V);
```

File

OleAuto

Description

This is function OleAuto.VarToInterface.

61.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TAutoClassInstancing (see page 5961)	This is record OleAuto.TAutoClassInstancing.
	TStartMode (see page 5962)	This is record OleAuto.TStartMode.

Records

	Name	Description
	TAutoClassInfo (see page 5961)	This is record OleAuto.TAutoClassInfo.

61.3.1 OleAuto.TAutoClassInfo Record

Pascal

```
TAutoClassInfo = record
  AutoClass: TAutoClass;
  ProgID: string;
  ClassID: string;
  Description: string;
  Instancing: TAutoClassInstancing;
end;
```

C++

```
struct TAutoClassInfo {
  TAutoClass AutoClass;
  UnicodeString ProgID;
  UnicodeString ClassID;
  UnicodeString Description;
  TAutoClassInstancing Instancing;
};
```

File

OleAuto

Description

This is record OleAuto.TAutoClassInfo.

61.3.2 OleAuto.TAutoClassInstancing Enumeration

Pascal

```
TAutoClassInstancing = (
  acInternal,
  acSingleInstance,
  acMultiInstance
);
```

C++

```
enum TAutoClassInstancing {
  acInternal,
  acSingleInstance,
  acMultiInstance
};
```

File

OleAuto

Description

This is record OleAuto.TAutoClassInstancing.

61.3.3 OleAuto.TStartMode Enumeration

Pascal

```
TStartMode = (
  smStandalone,
  smAutomation,
  smRegServer,
  smUnregServer
);
```

C++

```
enum TStartMode {
  smStandalone,
  smAutomation,
  smRegServer,
  smUnregServer
};
```

File

OleAuto

Description

This is record OleAuto.TStartMode.

61.4 Types

The following table lists types in this documentation.

Types

Name	Description
TAutoClass (see page 5963)	This is type OleAuto.TAutoClass.
TLastReleaseEvent (see page 5963)	This is type OleAuto.TLastReleaseEvent.

61.4.1 OleAuto.TAutoClass Type

Pascal

```
TAutoClass = class of TAutoObject;
```

C++

```
TAutoObject TAutoClass;
```

File

OleAuto

Description

This is type OleAuto.TAutoClass.

61.4.2 OleAuto.TLastReleaseEvent Type

Pascal

```
TLastReleaseEvent = procedure (var Shutdown: Boolean) of object;
```

C++

```
(var Shutdown: Boolean) ( TLastReleaseEvent)();
```

File

OleAuto

Description

This is type OleAuto.TLastReleaseEvent.

61.5 Variables

The following table lists variables in this documentation.

Variables

Name	Description
Automation (see page 5964)	This is variable OleAuto.Automation.

61.5.1 OleAuto.Automation Variable

Pascal

```
Automation: TAutomation;
```

C++

```
TAutomation Automation;
```

File

OleAuto

Description

This is variable OleAuto.Automation.

61.6 Constants

The following table lists constants in this documentation.

Constants

Name	Description
MaxDispArgs (see page 5965)	This is constant OleAuto.MaxDispArgs.

61.6.1 OleAuto.MaxDispArgs Constant

Pascal

```
MaxDispArgs = 32;
```

C++

```
MaxDispArgs = 32;
```

File

OleAuto

Description

This is constant OleAuto.MaxDispArgs.

62 OleCtnrs Namespace

This is namespace OleCtnrs.

Topics

Name	Description
Classes (see page 5969)	The following table lists classes in this documentation.
Interfaces (see page 6053)	The following table lists interfaces in this documentation.
Functions (see page 6055)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 6056)	The following table lists structs, records, enums in this documentation.
Types (see page 6060)	The following table lists types in this documentation.
Constants (see page 6061)	The following table lists constants in this documentation.

Classes

	Name	Description
	TOleContainer (see page 5969)	TOleContainer embeds or links OLE objects.
	TOleForm (see page 6050)	TOleForm is an object that provides OLE support for a TForm (see page 2241) object.

Constants

Name	Description
ovDiscardUndoState (see page 6061)	This is constant OleCtnrs.ovDiscardUndoState.
ovHide (see page 6061)	This is constant OleCtnrs.ovHide.
ovInPlaceActivate (see page 6062)	This is constant OleCtnrs.ovInPlaceActivate.
ovOpen (see page 6062)	This is constant OleCtnrs.ovOpen.
ovPrimary (see page 6062)	This is constant OleCtnrs.ovPrimary.
ovShow (see page 6063)	This is constant OleCtnrs.ovShow.
ovUIActivate (see page 6063)	This is constant OleCtnrs.ovUIActivate.

Functions

	Name	Description
	DestroyMetaPict (see page 6055)	Frees a metafile resource given its handle.

Interfaces

	Name	Description
	IVCLFrameForm (see page 6053)	This is class OleCtnrs.IVCLFrameForm.

Structs, Records, Enums

	Name	Description
	TAutoActivate (see page 6056)	This is record OleCtnrs.TAutoActivate.
	TCreateInfo (see page 6056)	This is record OleCtnrs.TCreateInfo.
	TCreateType (see page 6057)	This is record OleCtnrs.TCreateType.
	TObjectState (see page 6057)	This is record OleCtnrs.TObjectState.
	TSizeMode (see page 6058)	This is record OleCtnrs.TSizeMode.
	TVerbInfo (see page 6058)	This is record OleCtnrs.TVerbInfo.

Types

Name	Description
TObjectMoveEvent (see page 6060)	This is type OleCtnrs.TObjectMoveEvent.

62.1 Classes

The following table lists classes in this documentation.

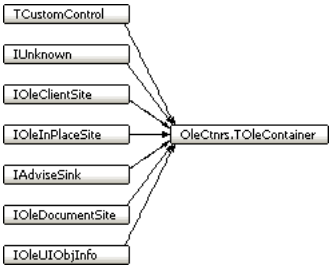
Classes

	Name	Description
	TOleContainer (see page 5969)	TOleContainer embeds or links OLE objects.
	TOleForm (see page 6050)	TOleForm is an object that provides OLE support for a TForm (see page 2241) object.

62.1.1 TOleContainer Class

TOleContainer embeds or links OLE objects.

Class Hierarchy



Pascal

```
TOleContainer = class(TCustomControl, IUnknown, IOleClientSite, IOleInPlaceSite, IAdviseSink,
IOleDocumentSite, IOleUIObjInfo);
```

C++

```
class TOleContainer : public TCustomControl, public IUnknown, public IOleClientSite, public
IOleInPlaceSite, public IAdviseSink, public IOleDocumentSite, public IOleUIObjInfo;
```

File

OleCtnrs

Description

Use TOleContainer to handle many of the complexities of OLE 2.0. TOleContainer lets the user choose an OLE object to insert by simply calling the InsertObjectDialog (see page 5982) method. TOleContainer can create either an embedded OLE object or a linked OLE object.

TOleContainer automatically handles menu merging -- the process of combining the container form's menu with that of an in-place activated OLE object's server application. The menu items' GroupIndex property settings control how menus are merged. Those main menu items with GroupIndex values of 0, 2, and 4 remain; TOleContainer merges the server application's menus and replaces the main menu items with GroupIndex values of 1, 3, and 5 (if they exist).

OLE objects that are activated in-place add their server's toolbars directly into the container application's window. Normally, any panels used for toolbars are replaced by the OLE object's server's toolbars. Prevent this by setting a panel's Locked property to true.

When using TOleContainer in an SDI application (the main form's FormStyle property is fsNormal rather than fsMDIForm), place the TOleContainer component inside a panel whose Align (see page 5991) property is set to alClient. TOleContainer replaces an SDI form's toolbars as described above, and using a panel automatically adjusts the amount of space available to the OLE container.

62.1.1.1 TOleContainer Members

The following tables list the members exposed by TOleContainer.

Protected Methods

	Name	Description
	_AddRef (see page 5974)	Called when an application uses a component interface.
	_Release (see page 5975)	Called when an application releases a component interface.
	Changed (see page 5975)	Sends a CM_CHANGED message to the control.
	CreateParams (see page 5979)	Initializes a window-creation parameter data structure.
	DblClick (see page 5980)	OnDblClick event dispatcher.
	DefineProperties (see page 5980)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DoEnter (see page 5981)	Respond to receiving input focus.
	GetPopupMenu (see page 5982)	Returns the pop-up menu associated with the control.
	KeyDown (see page 5983)	Respond to key press events.
	MouseDown (see page 5984)	OnMouseDown event dispatcher.
	Paint (see page 5985)	Renders the image of a custom control.
	QueryInterface (see page 5987)	Returns a reference to a specified interface if the object supports that interface.

Public Methods

	Name	Description
	ChangeIconDialog (see page 5976)	Displays the Change Icon OLE dialog box.
	Close (see page 5976)	Deactivates the OLE object.
	Copy (see page 5976)	Copies the OLE object to the Windows clipboard.
	Create (see page 5972)	Creates and initializes an instance of TOleContainer (see page 5969).
	CreateLinkToFile (see page 5977)	Creates a linked OLE object from the contents of a file.
	CreateObject (see page 5977)	Creates an embedded OLE object given its class name (also known as programmatic identifier).
	CreateObjectFromFile (see page 5978)	Creates an embedded OLE object from the contents of a file.
	CreateObjectFromInfo (see page 5979)	Creates an OLE object matching the specified TCreateInfo (see page 6056) record.
	Destroy (see page 5973)	Destroys an instance of TOleContainer (see page 5969).
	DestroyObject (see page 5981)	Destroys the container's OLE object.
	DoVerb (see page 5981)	Requests that the OLE object perform some action.

	GetIconMetaPict (see page 5982)	Returns the global memory handle of a metafile containing the OLE object's icon.
	InsertObjectDialog (see page 5982)	Displays the Insert Object OLE dialog box.
	LoadFromFile (see page 5984)	Loads an OLE object from the specified file.
	LoadFromStream (see page 5984)	Loads an OLE object from the specified stream.
	ObjectPropertiesDialog (see page 5985)	Displays the OLE Object Properties property sheet.
	Paste (see page 5986)	Pastes the contents of the Windows clipboard as an embedded object.
	PasteSpecialDialog (see page 5986)	Displays the Paste (see page 5986) Special OLE dialog box.
	Run (see page 5987)	Runs the OLE object's server application, but doesn't open or activate the OLE object itself.
	SaveAsDocument (see page 5987)	Saves the OLE object to the specified file in native OLE Document format.
	SaveToFile (see page 5989)	Saves the OLE object to the specified file.
	SaveToStream (see page 5989)	Saves the OLE object to the specified stream.
	UpdateObject (see page 5990)	Refreshes the OLE object.
	UpdateVerbs (see page 5990)	Refreshes the list of verbs the OLE object can respond to.

Public Properties

	Name	Description
R	CanPaste (see page 5997)	Indicates whether the Windows clipboard contains an OLE object that can be pasted into the OLE container.
R	Linked (see page 5005)	Indicates whether the OLE object is linked or embedded.
	Modified (see page 6006)	Indicates whether the OLE object has been modified.
R	NewInserted (see page 6006)	Indicates whether the OLE object was created rather than pasted in or created as a link to a file.
R	ObjectVerbs (see page 6006)	Lists the verbs that the OLE object supports.
R	OleClassName (see page 6007)	Specifies the class name of the OLE object.
R	OleObject (see page 6008)	Represents the OLE object hosted by the OLE container.
R	OleObjectInterface (see page 6008)	Provides access to the IOleObject interface for the OLE object.
R	PrimaryVerb (see page 6015)	Specifies the index of the primary (default) verb for the OLE object.
R	SourceDoc (see page 6017)	Specifies the name of the source document for a linked OLE object.
R	State (see page 6017)	Describes the state of the OLE object.
R	StorageInterface (see page 6018)	Provides access to the IStorage interface for the OLE object.

Published Events

	Name	Description
	OnActivate (see page 6021)	Occurs immediately after the OLE object is activated.
	OnDeactivate (see page 6022)	Occurs immediately after the OLE object is deactivated.
	OnDragDrop (see page 6022)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 6025)	Occurs when the user drags an object over a control.
	OnEndDrag (see page 6028)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6029)	Occurs when a control receives the input focus.
	OnExit (see page 6032)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 6035)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6038)	Occurs when a key is pressed.
	OnKeyUp (see page 6039)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 6041)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 6042)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseMove (see page 6044)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 6047)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnObjectMove (see page 6049)	Occurs when the OLE container is notified that the OLE object has moved or resized.
	OnResize (see page 6049)	Occurs immediately after the OLE container window is resized.

	OnStartDrag (see page 6049)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 5991)	Determines how the control aligns within its container (parent control).
	AllowActiveDoc (see page 5995)	Specifies whether the OLE container supports the IOleDocumentSite interface.
	AllowInPlace (see page 5995)	Determines whether the OLE container allows in-place activation.
	Anchors (see page 5996)	Specifies how the control is anchored to its parent.
	AutoActivate (see page 5996)	Determines how the object in an OLE container is activated.
	AutoVerbMenu (see page 5997)	Determines whether the OLE container automatically creates a pop-up menu containing the OLE object's verbs.
	BorderStyle (see page 5997)	Determines whether a single line is drawn around the OLE container.
	Caption (see page 5998)	Specifies a text string that identifies the control to the user.
	Color (see page 6000)	Specifies the background color of the control.
	Constraints (see page 6001)	Specifies the size constraints for the control.
	CopyOnSave (see page 6002)	Determines whether the SaveToFile (see page 5989) and SaveToStream (see page 5989) methods first create a copy of the OLE object.
	Ctl3D (see page 6002)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DragCursor (see page 6003)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragMode (see page 6003)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 6005)	Controls whether the control responds to mouse, keyboard, and timer events.
	Iconic (see page 6005)	Determines whether the OLE object is displayed as an icon.
	OldStreamFormat (see page 6007)	Indicates whether the OLE object is loaded and saved using the VCL format.
	ParentColor (see page 6008)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6009)	Determines where a component looks to determine if it should appear three dimensional.
	ParentShowHint (see page 6009)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 6010)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 6015)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	SizeMode (see page 6017)	Determines how the OLE object is sized in the OLE container.
	TabOrder (see page 6018)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6019)	Determines if the user can tab to a control.
	Visible (see page 6019)	Determines whether the component appears onscreen.

62.1.1.2 TOleContainer.Create Constructor

Creates and initializes an instance of TOleContainer (see page 5969).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TOleContainer(TComponent * AOwner);
```

Description

Call Create to instantiate a TOleContainer (see page 5969) object at runtime. OLE containers placed on forms at design time are created automatically.

Pass a component to the constructor to supply the OLE container with an Owner that is responsible for freeing it.

After calling the inherited constructor, Create

Sets ControlStyle to [csClickEvents, csSetCaption, csOpaque, csDoubleClicks].

Sets TabStop (see page 6019) to true.

Sets ParentColor (see page 6008) to false and BorderStyle (see page 5997) to bsSingle.

Sets AllowActiveDoc (see page 5995) and AllowInPlace (see page 5995) to true.

Sets AutoActivate (see page 5996) to aaDoubleClick and AutoVerbMenu (see page 5997) to true.

Sets CopyOnSave (see page 6002) to true.

See Also

AllowActiveDoc (see page 5995)

AllowInPlace (see page 5995)

AutoActivate (see page 5996)

AutoVerbMenu (see page 5997)

BorderStyle (see page 5997)

ControlStyle

CopyOnSave (see page 6002)

ParentColor

TabStop

62.1.1.3 TOleContainer.Destroy Destructor

Destroys an instance of TOleContainer (see page 5969).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TOleContainer();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the TOleContainer (see page 5969) reference is not nil, and only then calls Destroy.Destroy frees the OLE object before calling the inherited destructor.

See Also

DestroyObject (see page 5981)

System::TObject::Free

62.1.1.4 TOleContainer Methods

The methods of the TOleContainer class are listed here.

Protected Methods

	Name	Description
	_AddRef (see page 5974)	Called when an application uses a component interface.
	_Release (see page 5975)	Called when an application releases a component interface.
	Changed (see page 5975)	Sends a CM_CHANGED message to the control.
V	CreateParams (see page 5979)	Initializes a window-creation parameter data structure.

	DblClick (see page 5980)	OnDblClick event dispatcher.
	DefineProperties (see page 5980)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DoEnter (see page 5981)	Respond to receiving input focus.
	GetPopupMenu (see page 5982)	Returns the pop-up menu associated with the control.
	KeyDown (see page 5983)	Respond to key press events.
	MouseDown (see page 5984)	OnMouseDown event dispatcher.
	Paint (see page 5985)	Renders the image of a custom control.
	QueryInterface (see page 5987)	Returns a reference to a specified interface if the object supports that interface.

Public Methods

	Name	Description
	ChangeIconDialog (see page 5976)	Displays the Change Icon OLE dialog box.
	Close (see page 5976)	Deactivates the OLE object.
	Copy (see page 5976)	Copies the OLE object to the Windows clipboard.
	CreateLinkToFile (see page 5977)	Creates a linked OLE object from the contents of a file.
	CreateObject (see page 5977)	Creates an embedded OLE object given its class name (also known as programmatic identifier).
	CreateObjectFromFile (see page 5978)	Creates an embedded OLE object from the contents of a file.
	CreateObjectFromInfo (see page 5979)	Creates an OLE object matching the specified TCreateInfo (see page 6056) record.
	DestroyObject (see page 5981)	Destroys the container's OLE object.
	DoVerb (see page 5981)	Requests that the OLE object perform some action.
	GetIconMetaPict (see page 5982)	Returns the global memory handle of a metafile containing the OLE object's icon.
	InsertObjectDialog (see page 5982)	Displays the Insert Object OLE dialog box.
	LoadFromFile (see page 5984)	Loads an OLE object from the specified file.
	LoadFromStream (see page 5984)	Loads an OLE object from the specified stream.
	ObjectPropertiesDialog (see page 5985)	Displays the OLE Object Properties property sheet.
	Paste (see page 5986)	Pastes the contents of the Windows clipboard as an embedded object.
	PasteSpecialDialog (see page 5986)	Displays the Paste (see page 5986) Special OLE dialog box.
	Run (see page 5987)	Runs the OLE object's server application, but doesn't open or activate the OLE object itself.
	SaveAsDocument (see page 5987)	Saves the OLE object to the specified file in native OLE Document format.
	SaveToFile (see page 5989)	Saves the OLE object to the specified file.
	SaveToStream (see page 5989)	Saves the OLE object to the specified stream.
	UpdateObject (see page 5990)	Refreshes the OLE object.
	UpdateVerbs (see page 5990)	Refreshes the list of verbs the OLE object can respond to.

62.1.1.4.1 TOleContainer._AddRef Method

Called when an application uses a component interface.

Pascal

```
function _AddRef: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _AddRef();
```

Description

__AddRef is a basic implementation of the IInterface method, _AddRef.

Note: If the component is a wrapper for a COM object, __AddRef calls the _AddRef method of that COM object, and returns the resulting reference count.

In all other cases, __AddRef simply returns –1 and takes no action. This allows the component to implement interfaces where reference counting is not required. More sophisticated components should override __AddRef to implement reference counting.

See Also

Invoke

QueryInterface

_Release

ComObject

_AddRef

62.1.1.4.2 TOleContainer._Release Method

Called when an application releases a component interface.

Pascal

```
function _Release: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _Release();
```

Description

__Release is a basic implementation of the IInterface method, _Release.

__Release returns the resulting value of the reference count for the component's interface.

Note:

In all other cases, __Release simply returns –1 and takes no action. This allows the component to implement interfaces where reference counting is not required. More sophisticated components should override __Release to implement reference counting.

See Also

Invoke

QueryInterface

_AddRef

ComObject

62.1.1.4.3 TOleContainer.Changed Method

Sends a CM_CHANGED message to the control.

Pascal

```
procedure Changed; dynamic;
```

C++

```
__fastcall Changed();
```

Description

Call Changed after changing the properties of the control in a way that affects the properties of a parent object. Changed sends a CM_CHANGED message back to the control. If the control is a windowed control, this message is bubbled up to the parent so that it can make any necessary adjustments.

See Also

Parent

62.1.1.4.4 TOleContainer.ChangeIconDialog Method

Displays the Change Icon OLE dialog box.

Pascal

```
function ChangeIconDialog: Boolean;
```

C++

```
__fastcall Boolean ChangeIconDialog();
```

Description

Call ChangeIconDialog to let the user choose a different icon (from .ICO, .DLL, and .EXE files) to use when displaying the OLE object as an icon. An OLE object must already be loaded before calling ChangeIconDialog. ChangeIconDialog returns true if the dialog box was successfully displayed and the user chose the OK button. ChangeIconDialog returns false otherwise.

See Also

Iconic (see page 6005)

ObjectPropertiesDialog (see page 5985)

62.1.1.4.5 TOleContainer.Close Method

Deactivates the OLE object.

Pascal

```
procedure Close;
```

C++

```
__fastcall Close();
```

Description

Call Close to deactivate the OLE object and terminate its server application, without removing it from the container. Any changes the user made to the OLE object are automatically saved. After calling Close, the container's State (see page 6017) property is osLoaded.

Note: If Close is called when no OLE object is loaded, TOleContainer (see page 5969) raises an exception.

See Also

OnDeactivate (see page 6022)

State (see page 6017)

62.1.1.4.6 TOleContainer.Copy Method

Copies the OLE object to the Windows clipboard.

Pascal

```
procedure Copy;
```

C++

```
__fastcall Copy();
```

Description

Call Copy to write the OLE object to the clipboard. If there is no OLE object in the container, Copy raises an exception.

See Also

Paste (see page 5986)

PasteSpecialDialog (see page 5986)

SaveToFile (see page 5989)

SaveToStream (see page 5989)

62.1.1.4.7 TOleContainer.CreateLinkToFile Method

Creates a linked OLE object from the contents of a file.

Pascal

```
procedure CreateLinkToFile(const FileName: string; Iconic: Boolean);
```

C++

```
__fastcall CreateLinkToFile(const UnicodeString FileName, Boolean Iconic);
```

Description

Call CreateLinkToFile to create a linked OLE object from the file specified by the FileName parameter. Iconic (see page 6005) specifies whether the object is shown as an icon (true) or displayed as it would be in the server application (false). If there is already an OLE object in the container, it is destroyed and any changes the user made to it are discarded.

See Also

CreateObject (see page 5977)

CreateObjectFromFile (see page 5978)

CreateObjectFromInfo (see page 5979)

Creating Clients for Servers That Do Not Have a Type Library

62.1.1.4.8 TOleContainer.CreateObject Method

Creates an embedded OLE object given its class name (also known as programmatic identifier).

Pascal

```
procedure CreateObject(const OleClassName: string; Iconic: Boolean);
```

C++

```
__fastcall CreateObject(const UnicodeString OleClassName, Boolean Iconic);
```

Description

Call CreateObject to create an OLE object using the class name (also known as programmatic identifier) specified by the OleClassName (see page 6007) parameter. The Iconic (see page 6005) parameter indicates whether the object is shown as an icon (true) or displayed as it would be in the server application (false). If there's already an OLE object in the container, it is destroyed and any changes the user made to it are discarded.

See Also

CreateLinkToFile (see page 5977)

CreateObjectFromFile (see page 5978)

CreateObjectFromInfo (see page 5979)

OleClassName (see page 6007)

Creating Clients for Servers That Do Not Have a Type Library

62.1.1.4.9 TOleContainer.CreateObjectFromFile Method

Creates an embedded OLE object from the contents of a file.

Pascal

```
procedure CreateObjectFromFile(const FileName: string; Iconic: Boolean);
```

C++

```
__fastcall CreateObjectFromFile(const UnicodeString FileName, Boolean Iconic);
```

Description

Call CreateObjectFromFile to create an OLE object from the file specified by the FileName parameter. The Iconic (see page 6005) parameter indicates whether the object is shown as an icon (true) or displayed as it would be in the server application (false). If there's already an OLE object in the container, it is destroyed and any changes the user made to it are discarded.

Delphi Examples:

```
{
This example uses an OLE container and a main menu on a form.
When the user clicks the Open or Save options in the main menu,
an open/save dialog is displayed and by default,
the user is required to enter the name of a Word document.
Files with other extensions supported by the OLE container
can also be accessed. An additional test is made to assure that
the file to open exists and that no file overwriting is
going to take place.
}
procedure TForm1.Exit1Click(Sender: TObject);
begin
  Close;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  OpenDialog1.Filter := 'Documents (*.doc)|*.DOC|Any file (*.*)|*.*';
  SaveDialog1.Filter := 'Documents (*.doc)|*.DOC|Any file (*.*)|*.*';
end;

procedure TForm1.Open1Click(Sender: TObject);
begin
  if OpenDialog1.Execute then
    if FileExists(OpenDialog1.FileName) then
      OleContainer1.CreateObjectFromFile(OpenDialog1.FileName, false)
    else
      raise Exception.Create('File not found.');
end;

procedure TForm1.Save1Click(Sender: TObject);
begin
  if SaveDialog1.Execute then
    if FileExists(SaveDialog1.FileName) then
      raise Exception.Create('File already exists. Cannot overwrite.')
    else
      OleContainer1.SaveAsDocument(SaveDialog1.FileName);
end;
```

See Also

CreateLinkToFile (see page 5977)

CreateObject (see page 5977)

CreateObjectFromInfo (see page 5979)

Creating Clients for Servers That Do Not Have a Type Library

62.1.1.4.10 TOleContainer.CreateObjectFromInfo Method

Creates an OLE object matching the specified TCreateInfo (see page 6056) record.

Pascal

```
procedure CreateObjectFromInfo(const CreateInfo: TCreateInfo);
```

C++

```
__fastcall CreateObjectFromInfo(const TCreateInfo CreateInfo);
```

Description

Call CreateObjectFromInfo to create a linked or embedded OLE object based on the specifications in the CreateInfo parameter. CreateInfo specifies whether the object should be created from a file, from a data transfer object, or from a class identifier, and provides the necessary supporting information. CreateInfo also indicates whether the OLE object should be displayed as an Icon, and allows the icon to be specified. If there's already an OLE object in the container, it is destroyed and any changes the user made to it are discarded.

Note: The CreateLinkToFile (see page 5977), CreateObject (see page 5977), and CreateObjectFromFile (see page 5978) methods are one-line calls for the most common types of OLE objects. They can be used instead of filling out the TCreateInfo (see page 6056) record.

CreateLinkToFile (see page 5977)

CreateObject (see page 5977)

CreateObjectFromFile (see page 5978)

Creating Clients for Servers That Do Not Have a Type Library

62.1.1.4.11 TOleContainer.CreateParams Method

Initializes a window-creation parameter data structure.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. Override CreateParams to customize the way a control creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

CreateParams fills in the parameter that is passed as the value of the Params parameter. This data structure holds information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function.

TWinControl implements CreateParams by setting all the fields of Params to generic base values. A number of the standard controls override CreateParams to change one or more of the default values in Params.

See Also

CreateWindowHandle

CreateWnd

AddBiDiModeExStyle

62.1.1.4.12 TOleContainer.DblClick Method

OnDblClick event dispatcher.

Pascal

```
procedure DblClick; override;
```

C++

```
virtual __fastcall DblClick();
```

Description

DblClick calls any event handler attached to the OnDblClick event. Override DblClick to provide other responses in addition to the inherited event-handler call when the user double-clicks the control.

The DblClick method is triggered by left mouse-button double-click message (WM_LBUTTONDBLCLK) from Windows.

See Also

Click

OnDblClick

62.1.1.4.13 TOleContainer.DefineProperties Method

Provides methods to read and write the IsControl property to a stream such as a form file.

Pascal

```
procedure DefineProperties(Filer: TFiler); override;
```

C++

```
virtual __fastcall DefineProperties(TFiler Filer);
```

Description

DefineProperties is called automatically by the streaming system that loads and saves VCL components. It allows persistent objects to read and write properties that are not published. Published properties are loaded and stored automatically.

DefineProperties uses the methods of the filer passed as the Filer parameter to assign methods that can load and save the IsControl property.

Override DefineProperties to persist unpublished properties. Call the DefineBinaryProperty or DefineProperty method of the Filer parameter to assign methods that load or save property values.

Note: When overriding this method, call the parent class's DefineProperties method first.

See Also

DefineBinaryProperty

DefineProperty

DefineProperties

IsControl

62.1.1.4.14 TOleContainer.DestroyObject Method

Destroys the container's OLE object.

Pascal

```
procedure DestroyObject;
```

C++

```
__fastcall DestroyObject();
```

Description

Call DestroyObject to destroy the OLE object, discarding any unsaved changes the user made to it.

See Also

Close (see page 5976)

OleObject (see page 6008)

Creating Clients for Servers That Do Not Have a Type Library

62.1.1.4.15 TOleContainer.DoEnter Method

Respond to receiving input focus.

Pascal

```
procedure DoEnter; override;
```

C++

```
virtual __fastcall DoEnter();
```

Description

DoEnter is called automatically when the control receives the input focus. As implemented in TWinControl, DoEnter calls the OnEnter event handler, if defined.

Descendant classes that override DoEnter should always call the inherited method.

See Also

DoExit

OnEnter

62.1.1.4.16 TOleContainer.DoVerb Method

Requests that the OLE object perform some action.

Pascal

```
procedure DoVerb(Verb: Integer);
```

C++

```
__fastcall DoVerb(int Verb);
```

Description

Call DoVerb to request that the OLE object perform one of the actions listed by the ObjectVerbs (see page 6006) property.

OLE defines several verbs, such as ovShow (see page 6063) (to display the OLE object) and ovPrimary (see page 6062) (the default action, usually to activate the OLE object). OLE objects can also define their own custom verbs. Use the ObjectVerbs (see page 6006) property to get a list of those custom verbs.

See Also

ObjectVerbs (see page 6006)

Creating Clients for Servers That Do Not Have a Type Library

62.1.1.4.17 TOleContainer.GetIconMetaPict Method

Returns the global memory handle of a metafile containing the OLE object's icon.

Pascal

```
function GetIconMetaPict: HGlobal;
```

C++

```
__fastcall HGlobal GetIconMetaPict();
```

Description

Call GetIconMetaPict to obtain a metafile handle for drawing the OLE object's icon on another canvas. Use the global DestroyMetaPict (see page 6055) procedure to destroy the handle. If the OLE container is empty, GetIconMetaPict raises an exception.

See Also

DestroyMetaPict (see page 6055)

TMetafile (see page 2780)

TMetafileCanvas (see page 2794)

62.1.1.4.18 TOleContainer.GetPopupMenu Method

Returns the pop-up menu associated with the control.

Pascal

```
function GetPopupMenu: TPopupMenu; override;
```

C++

```
virtual __fastcall TPopupMenu GetPopupMenu();
```

Description

Call GetPopupMenu to find the popup menu associated with the control. Override GetPopupMenu to change which popup menu is associated with the control or to specify different popup menus depending on the state of the control.

GetPopupMenu returns the value of the Popup property.

See Also

PopupMenu

62.1.1.4.19 TOleContainer.InsertObjectDialog Method

Displays the Insert Object OLE dialog box.

Pascal

```
function InsertObjectDialog: Boolean;
```

C++

```
__fastcall Boolean InsertObjectDialog();
```

Description

Call InsertObjectDialog to let the user create an OLE object. The OLE object can be embedded or linked. InsertObjectDialog returns true if the dialog box was successfully displayed and the user chose the OK button. InsertObjectDialog returns false otherwise. If the user chose OK and there's already an OLE object in the container, it is destroyed and any changes the user made to it are discarded.

See Also

CreateObjectFromInfo (see page 5979)

ObjectPropertiesDialog (see page 5985)

PasteSpecialDialog (see page 5986)

62.1.1.4.20 TOleContainer.KeyDown Method

Respond to key press events.

Pascal

```
procedure KeyDown(var Key: Word; Shift: TShiftState); override;
```

C++

```
virtual __fastcall KeyDown(Word Key, TShiftState Shift);
```

Description

When a windowed control receives a key-down message (WM_KEYDOWN) from Windows, its message handler calls the DoKeyDown method. If DoKeyDown determines that the control should, in fact, process the character, it calls KeyDown, passing the key code and shift-key state in the Key and Shift parameters, respectively.

KeyDown calls any event handler attached to the OnKeyDown event. Override KeyDown to provide other responses in addition to the event-handler call.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use WinAPI virtual key codes to determine the key pressed. For more information, search for virtual key codes in the Win32 Developer's Reference (WIN32.HLP).

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

Either KeyDown or the OnKeyDown event handler it calls can suppress further processing of a key by setting the Key parameter to zero.

See Also

KeyUp

OnKeyDown

DoKeyDown

DoKeyPress

DoKeyUp

62.1.1.4.21 TOleContainer.LoadFromFile Method

Loads an OLE object from the specified file.

Pascal

```
procedure LoadFromFile(const FileName: string);
```

C++

```
__fastcall LoadFromFile(const UnicodeString FileName);
```

Description

Call LoadFromFile to load an OLE object that was saved using the SaveToFile (see page 5989) method. If OldStreamFormat (see page 6007) is true, LoadFromFile loads files saved by an TOleContainer (see page 5969) object as well as files saved using the current format; if OldStreamFormat (see page 6007) is false, LoadFromFile will not load files saved by the library. If there's already an OLE object in the container, it is destroyed and any changes the user made to it are discarded.

See Also

LoadFromStream (see page 5984)

OldStreamFormat (see page 6007)

SaveToFile (see page 5989)

62.1.1.4.22 TOleContainer.LoadFromStream Method

Loads an OLE object from the specified stream.

Pascal

```
procedure LoadFromStream(Stream: TStream);
```

C++

```
__fastcall LoadFromStream(TStream Stream);
```

Description

Call LoadFromStream to load an OLE object from a stream. If OldStreamFormat (see page 6007) is true, LoadFromStream loads OLE objects saved by a TOleContainer (see page 5969) object as well as OLE objects saved using the current format; if OldStreamFormat (see page 6007) is false, LoadFromStream will not load OLE objects saved by the library. If there's already an OLE object in the container, it is destroyed and any changes the user made to it are discarded.

See Also

LoadFromFile (see page 5984)

OldStreamFormat (see page 6007)

SaveToStream (see page 5989)

TStream

62.1.1.4.23 TOleContainer.MouseDown Method

OnMouseDown event dispatcher.

Pascal

```
procedure MouseDown(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer);
override;
```

C++

```
virtual __fastcall MouseDown(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

Override the protected MouseDown method to provide other responses in addition to calling the OnMouseDown event handler when the user presses the mouse button down while the cursor's hotspot is over the control.

The Button parameter determines which mouse button the user pressed. Shift indicates which shift keys (Shift, Ctrl, or Alt) were down when the user pressed the mouse button. X and Y are the pixel coordinates of the mouse pointer within the client area of the control.

A control calls MouseDown in response to any of the Windows mouse-down messages (WM_LBUTTONDOWN, WM_MBUTTONDOWN, WM_RBUTTONDOWN), decoding the message parameters into the shift-key state and position, which it passes in the Shift, X, and Y parameters, respectively. The value of the Button parameter indicates which mouse button was pressed down: left, right, or middle.

See Also

MouseMove

MouseUp

OnMouseDown

62.1.1.4.24 TOleContainer.ObjectPropertiesDialog Method

Displays the OLE Object Properties property sheet.

Pascal

```
function ObjectPropertiesDialog: Boolean;
```

C++

```
__fastcall Boolean ObjectPropertiesDialog();
```

Description

Call ObjectPropertiesDialog to let the user see and edit the properties of the OLE object. Any changes the user makes in the property sheet are automatically made to the OLE object. ObjectPropertiesDialog returns true if the property sheet was successfully displayed and the user chose the OK button. It returns false otherwise.

If the OLE container is empty, ObjectPropertiesDialog raises an exception.

See Also

DoVerb (see page 5981)

62.1.1.4.25 TOleContainer.Paint Method

Renders the image of a custom control.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

The Paint method for TCustomControl does nothing other than provide the interface for a method that responds to WM_PAINT

messages. Paint is called by the PaintWindow method, after that method has supplied the Canvas with the handle to a device context. When creating a custom control, always override Paint to draw the image of the control.

Tip: To determine which portions of the control's canvas need to be repainted when Paint is called, use the ClipRect property of the canvas.

See Also

Canvas

PaintWindow

GetDeviceContext

ClipRect (see page 2718)

62.1.1.4.26 TOleContainer.Paste Method

Pastes the contents of the Windows clipboard as an embedded object.

Pascal

```
procedure Paste;
```

C++

```
__fastcall Paste();
```

Description

Call Paste to embed the object on the clipboard in the OLE container. If there's already an OLE object in the container, it is destroyed and any changes the user made to it are discarded.

See Also

CanPaste (see page 5997)

CreateObjectFromInfo (see page 5979)

PasteSpecialDialog (see page 5986)

62.1.1.4.27 TOleContainer.PasteSpecialDialog Method

Displays the Paste (see page 5986) Special OLE dialog box.

Pascal

```
function PasteSpecialDialog: Boolean;
```

C++

```
__fastcall Boolean PasteSpecialDialog();
```

Description

Call PasteSpecialDialog to let the user control how the contents of the Windows clipboard are pasted into the container. The Paste (see page 5986) Special dialog box lets the user select the format of the data, whether it should be embedded or linked, and whether the OLE object should be displayed as an icon (and if so, to choose a different icon). PasteSpecialDialog returns true if the dialog box was successfully displayed and the user chose the OK button. It returns false otherwise. If the user chose the OK button when there's already an OLE object in the container, it is destroyed and any changes the user made to it are discarded.

See Also

CanPaste (see page 5997)

InsertObjectDialog (see page 5982)

Paste (see page 5986)

62.1.1.4.28 TOleContainer.QueryInterface Method

Returns a reference to a specified interface if the object supports that interface.

Pascal

```
function QueryInterface(const IID: TGUID; out Obj): HResult; override; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT QueryInterface(const TGUID IID,  Obj);
```

Description

QueryInterface checks whether the component supports the interface specified by IID, and if so, returns a reference to that interface as the Obj parameter. If the component does not support the interface, the Obj parameter returns nil (Delphi) or NULL (C++).

Note: For components that act as COM object wrapper, QueryInterface calls the QueryInterface method of the internal COM object.

See Also

_AddRef

_Release

QueryInterface

QueryInterface

Invoke

ComObject

62.1.1.4.29 TOleContainer.Run Method

Runs the OLE object's server application, but doesn't open or activate the OLE object itself.

Pascal

```
procedure Run;
```

C++

```
__fastcall Run();
```

Description

Call Run to ensure that the server application is running. Once the server application is running, opening and activating the OLE object happens much more quickly. An OLE object must already be loaded in the container before calling Run, Otherwise, Run raises an exception.

See Also

State (see page 6017)

62.1.1.4.30 TOleContainer.SaveAsDocument Method

Saves the OLE object to the specified file in native OLE Document format.

Pascal

```
procedure SaveAsDocument(const FileName: string);
```

C++

```
__fastcall SaveAsDocument(const UnicodeString FileName);
```

Description

Call SaveAsDocument to save the OLE object in its native OLE Document format. An OLE object must already be loaded in the container before calling SaveAsDocument. Otherwise, SaveAsDocument raises an exception.

Note: Saving an OLE object to a file or a stream limits the ability of another application, such as Word, to open the file, even if it is saved with the correct extension. Saving to a file or a stream loses information necessary to open such a file. Use SaveAsDocument when needing to save files in a native OLE Document format.

Delphi Examples:

```
{
This example uses an OLE container and a main menu on a form.
When the user clicks the Open or Save options in the main menu,
an open/save dialog is displayed and by default,
the user is required to enter the name of a Word document.
Files with other extensions supported by the OLE container
can also be accessed. An additional test is made to assure that
the file to open exists and that no file overwriting is
going to take place.
}
procedure TForm1.Exit1Click(Sender: TObject);
begin
  Close;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  OpenDialog1.Filter := 'Documents (*.doc)|*.DOC|Any file (*.*)|*.*';
  SaveDialog1.Filter := 'Documents (*.doc)|*.DOC|Any file (*.*)|*.*';
end;

procedure TForm1.Open1Click(Sender: TObject);
begin
  if OpenDialog1.Execute then
    if FileExists(OpenDialog1.FileName) then
      OleContainer1.CreateObjectFromFile(OpenDialog1.FileName, false)
    else
      raise Exception.Create('File not found.');
end;

procedure TForm1.Save1Click(Sender: TObject);
begin
  if SaveDialog1.Execute then
    if FileExists(SaveDialog1.FileName) then
      raise Exception.Create('File already exists. Cannot overwrite.')
    else
      OleContainer1.SaveAsDocument(SaveDialog1.FileName);
end;
```

See Also

SaveToFile (see page 5989)

SaveToStream (see page 5989)

62.1.1.4.31 TOleContainer.SaveToFile Method

Saves the OLE object to the specified file.

Pascal

```
procedure SaveToFile(const FileName: string);
```

C++

```
__fastcall SaveToFile(const UnicodeString FileName);
```

Description

Call SaveToFile to save the OLE object. If CopyOnSave (see page 6002) is true, SaveToFile first creates a temporary OLE object that compresses redundant data, saving space in the file that is saved. If OldStreamFormat (see page 6007) is true, SaveToFile writes a file that can be read by a TOleContainer (see page 5969) component.

An OLE object must already be loaded in the container before calling SaveToFile. Otherwise, SaveToFile raises an exception.

See Also

Copy (see page 5976)

CopyOnSave (see page 6002)

LoadFromFile (see page 5984)

OldStreamFormat (see page 6007)

SaveToStream (see page 5989)

62.1.1.4.32 TOleContainer.SaveToStream Method

Saves the OLE object to the specified stream.

Pascal

```
procedure SaveToStream(Stream: TStream);
```

C++

```
__fastcall SaveToStream(TStream Stream);
```

Description

Call SaveToStream to save the OLE object. If CopyOnSave (see page 6002) is true, SaveToStream first creates a temporary OLE object that compresses redundant data, reducing the information that must be saved. If OldStreamFormat (see page 6007) is true, SaveToStream writes the object in a format that can be read by a TOleContainer (see page 5969) component.

An OLE object must already be loaded in the container before calling SaveToStream. Otherwise, SaveToStream raises an exception.

See Also

Copy (see page 5976)

CopyOnSave (see page 6002)

LoadFromStream (see page 5984)

OldStreamFormat (see page 6007)

SaveToFile (see page 5989)

62.1.1.4.33 TOleContainer.UpdateObject Method

Refreshes the OLE object.

Pascal

```
procedure UpdateObject;
```

C++

```
__fastcall UpdateObject();
```

Description

Linked (see page 6005) OLE objects and embedded objects that contain linked OLE objects get out of date when the source of the link is updated. UpdateObject rereads the source to ensure that the OLE object has current data. If there is no OLE object loaded in the container, UpdateObject has no effect.

See Also

Linked (see page 6005)

UpdateVerbs (see page 5990)

62.1.1.4.34 TOleContainer.UpdateVerbs Method

Refreshes the list of verbs the OLE object can respond to.

Pascal

```
procedure UpdateVerbs;
```

C++

```
__fastcall UpdateVerbs();
```

Description

TOleContainer (see page 5969) automatically calls UpdateVerbs when the ObjectVerbs (see page 6006) property is first read, but some OLE objects change their verbs when they perform some actions. The Media Clip OLE object, for example, changes its Play verb to Stop while running. Call UpdateVerbs to ensure that the list of verbs is appropriate to the state of the OLE object.

An OLE object must already be loaded in the container before calling UpdateVerbs. Otherwise, UpdateVerbs raises an exception.

See Also

AutoVerbMenu (see page 5997)

ObjectVerbs (see page 6006)

62.1.1.5 TOleContainer Properties

The properties of the TOleContainer class are listed here.

Public Properties

	Name	Description
R	CanPaste (see page 5997)	Indicates whether the Windows clipboard contains an OLE object that can be pasted into the OLE container.
R	Linked (see page 6005)	Indicates whether the OLE object is linked or embedded.
	Modified (see page 6006)	Indicates whether the OLE object has been modified.

	NewInserted (see page 6006)	Indicates whether the OLE object was created rather than pasted in or created as a link to a file.
	ObjectVerbs (see page 6006)	Lists the verbs that the OLE object supports.
	OleClassName (see page 6007)	Specifies the class name of the OLE object.
	OleObject (see page 6008)	Represents the OLE object hosted by the OLE container.
	OleObjectInterface (see page 6008)	Provides access to the IOleObject interface for the OLE object.
	PrimaryVerb (see page 6015)	Specifies the index of the primary (default) verb for the OLE object.
	SourceDoc (see page 6017)	Specifies the name of the source document for a linked OLE object.
	State (see page 6017)	Describes the state of the OLE object.
	StorageInterface (see page 6018)	Provides access to the IStorage interface for the OLE object.

Published Properties

	Name	Description
	Align (see page 5991)	Determines how the control aligns within its container (parent control).
	AllowActiveDoc (see page 5995)	Specifies whether the OLE container supports the IOleDocumentSite interface.
	AllowInPlace (see page 5995)	Determines whether the OLE container allows in-place activation.
	Anchors (see page 5996)	Specifies how the control is anchored to its parent.
	AutoActivate (see page 5996)	Determines how the object in an OLE container is activated.
	AutoVerbMenu (see page 5997)	Determines whether the OLE container automatically creates a pop-up menu containing the OLE object's verbs.
	BorderStyle (see page 5997)	Determines whether a single line is drawn around the OLE container.
	Caption (see page 5998)	Specifies a text string that identifies the control to the user.
	Color (see page 6000)	Specifies the background color of the control.
	Constraints (see page 6001)	Specifies the size constraints for the control.
	CopyOnSave (see page 6002)	Determines whether the SaveToFile (see page 5989) and SaveToStream (see page 5989) methods first create a copy of the OLE object.
	Ctl3D (see page 6002)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DragCursor (see page 6003)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragMode (see page 6003)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 6005)	Controls whether the control responds to mouse, keyboard, and timer events.
	Iconic (see page 6005)	Determines whether the OLE object is displayed as an icon.
	OldStreamFormat (see page 6007)	Indicates whether the OLE object is loaded and saved using the VCL format.
	ParentColor (see page 6008)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6009)	Determines where a component looks to determine if it should appear three dimensional.
	ParentShowHint (see page 6009)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 6010)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 6015)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	SizeMode (see page 6017)	Determines how the OLE object is sized in the OLE container.
	TabOrder (see page 6018)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6019)	Determines if the user can tab to a control.
	Visible (see page 6019)	Determines whether the component appears onscreen.

62.1.1.5.1 TOleContainer.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
```

```
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var

Anchors

62.1.1.5.2 TOleContainer.AllowActiveDoc Property

Specifies whether the OLE container supports the IOleDocumentSite interface.

Pascal

```
property AllowActiveDoc: Boolean;
```

C++

```
__property Boolean AllowActiveDoc;
```

Description

Set AllowActiveDoc to true to specify that the OLE container can house an ActiveDoc (DocObject). Set AllowActiveDoc to false to limit the OLE container to hosting OLE controls that use the more usual interfaces such as IOleClientSite. ActiveDoc-enabled controls have a slightly different border. Set AllowActiveDoc to false to maintain a consistent appearance in forms that do not need to support the IOleDocumentSite interface.

See Also

AllowInPlace (see page 5995)

62.1.1.5.3 TOleContainer.AllowInPlace Property

Determines whether the OLE container allows in-place activation.

Pascal

```
property AllowInPlace: Boolean;
```

C++

```
__property Boolean AllowInPlace;
```

Description

Set AllowInPlace to specify what happens when the user activates the OLE object. If AllowInPlace is true and Iconic (see page 6005) is false, the OLE object is activated in place. If AllowInPlace is false, the OLE object is activated in a separate window. The default value is true.

See Also

AllowActiveDoc (see page 5995)

AutoActivate (see page 5996)

Iconic (see page 6005)

62.1.1.5.4 TOleContainer.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

62.1.1.5.5 TOleContainer.AutoActivate Property

Determines how the object in an OLE container is activated.

Pascal

```
property AutoActivate: TAutoActivate;
```

C++

```
__property TAutoActivate AutoActivate;
```

Description

Set AutoActivate to specify what actions activate the OLE object. AutoActivate takes one of the values in the following table:

Values	Meaning
aaManual	The OLE object must be activated programmatically by calling DoVerb (see page 5981) (ovShow (see page 6063)).
aaGetFocus	The OLE object is activated when the OLE container gets focus (by clicking on it with the mouse or pressing Tab to move the focus to it).
aaDoubleClick	(Default) The OLE object is activated by double-clicking it or pressing Enter while the container has the focus.

See Also

AllowActiveDoc (see page 5995)

DoVerb (see page 5981)

62.1.1.5.6 TOleContainer.AutoVerbMenu Property

Determines whether the OLE container automatically creates a pop-up menu containing the OLE object's verbs.

Pascal

```
property AutoVerbMenu: Boolean;
```

C++

```
__property Boolean AutoVerbMenu;
```

Description

Use AutoVerbMenu to specify whether the OLE object can replace the OLE container's popup menu. If AutoVerbMenu is true (the default), the OLE object replaces any existing PopupMenu (see page 6010) property. If AutoVerbMenu is false, no popup menu is automatically created.

See Also

DoVerb (see page 5981)

ObjectVerbs (see page 6006)

PopupMenu

62.1.1.5.7 TOleContainer.BorderStyle Property

Determines whether a single line is drawn around the OLE container.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Set BorderStyle to specify whether the OLE container should be framed by a single line. These are the possible values:

Value	Meaning
bsNone	No visible border
bsSingle	Single-line border

See Also

Ctl3D

62.1.1.5.8 TOleContainer.CanPaste Property

Indicates whether the Windows clipboard contains an OLE object that can be pasted into the OLE container.

Pascal

```
property CanPaste: Boolean;
```

C++

```
__property Boolean CanPaste;
```

Description

Read CanPaste before trying to paste or paste link an OLE object from the clipboard.

See Also

Paste (see page 5986)

PasteSpecialDialog (see page 5986)

62.1.1.5.9 TOleContainer.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
```

```
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>
#include <memory>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);  // The owner (toolBar) will clean this up.
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this); // The owner (this) will clean this up.
  myToolBar->Parent = this;
//  TStringList *captions = new TStringList();
  std::auto_ptr<TStringList> captions(new TStringList());

  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions.get());
//  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long to be the caption of this label';
end;
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
```

```
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
        Caption := ButtonCaptions[I];
        if (ButtonCaptions[I] = '|') then
          Style := tbsSeparator
        else
          Style := tbsButton;
      end;
    end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ToolBar1 := TToolBar.Create(Self);
  ToolBar1.Parent := Self;
  AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
  ToolBar1.ShowCaptions := True;
  ToolBar1.Height := 40;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  I: Integer;
begin
  for I := ToolBar1.ButtonCount - 1 downto 0 do
    ToolBar1.Buttons[I].Free;
  ToolBar1.Free;
end;
```

62.1.1.5.10 TOleContainer.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

ParentColor

62.1.1.5.11 TOleContainer.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

OnCanResize

62.1.1.5.12 TOleContainer.CopyOnSave Property

Determines whether the SaveToFile (see page 5989) and SaveToStream (see page 5989) methods first create a copy of the OLE object.

Pascal

```
property CopyOnSave: Boolean;
```

C++

```
__property Boolean CopyOnSave;
```

Description

When CopyOnSave is true, the SaveToFile (see page 5989) and SaveToStream (see page 5989) methods create a temporary OLE object, compressing redundant data to save space. This compressed copy is then saved to the file or stream. When CopyOnSave is false, the OLE object is saved directly to the file or stream without using a temporary copy to compress redundant information.

Set CopyOnSave to false when the container holds very large embedded objects and there might not be enough memory to make the temporary copy. The default value is true.

See Also

OleObject (see page 6008)

SaveToFile (see page 5989)

SaveToStream (see page 5989)

62.1.1.5.13 TOleContainer.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

62.1.1.5.14 TOleContainer.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

62.1.1.5.15 TOleContainer.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
```

```
    else if (HT.Contains(htOnIndent))
      AttachMode = naInsert;
    else
      return;
    TreeView1->Selected->MoveTo(Item, AttachMode);
  }

  void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
        int X, int Y, TDragState State, bool &Accept)
  {
    Accept = (Source == dynamic_cast<TObject *>(TreeView1));
  }
```

Delphi Examples:

```
  {
  The following code uses GetNodeAt to add a dragged node as a
  child of the node under the mouse when it is dropped.  This
  example requires a populated TreeView.  Also, the TTreeView
  DragMode property must be set to dmAutomatic, and the TTreeView
  OnDragOver event handler must be implemented to accept the
  drop.
  }
  procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
  var
    AnItem: TTreeNode;
    AttachMode: TNodeAttachMode;
    HT: THitTests;
  begin
    if TreeView1.Selected = nil then Exit;
    HT := TreeView1.GetHitTestInfoAt(X, Y);
    AnItem := TreeView1.GetNodeAt(X, Y);
    if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
    begin
      if (htOnItem in HT) or (htOnIcon in HT) then
        AttachMode := naAddChild
      else if htNowhere in HT then AttachMode := naAdd
      else if htOnIndent in HT then AttachMode := naInsert;
      TreeView1.Selected.MoveTo(AnItem, AttachMode);
    end;
  end;

  procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;

62.1.1.5.16 TOleContainer.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

62.1.1.5.17 TOleContainer.Iconic Property

Determines whether the OLE object is displayed as an icon.

Pascal

```
property Iconic: Boolean;
```

C++

```
__property Boolean Iconic;
```

Description

Set Iconic to specify whether the OLE container displays the icon for the server application instead of the image of the object. If Iconic is true, the OLE object is displayed as an icon; if false, it's displayed as it would be in the server application.

62.1.1.5.18 TOleContainer.Linked Property

Indicates whether the OLE object is linked or embedded.

Pascal

```
property Linked: Boolean;
```

C++

```
__property Boolean Linked;
```

Description

Read Linked to determine whether the OLE object is linked to the OLE server. If Linked is true, the OLE object is linked; if false, it's embedded. An OLE object must already be loaded in the container before accessing the Linked property.

See Also

UpdateObject (see page 5990)

62.1.1.5.19 TOleContainer.Modified Property

Indicates whether the OLE object has been modified.

Pascal

```
property Modified: Boolean;
```

C++

```
__property Boolean Modified;
```

Description

Use Modified to determine when the OLE object has been modified (including being deleted or replaced by another OLE object). To keep track of incremental changes, set Modified to false and later check it to see if the OLE object has been modified after since Modified was set to false. If there is no OLE object loaded into the container, Modified returns false.

See Also

OleObject (see page 6008)

62.1.1.5.20 TOleContainer.NewInserted Property

Indicates whether the OLE object was created rather than pasted in or created as a link to a file.

Pascal

```
property NewInserted: Boolean;
```

C++

```
__property Boolean NewInserted;
```

Description

Read NewInserted to determine whether the OLE object was newly created via a call to InsertObjectDialog (see page 5982). If there is no OLE object loaded into the container, NewInserted returns false. If NewInserted is true after a call to InsertObjectDialog (see page 5982), call DoVerb (see page 5981)(ovShow (see page 6063)) to let the user edit the object.

See Also

DoVerb (see page 5981)

InsertObjectDialog (see page 5982)

OleObject (see page 6008)

62.1.1.5.21 TOleContainer.ObjectVerbs Property

Lists the verbs that the OLE object supports.

Pascal

```
property ObjectVerbs: TStrings;
```

C++

```
__property TStrings ObjectVerbs;
```

Description

Read ObjectVerbs to determine the verbs that can be used with the OLE object. The verb names can have embedded ampersand (&) characters to indicate shortcut keys. An OLE object must already be loaded in the container before accessing the ObjectVerbs property.

See Also

AutoVerbMenu (see page 5997)

DoVerb (see page 5981)

PrimaryVerb (see page 6015)

TStrings

62.1.1.5.22 TOleContainer.OldStreamFormat Property

Indicates whether the OLE object is loaded and saved using the VCL format.

Pascal

```
property OldStreamFormat: Boolean;
```

C++

```
__property Boolean OldStreamFormat;
```

Description

Set OldStreamFormat to true to read OLE objects that were saved to file using VCL or to save OLE objects that will be used by VCL. If OldStreamFormat is false (the default), the LoadFromFile (see page 5984), LoadFromStream (see page 5984), SaveToFile (see page 5989), and SaveToStream (see page 5989) methods use the newer format that contains extra header information. The extra header information is used to validate a file or stream. This property is provided for backward compatibility only.

See Also

LoadFromFile (see page 5984)

LoadFromStream (see page 5984)

SaveToFile (see page 5989)

SaveToStream (see page 5989)

62.1.1.5.23 TOleContainer.OleClassName Property

Specifies the class name of the OLE object.

Pascal

```
property OleClassName: string;
```

C++

```
__property UnicodeString OleClassName;
```

Description

Read OleClassName to obtain the class name (programmatic identifier) for the OLE object. The class name is a string describing the class of OLE object that is registered in the Windows registry. An OLE object must already be loaded in the container before accessing the OleClassName property.

See Also

OleObject (see page 6008)

62.1.1.5.24 TOleContainer.OleObject Property

Represents the OLE object hosted by the OLE container.

Pascal

```
property OleObject: Variant;
```

C++

```
__property Variant OleObject;
```

Description

Read OleObject to access the OLE object hosted by the OLE container as a variant. To interact with the OLE object using the IOleObject interface, use the OleObjectInterface (see page 6008) property instead. If the OLE object is not loaded in the container before reading OleObject, an EOleError exception is raised.

See Also

EOleError

OleObjectInterface (see page 6008)

62.1.1.5.25 TOleContainer.OleObjectInterface Property

Provides access to the IOleObject interface for the OLE object.

Pascal

```
property OleObjectInterface: IOleObject;
```

C++

```
__property IOleObject OleObjectInterface;
```

Description

Use OleObjectInterface for low-level access to the OLE API. If there is no OLE object loaded into the container, OleObjectInterface returns nil (Delphi) or NULL (C++).

See Also

OleObject (see page 6008)

Creating Clients for Servers That Do Not Have a Type Library

62.1.1.5.26 TOleContainer.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its

own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

Color

Parent

ParentFont

ParentShowHint

62.1.1.5.27 TOleContainer.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

62.1.1.5.28 TOleContainer.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

62.1.1.5.29 TOleContainer.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
```

```
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
```

```
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
```

```
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

OnContextPopup

62.1.1.5.30 TOleContainer.PrimaryVerb Property

Specifies the index of the primary (default) verb for the OLE object.

Pascal

```
property PrimaryVerb: Integer;
```

C++

```
__property int PrimaryVerb;
```

Description

Use PrimaryVerb to determine which verb in the ObjectVerbs (see page 6006) list specifies the default action for the OLE object. In a call to the DoVerb (see page 5981) method, DoVerb (see page 5981)(ovPrimary (see page 6062)) is the same as DoVerb (see page 5981)(PrimaryVerb). An OLE object must already be loaded in the container before accessing the PrimaryVerb property.

See Also

DoVerb (see page 5981)

ObjectVerbs (see page 6006)

62.1.1.5.31 TOleContainer.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

Displaying Fly-over Help

62.1.1.5.32 TOleContainer.SizeMode Property

Determines how the OLE object is sized in the OLE container.

Pascal

```
property SizeMode: TSizeMode;
```

C++

```
__property TSizeMode SizeMode;
```

Description

Set SizeMode to specify how the OLE object is fit into the client area of the OLE container. The following table gives the possible values :

Value	Meaning
smClip	(Default)- Displays the OLE object at its normal size, clipping any parts that don't fit within the container.
smCenter	Displays the OLE object at its normal size, centering it within the container.
smScale	Scales or shrinks the view of the OLE object to fit within the container, by scaling width and height proportionally.
smStretch	Scales or shrinks the view of the OLE object to fill the OLE container, without regard to preserving the proportions of the OLE object.
smAutoSize	Displays the OLE object at its normal size and automatically resizes the container to fit the size of the OLE object.

See Also

AllowInPlace (see page 5995)

ClientRect

62.1.1.5.33 TOleContainer.SourceDoc Property

Specifies the name of the source document for a linked OLE object.

Pascal

```
property SourceDoc: string;
```

C++

```
__property UnicodeString SourceDoc;
```

Description

Read SourceDoc to obtain the name of the OLE object when it is linked. An OLE object must already be loaded in the container before accessing the SourceDoc property. If the OLE object isn't linked, SourceDoc returns an empty string.

See Also

Linked (see page 6005)

OleClassName (see page 6007)

62.1.1.5.34 TOleContainer.State Property

Describes the state of the OLE object.

Pascal

```
property State: TObjectState;
```

C++

```
__property TObjectState State;
```

Description

Read State to determine the state of the OLE object and its server application. State has one of the following values:

Values	Meaning
osEmpty	There is no OLE object in the container.
osLoaded	There is an OLE object in the container, but its server application isn't currently running.
osRunning	The OLE object's server is running.
osOpen	The OLE object is open in a separate window.
osInPlaceActive	The OLE object is activated in place, but hasn't yet merged its menus or toolbars. This is an intermediate state; the State property will shift to osUIActive as soon as the menus and toolbars have been merged.
osUIActive	The OLE object is activated in place and menus and toolbars have been merged

62.1.1.5.35 TOleContainer.StorageInterface Property

Provides access to the IStorage interface for the OLE object.

Pascal

```
property StorageInterface: IStorage;
```

C++

```
__property IStorage StorageInterface;
```

Description

Use StorageInterface for low-level access to the OLE API. If there is no OLE object loaded into the container, StorageInterface returns nil (Delphi) or NULL (C++).

See Also

OleObjectInterface (see page 6008)

62.1.1.5.36 TOleContainer.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

62.1.1.5.37 TOleContainer.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

62.1.1.5.38 TOleContainer.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
```

```
      begin
        PageControl := PageControl1;
        Caption := 'TabSheet' + IntToStr(i);
        with TEdit.Create(Self) do
        begin
          Parent := PageControl1.Pages[i];
          Left := Random(PageControl1.ActivePage.ClientWidth - Width);
          Top := Random(PageControl1.ActivePage.ClientHeight - Height);
        end;
      end;
      PageControl1Change(Sender);
  end;
```

62.1.1.6 TOleContainer Events

The events of the TOleContainer class are listed here.

Published Events

	Name	Description
	OnActivate (see page 6021)	Occurs immediately after the OLE object is activated.
	OnDeactivate (see page 6022)	Occurs immediately after the OLE object is deactivated.
	OnDragDrop (see page 6022)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 6025)	Occurs when the user drags an object over a control.
	OnEndDrag (see page 6028)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6029)	Occurs when a control receives the input focus.
	OnExit (see page 6032)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 6035)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6038)	Occurs when a key is pressed.
	OnKeyUp (see page 6039)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 6041)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 6042)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseMove (see page 6044)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 6047)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnObjectMove (see page 6049)	Occurs when the OLE container is notified that the OLE object has moved or resized.
	OnResize (see page 6049)	Occurs immediately after the OLE container window is resized.
	OnStartDrag (see page 6049)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

62.1.1.6.1 TOleContainer.OnActivate Event

Occurs immediately after the OLE object is activated.

Pascal

```
property OnActivate: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnActivate;
```

Description

Write an OnActivate event handler to take specific action when the OLE object becomes active.

See Also

AutoActivate (see page 5996)

DoVerb (see page 5981)

OnDeactivate (see page 6022)

State (see page 6017)

62.1.1.6.2 TOleContainer.OnDeactivate Event

Occurs immediately after the OLE object is deactivated.

Pascal

```
property OnDeactivate: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDeactivate;
```

Description

Write an OnDeactivate event handler to respond when the OLE object is deactivated.

See Also

Close (see page 5976)

OnActivate (see page 6021)

State (see page 6017)

62.1.1.6.3 TOleContainer.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
```

```
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}

62.1.1.6.4 TOleContainer.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*

62.1.1.6.5 TOleContainer.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;

62.1.1.6.6 TOleContainer.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/

62.1.1.6.7 TOleContainer.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
```

```
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

procedure TForm1.MaskEdit2Exit(Sender: TObject);

    IntToStr(sub_host1) + '.' + IntToStr(sub_host2);
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
```

```
  Memo1.Color := clWindow;
end;
```

62.1.1.6.8 TOleContainer.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown;
```

C++

```
__property OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/

OnKeyPress

OnKeyUp

62.1.1.6.9 TOleContainer.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress;
```

C++

```
__property OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII

character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;

OnKeyDown

OnKeyPress

62.1.1.6.11 TOleContainer.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

OnMouseMove

OnMouseUp

MouseCapture

62.1.1.6.12 TOleContainer.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
```

```
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:

MouseCapture

62.1.1.6.13 TOleContainer.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{

MouseCapture

62.1.1.6.14 TOleContainer.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp;
```

C++

```
__property OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is

OnMouseDown

OnMouseMove

Responding to a Mouse-up Action

62.1.1.6.15 TOleContainer.OnObjectMove Event

Occurs when the OLE container is notified that the OLE object has moved or resized.

Pascal

```
property OnObjectMove: TObjectMoveEvent;
```

C++

```
__property TObjectMoveEvent OnObjectMove;
```

Description

Write an OnObjectMove event handler to respond when the OLE object changes size or position. The Bounds parameter specifies the boundaries of the in-place object in the client coordinates of OLE container. OnObjectMove occurs before the OLE object's image is updated to reflect the change.

See Also

OnResize (see page 6049)

62.1.1.6.16 TOleContainer.OnResize Event

Occurs immediately after the OLE container window is resized.

Pascal

```
property OnResize: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnResize;
```

Description

Write an OnResize event handler to respond to changes in the size of the OLE container window. If SizeMode (see page 6017) is smAutoSize, the container window changes size whenever the OLE object resizes.

See Also

OnObjectMove (see page 6049)

SizeMode (see page 6017)

62.1.1.6.17 TOleContainer.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse

button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

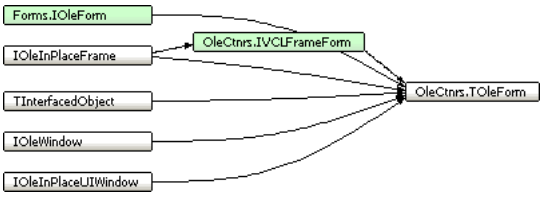
62.1.2 TOleForm Class

TOleForm is an object that provides OLE support for a TForm (see page 2241) object.

Class Hierarchy



Pascal

```
TOleForm = class(TInterfacedObject, IOleForm, IOleWindow, IOleInPlaceUIWindow,
IOleInPlaceFrame, IVCLFrameForm);
```

C++

```
class TOleForm : public TInterfacedObject, public IOleForm, public IOleWindow, public
IOleInPlaceUIWindow, public IOleInPlaceFrame, public IVCLFrameForm;
```

File

OleCtnrs

Description

TOleForm implements the IOleForm (see page 2572), IOleWindow, IOleInPlaceUIWindow, and IOleInPlaceFrame interfaces, as well as an interface for internal use. The implementation of the TOleForm object is used internally by the Visual Component Library.

62.1.2.1 TOleForm Members

The following tables list the members exposed by TOleForm.

Public Methods

	Name	Description
	AddContainer (see page 6054)	This is AddContainer, a member of class IVCLFrameForm.
	ClearBorderSpace (see page 6054)	This is ClearBorderSpace, a member of class IVCLFrameForm.
	Create (see page 6051)	Create creates a new instance of the TOleForm (see page 6050) object.
	Destroy (see page 6051)	Destroy frees the memory associated with this instance of the TOleForm (see page 6050) object.
	Form (see page 6054)	This is Form, a member of class IVCLFrameForm.
	OnDestroy (see page 2572)	This is OnDestroy, a member of class IOleForm.
	OnResize (see page 2573)	This is OnResize, a member of class IOleForm.
	RemoveContainer (see page 6054)	This is RemoveContainer, a member of class IVCLFrameForm.

62.1.2.2 TOleForm.Create Constructor

Create creates a new instance of the TOleForm (see page 6050) object.

Pascal

```
constructor Create(Form: TCustomForm);
```

C++

```
__fastcall TOleForm(TCustomForm Form);
```

Description

Create is used to create a new instance of the TOleForm (see page 6050) object. Form (see page 6054) is the form upon which to base the new TOleForm (see page 6050) object.

See Also

Destroy (see page 6051)

62.1.2.3 TOleForm.Destroy Destructor

Destroy frees the memory associated with this instance of the TOleForm (see page 6050) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TOleForm();
```

Description

Do not call Destroy directly. Instead, call Free, which calls Destroy if this instance of the TOleForm (see page 6050) object is not nil.

Destroy frees private objects allocated and used by this instance of the TOleForm (see page 6050) object.

See Also

Create (see page 6051)

62.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IVCLFrameForm (see page 6053)	This is class OleCtnrs.IVCLFrameForm.

62.2.1 IVCLFrameForm Interface

Class Hierarchy

Pascal

```
IVCLFrameForm = interface(IOleInPlaceFrame);
```

C++

```
__interface IVCLFrameForm : public IOleInPlaceFrame;
```

File

OleCtnrs

Description

This is class OleCtnrs.IVCLFrameForm.

62.2.1.1 IVCLFrameForm Members

The following tables list the members exposed by IVCLFrameForm.

Public Methods

	Name	Description
	AddContainer (see page 6054)	This is AddContainer, a member of class IVCLFrameForm.
	ClearBorderSpace (see page 6054)	This is ClearBorderSpace, a member of class IVCLFrameForm.
	Form (see page 6054)	This is Form, a member of class IVCLFrameForm.
	RemoveContainer (see page 6054)	This is RemoveContainer, a member of class IVCLFrameForm.

62.2.1.2 IVCLFrameForm Methods

The methods of the IVCLFrameForm class are listed here.

Public Methods

	Name	Description
	AddContainer (see page 6054)	This is AddContainer, a member of class IVCLFrameForm.
	ClearBorderSpace (see page 6054)	This is ClearBorderSpace, a member of class IVCLFrameForm.
	Form (see page 6054)	This is Form, a member of class IVCLFrameForm.

	RemoveContainer (see page 6054)	This is RemoveContainer, a member of class IVCLFrameForm.

62.2.1.2.1 IVCLFrameForm.AddContainer Method

Pascal

```
procedure AddContainer(Instance: TOleContainer);
```

C++

```
__fastcall AddContainer(TOleContainer Instance);
```

Description

This is AddContainer, a member of class IVCLFrameForm.

62.2.1.2.2 IVCLFrameForm.ClearBorderSpace Method

Pascal

```
procedure ClearBorderSpace;
```

C++

```
__fastcall ClearBorderSpace();
```

Description

This is ClearBorderSpace, a member of class IVCLFrameForm.

62.2.1.2.3 IVCLFrameForm.Form Method

Pascal

```
function Form: TCustomForm;
```

C++

```
__fastcall TCustomForm Form();
```

Description

This is Form, a member of class IVCLFrameForm.

62.2.1.2.4 IVCLFrameForm.RemoveContainer Method

Pascal

```
procedure RemoveContainer(Instance: TOleContainer);
```

C++

```
__fastcall RemoveContainer(TOleContainer Instance);
```

Description

This is RemoveContainer, a member of class IVCLFrameForm.

62.3 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	DestroyMetaPict (see page 6055)	Frees a metafile resource given its handle.

62.3.1 OleCtnrs.DestroyMetaPict Function

Frees a metafile resource given its handle.

Pascal

```
procedure DestroyMetaPict(MetaPict: HGlobal);
```

C++

```
DestroyMetaPict(HGlobal MetaPict);
```

File

OleCtnrs

Description

Call DestroyMetaPict to free a metafile obtained using the GetIconMetaPict method of TOleContainer (see page 5969).

You do not need to use DestroyMetaPict to free metafiles represented using TMetafile (see page 2780). These are freed automatically when the TMetafile (see page 2780) instance is destroyed. However, if you assign a new value to the Handle property of TMetafile (see page 2780), thereby replacing its old metafile, you must free the old metafile by calling DestroyMetaPict.

62.4 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TAutoActivate (see page 6056)	This is record OleCtnrs.TAutoActivate.
	TCreateType (see page 6057)	This is record OleCtnrs.TCreateType.
	TObjectState (see page 6057)	This is record OleCtnrs.TObjectState.
	TSizeMode (see page 6058)	This is record OleCtnrs.TSizeMode.

Records

	Name	Description
	TCreateInfo (see page 6056)	This is record OleCtnrs.TCreateInfo.
	TVerbInfo (see page 6058)	This is record OleCtnrs.TVerbInfo.

62.4.1 OleCtnrs.TAutoActivate Enumeration

Pascal

```
TAutoActivate = (
  aaManual,
  aaGetFocus,
  aaDoubleClick
);
```

C++

```
enum TAutoActivate {
  aaManual,
  aaGetFocus,
  aaDoubleClick
};
```

File

OleCtnrs

Description

This is record OleCtnrs.TAutoActivate.

62.4.2 OleCtnrs.TCreateInfo Record

Pascal

```
TCreateInfo = record
  CreateType: TCreateType;
  ShowAsIcon: Boolean;
  IconMetaPict: HGlobal;
  ClassID: TCLSID;
  FileName: WideString;
```

```
    DataObject: IDataObject;
  end;
```

C++

```
  struct TCreateInfo {
    TCreateType CreateType;
    Boolean ShowAsIcon;
    HGlobal IconMetaPict;
    TCLSID ClassID;
    BSTR FileName;
    IDataObject DataObject;
  };
```

File

OleCtnrs

Description

This is record OleCtnrs.TCreateInfo.

62.4.3 OleCtnrs.TCreateType Enumeration

Pascal

```
  TCreateType = (
    ctNewObject,
    ctFromFile,
    ctLinkToFile,
    ctFromData,
    ctLinkFromData
  );
```

C++

```
  enum TCreateType {
    ctNewObject,
    ctFromFile,
    ctLinkToFile,
    ctFromData,
    ctLinkFromData
  };
```

File

OleCtnrs

Description

This is record OleCtnrs.TCreateType.

62.4.4 OleCtnrs.TObjectState Enumeration

Pascal

```
  TObjectState = (
    osEmpty,
    osLoaded,
    osRunning,
    osOpen,
    osInPlaceActive,
```

```
    osUIActive
  );
```

C++

```
  enum TObjectState {
    osEmpty,
    osLoaded,
    osRunning,
    osOpen,
    osInPlaceActive,
    osUIActive
  };
```

File

OleCtnrs

Description

This is record OleCtnrs.TObjectState.

62.4.5 OleCtnrs.TSizeMode Enumeration

Pascal

```
  TSizeMode = (
    smClip,
    smCenter,
    smScale,
    smStretch,
    smAutoSize
  );
```

C++

```
  enum TSizeMode {
    smClip,
    smCenter,
    smScale,
    smStretch,
    smAutoSize
  };
```

File

OleCtnrs

Description

This is record OleCtnrs.TSizeMode.

62.4.6 OleCtnrs.TVerbInfo Record

Pascal

```
  TVerbInfo = packed record
    Verb: Smallint;
    Flags: Word;
  end;
```

C++

```
struct TVerbInfo {
  Smallint Verb;
  Word Flags;
};
```

File

OleCtnrs

Description

This is record OleCtnrs.TVerbInfo.

62.5 Types

The following table lists types in this documentation.

Types

Name	Description
TObjectMoveEvent (see page 6060)	This is type OleCtnrs.TObjectMoveEvent.

62.5.1 OleCtnrs.TObjectMoveEvent Type

Pascal

```
TObjectMoveEvent = procedure (OleContainer: TOleContainer; const Bounds: TRect) of object;
```

C++

```
(OleContainer: TOleContainer; const Bounds: TRect) ( TObjectMoveEvent)();
```

File

OleCtnrs

Description

This is type OleCtnrs.TObjectMoveEvent.

62.6 Constants

The following table lists constants in this documentation.

Constants

Name	Description
ovDiscardUndoState (see page 6061)	This is constant OleCtnrs.ovDiscardUndoState.
ovHide (see page 6061)	This is constant OleCtnrs.ovHide.
ovInPlaceActivate (see page 6062)	This is constant OleCtnrs.ovInPlaceActivate.
ovOpen (see page 6062)	This is constant OleCtnrs.ovOpen.
ovPrimary (see page 6062)	This is constant OleCtnrs.ovPrimary.
ovShow (see page 6063)	This is constant OleCtnrs.ovShow.
ovUIActivate (see page 6063)	This is constant OleCtnrs.ovUIActivate.

62.6.1 OleCtnrs.ovDiscardUndoState Constant

Pascal

```
ovDiscardUndoState = -6;
```

C++

```
ovDiscardUndoState = -6;
```

File

OleCtnrs

Description

This is constant OleCtnrs.ovDiscardUndoState.

62.6.2 OleCtnrs.ovHide Constant

Pascal

```
ovHide = -3;
```

C++

```
ovHide = -3;
```

File

OleCtnrs

Description

This is constant OleCtnrs.ovHide.

62.6.3 OleCtnrs.ovInPlaceActivate Constant

Pascal

```
ovInPlaceActivate = -5;
```

C++

```
ovInPlaceActivate = -5;
```

File

OleCtnrs

Description

This is constant OleCtnrs.ovInPlaceActivate.

62.6.4 OleCtnrs.ovOpen Constant

Pascal

```
ovOpen = -2;
```

C++

```
ovOpen = -2;
```

File

OleCtnrs

Description

This is constant OleCtnrs.ovOpen.

62.6.5 OleCtnrs.ovPrimary Constant

Pascal

```
ovPrimary = -65536;
```

C++

```
ovPrimary = -65536;
```

File

OleCtnrs

Description

This is constant OleCtnrs.ovPrimary.

62.6.6 OleCtnrs.ovShow Constant

Pascal

```
ovShow = -1;
```

C++

```
ovShow = -1;
```

File

OleCtnrs

Description

This is constant OleCtnrs.ovShow.

62.6.7 OleCtnrs.ovUIActivate Constant

Pascal

```
ovUIActivate = -4;
```

C++

```
ovUIActivate = -4;
```

File

OleCtnrs

Description

This is constant OleCtnrs.ovUIActivate.

63 OleCtrls Namespace

This is namespace OleCtrls.

Topics

Name	Description
Classes (see page 6067)	The following table lists classes in this documentation.
Functions (see page 6122)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 6124)	The following table lists structs, records, enums in this documentation.
Types (see page 6127)	The following table lists types in this documentation.

Classes

	Name	Description
	EOleCtrlError (see page 6067)	EOleCtrlError is the exception class for ActiveX controls.
	TEnumPropDesc (see page 6067)	TEnumPropDesc provides the mapping between strings used to name the values of a property in an OLE control object and the values themselves.
	TEventDispatch (see page 6070)	This is class OleCtrls.TEventDispatch.
	TOleControl (see page 6074)	TOleControl is the base class from which ActiveX controls are derived.

Functions

	Name	Description
	EmptyParam (see page 6122)	This is function OleCtrls.EmptyParam.
	FontToOleFont (see page 6122)	Returns a Variant containing an IFontDispatch interface that represents a TFont (see page 2730) object.
	OleFontToFont (see page 6123)	Fills in a TFont (see page 2730) structure to represent an IFontDispatch.

Structs, Records, Enums

	Name	Description
	TControlData (see page 6124)	This is record OleCtrls.TControlData.
	TControlData2 (see page 6125)	This is record OleCtrls.TControlData2.
	TEnumValue (see page 6125)	This is record OleCtrls.TEnumValue.

Types

Name	Description
PControlData (see page 6127)	This is type OleCtrls.PControlData.
PControlData2 (see page 6127)	This is type OleCtrls.PControlData2.
PEnumValueList (see page 6128)	This is type OleCtrls.PEnumValueList.
TEnumValueList (see page 6128)	This is type OleCtrls.TEnumValueList.

TOleEnum (see page 6128)	This is type OleCtrls.TOleEnum.
TServiceQuery (see page 6129)	This is type OleCtrls.TServiceQuery.

63.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EOleCtrlError (see page 6067)	EOleCtrlError is the exception class for ActiveX controls.
	TEnumPropDesc (see page 6067)	TEnumPropDesc provides the mapping between strings used to name the values of a property in an OLE control object and the values themselves.
	TEventDispatch (see page 6070)	This is class OleCtrls.TEventDispatch.
	TOleControl (see page 6074)	TOleControl is the base class from which ActiveX controls are derived.

63.1.1 EOleCtrlError Class

EOleCtrlError is the exception class for ActiveX controls.

Class Hierarchy

Pascal

```
EOleCtrlError = class(Exception);
```

C++

```
class EOleCtrlError : public Exception;
```

File

OleCtrls

Description

EOleCtrlError is raised when an application cannot link to an ActiveX control.

See Also

EOleError

63.1.2 TEnumPropDesc Class

TEnumPropDesc provides the mapping between strings used to name the values of a property in an OLE control object and the values themselves.

Class Hierarchy

Pascal

```
TEnumPropDesc = class;
```

C++

```
class TEnumPropDesc;
```

File

OleCtrls

Description

Use TEnumPropDesc to interpret the strings used by an OLE control object to represent the values of one of its properties. TEnumPropDesc can provide a list of possible value strings to a callback function, or map between the string names of property values and the values themselves. TEnumPropDesc objects are made available through the GetEnumPropDesc method of an OLE control object.

See Also

TOleControl (see page 6074)

63.1.2.1 TEnumPropDesc Members

The following tables list the members exposed by TEnumPropDesc.

Public Methods

	Name	Description
	Create (see page 6068)	Creates an instance of TEnumPropDesc (see page 6067).
	Destroy (see page 6069)	Destroys an instance of TEnumPropDesc (see page 6067).
	GetStrings (see page 6069)	Calls the callback Proc for each property value string.
	StringToValue (see page 6070)	Maps a string representation of the property value to the integer value.
	ValueToString (see page 6070)	Maps an integer that indicates the value of the property to the string representation of that value used by the OLE control object.

63.1.2.2 TEnumPropDesc.Create Constructor

Creates an instance of TEnumPropDesc (see page 6067).

Pascal

```
constructor Create(DispID: Integer; ValueCount: Integer; const TypeInfo: ITypeInfo);
```

C++

```
__fastcall TEnumPropDesc(int DispID, int ValueCount, const ITypeInfo TypeInfo);
```

Description

Create is called by an OLE control object to create an instance of TEnumPropDesc (see page 6067) to represent the values of one of its properties. Applications should not need to create instances of TEnumPropDesc (see page 6067). When working with OLE properties, get the TEnumPropDesc (see page 6067) objects from the OLE control object.

DispID identifies the property of the OLE object, ValueCount is the number of distinct values the property can take TypeInfo is an ITypeInfo object that the constructor can use to capture the values and their strings.

See Also

GetEnumPropDesc (see page 6088)

63.1.2.3 TEnumPropDesc.Destroy Destructor

Destroys an instance of TEnumPropDesc (see page 6067).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TEnumPropDesc();
```

Description

Do not call Destroy directly in an application. The TOleControl (see page 6074) object that owns the TEnumPropDesc (see page 6067) object will destroy it automatically.

Destroy frees the internal list used to map value strings to property values.

See Also

TOleControl (see page 6074)

System::TObject::Free

63.1.2.4 TEnumPropDesc Methods

The methods of the TEnumPropDesc class are listed here.

Public Methods

	Name	Description
	GetStrings (see page 6069)	Calls the callback Proc for each property value string.
	StringToValue (see page 6070)	Maps a string representation of the property value to the integer value.
	ValueToString (see page 6070)	Maps an integer that indicates the value of the property to the string representation of that value used by the OLE control object.

63.1.2.4.1 TEnumPropDesc.GetStrings Method

Calls the callback Proc for each property value string.

Pascal

```
procedure GetStrings(Proc: TGetStrProc);
```

C++

```
__fastcall GetStrings(TGetStrProc Proc);
```

Description

Use GetStrings to execute code for every property value string represented in the TEnumPropDesc (see page 6067) object. The callback Proc is called for every value, with the S parameter set to a string that gives the integer value followed by the string representation of that value.

For example, consider a TEnumPropDesc (see page 6067) object that represents a color property, with values equal to TColor (see page 2878) values. The callback Proc would be called for every built-in color name with strings of the form '255 - clRed (see page 2916)'.

See Also

StringToValue (see page 6070)

ValueToString (see page 6070)

63.1.2.4.2 TEnumPropDesc.StringToValue Method

Maps a string representation of the property value to the integer value.

Pascal

```
function StringToValue(const S: string): Integer;
```

C++

```
__fastcall int StringToValue(const UnicodeString S);
```

Description

Use StringToValue to map the string representation of a property value used by an OLE control object to an integer value that is a more accurate representation of the property value. If the property value is not an integer, the integer associated with the string can be a pointer to the value.

See Also

ValueToString (see page 6070)

63.1.2.4.3 TEnumPropDesc.ValueToString Method

Maps an integer that indicates the value of the property to the string representation of that value used by the OLE control object.

Pascal

```
function ValueToString(V: Integer): string;
```

C++

```
__fastcall UnicodeString ValueToString(int V);
```

Description

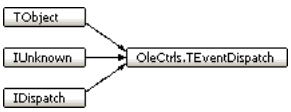
Use ValueToString to map the integer value of a property value to the string representation used by an OLE control object. If the property value is not an integer, the integer associated with the string can be a pointer to the value.

See Also

StringToValue (see page 6070)

63.1.3 TEventDispatch Class

Class Hierarchy



Pascal

```
TEventDispatch = class(TObject, IUnknown, IDispatch);
```

C++

```
class TEventDispatch : public TObject, public IUnknown, public IDispatch;
```

File

OleCtrls

Description

This is class OleCtrls.TEventDispatch.

63.1.3.1 TEventDispatch Members

The following tables list the members exposed by TEventDispatch.

Protected Methods

	Name	Description
	_AddRef (see page 6072)	This is _AddRef, a member of class TEventDispatch.
	_Release (see page 6072)	This is _Release, a member of class TEventDispatch.
	GetIDsOfNames (see page 6072)	This is GetIDsOfNames, a member of class TEventDispatch.
	GetTypeInfo (see page 6072)	This is GetTypeInfo, a member of class TEventDispatch.
	GetTypeInfoCount (see page 6073)	This is GetTypeInfoCount, a member of class TEventDispatch.
V	Invoke (see page 6073)	This is Invoke, a member of class TEventDispatch.
	QueryInterface (see page 6073)	This is QueryInterface, a member of class TEventDispatch.

Protected Properties

	Name	Description
R	Control (see page 6073)	This is Control, a member of class TEventDispatch.

Public Methods

	Name	Description
	Create (see page 6071)	This is Create, a member of class TEventDispatch.

63.1.3.2 TEventDispatch.Create Constructor

Pascal

```
constructor Create(Control: TOleControl);
```

C++

```
__fastcall TEventDispatch(TOleControl Control);
```

Description

This is Create, a member of class TEventDispatch.

63.1.3.3 TEventDispatch Methods

The methods of the TEventDispatch class are listed here.

Protected Methods

	Name	Description
	_AddRef (see page 6072)	This is _AddRef, a member of class TEventDispatch.
	_Release (see page 6072)	This is _Release, a member of class TEventDispatch.
	GetIDsOfNames (see page 6072)	This is GetIDsOfNames, a member of class TEventDispatch.
	GetTypeInfo (see page 6072)	This is GetTypeInfo, a member of class TEventDispatch.
	GetTypeInfoCount (see page 6073)	This is GetTypeInfoCount, a member of class TEventDispatch.

	Invoke (see page 6073)	This is Invoke, a member of class TEventDispatch.
	QueryInterface (see page 6073)	This is QueryInterface, a member of class TEventDispatch.

63.1.3.3.1 TEventDispatch._AddRef Method

Pascal

```
function _AddRef: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _AddRef();
```

Description

This is _AddRef, a member of class TEventDispatch.

63.1.3.3.2 TEventDispatch._Release Method

Pascal

```
function _Release: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _Release();
```

Description

This is _Release, a member of class TEventDispatch.

63.1.3.3.3 TEventDispatch.GetIDsOfNames Method

Pascal

```
function GetIDsOfNames(const IID: TGUID; Names: Pointer; NameCount: Integer; LocaleID:
Integer; DispIDs: Pointer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetIDsOfNames(const TGUID IID, void * Names, int NameCount, int
LocaleID, void * DispIDs);
```

Description

This is GetIDsOfNames, a member of class TEventDispatch.

63.1.3.3.4 TEventDispatch.GetTypeInfo Method

Pascal

```
function GetTypeInfo(Index: Integer; LocaleID: Integer; out TypeInfo): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetTypeInfo(int Index, int LocaleID,  TypeInfo);
```

Description

This is GetTypeInfo, a member of class TEventDispatch.

63.1.3.3.5 TEventDispatch.GetTypeInfoCount Method

Pascal

```
function GetTypeInfoCount(out Count: Integer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetTypeInfoCount(int Count);
```

Description

This is GetTypeInfoCount, a member of class TEventDispatch.

63.1.3.3.6 TEventDispatch.Invoke Method

Pascal

```
function Invoke(DispID: Integer; const IID: TGUID; LocaleID: Integer; Flags: Word; var Params;
VarResult: Pointer; ExcepInfo: Pointer; ArgErr: Pointer): HResult; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT Invoke(int DispID, const TGUID IID, int LocaleID, Word
Flags,  Params, void * VarResult, void * ExcepInfo, void * ArgErr);
```

Description

This is Invoke, a member of class TEventDispatch.

63.1.3.3.7 TEventDispatch.QueryInterface Method

Pascal

```
function QueryInterface(const IID: TGUID; out Obj): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT QueryInterface(const TGUID IID,  Obj);
```

Description

This is QueryInterface, a member of class TEventDispatch.

63.1.3.4 TEventDispatch Properties

The properties of the TEventDispatch class are listed here.

Protected Properties

	Name	Description
	Control (see page 6073)	This is Control, a member of class TEventDispatch.

63.1.3.4.1 TEventDispatch.Control Property

Pascal

```
property Control: TOleControl;
```

C++

```
__property TOleControl Control;
```

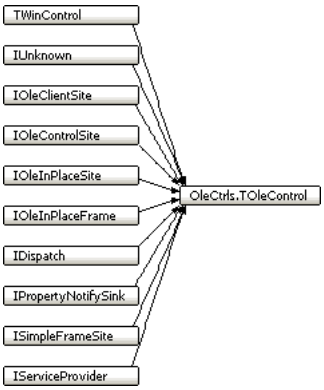
Description

This is Control, a member of class TEventDispatch.

63.1.4 TOleControl Class

TOleControl is the base class from which ActiveX controls are derived.

Class Hierarchy



Pascal

```
TOleControl = class(TWinControl, IUnknown, IOleClientSite, IOleControlSite, IOleInPlaceSite,
IOleInPlaceFrame, IDispatch, IPropertyNotifySink, ISimpleFrameSite, IServiceProvider);
```

C++

```
class TOleControl : public TWinControl, public IUnknown, public IOleClientSite, public
IOleControlSite, public IOleInPlaceSite, public IOleInPlaceFrame, public IDispatch, public
IPropertyNotifySink, public ISimpleFrameSite, public IServiceProvider;
```

File

OleCtrls

Description

TOleControl is derived from TWinControl and handles the interactions with COM necessary for using ActiveX controls. Most application do not need to explicitly derive a component from this class.

See Also

TOleContainer (see page 5969)

Code Generated When You Import Type Library Information

Using Component Wrappers

63.1.4.1 TOleControl Members

The following tables list the members exposed by TOleControl.

Protected Methods

	Name	Description
	_AddRef (see page 6081)	Called when an application uses a component interface.
	_Release (see page 6081)	Called when an application releases a component interface.
	_SetColorProp (see page 6082)	This is _SetColorProp, a member of class TOleControl.
	_SetTColorProp (see page 6082)	This is _SetTColorProp, a member of class TOleControl.
	_SetTFontProp (see page 6082)	This is _SetTFontProp, a member of class TOleControl.
	_SetTOleEnumProp (see page 6083)	This is _SetTOleEnumProp, a member of class TOleControl.
	_SetTPictureProp (see page 6083)	This is _SetTPictureProp, a member of class TOleControl.
	CanInPlaceActivate (see page 6083)	This is CanInPlaceActivate, a member of class TOleControl.
	ContextSensitiveHelp (see page 6083)	This is ContextSensitiveHelp, a member of class TOleControl.
V	CreateWnd (see page 6084)	Creates the underlying window.
	DeactivateAndUndo (see page 6084)	This is DeactivateAndUndo, a member of class TOleControl.
V	DefineProperties (see page 6085)	Provides methods to read and write the IsControl property to a stream such as a form file.
V	DestroyWindowHandle (see page 6085)	Destroys the window created in the CreateWindowHandle method.
	DiscardUndoState (see page 6086)	This is DiscardUndoState, a member of class TOleControl.
	EnableModeless (see page 6086)	This is EnableModeless, a member of class TOleControl.
	GetBorder (see page 6087)	This is GetBorder, a member of class TOleControl.
	GetByteProp (see page 6087)	This is GetByteProp, a member of class TOleControl.
	GetColorProp (see page 6087)	This is GetColorProp, a member of class TOleControl.
	GetCompProp (see page 6087)	This is GetCompProp, a member of class TOleControl.
	GetContainer (see page 6087)	This is GetContainer, a member of class TOleControl.
	GetCurrencyProp (see page 6088)	This is GetCurrencyProp, a member of class TOleControl.
	GetDoubleProp (see page 6088)	This is GetDoubleProp, a member of class TOleControl.
	GetExtendedControl (see page 6088)	This is GetExtendedControl, a member of class TOleControl.
	GetIDispatchProp (see page 6089)	This is GetIDispatchProp, a member of class TOleControl.
	GetIDsOfNames (see page 6089)	This is GetIDsOfNames, a member of class TOleControl.
	GetIntegerProp (see page 6089)	This is GetIntegerProp, a member of class TOleControl.
	GetIUnknownProp (see page 6090)	This is GetIUnknownProp, a member of class TOleControl.
	GetMoniker (see page 6090)	This is GetMoniker, a member of class TOleControl.
	GetOleBoolProp (see page 6090)	This is GetOleBoolProp, a member of class TOleControl.
	GetOleDateProp (see page 6091)	This is GetOleDateProp, a member of class TOleControl.
	GetOleEnumProp (see page 6091)	This is GetOleEnumProp, a member of class TOleControl.
	GetOleVariantProp (see page 6091)	This is GetOleVariantProp, a member of class TOleControl.
	GetProperty (see page 6092)	This is GetProperty, a member of class TOleControl.
	GetShortIntProp (see page 6092)	This is GetShortIntProp, a member of class TOleControl.
	GetSingleProp (see page 6092)	This is GetSingleProp, a member of class TOleControl.
	GetSmallintProp (see page 6093)	This is GetSmallintProp, a member of class TOleControl.
	GetStringProp (see page 6093)	This is GetStringProp, a member of class TOleControl.
	GetTColorProp (see page 6093)	This is GetTColorProp, a member of class TOleControl.
	GetTDateTimeProp (see page 6093)	This is GetTDateTimeProp, a member of class TOleControl.
	GetTFontProp (see page 6094)	This is GetTFontProp, a member of class TOleControl.
	GetTOleEnumProp (see page 6094)	This is GetTOleEnumProp, a member of class TOleControl.
	GetTPictureProp (see page 6094)	This is GetTPictureProp, a member of class TOleControl.
	GetTypeInfo (see page 6094)	This is GetTypeInfo, a member of class TOleControl.
	GetTypeInfoCount (see page 6094)	This is GetTypeInfoCount, a member of class TOleControl.
	GetVariantProp (see page 6095)	This is GetVariantProp, a member of class TOleControl.
	GetWideStringProp (see page 6095)	This is GetWideStringProp, a member of class TOleControl.
	GetWindowContext (see page 6095)	This is GetWindowContext, a member of class TOleControl.
	GetWordBoolProp (see page 6095)	This is GetWordBoolProp, a member of class TOleControl.
	GetWordProp (see page 6096)	This is GetWordProp, a member of class TOleControl.
A	InitControlData (see page 6096)	This is InitControlData, a member of class TOleControl.
V	InitControlInterface (see page 6096)	This is InitControlInterface, a member of class TOleControl.

	InsertMenus (see page 6096)	This is InsertMenus, a member of class TOleControl.
	Invoke (see page 6096)	This is Invoke, a member of class TOleControl.
V	InvokeEvent (see page 6097)	This is InvokeEvent, a member of class TOleControl.
	InvokeMethod (see page 6097)	This is InvokeMethod, a member of class TOleControl.
	LockInPlaceActive (see page 6098)	This is LockInPlaceActive, a member of class TOleControl.
	OleControlSite_TranslateAccelerator (see page 6098)	This is OleControlSite_TranslateAccelerator, a member of class TOleControl.
	OleInPlaceFrame_GetWindow (see page 6098)	This is OleInPlaceFrame_GetWindow, a member of class TOleControl.
	OleInPlaceFrame_TranslateAccelerator (see page 6098)	This is OleInPlaceFrame_TranslateAccelerator, a member of class TOleControl.
	OleInPlaceSite_GetWindow (see page 6099)	This is OleInPlaceSite_GetWindow, a member of class TOleControl.
V	OnChanged (see page 6099)	This is OnChanged, a member of class TOleControl.
	OnControlInfoChanged (see page 6099)	This is OnControlInfoChanged, a member of class TOleControl.
	OnFocus (see page 6099)	This is OnFocus, a member of class TOleControl.
	OnInPlaceActivate (see page 6100)	This is OnInPlaceActivate, a member of class TOleControl.
	OnInPlaceDeactivate (see page 6100)	This is OnInPlaceDeactivate, a member of class TOleControl.
	OnPosRectChange (see page 6100)	This is OnPosRectChange, a member of class TOleControl.
V	OnRequestEdit (see page 6100)	This is OnRequestEdit, a member of class TOleControl.
	OnShowWindow (see page 6100)	This is OnShowWindow, a member of class TOleControl.
	OnUIActivate (see page 6101)	This is OnUIActivate, a member of class TOleControl.
	OnUIDeactivate (see page 6101)	This is OnUIDeactivate, a member of class TOleControl.
V	PaletteChanged (see page 6101)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PictureChanged (see page 6102)	This is PictureChanged, a member of class TOleControl.
	PostMessageFilter (see page 6102)	This is PostMessageFilter, a member of class TOleControl.
	PreMessageFilter (see page 6102)	This is PreMessageFilter, a member of class TOleControl.
V	QueryInterface (see page 6103)	Returns a reference to a specified interface if the object supports that interface.
	QueryService (see page 6103)	This is QueryService, a member of class TOleControl.
	RemoveMenus (see page 6103)	This is RemoveMenus, a member of class TOleControl.
	RequestBorderSpace (see page 6104)	This is RequestBorderSpace, a member of class TOleControl.
	RequestNewObjectLayout (see page 6104)	This is RequestNewObjectLayout, a member of class TOleControl.
	SaveObject (see page 6104)	This is SaveObject, a member of class TOleControl.
	Scroll (see page 6104)	This is Scroll, a member of class TOleControl.
	SetActiveObject (see page 6104)	This is SetActiveObject, a member of class TOleControl.
	SetBorderSpace (see page 6105)	This is SetBorderSpace, a member of class TOleControl.
	SetByteProp (see page 6105)	This is SetByteProp, a member of class TOleControl.
	SetColorProp (see page 6105)	This is SetColorProp, a member of class TOleControl.
	SetCompProp (see page 6106)	This is SetCompProp, a member of class TOleControl.
	SetCurrencyProp (see page 6106)	This is SetCurrencyProp, a member of class TOleControl.
	SetDoubleProp (see page 6106)	This is SetDoubleProp, a member of class TOleControl.
	SetIDispatchProp (see page 6106)	This is SetIDispatchProp, a member of class TOleControl.
	SetIntegerProp (see page 6107)	This is SetIntegerProp, a member of class TOleControl.
	SetIUnknownProp (see page 6107)	This is SetIUnknownProp, a member of class TOleControl.
	SetMenu (see page 6107)	This is SetMenu, a member of class TOleControl.
V	SetName (see page 6107)	Sets the name of the control.
	SetOleBoolProp (see page 6108)	This is SetOleBoolProp, a member of class TOleControl.
	SetOleDateProp (see page 6108)	This is SetOleDateProp, a member of class TOleControl.
	SetOleEnumProp (see page 6108)	This is SetOleEnumProp, a member of class TOleControl.
	SetOleVariantProp (see page 6108)	This is SetOleVariantProp, a member of class TOleControl.
V	SetParent (see page 6108)	Sets the parent of the control.
	SetProperty (see page 6109)	This is SetProperty, a member of class TOleControl.
	SetShortIntProp (see page 6110)	This is SetShortIntProp, a member of class TOleControl.
	SetSingleProp (see page 6110)	This is SetSingleProp, a member of class TOleControl.
	SetSmallintProp (see page 6110)	This is SetSmallintProp, a member of class TOleControl.
	SetStatusText (see page 6110)	This is SetStatusText, a member of class TOleControl.
	SetStringProp (see page 6111)	This is SetStringProp, a member of class TOleControl.
	SetTColorProp (see page 6111)	This is SetTColorProp, a member of class TOleControl.

	SetTDateTimeProp (see page 6111)	This is SetTDateTimeProp, a member of class TOleControl.
	SetTFontProp (see page 6111)	This is SetTFontProp, a member of class TOleControl.
	SetTOleEnumProp (see page 6111)	This is SetTOleEnumProp, a member of class TOleControl.
	SetTPictureProp (see page 6112)	This is SetTPictureProp, a member of class TOleControl.
	SetVariantProp (see page 6112)	This is SetVariantProp, a member of class TOleControl.
	SetWideStringProp (see page 6112)	This is SetWideStringProp, a member of class TOleControl.
	SetWordBoolProp (see page 6112)	This is SetWordBoolProp, a member of class TOleControl.
	SetWordProp (see page 6113)	This is SetWordProp, a member of class TOleControl.
	ShowObject (see page 6113)	This is ShowObject, a member of class TOleControl.
	ShowPropertyFrame (see page 6113)	This is ShowPropertyFrame, a member of class TOleControl.
V	StandardEvent (see page 6113)	This is StandardEvent, a member of class TOleControl.
V	SuppressException (see page 6114)	This is SuppressException, a member of class TOleControl.
	TransformCoords (see page 6114)	This is TransformCoords, a member of class TOleControl.
V	WndProc (see page 6114)	Provides specific message responses for the control.

Protected Properties

	Name	Description
	ControlData (see page 6119)	This is ControlData, a member of class TOleControl.

Public Events

	Name	Description
	ServiceQuery (see page 6121)	This is ServiceQuery, a member of class TOleControl.

Public Methods

	Name	Description
	BrowseProperties (see page 6083)	Notifies the ActiveX control to display its Properties dialog box.
V	Create (see page 6077)	Creates a new instance of TOleControl (see page 6074).
V	DefaultHandler (see page 6084)	Handles all otherwise-unhandled messages.
V	Destroy (see page 6078)	Frees the memory associated with this instance of TOleControl (see page 6074).
	DoObjectVerb (see page 6086)	Notifies the ActiveX control to perform one of its actions.
	GetEnumPropDesc (see page 6088)	Returns descriptions of the ActiveX control's properties.
	GetHelpContext (see page 6089)	Retrieves the Help context of a member of the ActiveX control.
	GetObjectVerbs (see page 6090)	Retrieves the names of the verbs implemented by the ActiveX control.
	GetPropDisplayString (see page 6091)	Returns the display string for an interface for the ActiveX control.
	GetPropDisplayStrings (see page 6092)	Returns the display strings for an interface for the ActiveX control.
	IsCustomProperty (see page 6097)	Indicates whether an interface for the ActiveX control is a custom property.
	IsPropPageProperty (see page 6097)	Indicates whether an interface for the OCX control is a property page property.
V	SetBounds (see page 6105)	Sets the boundaries of the ActiveX control.
	SetPropDisplayString (see page 6109)	Sets the display string for an interface for the ActiveX control.
	ShowAboutBox (see page 6113)	Notifies the ActiveX control to display its About box.

Public Properties

	Name	Description
	Anchors (see page 6119)	Specifies how the control is anchored to its parent.
R	DefaultDispatch (see page 6120)	The default dispatch interface.
R	OleObject (see page 6120)	The ActiveX control associated with the TOleControl (see page 6074) object.
R	PerPropBrowsing (see page 6120)	Provides access to information about the property page properties of the OleControl.
	TabStop (see page 6121)	Determines if the user can tab to a control.

63.1.4.2 TOleControl.Create Constructor

Creates a new instance of TOleControl (see page 6074).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TOleControl(TComponent * AOwner);
```

Description

Use Create to create a new instance of the TOleControl (see page 6074) object. Create calls the inherited Create method and creates and initializes internal objects.

See Also

Destroy (see page 6078)

Create

63.1.4.3 TOleControl.Destroy Destructor

Frees the memory associated with this instance of TOleControl (see page 6074).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TOleControl();
```

Description

Do not call Destroy. Instead, call Free, which calls Destroy if this instance of TOleControl (see page 6074) is not nil.

See Also

Create (see page 6077)

System::TObject::Free

63.1.4.4 TOleControl Methods

The methods of the TOleControl class are listed here.

Protected Methods

	Name	Description
	_AddRef (see page 6081)	Called when an application uses a component interface.
	_Release (see page 6081)	Called when an application releases a component interface.
	_SetColorProp (see page 6082)	This is _SetColorProp, a member of class TOleControl.
	_SetTColorProp (see page 6082)	This is _SetTColorProp, a member of class TOleControl.
	_SetTFontProp (see page 6082)	This is _SetTFontProp, a member of class TOleControl.
	_SetTOleEnumProp (see page 6083)	This is _SetTOleEnumProp, a member of class TOleControl.
	_SetTPictureProp (see page 6083)	This is _SetTPictureProp, a member of class TOleControl.
	CanInPlaceActivate (see page 6083)	This is CanInPlaceActivate, a member of class TOleControl.
	ContextSensitiveHelp (see page 6083)	This is ContextSensitiveHelp, a member of class TOleControl.
V	CreateWnd (see page 6084)	Creates the underlying window.
	DeactivateAndUndo (see page 6084)	This is DeactivateAndUndo, a member of class TOleControl.
V	DefineProperties (see page 6085)	Provides methods to read and write the IsControl property to a stream such as a form file.
V	DestroyWindowHandle (see page 6085)	Destroys the window created in the CreateWindowHandle method.

	DiscardUndoState (see page 6086)	This is DiscardUndoState, a member of class TOleControl.
	EnableModeless (see page 6086)	This is EnableModeless, a member of class TOleControl.
	GetBorder (see page 6087)	This is GetBorder, a member of class TOleControl.
	GetByteProp (see page 6087)	This is GetByteProp, a member of class TOleControl.
	GetColorProp (see page 6087)	This is GetColorProp, a member of class TOleControl.
	GetCompProp (see page 6087)	This is GetCompProp, a member of class TOleControl.
	GetContainer (see page 6087)	This is GetContainer, a member of class TOleControl.
	GetCurrencyProp (see page 6088)	This is GetCurrencyProp, a member of class TOleControl.
	GetDoubleProp (see page 6088)	This is GetDoubleProp, a member of class TOleControl.
	GetExtendedControl (see page 6088)	This is GetExtendedControl, a member of class TOleControl.
	GetIDispatchProp (see page 6089)	This is GetIDispatchProp, a member of class TOleControl.
	GetIDsOfNames (see page 6089)	This is GetIDsOfNames, a member of class TOleControl.
	GetIntegerProp (see page 6089)	This is GetIntegerProp, a member of class TOleControl.
	GetIUnknownProp (see page 6090)	This is GetIUnknownProp, a member of class TOleControl.
	GetMoniker (see page 6090)	This is GetMoniker, a member of class TOleControl.
	GetOleBoolProp (see page 6090)	This is GetOleBoolProp, a member of class TOleControl.
	GetOleDateProp (see page 6091)	This is GetOleDateProp, a member of class TOleControl.
	GetOleEnumProp (see page 6091)	This is GetOleEnumProp, a member of class TOleControl.
	GetOleVariantProp (see page 6091)	This is GetOleVariantProp, a member of class TOleControl.
	GetProperty (see page 6092)	This is GetProperty, a member of class TOleControl.
	GetShortIntProp (see page 6092)	This is GetShortIntProp, a member of class TOleControl.
	GetSingleProp (see page 6092)	This is GetSingleProp, a member of class TOleControl.
	GetSmallintProp (see page 6093)	This is GetSmallintProp, a member of class TOleControl.
	GetStringProp (see page 6093)	This is GetStringProp, a member of class TOleControl.
	GetTColorProp (see page 6093)	This is GetTColorProp, a member of class TOleControl.
	GetTDateTimeProp (see page 6093)	This is GetTDateTimeProp, a member of class TOleControl.
	GetTFontProp (see page 6094)	This is GetTFontProp, a member of class TOleControl.
	GetTOleEnumProp (see page 6094)	This is GetTOleEnumProp, a member of class TOleControl.
	GetTPictureProp (see page 6094)	This is GetTPictureProp, a member of class TOleControl.
	GetTypeInfo (see page 6094)	This is GetTypeInfo, a member of class TOleControl.
	GetTypeInfoCount (see page 6094)	This is GetTypeInfoCount, a member of class TOleControl.
	GetVariantProp (see page 6095)	This is GetVariantProp, a member of class TOleControl.
	GetWideStringProp (see page 6095)	This is GetWideStringProp, a member of class TOleControl.
	GetWindowContext (see page 6095)	This is GetWindowContext, a member of class TOleControl.
	GetWordBoolProp (see page 6095)	This is GetWordBoolProp, a member of class TOleControl.
	GetWordProp (see page 6096)	This is GetWordProp, a member of class TOleControl.
	InitControlData (see page 6096)	This is InitControlData, a member of class TOleControl.
	InitControlInterface (see page 6096)	This is InitControlInterface, a member of class TOleControl.
	InsertMenus (see page 6096)	This is InsertMenus, a member of class TOleControl.
	Invoke (see page 6096)	This is Invoke, a member of class TOleControl.
	InvokeEvent (see page 6097)	This is InvokeEvent, a member of class TOleControl.
	InvokeMethod (see page 6097)	This is InvokeMethod, a member of class TOleControl.
	LockInPlaceActive (see page 6098)	This is LockInPlaceActive, a member of class TOleControl.
	OleControlSite_TranslateAccelerator (see page 6098)	This is OleControlSite_TranslateAccelerator, a member of class TOleControl.
	OleInPlaceFrame_GetWindow (see page 6098)	This is OleInPlaceFrame_GetWindow, a member of class TOleControl.
	OleInPlaceFrame_TranslateAccelerator (see page 6098)	This is OleInPlaceFrame_TranslateAccelerator, a member of class TOleControl.
	OleInPlaceSite_GetWindow (see page 6099)	This is OleInPlaceSite_GetWindow, a member of class TOleControl.
	OnChanged (see page 6099)	This is OnChanged, a member of class TOleControl.
	OnControlInfoChanged (see page 6099)	This is OnControlInfoChanged, a member of class TOleControl.
	OnFocus (see page 6099)	This is OnFocus, a member of class TOleControl.
	OnInPlaceActivate (see page 6100)	This is OnInPlaceActivate, a member of class TOleControl.
	OnInPlaceDeactivate (see page 6100)	This is OnInPlaceDeactivate, a member of class TOleControl.
	OnPosRectChange (see page 6100)	This is OnPosRectChange, a member of class TOleControl.
	OnRequestEdit (see page 6100)	This is OnRequestEdit, a member of class TOleControl.

	OnShowWindow (see page 6100)	This is OnShowWindow, a member of class TOleControl.
	OnUIActivate (see page 6101)	This is OnUIActivate, a member of class TOleControl.
	OnUIDeactivate (see page 6101)	This is OnUIDeactivate, a member of class TOleControl.
V	PaletteChanged (see page 6101)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PictureChanged (see page 6102)	This is PictureChanged, a member of class TOleControl.
	PostMessageFilter (see page 6102)	This is PostMessageFilter, a member of class TOleControl.
	PreMessageFilter (see page 6102)	This is PreMessageFilter, a member of class TOleControl.
V	QueryInterface (see page 6103)	Returns a reference to a specified interface if the object supports that interface.
	QueryService (see page 6103)	This is QueryService, a member of class TOleControl.
	RemoveMenus (see page 6103)	This is RemoveMenus, a member of class TOleControl.
	RequestBorderSpace (see page 6104)	This is RequestBorderSpace, a member of class TOleControl.
	RequestNewObjectLayout (see page 6104)	This is RequestNewObjectLayout, a member of class TOleControl.
	SaveObject (see page 6104)	This is SaveObject, a member of class TOleControl.
	Scroll (see page 6104)	This is Scroll, a member of class TOleControl.
	SetActiveObject (see page 6104)	This is SetActiveObject, a member of class TOleControl.
	SetBorderSpace (see page 6105)	This is SetBorderSpace, a member of class TOleControl.
	SetByteProp (see page 6105)	This is SetByteProp, a member of class TOleControl.
	SetColorProp (see page 6105)	This is SetColorProp, a member of class TOleControl.
	SetCompProp (see page 6106)	This is SetCompProp, a member of class TOleControl.
	SetCurrencyProp (see page 6106)	This is SetCurrencyProp, a member of class TOleControl.
	SetDoubleProp (see page 6106)	This is SetDoubleProp, a member of class TOleControl.
	SetIDispatchProp (see page 6106)	This is SetIDispatchProp, a member of class TOleControl.
	SetIntegerProp (see page 6107)	This is SetIntegerProp, a member of class TOleControl.
	SetIUnknownProp (see page 6107)	This is SetIUnknownProp, a member of class TOleControl.
	SetMenu (see page 6107)	This is SetMenu, a member of class TOleControl.
V	SetName (see page 6107)	Sets the name of the control.
	SetOleBoolProp (see page 6108)	This is SetOleBoolProp, a member of class TOleControl.
	SetOleDateProp (see page 6108)	This is SetOleDateProp, a member of class TOleControl.
	SetOleEnumProp (see page 6108)	This is SetOleEnumProp, a member of class TOleControl.
	SetOleVariantProp (see page 6108)	This is SetOleVariantProp, a member of class TOleControl.
V	SetParent (see page 6108)	Sets the parent of the control.
	SetProperty (see page 6109)	This is SetProperty, a member of class TOleControl.
	SetShortIntProp (see page 6110)	This is SetShortIntProp, a member of class TOleControl.
	SetSingleProp (see page 6110)	This is SetSingleProp, a member of class TOleControl.
	SetSmallintProp (see page 6110)	This is SetSmallintProp, a member of class TOleControl.
	SetStatusText (see page 6110)	This is SetStatusText, a member of class TOleControl.
	SetStringProp (see page 6111)	This is SetStringProp, a member of class TOleControl.
	SetTColorProp (see page 6111)	This is SetTColorProp, a member of class TOleControl.
	SetTDateTimeProp (see page 6111)	This is SetTDateTimeProp, a member of class TOleControl.
	SetTFontProp (see page 6111)	This is SetTFontProp, a member of class TOleControl.
	SetTOleEnumProp (see page 6111)	This is SetTOleEnumProp, a member of class TOleControl.
	SetTPictureProp (see page 6112)	This is SetTPictureProp, a member of class TOleControl.
	SetVariantProp (see page 6112)	This is SetVariantProp, a member of class TOleControl.
	SetWideStringProp (see page 6112)	This is SetWideStringProp, a member of class TOleControl.
	SetWordBoolProp (see page 6112)	This is SetWordBoolProp, a member of class TOleControl.
	SetWordProp (see page 6113)	This is SetWordProp, a member of class TOleControl.
	ShowObject (see page 6113)	This is ShowObject, a member of class TOleControl.
	ShowPropertyFrame (see page 6113)	This is ShowPropertyFrame, a member of class TOleControl.
V	StandardEvent (see page 6113)	This is StandardEvent, a member of class TOleControl.
V	SuppressException (see page 6114)	This is SuppressException, a member of class TOleControl.
	TransformCoords (see page 6114)	This is TransformCoords, a member of class TOleControl.
V	WndProc (see page 6114)	Provides specific message responses for the control.

Public Methods

	Name	Description
	BrowseProperties (see page 6083)	Notifies the ActiveX control to display its Properties dialog box.
V	DefaultHandler (see page 6084)	Handles all otherwise-unhandled messages.
	DoObjectVerb (see page 6086)	Notifies the ActiveX control to perform one of its actions.
	GetEnumPropDesc (see page 6088)	Returns descriptions of the ActiveX control's properties.
	GetHelpContext (see page 6089)	Retrieves the Help context of a member of the ActiveX control.
	GetObjectVerbs (see page 6090)	Retrieves the names of the verbs implemented by the ActiveX control.
	GetPropDisplayString (see page 6091)	Returns the display string for an interface for the ActiveX control.
	GetPropDisplayStrings (see page 6092)	Returns the display strings for an interface for the ActiveX control.
	IsCustomProperty (see page 6097)	Indicates whether an interface for the ActiveX control is a custom property.
	IsPropPageProperty (see page 6097)	Indicates whether an interface for the OCX control is a property page property.
V	SetBounds (see page 6105)	Sets the boundaries of the ActiveX control.
	SetPropDisplayString (see page 6109)	Sets the display string for an interface for the ActiveX control.
	ShowAboutBox (see page 6113)	Notifies the ActiveX control to display its About box.

63.1.4.4.1 TOleControl._AddRef Method

Called when an application uses a component interface.

Pascal

```
function _AddRef: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _AddRef();
```

Description

__AddRef is a basic implementation of the IInterface method, _AddRef.

Note: If the component is a wrapper for a COM object, __AddRef calls the _AddRef method of that COM object, and returns the resulting reference count.

In all other cases, __AddRef simply returns –1 and takes no action. This allows the component to implement interfaces where reference counting is not required. More sophisticated components should override __AddRef to implement reference counting.

See Also

Invoke

QueryInterface

_Release

ComObject

_AddRef

63.1.4.4.2 TOleControl._Release Method

Called when an application releases a component interface.

Pascal

```
function _Release: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _Release();
```

Description

__Release is a basic implementation of the IInterface method, _Release.

__Release returns the resulting value of the reference count for the component's interface.

Note:

In all other cases, __Release simply returns –1 and takes no action. This allows the component to implement interfaces where reference counting is not required. More sophisticated components should override __Release to implement reference counting.

ComObject

63.1.4.4.3 TOleControl._SetColorProp Method

Pascal

```
procedure _SetColorProp(Index: Integer; Value: TColor);
```

C++

```
__fastcall _SetColorProp(int Index, TColor Value);
```

Description

This is _SetColorProp, a member of class TOleControl.

63.1.4.4.4 TOleControl._SetTColorProp Method

Pascal

```
procedure _SetTColorProp(Index: Integer; Value: TColor);
```

C++

```
__fastcall _SetTColorProp(int Index, TColor Value);
```

Description

This is _SetTColorProp, a member of class TOleControl.

63.1.4.4.5 TOleControl._SetTFontProp Method

Pascal

```
procedure _SetTFontProp(Index: Integer; Value: TFont);
```

C++

```
__fastcall _SetTFontProp(int Index, TFont Value);
```

Description

This is _SetTFontProp, a member of class TOleControl.

63.1.4.4.6 TOleControl._SetTOleEnumProp Method

Pascal

```
procedure _SetTOleEnumProp(Index: Integer; Value: TOleEnum);
```

C++

```
__fastcall _SetTOleEnumProp(int Index, TOleEnum Value);
```

Description

This is _SetTOleEnumProp, a member of class TOleControl.

63.1.4.4.7 TOleControl._SetTPictureProp Method

Pascal

```
procedure _SetTPictureProp(Index: Integer; Value: TPicture);
```

C++

```
__fastcall _SetTPictureProp(int Index, TPicture Value);
```

Description

This is _SetTPictureProp, a member of class TOleControl.

63.1.4.4.8 TOleControl.BrowseProperties Method

Notifies the ActiveX control to display its Properties dialog box.

Pascal

```
procedure BrowseProperties;
```

C++

```
__fastcall BrowseProperties();
```

Description

Use BrowseProperties to notify the ActiveX control to display its Properties dialog box. The Properties dialog box contains property pages for the ActiveX control.

63.1.4.4.9 TOleControl.CanInPlaceActivate Method

Pascal

```
function CanInPlaceActivate: HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT CanInPlaceActivate();
```

Description

This is CanInPlaceActivate, a member of class TOleControl.

63.1.4.4.10 TOleControl.ContextSensitiveHelp Method

Pascal

```
function ContextSensitiveHelp(fEnterMode: BOOL): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT ContextSensitiveHelp(BOOL fEnterMode);
```

Description

This is ContextSensitiveHelp, a member of class TOleControl.

63.1.4.4.11 TOleControl.CreateWnd Method

Creates the underlying window.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the control is first created or when the underlying screen object must be destroyed and recreated to reflect property changes. Override CreateWnd to pass additional initialization messages to the screen object when it is created.

See Also

CreateParams

CreateWindowHandle

Perform

DestroyWnd

63.1.4.4.12 TOleControl.DeactivateAndUndo Method

Pascal

```
function DeactivateAndUndo: HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT DeactivateAndUndo();
```

Description

This is DeactivateAndUndo, a member of class TOleControl.

63.1.4.4.13 TOleControl.DefaultHandler Method

Handles all otherwise-unhandled messages.

Pascal

```
procedure DefaultHandler(var Message); override;
```

C++

```
virtual __fastcall DefaultHandler( Message);
```

Description

DefaultHandler handles all messages not already handled in a control's WndProc (see page 6114) or message handling methods. The inherited method should always be called for unhandled messages.

See Also

DefaultHandler

63.1.4.4.14 TOleControl.DefineProperties Method

Provides methods to read and write the IsControl property to a stream such as a form file.

Pascal

```
procedure DefineProperties(Filer: TFiler); override;
```

C++

```
virtual __fastcall DefineProperties(TFiler Filer);
```

Description

DefineProperties is called automatically by the streaming system that loads and saves VCL components. It allows persistent objects to read and write properties that are not published. Published properties are loaded and stored automatically.

DefineProperties uses the methods of the filer passed as the Filer parameter to assign methods that can load and save the IsControl property.

Override DefineProperties to persist unpublished properties. Call the DefineBinaryProperty or DefineProperty method of the Filer parameter to assign methods that load or save property values.

Note: When overriding this method, call the parent class's DefineProperties method first.

See Also

DefineBinaryProperty

DefineProperty

DefineProperties

IsControl

63.1.4.4.15 TOleControl.DestroyWindowHandle Method

Destroys the window created in the CreateWindowHandle method.

Pascal

```
procedure DestroyWindowHandle; override;
```

C++

```
virtual __fastcall DestroyWindowHandle();
```

Description

Call DestroyWindowHandle to dispose of the window for the control.

TWinControl's Destroy method calls DestroyWindowHandle to destroy any window associated with a windowed control before destroying the object. The DestroyWnd method also calls DestroyWindowHandle.

See Also

CreateWindowHandle

Destroy

DestroyWnd

63.1.4.4.16 TOleControl.DiscardUndoState Method

Pascal

```
function DiscardUndoState: HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT DiscardUndoState();
```

Description

This is DiscardUndoState, a member of class TOleControl.

63.1.4.4.17 TOleControl.DoObjectVerb Method

Notifies the ActiveX control to perform one of its actions.

Pascal

```
procedure DoObjectVerb(Verb: Integer);
```

C++

```
__fastcall DoObjectVerb(int Verb);
```

Description

Use DoObjectVerb to notify the ActiveX control to perform one of its actions. Verb is an integer that corresponds to the action. Most application-defined verbs are small positive integers.

Verb Name	Verb
OLEIVERB_PRIMARY	0
OLEIVERB_SHOW	–1
OLEIVERB_OPEN	–2
OLEIVERB_HIDE	–3
OLEIVERB_UIACTIVATE	–4
OLEIVERB_INPLACEACTIVATE	–5
OLEIVERB_DISCARDUNDOSTATE	–6
OLEIVERB_PROPERTIES	–7

For more information about verbs, search the OLE.HLP file or the latest Microsoft Developer Network CD.

63.1.4.4.18 TOleControl.EnableModeless Method

Pascal

```
function EnableModeless(fEnable: BOOL): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT EnableModeless(BOOL fEnable);
```

Description

This is EnableModeless, a member of class TOleControl.

63.1.4.4.19 TOleControl.GetBorder Method

Pascal

```
function GetBorder(out rectBorder: TRect): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetBorder(TRect rectBorder);
```

Description

This is GetBorder, a member of class TOleControl.

63.1.4.4.20 TOleControl.GetByteProp Method

Pascal

```
function GetByteProp(Index: Integer): Byte;
```

C++

```
__fastcall Byte GetByteProp(int Index);
```

Description

This is GetByteProp, a member of class TOleControl.

63.1.4.4.21 TOleControl.GetColorProp Method

Pascal

```
function GetColorProp(Index: Integer): TColor;
```

C++

```
__fastcall TColor GetColorProp(int Index);
```

Description

This is GetColorProp, a member of class TOleControl.

63.1.4.4.22 TOleControl.GetCompProp Method

Pascal

```
function GetCompProp(Index: Integer): Comp;
```

C++

```
__fastcall Comp GetCompProp(int Index);
```

Description

This is GetCompProp, a member of class TOleControl.

63.1.4.4.23 TOleControl.GetContainer Method

Pascal

```
function GetContainer(out container: IOleContainer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetContainer(IOleContainer container);
```

Description

This is GetContainer, a member of class TOleControl.

63.1.4.4.24 TOleControl.GetCurrencyProp Method

Pascal

```
function GetCurrencyProp(Index: Integer): Currency;
```

C++

```
__fastcall Currency GetCurrencyProp(int Index);
```

Description

This is GetCurrencyProp, a member of class TOleControl.

63.1.4.4.25 TOleControl.GetDoubleProp Method

Pascal

```
function GetDoubleProp(Index: Integer): Double;
```

C++

```
__fastcall Double GetDoubleProp(int Index);
```

Description

This is GetDoubleProp, a member of class TOleControl.

63.1.4.4.26 TOleControl.GetEnumPropDesc Method

Returns descriptions of the ActiveX control's properties.

Pascal

```
function GetEnumPropDesc(DispID: Integer): TEnumPropDesc;
```

C++

```
__fastcall TEnumPropDesc GetEnumPropDesc(int DispID);
```

Description

Use GetEnumPropDesc to return descriptions of the ActiveX control's properties. GetEnumPropDesc returns the descriptions in a TEnumPropDesc (see page 6067) object.

63.1.4.4.27 TOleControl.GetExtendedControl Method

Pascal

```
function GetExtendedControl(out disp: IDispatch): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetExtendedControl(IDispatch disp);
```

Description

This is GetExtendedControl, a member of class TOleControl.

63.1.4.4.28 TOleControl.GetHelpContext Method

Retrieves the Help context of a member of the ActiveX control.

Pascal

```
function GetHelpContext(Member: string; var HelpCtx: Integer; var HelpFile: string): Boolean;
```

C++

```
__fastcall Boolean GetHelpContext(UnicodeString Member, int HelpCtx, UnicodeString HelpFile);
```

Description

Use GetHelpContext to retrieve the Help context of a member of the ActiveX control.

Member is the name of a property, method, or event of the ActiveX control. To retrieve the help context of the ActiveX control itself, set Member to nil (Delphi) or NULL (C++).

HelpCtx is a variable in which the Help context identifier of Member is to be stored.

HelpFile is a variable in which the name of the Help file containing HelpCtx is to be stored.

The information about the ActiveX control is retrieved from its ITypeInfo interfaces. For more information, search the OLE.HLP file for ITypeInfo.

GetHelpContext returns false if Member is not found; otherwise, GetHelpContext returns true.

63.1.4.4.29 TOleControl.GetIDispatchProp Method

Pascal

```
function GetIDispatchProp(Index: Integer): IDispatch;
```

C++

```
__fastcall IDispatch GetIDispatchProp(int Index);
```

Description

This is GetIDispatchProp, a member of class TOleControl.

63.1.4.4.30 TOleControl.GetIDsOfNames Method

Pascal

```
function GetIDsOfNames(const IID: TGUID; Names: Pointer; NameCount: Integer; LocaleID:
Integer; DispIDs: Pointer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetIDsOfNames(const TGUID IID, void * Names, int NameCount, int
LocaleID, void * DispIDs);
```

Description

This is GetIDsOfNames, a member of class TOleControl.

63.1.4.4.31 TOleControl.GetIntegerProp Method

Pascal

```
function GetIntegerProp(Index: Integer): Integer;
```

C++

```
__fastcall int GetIntegerProp(int Index);
```

Description

This is GetIntegerProp, a member of class TOleControl.

63.1.4.4.32 TOleControl.GetIUnknownProp Method

Pascal

```
function GetIUnknownProp(Index: Integer): IUnknown;
```

C++

```
__fastcall IUnknown GetIUnknownProp(int Index);
```

Description

This is GetIUnknownProp, a member of class TOleControl.

63.1.4.4.33 TOleControl.GetMoniker Method

Pascal

```
function GetMoniker(dwAssign: Longint; dwWhichMoniker: Longint; out mk: IMoniker): HResult;
stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetMoniker(Longint dwAssign, Longint dwWhichMoniker, IMoniker mk);
```

Description

This is GetMoniker, a member of class TOleControl.

63.1.4.4.34 TOleControl.GetObjectVerbs Method

Retrieves the names of the verbs implemented by the ActiveX control.

Pascal

```
procedure GetObjectVerbs(List: TStrings);
```

C++

```
__fastcall GetObjectVerbs(TStrings List);
```

Description

Use GetObjectVerbs to retrieve the names of the verbs implemented by the ActiveX control.

List is where the names of the verbs are to be stored.

63.1.4.4.35 TOleControl.GetOleBoolProp Method

Pascal

```
function GetOleBoolProp(Index: Integer): TOleBool;
```

C++

```
__fastcall TOleBool GetOleBoolProp(int Index);
```

Description

This is GetOleBoolProp, a member of class TOleControl.

63.1.4.4.36 TOleControl.GetOleDateProp Method

Pascal

```
function GetOleDateProp(Index: Integer): TOleDate;
```

C++

```
__fastcall TOleDate GetOleDateProp(int Index);
```

Description

This is GetOleDateProp, a member of class TOleControl.

63.1.4.4.37 TOleControl.GetOleEnumProp Method

Pascal

```
function GetOleEnumProp(Index: Integer): TOleEnum;
```

C++

```
__fastcall TOleEnum GetOleEnumProp(int Index);
```

Description

This is GetOleEnumProp, a member of class TOleControl.

63.1.4.4.38 TOleControl.GetOleVariantProp Method

Pascal

```
function GetOleVariantProp(Index: Integer): OleVariant;
```

C++

```
__fastcall OleVariant GetOleVariantProp(int Index);
```

Description

This is GetOleVariantProp, a member of class TOleControl.

63.1.4.4.39 TOleControl.GetPropDisplayString Method

Returns the display string for an interface for the ActiveX control.

Pascal

```
function GetPropDisplayString(DispID: Integer): string;
```

C++

```
__fastcall UnicodeString GetPropDisplayString(int DispID);
```

Description

GetPropDisplayString returns the display string for an interface for the ActiveX control.

DispID is the identifier for the interface. For more information, search the OLE.HLP file for DISPID.

For more information about GetPropDisplayString, search the latest Microsoft Developer Network CD for GetDisplayStrings.

See Also

GetPropDisplayStrings (see page 6092)

SetPropDisplayString (see page 6109)

63.1.4.4.40 TOleControl.GetPropDisplayStrings Method

Returns the display strings for an interface for the ActiveX control.

Pascal

```
procedure GetPropDisplayStrings(DispID: Integer; List: TStrings);
```

C++

```
__fastcall GetPropDisplayStrings(int DispID, TStrings List);
```

Description

List is where the strings are to be stored.

For more information about GetPropDisplayStrings, search the latest Microsoft Developer Network CD for GetDisplayStrings.

See Also

GetPropDisplayString (see page 6091)

63.1.4.4.41 TOleControl.GetProperty Method

Pascal

```
procedure GetProperty(Index: Integer; var Value: TVarData);
```

C++

```
__fastcall GetProperty(int Index, TVarData Value);
```

Description

This is GetProperty, a member of class TOleControl.

63.1.4.4.42 TOleControl.GetShortIntProp Method

Pascal

```
function GetShortIntProp(Index: Integer): ShortInt;
```

C++

```
__fastcall ShortInt GetShortIntProp(int Index);
```

Description

This is GetShortIntProp, a member of class TOleControl.

63.1.4.4.43 TOleControl.GetSingleProp Method

Pascal

```
function GetSingleProp(Index: Integer): Single;
```

C++

```
__fastcall Single GetSingleProp(int Index);
```

Description

This is GetSingleProp, a member of class TOleControl.

63.1.4.4.44 TOleControl.GetSmallintProp Method

Pascal

```
function GetSmallintProp(Index: Integer): Smallint;
```

C++

```
__fastcall Smallint GetSmallintProp(int Index);
```

Description

This is GetSmallintProp, a member of class TOleControl.

63.1.4.4.45 TOleControl.GetStringProp Method

Pascal

```
function GetStringProp(Index: Integer): string;
```

C++

```
__fastcall UnicodeString GetStringProp(int Index);
```

Description

This is GetStringProp, a member of class TOleControl.

63.1.4.4.46 TOleControl.GetTColorProp Method

Pascal

```
function GetTColorProp(Index: Integer): TColor;
```

C++

```
__fastcall TColor GetTColorProp(int Index);
```

Description

This is GetTColorProp, a member of class TOleControl.

63.1.4.4.47 TOleControl.GetTDateTimeProp Method

Pascal

```
function GetTDateTimeProp(Index: Integer): TDateTime;
```

C++

```
__fastcall TDateTime GetTDateTimeProp(int Index);
```

Description

This is GetTDateTimeProp, a member of class TOleControl.

63.1.4.4.48 TOleControl.GetTFontProp Method

Pascal

```
function GetTFontProp(Index: Integer): TFont;
```

C++

```
__fastcall TFont GetTFontProp(int Index);
```

Description

This is GetTFontProp, a member of class TOleControl.

63.1.4.4.49 TOleControl.GetTOleEnumProp Method

Pascal

```
function GetTOleEnumProp(Index: Integer): TOleEnum;
```

C++

```
__fastcall TOleEnum GetTOleEnumProp(int Index);
```

Description

This is GetTOleEnumProp, a member of class TOleControl.

63.1.4.4.50 TOleControl.GetTPictureProp Method

Pascal

```
function GetTPictureProp(Index: Integer): TPicture;
```

C++

```
__fastcall TPicture GetTPictureProp(int Index);
```

Description

This is GetTPictureProp, a member of class TOleControl.

63.1.4.4.51 TOleControl.GetTypeInfo Method

Pascal

```
function GetTypeInfo(Index: Integer; LocaleID: Integer; out TypeInfo): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetTypeInfo(int Index, int LocaleID,  TypeInfo);
```

Description

This is GetTypeInfo, a member of class TOleControl.

63.1.4.4.52 TOleControl.GetTypeInfoCount Method

Pascal

```
function GetTypeInfoCount(out Count: Integer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetTypeInfoCount(int Count);
```

Description

This is GetTypeInfoCount, a member of class TOleControl.

63.1.4.4.53 TOleControl.GetVariantProp Method

Pascal

```
function GetVariantProp(Index: Integer): Variant;
```

C++

```
__fastcall Variant GetVariantProp(int Index);
```

Description

This is GetVariantProp, a member of class TOleControl.

63.1.4.4.54 TOleControl.GetWideStringProp Method

Pascal

```
function GetWideStringProp(Index: Integer): WideString;
```

C++

```
__fastcall BSTR GetWideStringProp(int Index);
```

Description

This is GetWideStringProp, a member of class TOleControl.

63.1.4.4.55 TOleControl.GetWindowContext Method

Pascal

```
function GetWindowContext(out frame: IOleInPlaceFrame; out doc: IOleInPlaceUIWindow; out
rcPosRect: TRect; out rcClipRect: TRect; out frameInfo: TOleInPlaceFrameInfo): HResult;
stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetWindowContext(IOleInPlaceFrame frame, IOleInPlaceUIWindow doc,
TRect rcPosRect, TRect rcClipRect, TOleInPlaceFrameInfo frameInfo);
```

Description

This is GetWindowContext, a member of class TOleControl.

63.1.4.4.56 TOleControl.GetWordBoolProp Method

Pascal

```
function GetWordBoolProp(Index: Integer): WordBool;
```

C++

```
__fastcall WordBool GetWordBoolProp(int Index);
```

Description

This is GetWordBoolProp, a member of class TOleControl.

63.1.4.4.57 TOleControl.GetWordProp Method

Pascal

```
function GetWordProp(Index: Integer): Word;
```

C++

```
__fastcall Word GetWordProp(int Index);
```

Description

This is GetWordProp, a member of class TOleControl.

63.1.4.4.58 TOleControl.InitControlData Method

Pascal

```
procedure InitControlData; virtual; abstract;
```

C++

```
virtual __fastcall InitControlData() = 0;
```

Description

This is InitControlData, a member of class TOleControl.

63.1.4.4.59 TOleControl.InitControlInterface Method

Pascal

```
procedure InitControlInterface(const Obj: IUnknown); virtual;
```

C++

```
virtual __fastcall InitControlInterface(const IUnknown Obj);
```

Description

This is InitControlInterface, a member of class TOleControl.

63.1.4.4.60 TOleControl.InsertMenus Method

Pascal

```
function InsertMenus(hmenuShared: HMenu; var menuWidths: TOleMenuGroupWidths): HResult;
stdcall;
```

C++

```
__fastcall __stdcall HRESULT InsertMenus(HMenu hmenuShared, TOleMenuGroupWidths menuWidths);
```

Description

This is InsertMenus, a member of class TOleControl.

63.1.4.4.61 TOleControl.Invoke Method

Pascal

```
function Invoke(DispID: Integer; const IID: TGUID; LocaleID: Integer; Flags: Word; var Params;
VarResult: Pointer; ExcepInfo: Pointer; ArgErr: Pointer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT Invoke(int DispID, const TGUID IID, int LocaleID, Word Flags,
Params, void * VarResult, void * ExcepInfo, void * ArgErr);
```

Description

This is Invoke, a member of class TOleControl.

63.1.4.4.62 TOleControl.InvokeEvent Method

Pascal

```
procedure InvokeEvent(DispID: TDispID; var Params: TDispParams); virtual;
```

C++

```
virtual __fastcall InvokeEvent(TDispID DispID, TDispParams Params);
```

Description

This is InvokeEvent, a member of class TOleControl.

63.1.4.4.63 TOleControl.InvokeMethod Method

Pascal

```
procedure InvokeMethod(const DispInfo; Result: Pointer);
```

C++

```
__fastcall InvokeMethod(const  DispInfo, void * Result);
```

Description

This is InvokeMethod, a member of class TOleControl.

63.1.4.4.64 TOleControl.IsCustomProperty Method

Indicates whether an interface for the ActiveX control is a custom property.

Pascal

```
function IsCustomProperty(DispID: Integer): Boolean;
```

C++

```
__fastcall Boolean IsCustomProperty(int DispID);
```

Description

Use IsCustomProperty to determine whether an interface for the ActiveX control is a custom property.

DispID is the identifier for the interface. For more information, search the OLE.HLP file for DISPID.

IsCustomProperty returns true if an interface is a custom property; otherwise, IsCustomProperty returns false.

63.1.4.4.65 TOleControl.IsPropPageProperty Method

Indicates whether an interface for the OCX control is a property page property.

Pascal

```
function IsPropPageProperty(DispID: Integer): Boolean;
```

C++

```
__fastcall Boolean IsPropPageProperty(int DispID);
```

Description

Use IsPropPageProperty to determine whether an interface for the OCX control is a property page property.

DispID is the identifier for the interface. For more information, search the OLE.HLP file for DISPID.

IsPropPageProperty returns true if an interface is a property page property; otherwise, IsPropPageProperty returns false.

63.1.4.4.66 TOleControl.LockInPlaceActive Method

Pascal

```
function LockInPlaceActive(fLock: BOOL): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT LockInPlaceActive(BOOL fLock);
```

Description

This is LockInPlaceActive, a member of class TOleControl.

63.1.4.4.67 TOleControl.OleControlSite_TranslateAccelerator Method

Pascal

```
function OleControlSite_TranslateAccelerator(msg: PMsg; grfModifiers: Longint): HResult;
stdcall;
```

C++

```
__fastcall __stdcall HRESULT OleControlSite_TranslateAccelerator(PMsg msg, Longint
grfModifiers);
```

Description

This is OleControlSite_TranslateAccelerator, a member of class TOleControl.

63.1.4.4.68 TOleControl.OleInPlaceFrame_GetWindow Method

Pascal

```
function OleInPlaceFrame_GetWindow(out wnd: HWnd): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT OleInPlaceFrame_GetWindow(HWnd wnd);
```

Description

This is OleInPlaceFrame_GetWindow, a member of class TOleControl.

63.1.4.4.69 TOleControl.OleInPlaceFrame_TranslateAccelerator Method

Pascal

```
function OleInPlaceFrame_TranslateAccelerator(var msg: TMsg; wID: Word): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT OleInPlaceFrame_TranslateAccelerator(TMsg msg, Word wID);
```

Description

This is OleInPlaceFrame_TranslateAccelerator, a member of class TOleControl.

63.1.4.4.70 TOleControl.OleInPlaceSite_GetWindow Method

Pascal

```
function OleInPlaceSite_GetWindow(out wnd: HWnd): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT OleInPlaceSite_GetWindow(HWnd wnd);
```

Description

This is OleInPlaceSite_GetWindow, a member of class TOleControl.

63.1.4.4.71 TOleControl.OnChanged Method

Pascal

```
function OnChanged(dispid: TDispID): HResult; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT OnChanged(TDispID dispid);
```

Description

This is OnChanged, a member of class TOleControl.

63.1.4.4.72 TOleControl.OnControlInfoChanged Method

Pascal

```
function OnControlInfoChanged: HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT OnControlInfoChanged();
```

Description

This is OnControlInfoChanged, a member of class TOleControl.

63.1.4.4.73 TOleControl.OnFocus Method

Pascal

```
function OnFocus(fGotFocus: BOOL): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT OnFocus(BOOL fGotFocus);
```

Description

This is OnFocus, a member of class TOleControl.

63.1.4.4.74 TOleControl.OnInPlaceActivate Method

Pascal

```
function OnInPlaceActivate: HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT OnInPlaceActivate();
```

Description

This is OnInPlaceActivate, a member of class TOleControl.

63.1.4.4.75 TOleControl.OnInPlaceDeactivate Method

Pascal

```
function OnInPlaceDeactivate: HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT OnInPlaceDeactivate();
```

Description

This is OnInPlaceDeactivate, a member of class TOleControl.

63.1.4.4.76 TOleControl.OnPosRectChange Method

Pascal

```
function OnPosRectChange(const rcPosRect: TRect): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT OnPosRectChange(const TRect rcPosRect);
```

Description

This is OnPosRectChange, a member of class TOleControl.

63.1.4.4.77 TOleControl.OnRequestEdit Method

Pascal

```
function OnRequestEdit(dispid: TDispID): HResult; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT OnRequestEdit(TDispID dispid);
```

Description

This is OnRequestEdit, a member of class TOleControl.

63.1.4.4.78 TOleControl.OnShowWindow Method

Pascal

```
function OnShowWindow(fShow: BOOL): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT OnShowWindow(BOOL fShow);
```

Description

This is OnShowWindow, a member of class TOleControl.

63.1.4.4.79 TOleControl.OnUIActivate Method

Pascal

```
function OnUIActivate: HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT OnUIActivate();
```

Description

This is OnUIActivate, a member of class TOleControl.

63.1.4.4.80 TOleControl.OnUIDeactivate Method

Pascal

```
function OnUIDeactivate(fUndoable: BOOL): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT OnUIDeactivate(BOOL fUndoable);
```

Description

This is OnUIDeactivate, a member of class TOleControl.

63.1.4.4.81 TOleControl.PaletteChanged Method

Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.

Pascal

```
function PaletteChanged(Foreground: Boolean): Boolean; override;
```

C++

```
virtual __fastcall Boolean PaletteChanged(Boolean Foreground);
```

Description

PaletteChanged is called automatically when the Windows system palette changes. TWinControl responds to these notifications by trying to realize the windowed control's palette, if any, into the current device context, and then passing on the PaletteChanged notification to each of the child controls in turn. If the change in the system palette causes the actual value of the control's palette to change, PaletteChanged will invalidate the control so that it can repaint with the new palette.

Windows paints the active window with a foreground palette, while other windows are forced to use background palettes. Background palettes are approximate matches to the colors specified by the control's logical palette, given the limitations imposed by implementing the foreground palette. Windows only allows a single foreground palette.

PaletteChanged allows the control to obtain a new realization of its palette when the system palette changes. When Foreground is true, the form has been activated and the control is specifying the new foreground palette. When Foreground is false, another application or form has changed the foreground palette, and controls that are sensitive to the available palette should realize new background palettes to best match their logical palettes.

If the control does not have a logical palette to be realized into the current device context, GetPalette will return a handle of 0, and PaletteChanged will not try to realize a palette for the windowed control. Instead, it simply passes the notification on to the child controls. If the windowed control or any of its child controls realize a palette into the current device context in response to

PaletteChanged, this method returns true.

Override PaletteChanged to change the way in which controls are given an opportunity to realize a new palette when the Windows system palette changes. For example, override PaletteChanged to change the order in which child controls realize their palettes, giving a particular control the foreground palette when the form is activated, or to pass palette change notification to custom controls implemented outside of the VCL, such as in DLLs.

Override GetPalette instead to affect whether the windowed control actually has a palette to realize, or to change the value of the control's logical palette.

Note: PaletteChanged is called only when the run-time video mode requires palette support, such as for 256 color mode, but not 16 million color mode.

GetPalette

63.1.4.4.82 TOleControl.PictureChanged Method

Pascal

```
procedure PictureChanged(Sender: TObject);
```

C++

```
__fastcall PictureChanged(TObject * Sender);
```

Description

This is PictureChanged, a member of class TOleControl.

63.1.4.4.83 TOleControl.PostMessageFilter Method

Pascal

```
function PostMessageFilter(wnd: HWnd; msg: Integer; wp: Integer; lp: Integer; out res:
Integer; Cookie: Longint): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT PostMessageFilter(HWnd wnd, int msg, int wp, int lp, int res,
Longint Cookie);
```

Description

This is PostMessageFilter, a member of class TOleControl.

63.1.4.4.84 TOleControl.PreMessageFilter Method

Pascal

```
function PreMessageFilter(wnd: HWnd; msg: Integer; wp: Integer; lp: Integer; out res: Integer;
out Cookie: Longint): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT PreMessageFilter(HWnd wnd, int msg, int wp, int lp, int res,
Longint Cookie);
```

Description

This is PreMessageFilter, a member of class TOleControl.

63.1.4.4.85 TOleControl.QueryInterface Method

Returns a reference to a specified interface if the object supports that interface.

Pascal

```
function QueryInterface(const IID: TGUID; out Obj): HResult; override;
```

C++

```
virtual __fastcall HRESULT QueryInterface(const TGUID IID,  Obj);
```

Description

QueryInterface checks whether the component supports the interface specified by IID, and if so, returns a reference to that interface as the Obj parameter. If the component does not support the interface, the Obj parameter returns nil (Delphi) or NULL (C++).

Note: For components that act as COM object wrapper, QueryInterface calls the QueryInterface method of the internal COM object.

63.1.4.4.86 TOleControl.QueryService Method

Pascal

```
function QueryService(const rsid: TGuid; const iid: TGuid; out obj): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT QueryService(const TGuid rsid, const TGuid iid,  obj);
```

Description

This is QueryService, a member of class TOleControl.

63.1.4.4.87 TOleControl.RemoveMenus Method

Pascal

```
function RemoveMenus(hmenuShared: HMenu): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT RemoveMenus(HMenu hmenuShared);
```

Description

This is RemoveMenus, a member of class TOleControl.

63.1.4.4.88 TOleControl.RequestBorderSpace Method

Pascal

```
function RequestBorderSpace(const borderwidths: TRect): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT RequestBorderSpace(const TRect borderwidths);
```

Description

This is RequestBorderSpace, a member of class TOleControl.

63.1.4.4.89 TOleControl.RequestNewObjectLayout Method

Pascal

```
function RequestNewObjectLayout: HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT RequestNewObjectLayout();
```

Description

This is RequestNewObjectLayout, a member of class TOleControl.

63.1.4.4.90 TOleControl.SaveObject Method

Pascal

```
function SaveObject: HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT SaveObject();
```

Description

This is SaveObject, a member of class TOleControl.

63.1.4.4.91 TOleControl.Scroll Method

Pascal

```
function Scroll(scrollExtent: TPoint): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT Scroll(TPoint scrollExtent);
```

Description

This is Scroll, a member of class TOleControl.

63.1.4.4.92 TOleControl.SetActiveObject Method

Pascal

```
function SetActiveObject(const activeObject: IOleInPlaceActiveObject; pszObjName: POleStr):
HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT SetActiveObject(const IOleInPlaceActiveObject activeObject,
POleStr pszObjName);
```

Description

This is SetActiveObject, a member of class TOleControl.

63.1.4.4.93 TOleControl.SetBorderSpace Method

Pascal

```
function SetBorderSpace(pborderwidths: PRect): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT SetBorderSpace(PRect pborderwidths);
```

Description

This is SetBorderSpace, a member of class TOleControl.

63.1.4.4.94 TOleControl.SetBounds Method

Sets the boundaries of the ActiveX control.

Pascal

```
procedure SetBounds(ALeft: Integer; ATop: Integer; AWidth: Integer; AHeight: Integer);
override;
```

C++

```
virtual __fastcall SetBounds(int ALeft, int ATop, int AWidth, int AHeight);
```

Description

Use SetBounds to set the boundaries of the ActiveX control.

ALeft, ATop, AWidth, and AHeight are the x-coordinate of the upper-left corner, the y-coordinate of the upper-left corner, the width and the height of the ActiveX control.

63.1.4.4.95 TOleControl.SetByteProp Method

Pascal

```
procedure SetByteProp(Index: Integer; Value: Byte);
```

C++

```
__fastcall SetByteProp(int Index, Byte Value);
```

Description

This is SetByteProp, a member of class TOleControl.

63.1.4.4.96 TOleControl.SetColorProp Method

Pascal

```
procedure SetColorProp(Index: Integer; Value: TColor);
```

C++

```
__fastcall SetColorProp(int Index, TColor Value);
```

Description

This is SetColorProp, a member of class TOleControl.

63.1.4.4.97 TOleControl.SetCompProp Method

Pascal

```
procedure SetCompProp(Index: Integer; const Value: Comp);
```

C++

```
__fastcall SetCompProp(int Index, const Comp Value);
```

Description

This is SetCompProp, a member of class TOleControl.

63.1.4.4.98 TOleControl.SetCurrencyProp Method

Pascal

```
procedure SetCurrencyProp(Index: Integer; const Value: Currency);
```

C++

```
__fastcall SetCurrencyProp(int Index, const Currency Value);
```

Description

This is SetCurrencyProp, a member of class TOleControl.

63.1.4.4.99 TOleControl.SetDoubleProp Method

Pascal

```
procedure SetDoubleProp(Index: Integer; const Value: Double);
```

C++

```
__fastcall SetDoubleProp(int Index, const Double Value);
```

Description

This is SetDoubleProp, a member of class TOleControl.

63.1.4.4.100 TOleControl.SetIDispatchProp Method

Pascal

```
procedure SetIDispatchProp(Index: Integer; const Value: IDispatch);
```

C++

```
__fastcall SetIDispatchProp(int Index, const IDispatch Value);
```

Description

This is SetIDispatchProp, a member of class TOleControl.

63.1.4.4.101 TOleControl.SetIntegerProp Method

Pascal

```
procedure SetIntegerProp(Index: Integer; Value: Integer);
```

C++

```
__fastcall SetIntegerProp(int Index, int Value);
```

Description

This is SetIntegerProp, a member of class TOleControl.

63.1.4.4.102 TOleControl.SetIUnknownProp Method

Pascal

```
procedure SetIUnknownProp(Index: Integer; const Value: IUnknown);
```

C++

```
__fastcall SetIUnknownProp(int Index, const IUnknown Value);
```

Description

This is SetIUnknownProp, a member of class TOleControl.

63.1.4.4.103 TOleControl.SetMenu Method

Pascal

```
function SetMenu(hmenuShared: HMenu; holemenu: HMenu; hwndActiveObject: HWnd): HResult;
stdcall;
```

C++

```
__fastcall __stdcall HRESULT SetMenu(HMenu hmenuShared, HMenu holemenu, HWnd hwndActiveObject);
```

Description

This is SetMenu, a member of class TOleControl.

63.1.4.4.104 TOleControl.SetName Method

Sets the name of the control.

Pascal

```
procedure SetName(const Value: TComponentName); override;
```

C++

```
virtual __fastcall SetName(const TComponentName Value);
```

Description

SetName is the protected write implementation of the Name property. TControl updates the Text or Caption property, if appropriate, after changing the value of Name.

Override SetName to execute additional code when the value of the Name property changes.

Name

Caption

Text

63.1.4.4.105 TOleControl.SetOleBoolProp Method

Pascal

```
procedure SetOleBoolProp(Index: Integer; Value: TOleBool);
```

C++

```
__fastcall SetOleBoolProp(int Index, TOleBool Value);
```

Description

This is SetOleBoolProp, a member of class TOleControl.

63.1.4.4.106 TOleControl.SetOleDateProp Method

Pascal

```
procedure SetOleDateProp(Index: Integer; const Value: TOleDate);
```

C++

```
__fastcall SetOleDateProp(int Index, const TOleDate Value);
```

Description

This is SetOleDateProp, a member of class TOleControl.

63.1.4.4.107 TOleControl.SetOleEnumProp Method

Pascal

```
procedure SetOleEnumProp(Index: Integer; Value: TOleEnum);
```

C++

```
__fastcall SetOleEnumProp(int Index, TOleEnum Value);
```

Description

This is SetOleEnumProp, a member of class TOleControl.

63.1.4.4.108 TOleControl.SetOleVariantProp Method

Pascal

```
procedure SetOleVariantProp(Index: Integer; const Value: OleVariant);
```

C++

```
__fastcall SetOleVariantProp(int Index, const OleVariant Value);
```

Description

This is SetOleVariantProp, a member of class TOleControl.

63.1.4.4.109 TOleControl.SetParent Method

Sets the parent of the control.

Pascal

```
procedure SetParent(AParent: TWinControl); override;
```

C++

```
virtual __fastcall SetParent(TWinControl * AParent);
```

Description

SetParent is the protected implementation of the Parent property. Override SetParent to execute additional code when the value of the Parent property changes.

The AParent parameter specifies the new parent of the control.

If the control already has a parent, SetParent removes the control from that parent's list of controls by calling the parent's RemoveControl method. If AParent is not nil (Delphi) or NULL (C++), SetParent calls its InsertControl method to add the control to its list of controls.

The TControl destructor calls SetParent(nil (Delphi) or NULL (C++)) to remove the control from its parent's control list before destroying the component.

63.1.4.4.110 TOleControl.SetPropDisplayString Method

Sets the display string for an interface for the ActiveX control.

Pascal

```
procedure SetPropDisplayString(DispID: Integer; const Value: string);
```

C++

```
__fastcall SetPropDisplayString(int DispID, const UnicodeString Value);
```

Description

Use SetPropDisplayString to set the display string for an interface for the ActiveX control.

DispID is the identifier for the interface. For more information, search the OLE.HLP file for DISPID.

Value is the new display string for the interface.

GetPropDisplayStrings (see page 6092)

SetPropDisplayString

63.1.4.4.111 TOleControl.SetProperty Method

Pascal

```
procedure SetProperty(Index: Integer; const Value: TVarData);
```

C++

```
__fastcall SetProperty(int Index, const TVarData Value);
```

Description

This is SetProperty, a member of class TOleControl.

63.1.4.4.112 TOleControl.SetShortIntProp Method

Pascal

```
procedure SetShortIntProp(Index: Integer; Value: Shortint);
```

C++

```
__fastcall SetShortIntProp(int Index, Shortint Value);
```

Description

This is SetShortIntProp, a member of class TOleControl.

63.1.4.4.113 TOleControl.SetSingleProp Method

Pascal

```
procedure SetSingleProp(Index: Integer; const Value: Single);
```

C++

```
__fastcall SetSingleProp(int Index, const Single Value);
```

Description

This is SetSingleProp, a member of class TOleControl.

63.1.4.4.114 TOleControl.SetSmallintProp Method

Pascal

```
procedure SetSmallintProp(Index: Integer; Value: Smallint);
```

C++

```
__fastcall SetSmallintProp(int Index, Smallint Value);
```

Description

This is SetSmallintProp, a member of class TOleControl.

63.1.4.4.115 TOleControl.SetStatusText Method

Pascal

```
function SetStatusText(pszStatusText: POleStr): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT SetStatusText(POleStr pszStatusText);
```

Description

This is SetStatusText, a member of class TOleControl.

63.1.4.4.116 TOleControl.SetStringProp Method

Pascal

```
procedure SetStringProp(Index: Integer; const Value: string);
```

C++

```
__fastcall SetStringProp(int Index, const UnicodeString Value);
```

Description

This is SetStringProp, a member of class TOleControl.

63.1.4.4.117 TOleControl.SetTColorProp Method

Pascal

```
procedure SetTColorProp(Index: Integer; Value: TColor);
```

C++

```
__fastcall SetTColorProp(int Index, TColor Value);
```

Description

This is SetTColorProp, a member of class TOleControl.

63.1.4.4.118 TOleControl.SetTDateTimeProp Method

Pascal

```
procedure SetTDateTimeProp(Index: Integer; const Value: TDateTime);
```

C++

```
__fastcall SetTDateTimeProp(int Index, const TDateTime Value);
```

Description

This is SetTDateTimeProp, a member of class TOleControl.

63.1.4.4.119 TOleControl.SetTFontProp Method

Pascal

```
procedure SetTFontProp(Index: Integer; Value: TFont);
```

C++

```
__fastcall SetTFontProp(int Index, TFont Value);
```

Description

This is SetTFontProp, a member of class TOleControl.

63.1.4.4.120 TOleControl.SetTOleEnumProp Method

Pascal

```
procedure SetTOleEnumProp(Index: Integer; Value: TOleEnum);
```

C++

```
__fastcall SetTOleEnumProp(int Index, TOleEnum Value);
```

Description

This is SetTOleEnumProp, a member of class TOleControl.

63.1.4.4.121 TOleControl.SetTPictureProp Method

Pascal

```
procedure SetTPictureProp(Index: Integer; Value: TPicture);
```

C++

```
__fastcall SetTPictureProp(int Index, TPicture Value);
```

Description

This is SetTPictureProp, a member of class TOleControl.

63.1.4.4.122 TOleControl.SetVariantProp Method

Pascal

```
procedure SetVariantProp(Index: Integer; const Value: Variant);
```

C++

```
__fastcall SetVariantProp(int Index, const Variant Value);
```

Description

This is SetVariantProp, a member of class TOleControl.

63.1.4.4.123 TOleControl.SetWideStringProp Method

Pascal

```
procedure SetWideStringProp(Index: Integer; const Value: WideString);
```

C++

```
__fastcall SetWideStringProp(int Index, const BSTR Value);
```

Description

This is SetWideStringProp, a member of class TOleControl.

63.1.4.4.124 TOleControl.SetWordBoolProp Method

Pascal

```
procedure SetWordBoolProp(Index: Integer; Value: WordBool);
```

C++

```
__fastcall SetWordBoolProp(int Index, WordBool Value);
```

Description

This is SetWordBoolProp, a member of class TOleControl.

63.1.4.4.125 TOleControl.SetWordProp Method

Pascal

```
procedure SetWordProp(Index: Integer; Value: Word);
```

C++

```
__fastcall SetWordProp(int Index, Word Value);
```

Description

This is SetWordProp, a member of class TOleControl.

63.1.4.4.126 TOleControl.ShowAboutBox Method

Notifies the ActiveX control to display its About box.

Pascal

```
procedure ShowAboutBox;
```

C++

```
__fastcall ShowAboutBox();
```

Description

Use ShowAboutBox to notify the ActiveX control to display its About box.

63.1.4.4.127 TOleControl.ShowObject Method

Pascal

```
function ShowObject: HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT ShowObject();
```

Description

This is ShowObject, a member of class TOleControl.

63.1.4.4.128 TOleControl.ShowPropertyFrame Method

Pascal

```
function ShowPropertyFrame: HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT ShowPropertyFrame();
```

Description

This is ShowPropertyFrame, a member of class TOleControl.

63.1.4.4.129 TOleControl.StandardEvent Method

Pascal

```
procedure StandardEvent(DispID: TDispID; var Params: TDispParams); virtual;
```

C++

```
virtual __fastcall StandardEvent(TDispID DispID, TDispParams Params);
```

Description

This is StandardEvent, a member of class TOleControl.

63.1.4.4.130 TOleControl.SuppressException Method

Pascal

```
function SuppressException(E: Exception): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean SuppressException(Exception E);
```

Description

This is SuppressException, a member of class TOleControl.

63.1.4.4.131 TOleControl.TransformCoords Method

Pascal

```
function TransformCoords(var ptlHimetric: TPoint; var ptfContainer: TPointF; flags: Longint):
HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT TransformCoords(TPoint ptlHimetric, TPointF ptfContainer, Longint
flags);
```

Description

This is TransformCoords, a member of class TOleControl.

63.1.4.4.132 TOleControl.WndProc Method

Provides specific message responses for the control.

Pascal

```
procedure WndProc(var Message: TMessage); override;
```

C++

```
virtual __fastcall WndProc(TMessage Message);
```

Description

Override WndProc to change the initial Windows message handler for the control. The WindowProc property is initialized to point to the WndProc method.

WndProc for TWinControl overrides the inherited method to define responses for focus, mouse, and keyboard messages. It sends all others to its inherited WndProc.

When overriding WndProc to provide specialized responses to messages, call the inherited WndProc at the end to dispatch any unhandled messages.

C++ Examples:

```
/*
This example shows how to use the WndProc method and the
WindowProc property to subclass a custom control's window
```

```
procedure.  This example subclasses the window procedure of
a TListBox descendant to respond to a user-defined message
called WM_STYLEMESSAGE. The subclassed window procedure can
be turned on or off by pressing a radio button.
*/
class TMyListBoxDescendant : public TListBox
{
__published:    // IDE-managed Components
    void __fastcall SubClassWndProc(Messages::TMessage &Message);
    void __fastcall ToggleSubClass(bool On);
    void __fastcall OnDrawItemProc(
      TWinControl *Control, int Index, const TRect &Rect,

63.1.4.5 TOleControl Properties

The properties of the TOleControl class are listed here.

Protected Properties

	Name	Description
	ControlData (see page 6119)	This is ControlData, a member of class TOleControl.

Public Properties

	Name	Description
	Anchors (see page 6119)	Specifies how the control is anchored to its parent.
R	DefaultDispatch (see page 6120)	The default dispatch interface.
R	OleObject (see page 6120)	The ActiveX control associated with the TOleControl (see page 6074) object.
R	PerPropBrowsing (see page 6120)	Provides access to information about the property page properties of the OleControl.
	TabStop (see page 6121)	Determines if the user can tab to a control.

63.1.4.5.1 TOleControl.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

63.1.4.5.2 TOleControl.ControlData Property

Pascal

```
property ControlData: PControlData;
```

C++

```
__property PControlData ControlData;
```

Description

This is ControlData, a member of class TOleControl.

63.1.4.5.3 TOleControl.DefaultDispatch Property

The default dispatch interface.

Pascal

```
property DefaultDispatch: IDispatch;
```

C++

```
__property IDispatch DefaultDispatch;
```

Description

DefaultDispatch default dispatch interface that the TOleControl (see page 6074) object encapsulates. For those ActiveX controls that have multiple dispatch interfaces, one is typically identified as the default.

63.1.4.5.4 TOleControl.OleObject Property

The ActiveX control associated with the TOleControl (see page 6074) object.

Pascal

```
property OleObject: Variant;
```

C++

```
__property Variant OleObject;
```

Description

OleObject is used to get the ActiveX control that is associated with the TOleControl (see page 6074)

63.1.4.5.5 TOleControl.PerPropBrowsing Property

Provides access to information about the property page properties of the OleControl.

Pascal

```
property PerPropBrowsing: IPerPropertyBrowsing;
```

C++

```
__property IPerPropertyBrowsing PerPropBrowsing;
```

Description

PerPropBrowsing is an interface to information about the properties of the OleControl as they appear on the associated property page.

See Also

BrowseProperties (see page 6083)

63.1.4.5.6 TOleControl.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

TabOrder

63.1.4.6 TOleControl Events

The events of the TOleControl class are listed here.

Public Events

	Name	Description
	ServiceQuery (see page 6121)	This is ServiceQuery, a member of class TOleControl.

63.1.4.6.1 TOleControl.ServiceQuery Event

Pascal

```
property ServiceQuery: TServiceQuery;
```

C++

```
__property TServiceQuery ServiceQuery;
```

Description

This is ServiceQuery, a member of class TOleControl.

63.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	EmptyParam (see page 6122)	This is function OleCtrls.EmptyParam.
	FontToOleFont (see page 6122)	Returns a Variant containing an IFontDispatch interface that represents a TFont (see page 2730) object.
	OleFontToFont (see page 6123)	Fills in a TFont (see page 2730) structure to represent an IFontDispatch.

63.2.1 OleCtrls.EmptyParam Function

Pascal

```
function EmptyParam: OleVariant;
```

C++

```
OleVariant EmptyParam();
```

File

OleCtrls

Description

This is function OleCtrls.EmptyParam.

63.2.2 OleCtrls.FontToOleFont Function

Returns a Variant containing an IFontDispatch interface that represents a TFont (see page 2730) object.

Pascal

```
function FontToOleFont(Font: TFont): Variant;
```

C++

```
Variant FontToOleFont(TFont Font);
```

File

OleCtrls

Description

Use FontToOleFont to convert a font from TFont (see page 2730) to IFontDispatch format. The interface uses the TFont (see page 2730) object to implement the methods of the interface.

See Also

OleFontToFont (see page 6123)

OleStrToStrVar

StringToOleStr

OleStrToString

63.2.3 OleCtrls.OleFontToFont Function

Fills in a TFont (see page 2730) structure to represent an IFontDispatch.

Pascal

```
procedure OleFontToFont(const OleFont: Variant; Font: TFont);
```

C++

```
OleFontToFont(const Variant OleFont, TFont Font);
```

File

OleCtrls

Description

Use OleFontToFont to convert a font from COM (IFontDispatch) to TFont (see page 2730) format.

See Also

FontToOleFont (see page 6122)

OleStrToStrVar

StringToOleStr

OleStrToString

63.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Records

	Name	Description
	TControlData (see page 6124)	This is record OleCtrls.TControlData.
	TControlData2 (see page 6125)	This is record OleCtrls.TControlData2.
	TEnumValue (see page 6125)	This is record OleCtrls.TEnumValue.

63.3.1 OleCtrls.TControlData Record

Pascal

```
TControlData = record
  ClassID: TGUID;
  EventIID: TGUID;
  EventCount: Longint;
  EventDispIDs: Pointer;
  LicenseKey: Pointer;
  Flags: DWORD;
  Version: Integer;
  FontCount: Integer;
  FontIDs: PDispIDList;
  PictureCount: Integer;
  PictureIDs: PDispIDList;
  Reserved: Integer;
  InstanceCount: Integer;
  EnumPropDescs: TList;
end;
```

C++

```
struct TControlData {
  TGUID ClassID;
  TGUID EventIID;
  Longint EventCount;
  void * EventDispIDs;
  void * LicenseKey;
  DWORD Flags;
  int Version;
  int FontCount;
  PDispIDList FontIDs;
  int PictureCount;
  PDispIDList PictureIDs;
  int Reserved;
  int InstanceCount;
  TList EnumPropDescs;
};
```

File

OleCtrls

Description

This is record OleCtrls.TControlData.

63.3.2 OleCtrls.TControlData2 Record

Pascal

```
TControlData2 = record
  ClassID: TGUID;
  EventIID: TGUID;
  EventCount: Longint;
  EventDispIDs: Pointer;
  LicenseKey: Pointer;
  Flags: DWORD;
  Version: Integer;
  FontCount: Integer;
  FontIDs: PDispIDList;
  PictureCount: Integer;
  PictureIDs: PDispIDList;
  Reserved: Integer;
  InstanceCount: Integer;
  EnumPropDescs: TList;
  FirstEventOfs: Cardinal;
end;
```

C++

```
struct TControlData2 {
  TGUID ClassID;
  TGUID EventIID;
  Longint EventCount;
  void * EventDispIDs;
  void * LicenseKey;
  DWORD Flags;
  int Version;
  int FontCount;
  PDispIDList FontIDs;
  int PictureCount;
  PDispIDList PictureIDs;
  int Reserved;
  int InstanceCount;
  TList EnumPropDescs;
  unsigned FirstEventOfs;
};
```

File

OleCtrls

Description

This is record OleCtrls.TControlData2.

63.3.3 OleCtrls.TEnumValue Record

Pascal

```
TEnumValue = record
  Value: Longint;
  Ident: string;
end;
```

C++

```
struct TEnumValue {
  Longint Value;
  UnicodeString Ident;
};
```

File

OleCtrls

Description

This is record OleCtrls.TEnumValue.

63.4 Types

The following table lists types in this documentation.

Types

Name	Description
PControlData (see page 6127)	This is type OleCtrls.PControlData.
PControlData2 (see page 6127)	This is type OleCtrls.PControlData2.
PEnumValueList (see page 6128)	This is type OleCtrls.PEnumValueList.
TEnumValueList (see page 6128)	This is type OleCtrls.TEnumValueList.
TOleEnum (see page 6128)	This is type OleCtrls.TOleEnum.
TServiceQuery (see page 6129)	This is type OleCtrls.TServiceQuery.

63.4.1 OleCtrls.PControlData Type

Pascal

```
PControlData = ^TControlData;
```

C++

```
^TControlData PControlData;
```

File

OleCtrls

Description

This is type OleCtrls.PControlData.

63.4.2 OleCtrls.PControlData2 Type

Pascal

```
PControlData2 = ^TControlData2;
```

C++

```
^TControlData2 PControlData2;
```

File

OleCtrls

Description

This is type OleCtrls.PControlData2.

63.4.3 OleCtrls.PEnumValueList Type

Pascal

```
PEnumValueList = ^TEnumValueList;
```

C++

```
^TEnumValueList PEnumValueList;
```

File

OleCtrls

Description

This is type OleCtrls.PEnumValueList.

63.4.4 OleCtrls.TEnumValueList Type

Pascal

```
TEnumValueList = array[0..32767] of TEnumValue;
```

C++

```
array[0..32767] of TEnumValue TEnumValueList;
```

File

OleCtrls

Description

This is type OleCtrls.TEnumValueList.

63.4.5 OleCtrls.TOleEnum Type

Pascal

```
TOleEnum = ActiveX.TOleEnum;
```

C++

```
ActiveX.TOleEnum TOleEnum;
```

File

OleCtrls

Description

This is type OleCtrls.TOleEnum.

63.4.6 OleCtrls.TServiceQuery Type

Pascal

```
TServiceQuery = function (const rsid, iid: TGuid; out obj): HResult of object;
```

C++

```
(const rsid, iid: TGuid; out obj): HResult ( TServiceQuery)();
```

File

OleCtrls

Description

This is type OleCtrls.TServiceQuery.

64 OleServer Namespace

This is namespace OleServer.

Topics

Name	Description
Classes (see page 6132)	The following table lists classes in this documentation.
Structs, Records, Enums (see page 6148)	The following table lists structs, records, enums in this documentation.
Types (see page 6150)	The following table lists types in this documentation.

Classes

	Name	Description
	TOleServer (see page 6132)	TOleServer is the base class for components that represent an imported COM server.
	TServerEventDispatch (see page 6144)	This is class OleServer.TServerEventDispatch.

Structs, Records, Enums

	Name	Description
	TConnectKind (see page 6148)	This is record OleServer.TConnectKind.
	TServerData (see page 6148)	This is record OleServer.TServerData.

Types

Name	Description
PServerData (see page 6150)	This is type OleServer.PServerData.
TVariantArray (see page 6150)	This is type OleServer.TVariantArray.

64.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TOleServer (see page 6132)	TOleServer is the base class for components that represent an imported COM server.
	TServerEventDispatch (see page 6144)	This is class OleServer.TServerEventDispatch.

64.1.1 TOleServer Class

TOleServer is the base class for components that represent an imported COM server.

Class Hierarchy

Pascal

```
TOleServer = class(TComponent, IUnknown);
```

C++

```
class TOleServer : public TComponent, public IUnknown;
```

File

OleServer

Description

TOleServer is the base class for COM servers that are imported by choosing Project|Import Type Library from the IDE. TOleServer introduces several properties and methods that manage the connection to a COM server and for invoking its default events.

Descendants of TOleServer expose the properties, methods, and events of the server CoClass. When an application calls one of the TOleServer descendant's methods or sets one of its properties, the component automatically establishes a connection to the COM server. You can also connect explicitly by calling the Connect (see page 6136) method.

Do not create instances of TOleServer. TOleServer relies on abstract pure virtual methods to establish and break a connection to the COM server. Instead, use a descendant of TOleServer that wraps the desired server. Numerous TOleServer descendants are provided on the Servers tab of the Component Palette. In addition, you can create your own descendants by importing a server's type library.

See Also

Code Generated When You Import Type Library Information

64.1.1.1 TOleServer Members

The following tables list the members exposed by TOleServer.

Protected Methods

	Name	Description
	_AddRef (see page 6135)	Increments the reference count for the number of interface references dependent on the OLE server.
	_Release (see page 6136)	Decrements the reference count for the calling interface on a object.
	ConnectEvents (see page 6137)	Establishes a connection using the EventDispatch (see page 6143) property as an event sink.
	DisconnectEvents (see page 6137)	Terminates a connection that was established using the ConnectEvents (see page 6137) method.
	GetAutoConnect (see page 6138)	Returns the value of the AutoConnect (see page 6141) property.
	GetConnectKind (see page 6138)	Returns the value of the ConnectKind (see page 6142) property.
V	GetServer (see page 6138)	Returns an interface for the COM server.
A	InitServerData (see page 6139)	Initializes the ServerData (see page 6143) property to reflect the type library information of the COM server.
V	InvokeEvent (see page 6139)	Dispatches an event from the COM server to the appropriate event handler.
V	Loaded (see page 6140)	Connects to the COM server when the Loaded object is first loaded into memory if AutoConnect (see page 6141) is True true.
V	QueryInterface (see page 6140)	Returns a reference to a specified interface if the OLE server supports that interface.
	SetAutoConnect (see page 6140)	Sets the value of the AutoConnect (see page 6141) property.
	SetConnectKind (see page 6141)	Sets the value of the ConnectKind (see page 6142) property.

Protected Properties

	Name	Description
	EventDispatch (see page 6143)	This is EventDispatch, a member of class TOleServer.
	ServerData (see page 6143)	Encodes information about the COM server to which ServerData connects.

Public Methods

	Name	Description
A	Connect (see page 6136)	Establishes a connection to the COM server.
V	Create (see page 6133)	Allocates memory and constructs a safely initialized instance of a component.
V	Destroy (see page 6134)	Disposes of the component and its owned components.
A	Disconnect (see page 6137)	Terminates the connection to the COM server.

Published Properties

	Name	Description
	AutoConnect (see page 6141)	Specifies whether the component automatically connects to the server.
	ConnectKind (see page 6142)	Indicates the type of process to which the ConnectKind component establishes a connection.
	RemoteMachineName (see page 6143)	Specifies the machine running the COM server when ConnectKind (see page 6142) is ckRemote.

64.1.1.2 TOleServer.Create Constructor

Allocates memory and constructs a safely initialized instance of a component.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TOleServer(TComponent * AOwner);
```

Description

All objects have a Create method that constructs the object. TComponent redefines Create so that, for components, Create also:

establishes the relationship of a component and its Owner, as indicated by the AOwner parameter

sets the ComponentStyle property to csInheritable, meaning that the component can be inherited by a descendant form type

It is not necessary to explicitly create components added in the form designer. These components are created automatically when the application is run, and they are destroyed when the application is closed.

For components created programmatically, that is, not created in the form designer, call Create and pass in an owner component as the AOwner parameter. The owner disposes of the component when it is destroyed. If the component is not owned, then use Free when it needs to be destroyed.

Tip: When passing in Self as the Owner parameter, consider what Self references. If a component creates another component in one of its methods, then Self refers to the first component and not the component being created, which is then owned by the first component.

Note: The TComponent constructor is virtual in part to allow polymorphic instantiation of class references. This is critical to the streaming system and to the form designer. Do not forget to use the override directive when declaring a new component's Create constructor.

Components

ComponentStyle

System::TObject::Create

Destroy

System::TObject::Free

Owner

64.1.1.3 TOleServer.Destroy Destructor

Disposes of the component and its owned components.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TOleServer();
```

Description

Do not call Destroy directly. Call Free instead. Free verifies that the component is not nil, and only then calls Destroy.

Never explicitly free a component in one of its own event handlers, nor free a component from the event handler of a component that it owns or contains.

To destroy a form, call its Release method. Release waits for all the form's event handlers and the event handlers of the form's components to finish executing before destroying the form.

Note: A form owns all the controls and non-visual components that are placed on it in design mode. When it is freed, all of these components are automatically freed as well. By default, all forms are owned by the global Application object. When an application terminates, it frees the global Application object, which frees all forms. For objects that are not components, and for components created with a nil owner, be sure to call Free after finishing with the object; otherwise the memory allocated for the object will be lost until the application terminates.

Components

64.1.1.4 TOleServer Methods

The methods of the TOleServer class are listed here.

Protected Methods

	Name	Description
	_AddRef (see page 6135)	Increments the reference count for the number of interface references dependent on the OLE server.
	_Release (see page 6136)	Decrements the reference count for the calling interface on a object.
	ConnectEvents (see page 6137)	Establishes a connection using the EventDispatch (see page 6143) property as an event sink.
	DisconnectEvents (see page 6137)	Terminates a connection that was established using the ConnectEvents (see page 6137) method.
	GetAutoConnect (see page 6138)	Returns the value of the AutoConnect (see page 6141) property.
	GetConnectKind (see page 6138)	Returns the value of the ConnectKind (see page 6142) property.
V	GetServer (see page 6138)	Returns an interface for the COM server.
A	InitServerData (see page 6139)	Initializes the ServerData (see page 6143) property to reflect the type library information of the COM server.
V	InvokeEvent (see page 6139)	Dispatches an event from the COM server to the appropriate event handler.
V	Loaded (see page 6140)	Connects to the COM server when the Loaded object is first loaded into memory if AutoConnect (see page 6141) is True true.
V	QueryInterface (see page 6140)	Returns a reference to a specified interface if the OLE server supports that interface.
	SetAutoConnect (see page 6140)	Sets the value of the AutoConnect (see page 6141) property.
	SetConnectKind (see page 6141)	Sets the value of the ConnectKind (see page 6142) property.

Public Methods

	Name	Description
A	Connect (see page 6136)	Establishes a connection to the COM server.
A	Disconnect (see page 6137)	Terminates the connection to the COM server.

64.1.1.4.1 TOleServer._AddRef Method

Increments the reference count for the number of interface references dependent on the OLE server.

Pascal

```
function _AddRef: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _AddRef();
```

Description

_AddRef implements the IUnknown interface method, AddRef, which increments the reference count of objects using the OLE server's interface. _AddRef returns the resulting value of the reference count.

See Also

Invoke

QueryInterface (see page 6140)

_Release (see page 6136)

64.1.1.4.2 TOleServer._Release Method

Decrements the reference count for the calling interface on a object.

Pascal

```
function _Release: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _Release();
```

Description

_Release implements the IUnknown interface method, Release, which decrements the reference count of objects using the OLE server's interface. If the reference count on the interface falls to 0, the server object is freed from memory.

_Release returns the resulting value of the reference count.

See Also

Invoke

QueryInterface (see page 6140)

_AddRef (see page 6135)

64.1.1.4.3 TOleServer.Connect Method

Establishes a connection to the COM server.

Pascal

```
procedure Connect; virtual; abstract;
```

C++

```
virtual __fastcall Connect() = 0;
```

Description

Call Connect to connect the Connect component to the COM server it represents. If the AutoConnect (see page 6141) property is True true, the Connect component automatically calls Connect when the application is first run.

Do not use Connect if the value of ConnectKind (see page 6142) is ckAttachToInterface. When attaching to an interface, use the ConnectTo method, which is introduced by descendant classes, instead.

If the value of ConnectKind (see page 6142) is ckRemote, the RemoteMachineName (see page 6143) property must be set before calling Connect.

Connect introduces Connect as an abstract a pure virtual method. Descendant classes must override this method to let the Connect component connect to a specific type of COM server.

See Also

AutoConnect (see page 6141)

ConnectKind (see page 6142)

RemoteMachineName (see page 6143)

Disconnect (see page 6137)

Using Component Wrappers

64.1.1.4.4 TOleServer.ConnectEvents Method

Establishes a connection using the EventDispatch (see page 6143) property as an event sink.

Pascal

```
procedure ConnectEvents(const Obj: IUnknown);
```

C++

```
__fastcall ConnectEvents(const IUnknown Obj);
```

Description

ConnectEvents descendants use ConnectEvents internally to implement their event handlers for events on the COM server. If the ConnectEvents descendant does not expose any server events, ConnectEvents is not used.

The Obj parameter is an interface for the COM server that generates events.

See Also

EventDispatch (see page 6143)

DisconnectEvents (see page 6137)

64.1.1.4.5 TOleServer.Disconnect Method

Terminates the connection to the COM server.

Pascal

```
procedure Disconnect; virtual; abstract;
```

C++

```
virtual __fastcall Disconnect() = 0;
```

Description

Call Disconnect to terminate a connection formed using the Connect (see page 6136) method.

Disconnect introduces Disconnect as an abstract a pure virtual method. Descendant classes must override this method to let the Disconnect component disconnect from a specific type of COM server.

See Also

Connect (see page 6136)

Using Component Wrappers

64.1.1.4.6 TOleServer.DisconnectEvents Method

Terminates a connection that was established using the ConnectEvents (see page 6137) method.

Pascal

```
procedure DisconnectEvents(const Obj: Iunknown);
```

C++

```
__fastcall DisconnectEvents(const Iunknown Obj);
```

Description

DisconnectEvents descendants use DisconnectEvents internally to terminate the connection established by ConnectEvents (see page 6137). If the DisconnectEvents descendant does not expose any server events, DisconnectEvents is not used.

The Obj parameter is an interface for the COM server that generates events.

See Also

ConnectEvents (see page 6137)

64.1.1.4.7 TOleServer.GetAutoConnect Method

Returns the value of the AutoConnect (see page 6141) property.

Pascal

```
function GetAutoConnect: Boolean;
```

C++

```
__fastcall Boolean GetAutoConnect();
```

Description

GetAutoConnect is the protected read implementation for the AutoConnect (see page 6141) property.

See Also

AutoConnect (see page 6141)

64.1.1.4.8 TOleServer.GetConnectKind Method

Returns the value of the ConnectKind (see page 6142) property.

Pascal

```
function GetConnectKind: TConnectKind;
```

C++

```
__fastcall TConnectKind GetConnectKind();
```

Description

GetConnectKind is the protected read implementation for the ConnectKind (see page 6142) property.

See Also

ConnectKind (see page 6142)

64.1.1.4.9 TOleServer.GetServer Method

Returns an interface for the COM server.

Pascal

```
function GetServer: IUnknown; virtual;
```

C++

```
virtual __fastcall IUnknown GetServer();
```

Description

GetServer descendants call GetServer from the implementation of their Connect (see page 6136) methods. GetServer obtains an interface for the COM server described by ServerData (see page 6143). The ConnectKind (see page 6142) property indicates how GetServer can obtain the interface.

See Also

Connect (see page 6136)

ConnectKind (see page 6142)

ServerData (see page 6143)

64.1.1.4.10 TOleServer.InitServerData Method

Initializes the ServerData (see page 6143) property to reflect the type library information of the COM server.

Pascal

```
procedure InitServerData; virtual; abstract;
```

C++

```
virtual __fastcall InitServerData() = 0;
```

Description

The InitServerData constructor calls InitServerData to initialize ServerData (see page 6143) with information from the COM server's type library.

InitServerData is an abstract a pure virtual method in InitServerData. Each InitServerData descendant implements this method so that the ServerData (see page 6143) property reflects its particular COM server.

See Also

ServerData (see page 6143)

Create (see page 6133)

64.1.1.4.11 TOleServer.InvokeEvent Method

Dispatches an event from the COM server to the appropriate event handler.

Pascal

```
procedure InvokeEvent(DispID: TDispID; var Params: TVariantArray); virtual;
```

C++

```
virtual __fastcall InvokeEvent(TDispID DispID, TVariantArray Params);
```

Description

InvokeEvent descendants use InvokeEvent internally to link their event handlers to events on the COM server.

DispID is the dispatch ID for the appropriate event handler.

Params passes the parameters of the event handler as an array of OleVariants.

As implemented in InvokeEvent, InvokeEvent does nothing, because InvokeEvent has no events. Descendants that surface events from a COM server override this method so that the event sink specified by EventDispatch (see page 6143) can pass

events on to the appropriate event handlers.

See Also

EventDispatch (see page 6143)

64.1.1.4.12 TOleServer.Loaded Method

Connects to the COM server when the Loaded object is first loaded into memory if AutoConnect (see page 6141) is True true.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

The VCL streaming system automatically calls Loaded after the Loaded component is loaded into memory.

Loaded checks the AutoConnect (see page 6141) property, and if it is True true, calls the Connect (see page 6136) method to establish a connection.

See Also

AutoConnect (see page 6141)

Loaded

64.1.1.4.13 TOleServer.QueryInterface Method

Returns a reference to a specified interface if the OLE server supports that interface.

Pascal

```
function QueryInterface(const IID: TGUID; out Obj): HResult; override;
```

C++

```
virtual __fastcall HRESULT QueryInterface(const TGUID IID,  Obj);
```

Description

QueryInterface implements the IUnknown interface method QueryInterface. QueryInterface returns a reference to the interface specified by the IID parameter as the Obj parameter. If the OLE server does not support the interface, the Obj parameter returns nil NULL and QueryInterface returns a nonzero error code.

See Also

_AddRef (see page 6135)

_Release (see page 6136)

Invoke

64.1.1.4.14 TOleServer.SetAutoConnect Method

Sets the value of the AutoConnect (see page 6141) property.

Pascal

```
procedure SetAutoConnect(flag: Boolean);
```

C++

```
__fastcall SetAutoConnect(Boolean flag);
```

Description

SetAutoConnect is the protected write implementation for the AutoConnect (see page 6141) property.

See Also

AutoConnect (see page 6141)

64.1.1.4.15 TOleServer.SetConnectKind Method

Sets the value of the ConnectKind (see page 6142) property.

Pascal

```
procedure SetConnectKind(ck: TConnectKind);
```

C++

```
__fastcall SetConnectKind(TConnectKind ck);
```

Description

SetConnectKind is the protected write implementation for the ConnectKind (see page 6142) property.

See Also

ConnectKind (see page 6142)

64.1.1.5 TOleServer Properties

The properties of the TOleServer class are listed here.

Protected Properties

	Name	Description
	EventDispatch (see page 6143)	This is EventDispatch, a member of class TOleServer.
	ServerData (see page 6143)	Encodes information about the COM server to which ServerData connects.

Published Properties

	Name	Description
	AutoConnect (see page 6141)	Specifies whether the component automatically connects to the server.
	ConnectKind (see page 6142)	Indicates the type of process to which the ConnectKind component establishes a connection.
	RemoteMachineName (see page 6143)	Specifies the machine running the COM server when ConnectKind (see page 6142) is ckRemote.

64.1.1.5.1 TOleServer.AutoConnect Property

Specifies whether the component automatically connects to the server.

Pascal

```
property AutoConnect: Boolean;
```

C++

```
__property Boolean AutoConnect;
```

Description

Set AutoConnect to True true to specify whether the server should be loaded automatically when the application first starts up. If AutoConnect is False false, the application establishes a connection when it calls one of the AutoConnect descendant's methods, sets a property, or calls the Connect (see page 6136) method.

Note: AutoConnect only establishes a connection when the application is first run. Changing the AutoConnect property at runtime has no effect.

See Also

Connect (see page 6136)

Using Component Wrappers

64.1.1.5.2 TOleServer.ConnectKind Property

Indicates the type of process to which the ConnectKind component establishes a connection.

Pascal

```
property ConnectKind: TConnectKind;
```

C++

```
__property TConnectKind ConnectKind;
```

Description

Set ConnectKind to indicate how the ConnectKind component establishes a connection. ConnectKind establishes the connection when the application is run (if AutoConnect (see page 6141) is True true) or when the application calls the Connect (see page 6136) (or ConnectTo) method.

The following table lists the possible values:

Value	Meaning
ckRunningOrNew	Attach to a running server or create a new instance of the server.
ckNewInstance	Always create a new instance of the server.
ckRunningInstance	Only attach to a running instance of the server.
ckRemote	Bind to a remote instance of the server. When using this option, you must supply a value for RemoteMachineName (see page 6143).
ckAttachToInterface	Don't bind to the server. Instead, the application supplies an interface using the ConnectTo method, which is introduced in descendant classes. This option can't be used with the AutoConnect (see page 6141) property.

See Also

Connect (see page 6136)

RemoteMachineName (see page 6143)

AutoConnect (see page 6141)

Using Component Wrappers

64.1.1.5.3 TOleServer.EventDispatch Property

Pascal

```
property EventDispatch: TServerEventDispatch;
```

C++

```
__property TServerEventDispatch EventDispatch;
```

Description

This is EventDispatch, a member of class TOleServer.

64.1.1.5.4 TOleServer.RemoteMachineName Property

Specifies the machine running the COM server when ConnectKind (see page 6142) is ckRemote.

Pascal

```
property RemoteMachineName: string;
```

C++

```
__property UnicodeString RemoteMachineName;
```

Description

Use RemoteMachineName when the COM server instance is running remotely on another machine. Specify the name of the machine on which the COM server is running as the value of RemoteMachineName.

Note: RemoteMachineName is only used if ConnectKind (see page 6142) is ckRemote. Setting RemoteMachineName to a non-empty string sets ConnectKind (see page 6142) to ckRemote.

See Also

ConnectKind (see page 6142)

Connect (see page 6136)

Using Component Wrappers

64.1.1.5.5 TOleServer.ServerData Property

Encodes information about the COM server to which ServerData connects.

Pascal

```
property ServerData: PServerData;
```

C++

```
__property PServerData ServerData;
```

Description

ServerData uses ServerData internally to store type library information describing its COM server. Each ServerData descendant initializes this property in the constructor, specifying the information it needs to establish a connection.

See Also

InitServerData (see page 6139)

64.1.2 TServerEventDispatch Class

Class Hierarchy

Pascal

```
TServerEventDispatch = class(TObject, IUnknown, IDispatch);
```

C++

```
class TServerEventDispatch : public TObject, public IUnknown, public IDispatch;
```

File

OleServer

Description

This is class OleServer.TServerEventDispatch.

64.1.2.1 TServerEventDispatch Members

The following tables list the members exposed by TServerEventDispatch.

Protected Methods

	Name	Description
	_AddRef (see page 6145)	This is _AddRef, a member of class TServerEventDispatch.
	_Release (see page 6145)	This is _Release, a member of class TServerEventDispatch.
	GetIDsOfNames (see page 6145)	This is GetIDsOfNames, a member of class TServerEventDispatch.
	GetTypeInfo (see page 6146)	This is GetTypeInfo, a member of class TServerEventDispatch.
	GetTypeInfoCount (see page 6146)	This is GetTypeInfoCount, a member of class TServerEventDispatch.
	Invoke (see page 6146)	This is Invoke, a member of class TServerEventDispatch.
	QueryInterface (see page 6146)	This is QueryInterface, a member of class TServerEventDispatch.
	ServerDisconnect (see page 6147)	This is ServerDisconnect, a member of class TServerEventDispatch.

Protected Properties

	Name	Description
	Server (see page 6147)	This is Server, a member of class TServerEventDispatch.

Public Methods

	Name	Description
	Create (see page 6144)	This is Create, a member of class TServerEventDispatch.

64.1.2.2 TServerEventDispatch.Create Constructor

Pascal

```
constructor Create(Server: TOleServer);
```

C++

```
__fastcall TServerEventDispatch(TOleServer Server);
```

Description

This is Create, a member of class TServerEventDispatch.

64.1.2.3 TServerEventDispatch Methods

The methods of the TServerEventDispatch class are listed here.

Protected Methods

	Name	Description
	_AddRef (see page 6145)	This is _AddRef, a member of class TServerEventDispatch.
	_Release (see page 6145)	This is _Release, a member of class TServerEventDispatch.
	GetIDsOfNames (see page 6145)	This is GetIDsOfNames, a member of class TServerEventDispatch.
	GetTypeInfo (see page 6146)	This is GetTypeInfo, a member of class TServerEventDispatch.
	GetTypeInfoCount (see page 6146)	This is GetTypeInfoCount, a member of class TServerEventDispatch.
	Invoke (see page 6146)	This is Invoke, a member of class TServerEventDispatch.
	QueryInterface (see page 6146)	This is QueryInterface, a member of class TServerEventDispatch.
	ServerDisconnect (see page 6147)	This is ServerDisconnect, a member of class TServerEventDispatch.

64.1.2.3.1 TServerEventDispatch._AddRef Method

Pascal

```
function _AddRef: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _AddRef();
```

Description

This is _AddRef, a member of class TServerEventDispatch.

64.1.2.3.2 TServerEventDispatch._Release Method

Pascal

```
function _Release: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _Release();
```

Description

This is _Release, a member of class TServerEventDispatch.

64.1.2.3.3 TServerEventDispatch.GetIDsOfNames Method

Pascal

```
function GetIDsOfNames(const IID: TGUID; Names: Pointer; NameCount: Integer; LocaleID:
Integer; DispIDs: Pointer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetIDsOfNames(const TGUID IID, void * Names, int NameCount, int
```

```
  LocaleID, void * DispIDs);
```

Description

This is GetIDsOfNames, a member of class TServerEventDispatch.

64.1.2.3.4 TServerEventDispatch.GetTypeInfo Method

Pascal

```
function GetTypeInfo(Index: Integer; LocaleID: Integer; out TypeInfo): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetTypeInfo(int Index, int LocaleID,  TypeInfo);
```

Description

This is GetTypeInfo, a member of class TServerEventDispatch.

64.1.2.3.5 TServerEventDispatch.GetTypeInfoCount Method

Pascal

```
function GetTypeInfoCount(out Count: Integer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetTypeInfoCount(int Count);
```

Description

This is GetTypeInfoCount, a member of class TServerEventDispatch.

64.1.2.3.6 TServerEventDispatch.Invoke Method

Pascal

```
function Invoke(DispID: Integer; const IID: TGUID; LocaleID: Integer; Flags: Word; var Params;
VarResult: Pointer; ExcepInfo: Pointer; ArgErr: Pointer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT Invoke(int DispID, const TGUID IID, int LocaleID, Word Flags,
Params, void * VarResult, void * ExcepInfo, void * ArgErr);
```

Description

This is Invoke, a member of class TServerEventDispatch.

64.1.2.3.7 TServerEventDispatch.QueryInterface Method

Pascal

```
function QueryInterface(const IID: TGUID; out Obj): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT QueryInterface(const TGUID IID,  Obj);
```

Description

This is QueryInterface, a member of class TServerEventDispatch.

64.1.2.3.8 TServerEventDispatch.ServerDisconnect Method

Pascal

```
function ServerDisconnect: Boolean;
```

C++

```
__fastcall Boolean ServerDisconnect();
```

Description

This is ServerDisconnect, a member of class TServerEventDispatch.

64.1.2.4 TServerEventDispatch Properties

The properties of the TServerEventDispatch class are listed here.

Protected Properties

	Name	Description
	Server (see page 6147)	This is Server, a member of class TServerEventDispatch.

64.1.2.4.1 TServerEventDispatch.Server Property

Pascal

```
property Server: TOleServer;
```

C++

```
__property TOleServer Server;
```

Description

This is Server, a member of class TServerEventDispatch.

64.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TConnectKind (see page 6148)	This is record OleServer.TConnectKind.

Records

	Name	Description
	TServerData (see page 6148)	This is record OleServer.TServerData.

64.2.1 OleServer.TConnectKind Enumeration

Pascal

```
TConnectKind = (
  ckRunningOrNew,
  ckNewInstance,
  ckRunningInstance,
  ckRemote,
  ckAttachToInterface
);
```

C++

```
enum TConnectKind {
  ckRunningOrNew,
  ckNewInstance,
  ckRunningInstance,
  ckRemote,
  ckAttachToInterface
};
```

File

OleServer

Description

This is record OleServer.TConnectKind.

64.2.2 OleServer.TServerData Record

Pascal

```
TServerData = record
  ClassID: TGUID;
  IntfIID: TGUID;
  EventIID: TGUID;
  LicenseKey: Pointer;
  Version: Integer;
  InstanceCount: Integer;
```

```
  end;
```

C++

```
  struct TServerData {
    TGUID ClassID;
    TGUID IntfIID;
    TGUID EventIID;
    void * LicenseKey;
    int Version;
    int InstanceCount;
  };
```

File

OleServer

Description

This is record OleServer.TServerData.

64.3 Types

The following table lists types in this documentation.

Types

Name	Description
PServerData (see page 6150)	This is type OleServer.PServerData.
TVariantArray (see page 6150)	This is type OleServer.TVariantArray.

64.3.1 OleServer.PServerData Type

Pascal

```
PServerData = ^TServerData;
```

C++

```
^TServerData PServerData;
```

File

OleServer

Description

This is type OleServer.PServerData.

64.3.2 OleServer.TVariantArray Type

Pascal

```
TVariantArray = Array of OleVariant;
```

C++

```
Array of OleVariant TVariantArray;
```

File

OleServer

Description

This is type OleServer.TVariantArray.

65 OPConvert Namespace

This is namespace OPConvert.

Topics

Name	Description
Interfaces (see page 6152)	The following table lists interfaces in this documentation.
Structs, Records, Enums (see page 6162)	The following table lists structs, records, enums in this documentation.
Types (see page 6163)	The following table lists types in this documentation.

Interfaces

	Name	Description
	IOPConvert (see page 6152)	IOPConvert is the interface for marshaling and unmarshaling method calls on an invokable interface.

Structs, Records, Enums

	Name	Description
	TSOAPConvertOption (see page 6162)	This is record OPConvert.TSOAPConvertOption.

Types

Name	Description
TSOAPConvertOptions (see page 6163)	This is type OPConvert.TSOAPConvertOptions.

65.1 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IOPConvert (see page 6152)	IOPConvert is the interface for marshaling and unmarshaling method calls on an invokable interface.

65.1.1 IOPConvert Interface

IOPConvert is the interface for marshaling and unmarshaling method calls on an invokable interface.

Class Hierarchy

Pascal

```
IOPConvert = interface;
```

C++

```
__interface IOPConvert;
```

File

OPConvert

Description

IOPConvert is implemented by classes that marshal and unmarshal method calls in Web Service applications. It defines methods for marshaling and unmarshaling method calls, as well as any exceptions that occur when attempting to execute those method calls.

The IOPConvert interface is used by remote interfaced objects on the client (TRIO descendants) and invoker components on the server (TSoapPascalInvoker descendants). Both the remote interfaced object and the invoker classes use the same IOPConvert implementation class, which represents a single encoding system (such as SOAP).

Classes that implement IOPConvert use the runtime type information (RTTI) on an invokable interface to interpret or encode method calls. They do not execute these calls, but rather, convert between transportable strings that are the encoding of interface method calls and an invocation context (TInvContext (see page 4369) object).

Note: C++ method declarations that use IOPConvert use the _di_IOPConvert type instead. This type is a DelphiInterface wrapper around the IOPConvert interface:

```
typedef System::DelphiInterfaceDelphiInterface_object< IOPConvert >  _di_IOPConvert;
```

See Also

TOPToSoapDomConvert (see page 6167)

TRio

TSoapPascalInvoker

TInvContext (see page 4369)

65.1.1.1 IOPConvert Members

The following tables list the members exposed by IOPConvert.

Public Methods

	Name	Description
	GetAttachments (see page 6154)	Returns the value of the Attachments (see page 6160) property.
	GetEncoding (see page 6154)	Returns the value of the Encoding (see page 6160) property.
	GetOptions (see page 6154)	Returns the value of the Options (see page 6161) property.
	GetTempDir (see page 6154)	Returns the value of the TempDir (see page 6161) property.
	InvContextToMsg (see page 6155)	Marshals a method call from an invocation context to a transportable string.
	MakeFault (see page 6155)	Encodes an exception that was raised when trying to execute a method on an invokable interface.
	MakeResponse (see page 6156)	Encodes the results of successfully executing a method on an invokable interface.
	MsgToInvContext (see page 6156)	This is the overview for the MsgToInvContext method overload.
	ProcessResponse (see page 6157)	This is the overview for the ProcessResponse method overload.
	SetAttachments (see page 6158)	Sets the value of the Attachments (see page 6160) property.
	SetEncoding (see page 6159)	Sets the value of the Encoding (see page 6160) property.
	SetOptions (see page 6159)	Sets the value of the Options (see page 6161) property.
	SetTempDir (see page 6159)	Sets the value of the TempDir (see page 6161) property.

Public Properties

	Name	Description
	Attachments (see page 6160)	Lists the objects that encapsulate the attachments included with the SOAP request or its response.
	Encoding (see page 6160)	Indicates the character set to use for encoded method calls.
	Options (see page 6161)	Controls how certain types of conversions are performed.
	TempDir (see page 6161)	Specifies the directory where temporary files for attachments are saved.

65.1.1.2 IOPConvert Methods

The methods of the IOPConvert class are listed here.

Public Methods

	Name	Description
	GetAttachments (see page 6154)	Returns the value of the Attachments (see page 6160) property.
	GetEncoding (see page 6154)	Returns the value of the Encoding (see page 6160) property.
	GetOptions (see page 6154)	Returns the value of the Options (see page 6161) property.
	GetTempDir (see page 6154)	Returns the value of the TempDir (see page 6161) property.
	InvContextToMsg (see page 6155)	Marshals a method call from an invocation context to a transportable string.
	MakeFault (see page 6155)	Encodes an exception that was raised when trying to execute a method on an invokable interface.
	MakeResponse (see page 6156)	Encodes the results of successfully executing a method on an invokable interface.
	MsgToInvContext (see page 6156)	This is the overview for the MsgToInvContext method overload.
	ProcessResponse (see page 6157)	This is the overview for the ProcessResponse method overload.
	SetAttachments (see page 6158)	Sets the value of the Attachments (see page 6160) property.
	SetEncoding (see page 6159)	Sets the value of the Encoding (see page 6160) property.
	SetOptions (see page 6159)	Sets the value of the Options (see page 6161) property.
	SetTempDir (see page 6159)	Sets the value of the TempDir (see page 6161) property.

65.1.1.2.1 IOPConvert.GetAttachments Method

Returns the value of the Attachments (see page 6160) property.

Pascal

```
function GetAttachments: TSoapDataList;
```

C++

```
__fastcall TSoapDataList GetAttachments();
```

Description

GetAttachments is the read implementation for the Attachments (see page 6160) property.

See Also

Attachments (see page 6160)

65.1.1.2.2 IOPConvert.GetEncoding Method

Returns the value of the Encoding (see page 6160) property.

Pascal

```
function GetEncoding: DOMString;
```

C++

```
__fastcall DOMString GetEncoding();
```

Description

GetEncoding is the read implementation for the Encoding (see page 6160) property.

See Also

Encoding (see page 6160)

65.1.1.2.3 IOPConvert.GetOptions Method

Returns the value of the Options (see page 6161) property.

Pascal

```
function GetOptions: TSOAPConvertOptions;
```

C++

```
__fastcall TSOAPConvertOptions GetOptions();
```

Description

GetOptions is the read implementation for the Options (see page 6161) property.

See Also

Options (see page 6161)

65.1.1.2.4 IOPConvert.GetTempDir Method

Returns the value of the TempDir (see page 6161) property.

Pascal

```
function GetTempDir: string;
```

C++

```
__fastcall UnicodeString GetTempDir();
```

Description

GetTempDir is the read implementation for the TempDir (see page 6161) property.

See Also

TempDir (see page 6161)

65.1.1.2.5 IOPConvert.InvContextToMsg Method

Marshals a method call from an invocation context to a transportable string.

Pascal

```
function InvContextToMsg(const IntfMD: TIntfMetaData; MethNum: Integer; Con: TInvContext;
Headers: THeaderList): TStream;
```

C++

```
__fastcall TStream InvContextToMsg(const TIntfMetaData IntfMD, int MethNum, TInvContext Con,
THeaderList Headers);
```

Description

InvContextToMsg looks up a specified method call, including the types and values of any arguments, from an invocation context, and returns an encoded version of that method call that can be transported to the application that executes it.

IntfMD represents the runtime type information (RTTI) from the interface whose method is called.

MethNum identifies the called method by its position in the interface's method table.

Con is the invocation context that contains details of the method call, including the parameter values passed in, the calling conventions, and any other temporary data used when making the call.

Headers is a list of TSOAPHeader (see page 4448) descendants that represent the headers of the SOAP envelope that contained the method call.

InvContextToMsg returns a stream from which an application can read the encoded version of the method call. This encoded method call can then be passed to an IWebNode interface for execution.

See Also

MsgToInvContext (see page 6157)

Execute

65.1.1.2.6 IOPConvert.MakeFault Method

Encodes an exception that was raised when trying to execute a method on an invokable interface.

Pascal

```
procedure MakeFault(const Ex: Exception; EStream: TStream);
```

C++

```
__fastcall MakeFault(const Exception Ex, TStream EStream);
```

Description

MakeFault encodes an exception that a Web Service application catches when trying to execute a method on an invokable interface. It generates an encoded exception packet, which the client can decode and use to raise the exception on the client application.

Ex is the exception object that represents the exception that occurred.

EStream is a stream to which MakeFault writes the encoded exception packet.

See Also

MakeResponse (see page 6156)

65.1.1.2.7 IOPConvert.MakeResponse Method

Encodes the results of successfully executing a method on an invokable interface.

Pascal

```
procedure MakeResponse(const IntfMD: TIntfMetaData; const MethNum: Integer; Context:
TInvContext; Response: TStream; Headers: THeaderList);
```

C++

```
__fastcall MakeResponse(const TIntfMetaData IntfMD, const int MethNum, TInvContext Context,
TStream Response, THeaderList Headers);
```

Description

MakeResponse retrieves the results of executing a method on an invokable interface from an invocation context and packages them into a transportable string, which it writes to a stream. This string is passed back to the client, which can unpack it using the ProcessResponse (see page 6158) method.

IntfMD represents the runtime type information (RTTI) from the interface whose method was executed.

MethNum identifies the called method by its position in the interface's method table.

Context is the invocation context that contains details of the method call.

Response is a stream to which MakeResponse writes the encoded version of the method result and any output parameters.

Headers is a list of TSOAPHeader (see page 4448) descendants that represent the headers that should be added to the response message.

See Also

MakeFault (see page 6155)

ProcessResponse (see page 6158)

65.1.1.2.8 MsgToInvContext Method

This is the overview for the MsgToInvContext method overload.

Overload List

	Name	Description
	IOPConvert.MsgToInvContext (InvString, TIntfMetaData, Integer, TInvContext) (see page 6157)	Unpacks an encoded method call into an invocation context so that it can be executed.

	IOPConvert.MsgToInvContext (TStream, TIntfMetaData, Integer, TInvContext, THeaderList) (see page 6157)	Unpacks an encoded method call into an invocation context so that it can be executed.

65.1.1.2.8.1 IOPConvert.MsgToInvContext Method (InvString, TIntfMetaData, Integer, TInvContext)

Unpacks an encoded method call into an invocation context so that it can be executed.

Pascal

```
procedure MsgToInvContext(const Request: InvString; const IntfMD: TIntfMetaData; var MethNum:
Integer; Context: TInvContext); overload;
procedure MsgToInvContext(const Request: TStream; const IntfMD: TIntfMetaData; var MethNum:
Integer; Context: TInvContext; Headers: THeaderList); overload;
```

C++

```
__fastcall MsgToInvContext(const InvString Request, const TIntfMetaData IntfMD, int MethNum,
TInvContext Context);
__fastcall MsgToInvContext(const TStream Request, const TIntfMetaData IntfMD, int MethNum,
TInvContext Context, THeaderList Headers);
```

Description

MsgToInvContext takes an encoded message that a server application receives and uses it to fill out an invocation context, which can then be used to execute the method call.

Request is the encoded method call, or a stream from which to read that method call. It is generated on the client by a call to InvContextToMsg (see page 6155).

IntfMD represents the runtime type information (RTTI) from the interface whose method is called.

MethNum returns the position of the called method in the interface's method table.

Context is the invocation context to which this method adds the information encoded in Request.

Headers is an object list to which MsgToInvContext adds TSOAPHeader (see page 4448) descendants to represent every header in the encoded message.

See Also

InvContextToMsg (see page 6155)

65.1.1.2.9 ProcessResponse Method

This is the overview for the ProcessResponse method overload.

Overload List

	Name	Description
	IOPConvert.ProcessResponse (InvString, TIntfMetaData, TIntfMethEntry, TInvContext) (see page 6158)	Unpacks the response packet from a method call into an invocation context.
	IOPConvert.ProcessResponse (TStream, TIntfMetaData, TIntfMethEntry, TInvContext, THeaderList) (see page 6158)	Unpacks the response packet from a method call into an invocation context.

65.1.1.2.9.1 IOPConvert.ProcessResponse Method (InvString, TIntfMetaData, TIntfMethEntry, TInvContext)

Unpacks the response packet from a method call into an invocation context.

Pascal

```
procedure ProcessResponse(const Resp: TStream; const IntfMD: TIntfMetaData; const MD:
TIntfMethEntry; Context: TInvContext; Headers: THeaderList); overload;
procedure ProcessResponse(const Resp: InvString; const IntfMD: TIntfMetaData; const MD:
TIntfMethEntry; Context: TInvContext); overload; deprecated;
```

C++

```
__fastcall ProcessResponse(const TStream Resp, const TIntfMetaData IntfMD, const
TIntfMethEntry MD, TInvContext Context, THeaderList Headers);
__fastcall ProcessResponse(const InvString Resp, const TIntfMetaData IntfMD, const
TIntfMethEntry MD, TInvContext Context);
```

Description

ProcessResponse takes the encoded results of executing a method on an invokable interface from an invocation context and unpacks them into an invocation context.

Response is the encoded results of executing a method on the invokable interface, or a stream from which those results can be read. It is generated on the server by the MakeResponse (see page 6156) method if the call was successful, or the MakeFault (see page 6155) method if the call was unsuccessful.

XMLDoc is the interface to an XML document that represents the results of executing a method on the invokable interface. The values of its nodes come from the MakeResponse (see page 6156) method if the call was successful, or the MakeFault (see page 6155) method if the call was unsuccessful.

IntfMD describes the runtime type information (RTTI) of the interface whose method was called.

MD describes the runtime type information (RTTI) of the method that was called.

Context is the invocation context that ProcessResponse fills out based on the contents of Response.

Headers is a list that ProcessResponse fills with TSOAPHeader (see page 4448) descendants that represent the headers of the encoded result message.

See Also

MakeFault (see page 6155)

MakeResponse (see page 6156)

65.1.1.2.10 IOPConvert.SetAttachments Method

Sets the value of the Attachments (see page 6160) property.

Pascal

```
procedure SetAttachments(Value: TSoapDataList);
```

C++

```
__fastcall SetAttachments(TSoapDataList Value);
```

Description

SetAttachments is the write implementation for the Attachments (see page 6160) property.

Value is a list of TSoapAttachment objects that encapsulate the current set of attachments.

See Also

Attachments (see page 6160)

65.1.1.2.11 IOPConvert.SetEncoding Method

Sets the value of the Encoding (see page 6160) property.

Pascal

```
procedure SetEncoding(const Encoding: DOMString);
```

C++

```
__fastcall SetEncoding(const DOMString Encoding);
```

Description

SetEncoding is the write implementation for the Encoding (see page 6160) property.

Encoding (see page 6160) is the name of the new encoding to use for method calls.

See Also

Encoding (see page 6160)

65.1.1.2.12 IOPConvert.SetOptions Method

Sets the value of the Options (see page 6161) property.

Pascal

```
procedure SetOptions(const Value: TSOAPConvertOptions);
```

C++

```
__fastcall SetOptions(const TSOAPConvertOptions Value);
```

Description

SetOptions is the write implementation for the Options (see page 6161) property.

Value is the new set of options to use when marshaling and unmarshaling method calls.

See Also

Options (see page 6161)

65.1.1.2.13 IOPConvert.SetTempDir Method

Sets the value of the TempDir (see page 6161) property.

Pascal

```
procedure SetTempDir(const Value: string);
```

C++

```
__fastcall SetTempDir(const UnicodeString Value);
```

Description

SetTempDir is the write implementation for the TempDir (see page 6161) property.

Value is the new temporary directory to use.

See Also

TempDir (see page 6161)

65.1.1.3 IOPConvert Properties

The properties of the IOPConvert class are listed here.

Public Properties

	Name	Description
	Attachments (see page 6160)	Lists the objects that encapsulate the attachments included with the SOAP request or its response.
	Encoding (see page 6160)	Indicates the character set to use for encoded method calls.
	Options (see page 6161)	Controls how certain types of conversions are performed.
	TempDir (see page 6161)	Specifies the directory where temporary files for attachments are saved.

65.1.1.3.1 IOPConvert.Attachments Property

Lists the objects that encapsulate the attachments included with the SOAP request or its response.

Pascal

```
property Attachments: TSoapDataList;
```

C++

```
__property TSoapDataList Attachments;
```

Description

When a method on an invokable interface requires the user to send or receive attachments, these attachments are each represented by a TSoapAttachment object. Attachments lists the TSoapAttachment objects for each attachment of the current method.

Note: When the application that contains IOPConvert (see page 6152) receives attachments, it writes them to a temporary file rather than storing them in memory. The location for these temporary files is specified by the TempDir (see page 6161) property.

See Also

TempDir (see page 6161)

TSOAPAttachment (see page 4435)

65.1.1.3.2 IOPConvert.Encoding Property

Indicates the character set to use for encoded method calls.

Pascal

```
property Encoding: DOMString;
```

C++

```
__property DOMString Encoding;
```

Description

Use Encoding to indicate the character set that is used for encoded method calls. If you do not specify an encoding (that is, if Encoding is an empty string), UTF-8 is assumed.

See Also

DefaultDOMVendor

Encoding

65.1.1.3.3 IOPConvert.Options Property

Controls how certain types of conversions are performed.

Pascal

```
property Options: TSOAPConvertOptions;
```

C++

```
__property TSOAPConvertOptions Options;
```

Description

Set Options to indicate how you want to handle various types of conversions. This set can include zero or more of the TSOAPConvertOption (see page 6162) flags.

See Also

MsgToInvContext (see page 6157)

ClassOptions (see page 4417)

InvContextToMsg (see page 6155)

65.1.1.3.4 IOPConvert.TempDir Property

Specifies the directory where temporary files for attachments are saved.

Pascal

```
property TempDir: string;
```

C++

```
__property UnicodeString TempDir;
```

Description

When the application receives an attachment as the value of a parameter (or the return value) of the current method on the invokable interface, it writes the attachment to a temporary file. This temporary file becomes the value of the CacheFile property on the TSoapAttachment object that represents the attachment.

Use TempDir to specify the directory where temporary files for attachments are written.

Note: If TempDir is not set, the application uses the default temporary directory. On Windows, this is the directory that the Windows API GetTempPath returns. On Linux, this is obtained from the TMPDIR environment setting (or, if TMPDIR is not set, /tmp/)

See Also

Attachments (see page 6160)

CacheFile (see page 4444)

65.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TSOAPConvertOption (see page 6162)	This is record OPConvert.TSOAPConvertOption.

65.2.1 OPConvert.TSOAPConvertOption Enumeration

Pascal

```
TSOAPConvertOption = (
  soSendUntyped,
  soSendMultiRefObj,
  soSendMultiRefArray,
  soTryAllSchema,
  soRootRefNodesToBody,
  soDocument,
  soReturnSuccessForFault,
  soUTF8InHeader,
  soDontSendEmptyNodes,
  soCacheMimeResponse,
  soDontClearOutBoundHeaders,
  soCustomFaultAtDetailsNode,
  soLiteralParams,
  soUTF8EncodeXML,
  soXXXXHdr
);
```

C++

```
enum TSOAPConvertOption {
  soSendUntyped,
  soSendMultiRefObj,
  soSendMultiRefArray,
  soTryAllSchema,
  soRootRefNodesToBody,
  soDocument,
  soReturnSuccessForFault,
  soUTF8InHeader,
  soDontSendEmptyNodes,
  soCacheMimeResponse,
  soDontClearOutBoundHeaders,
  soCustomFaultAtDetailsNode,
  soLiteralParams,
  soUTF8EncodeXML,
  soXXXXHdr
};
```

File

OPConvert

Description

This is record OPConvert.TSOAPConvertOption.

65.3 Types

The following table lists types in this documentation.

Types

Name	Description
TSOAPConvertOptions (see page 6163)	This is type OPConvert.TSOAPConvertOptions.

65.3.1 OPConvert.TSOAPConvertOptions Type

Pascal

```
TSOAPConvertOptions = set of TSOAPConvertOption;
```

C++

```
TSOAPConvertOption TSOAPConvertOptions;
```

File

OPConvert

Description

This is type OPConvert.TSOAPConvertOptions.

66 OPToSOAPDomConv Namespace

This is namespace OPToSOAPDomConv.

Topics

Name	Description
Classes (see page 6167)	The following table lists classes in this documentation.
Functions (see page 6203)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 6204)	The following table lists structs, records, enums in this documentation.
Types (see page 6206)	The following table lists types in this documentation.
Variables (see page 6209)	The following table lists variables in this documentation.
Constants (see page 6210)	The following table lists constants in this documentation.

Classes

	Name	Description
	ESOAPDomConvertError (see page 6167)	ESOAPDomConvertError is the class for exceptions that occur when marshaling or unmarshaling a SOAP request.
	TOPToSoapDomConvert (see page 6167)	TOPToSoapDomConvert handles the marshaling and unmarshaling of SOAP method calls.
	TSOAPDomConv (see page 6178)	TSOAPDomConv is the base class for components that use a DOM to interpret and create SOAP method calls.

Constants

Name	Description
SVarArrayType (see page 6210)	This is constant OPToSOAPDomConv.SVarArrayType.

Functions

	Name	Description
	GetOrdPropEx (see page 6203)	This is function OPToSOAPDomConv.GetOrdPropEx.

Structs, Records, Enums

	Name	Description
	ConvNodeState (see page 6204)	This is record OPToSOAPDomConv.ConvNodeState.
	TMultiRefNodeElem (see page 6204)	This is record OPToSOAPDomConv.TMultiRefNodeElem.
	TMultiRefNodeMapElem (see page 6205)	This is record OPToSOAPDomConv.TMultiRefNodeMapElem.
	TSOAPArrayElemDesc (see page 6205)	This is record OPToSOAPDomConv.TSOAPArrayElemDesc.

Types

Name	Description
TMemberDataNotReceivedEvent (see page 6206)	This is type OPToSOAPDomConv.TMemberDataNotReceivedEvent.
TMultiRefNodeMap (see page 6206)	This is type OPToSOAPDomConv.TMultiRefNodeMap.
TMultiRefNodes (see page 6207)	This is type OPToSOAPDomConv.TMultiRefNodes.
TSOAPArrayDesc (see page 6207)	This is type OPToSOAPDomConv.TSOAPArrayDesc.
TUnhandledNodeEvent (see page 6207)	This is type OPToSOAPDomConv.TUnhandledNodeEvent.
TXMLNodeArray (see page 6208)	This is type OPToSOAPDomConv.TXMLNodeArray.

Variables

Name	Description
DefArrayElemName (see page 6209)	This is variable OPToSOAPDomConv.DefArrayElemName.

66.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	ESOAPDomConvertError (see page 6167)	ESOAPDomConvertError is the class for exceptions that occur when marshaling or unmarshaling a SOAP request.
	TOPToSoapDomConvert (see page 6167)	TOPToSoapDomConvert handles the marshaling and unmarshaling of SOAP method calls.
	TSOAPDomConv (see page 6178)	TSOAPDomConv is the base class for components that use a DOM to interpret and create SOAP method calls.

66.1.1 ESOAPDomConvertError Class

ESOAPDomConvertError is the class for exceptions that occur when marshaling or unmarshaling a SOAP request.

Class Hierarchy

Pascal

```
ESOAPDomConvertError = class(Exception);
```

C++

```
class ESOAPDomConvertError : public Exception;
```

File

OPToSOAPDomConv

Description

TOPToSoapDomConvert (see page 6167) raises ESOAPDomConvertError exceptions when it can't marshal or unmarshal a SOAP packet that encodes a method call or its results.

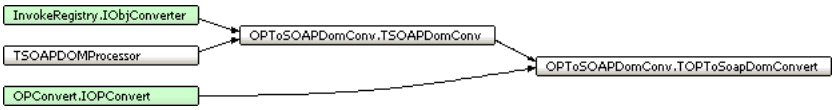
See Also

TOPToSoapDOMConvert

66.1.2 TOPToSoapDomConvert Class

TOPToSoapDomConvert handles the marshaling and unmarshaling of SOAP method calls.

Class Hierarchy



Pascal

```
TOPToSoapDomConvert = class(TSOAPDomConv, IOPConvert);
```

C++

```
class TOPToSoapDomConvert : public TSOAPDomConv, public IOPConvert;
```

File

OPToSOAPDomConv

Description

TOPToSoapDomConvert is an implementation of the IOPConvert (see page 6152) interface that handles the marshaling and unmarshaling of SOAP method calls. It uses a DOM parser to parse and edit the SOAP encoding of a method call and its results.

Typically, applications do not use TOPToSoapDomConvert directly. Rather, It is created and used by THTTPRio on client applications and THTTPSoapPascalInvoker or THTTPSoapCppInvoker on server applications.

TOPToSoapDomConvert converts between the SOAP encoding of a method call or its results and an invocation context. If the method call results in an exception, TOPToSoapDomConvert generates a SOAP error packet for that exception so that the client can raise the exception remotely.

66.1.2.1 TOPToSoapDomConvert Members

The following tables list the members exposed by TOPToSoapDomConvert.

Protected Methods

	Name	Description
	AddAttachment (see page 6183)	Stores information about a SOAP attachment so that it is included in the final message that is created.
	AddMultiRefNode (see page 6183)	This is AddMultiRefNode, a member of class TSOAPDomConv.
	AddNamespaceDecl (see page 6183)	This is AddNamespaceDecl, a member of class TSOAPDomConv.
	AddObjectAsWriting (see page 6184)	This is AddObjectAsWriting, a member of class TSOAPDomConv.
	CheckEncodingStyle (see page 6184)	This is CheckEncodingStyle, a member of class TSOAPDomConv.
	ChildNodesAreNull (see page 6184)	This is ChildNodesAreNull, a member of class TSOAPDomConv.
	ConvertByteArrayToSoap (see page 6184)	This is ConvertByteArrayToSoap, a member of class TSOAPDomConv.
	ConvertEnumToSoap (see page 6184)	This is ConvertEnumToSoap, a member of class TSOAPDomConv.
	ConvertNativeArrayToSoap (see page 6185)	This is ConvertNativeArrayToSoap, a member of class TSOAPDomConv.
	ConvertObjectToSOAP (see page 6186)	This is ConvertObjectToSOAP, a member of class TSOAPDomConv.
	ConvertSoapToEnum (see page 6186)	This is ConvertSoapToEnum, a member of class TSOAPDomConv.
	ConvertSoapToNativeArray (see page 6186)	This is ConvertSoapToNativeArray, a member of class TSOAPDomConv.
	ConvertSoapToNativeArrayElem (see page 6186)	This is ConvertSoapToNativeArrayElem, a member of class TSOAPDomConv.
	ConvertSOAPToObject (see page 6187)	This is ConvertSOAPToObject, a member of class TSOAPDomConv.
	ConvertSoapToVariant (see page 6187)	This is ConvertSoapToVariant, a member of class TSOAPDomConv.
	ConvertVariantToSoap (see page 6188)	This is ConvertVariantToSoap, a member of class TSOAPDomConv.

	CreateMultiRefNode (see page 6188)	This is CreateMultiRefNode, a member of class TSOAPDomConv.
	CreateNULLNode (see page 6188)	This is CreateNULLNode, a member of class TSOAPDomConv.
	CreateObjectNode (see page 6188)	This is CreateObjectNode, a member of class TSOAPDomConv.
	CreateScalarNodeXS (see page 6189)	This is CreateScalarNodeXS, a member of class TSOAPDomConv.
	CreateTypedNode (see page 6189)	This is CreateTypedNode, a member of class TSOAPDomConv.
	FinalizeMultiRefNodes (see page 6189)	This is FinalizeMultiRefNodes, a member of class TSOAPDomConv.
	FindAttachment (see page 6189)	Returns a TSOAPAttachment instance that represent the attachment with a specified ID.
	FindMultiRefNodeByID (see page 6190)	This is FindMultiRefNodeByID, a member of class TSOAPDomConv.
	FindMultiRefNodeByInstance (see page 6190)	This is FindMultiRefNodeByInstance, a member of class TSOAPDomConv.
	FindNodeByHREF (see page 6190)	This is FindNodeByHREF, a member of class TSOAPDomConv.
	FindPrefixForURI (see page 6190)	This is FindPrefixForURI, a member of class TSOAPDomConv.
	GetDataNode (see page 6191)	This is GetDataNode, a member of class TSOAPDomConv.
	GetElementType (see page 6191)	This is GetElementType, a member of class TSOAPDomConv.
	GetNewID (see page 6191)	This is GetNewID, a member of class TSOAPDomConv.
	GetNodeAsText (see page 6191)	This is GetNodeAsText, a member of class TSOAPDomConv.
	GetObjectPropAsText (see page 6192)	This is GetObjectPropAsText, a member of class TSOAPDomConv.
	GetOptions (see page 6192)	This is GetOptions, a member of class TSOAPDomConv.
	GetTypeBySchemaNS (see page 6192)	This is GetTypeBySchemaNS, a member of class TSOAPDomConv.
	InitObjectFromSOAP (see page 6192)	Initializes an instance of a remotable object to reflect the values in its SOAP representation.
	IsNodeAVarArray (see page 6193)	This is IsNodeAVarArray, a member of class TSOAPDomConv.
	IsObjectWriting (see page 6193)	This is IsObjectWriting, a member of class TSOAPDomConv.
	LoadObject (see page 6193)	This is LoadObject, a member of class TSOAPDomConv.
	MakeArrayNode (see page 6193)	This is the overview for the MakeArrayNode method overload.
	MultiRefObject (see page 6194)	This is MultiRefObject, a member of class TSOAPDomConv.
	NewXMLDocument (see page 6174)	Creates a new empty XML document to hold the SOAP representation and returns its interface.
	NodeIsNULL (see page 6194)	This is NodeIsNULL, a member of class TSOAPDomConv.
	ObjectMemberNoShow (see page 6195)	This is ObjectMemberNoShow, a member of class TSOAPDomConv.
	ObjInstanceToSOAP (see page 6195)	Returns the SOAP representation of a remotable object.
	ReadHeader (see page 6195)	This is ReadHeader, a member of class TSOAPDomConv.
	ReadRectDynArray (see page 6196)	This is ReadRectDynArray, a member of class TSOAPDomConv.
	ReadRectDynArrayElem (see page 6196)	This is ReadRectDynArrayElem, a member of class TSOAPDomConv.
	ReadRow (see page 6196)	This is ReadRow, a member of class TSOAPDomConv.
	ReadVarArrayDim (see page 6196)	This is ReadVarArrayDim, a member of class TSOAPDomConv.
	ReadVariant (see page 6197)	This is ReadVariant, a member of class TSOAPDomConv.
	RemoveObjectAsWriting (see page 6197)	This is RemoveObjectAsWriting, a member of class TSOAPDomConv.
	ResetMultiRef (see page 6197)	This is ResetMultiRef, a member of class TSOAPDomConv.
	SerializationOptions (see page 6197)	This is the overview for the SerializationOptions method overload.
	SetNodeType (see page 6198)	This is SetNodeType, a member of class TSOAPDomConv.
	SetObjectPropFromText (see page 6198)	This is SetObjectPropFromText, a member of class TSOAPDomConv.
	SetOptions (see page 6199)	This is SetOptions, a member of class TSOAPDomConv.
	UnhandledNode (see page 6199)	This is UnhandledNode, a member of class TSOAPDomConv.
	WriteHeader (see page 6199)	This is WriteHeader, a member of class TSOAPDomConv.
	WriteNonRectDynArray (see page 6199)	This is WriteNonRectDynArray, a member of class TSOAPDomConv.
	WriteNonRectDynArrayElem (see page 6200)	This is WriteNonRectDynArrayElem, a member of class TSOAPDomConv.
	WriteRectDynArray (see page 6200)	This is WriteRectDynArray, a member of class TSOAPDomConv.
	WriteRectDynArrayElem (see page 6200)	This is WriteRectDynArrayElem, a member of class TSOAPDomConv.
	WriteVarArray (see page 6200)	This is WriteVarArray, a member of class TSOAPDomConv.
	WriteVarArrayAsB64 (see page 6201)	This is WriteVarArrayAsB64, a member of class TSOAPDomConv.
	WriteVariant (see page 6201)	This is WriteVariant, a member of class TSOAPDomConv.

Public Methods

	Name	Description
	AddAttachment (see page 4462)	Stores information about a SOAP attachment so that it is included in the final message that is created.
	ConvertNativeDataToSoap (see page 6185)	Converts a native type to its SOAP representation.
	ConvertSoapToNativeData (see page 6187)	Converts the SOAP representation of a value to a pointer to the corresponding native representation.
	Create (see page 6171)	Creates a new TOPToSoapDomConvert (see page 6167) object.
	Destroy (see page 6171)	Frees the memory associated with the TOPToSoapDomConvert (see page 6167) object.
	FindAttachment (see page 4463)	Returns a TSOAPAttachment (see page 4435) instance that represent the attachment with a specified ID.
	GetAttachments (see page 6154)	Returns the value of the Attachments (see page 6160) property.
	GetEncoding (see page 6154)	Returns the value of the Encoding (see page 6160) property.
	GetOptions (see page 6154)	Returns the value of the Options (see page 6161) property.
	GetTempDir (see page 6154)	Returns the value of the TempDir (see page 6161) property.
	InitObjectFromSOAP (see page 4463)	Initializes an instance of a remotable object to reflect the values in its SOAP representation.
	InvContextToMsg (see page 6172)	Marshals a method call from an invocation context to a transportable string.
	MakeFault (see page 6172)	Encodes an exception that was raised when trying to execute a method on an invokable interface.
	MakeResponse (see page 6173)	Encodes the results of successfully executing a method on an invokable interface.
	MsgToInvContext (see page 6156)	This is the overview for the MsgToInvContext method overload.
	MsgToInvContext (see page 6173)	This is the overview for the MsgToInvContext method overload.
	ObjInstanceToSOAP (see page 4463)	Returns the SOAP representation of a remotable object.
	ProcessResponse (see page 6157)	This is the overview for the ProcessResponse method overload.
	ProcessResponse (see page 6175)	This is the overview for the ProcessResponse method overload.
	SetAttachments (see page 6158)	Sets the value of the Attachments (see page 6160) property.
	SetEncoding (see page 6159)	Sets the value of the Encoding (see page 6160) property.
	SetOptions (see page 6159)	Sets the value of the Options (see page 6161) property.
	SetTempDir (see page 6159)	Sets the value of the TempDir (see page 6161) property.

Public Properties

	Name	Description
	Attachments (see page 6176)	Lists the objects that encapsulate the attachments included with the SOAP request or its response.
	Options (see page 6161)	Controls how certain types of conversions are performed.

Published Events

	Name	Description
	OnMemberDataNotReceived (see page 6202)	Occurs when converting a SOAP representation to a remotable object and an expected class member was not found.
	OnUnhandledNode (see page 6202)	Occurs when a SOAP representation includes an XML node that the converter does not know how to handle.

Published Properties

	Name	Description
	Encoding (see page 6177)	Indicates the character set to use for encoded method calls.
	Options (see page 6201)	Controls how the TSOAPDomConv (see page 6178) object performs certain types of conversions.
	TempDir (see page 6177)	Specifies the directory where temporary files for attachments are saved.
	WSDLView (see page 6178)	Provides access to information in a WSDL document that represents the SOAP request.

66.1.2.2 TOPToSoapDomConvert.Create Constructor

Creates a new TOPToSoapDomConvert (see page 6167) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TOPToSoapDomConvert(TComponent * AOwner);
```

Description

Most applications do not create instances of TOPToSoapDomConvert (see page 6167). It is created by the THTTPRio and TSoapPascalInvoker objects to handle the marshaling and unmarshaling of SOAP method calls.

The AOwner parameter specifies the component that is responsible for freeing the TOPToSoapDomConvert (see page 6167) instance.

See Also

Owner

THTTPRio

TSoapPascalInvoker

66.1.2.3 TOPToSoapDomConvert.Destroy Destructor

Frees the memory associated with the TOPToSoapDomConvert (see page 6167) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TOPToSoapDomConvert();
```

Description

Typically, TOPToSoapDomConvert (see page 6167) objects are freed by the objects that create them to handle the marshaling and unmarshaling of SOAP method calls.

Do not call Destroy directly in an application. Instead, use the Free method, that checks whether the reference is nil before calling Destroy.

See Also

Create (see page 6171)

System::TObject::Free

66.1.2.4 TOPToSoapDomConvert Methods

The methods of the TOPToSoapDomConvert class are listed here.

Protected Methods

	Name	Description
	NewXMLDocument (see page 6174)	Creates a new empty XML document to hold the SOAP representation and returns its interface.

Public Methods

	Name	Description
	InvContextToMsg (see page 6172)	Marshals a method call from an invocation context to a transportable string.
	MakeFault (see page 6172)	Encodes an exception that was raised when trying to execute a method on an invokable interface.
	MakeResponse (see page 6173)	Encodes the results of successfully executing a method on an invokable interface.
	MsgToInvContext (see page 6173)	This is the overview for the MsgToInvContext method overload.
	ProcessResponse (see page 6175)	This is the overview for the ProcessResponse method overload.

66.1.2.4.1 TOPToSoapDomConvert.InvContextToMsg Method

Marshals a method call from an invocation context to a transportable string.

Pascal

```
function InvContextToMsg(const IntfMD: TIntfMetaData; MethNum: Integer; Con: TInvContext;
Headers: THeaderList): TStream;
```

C++

```
__fastcall TStream InvContextToMsg(const TIntfMetaData IntfMD, int MethNum, TInvContext Con,
THeaderList Headers);
```

Description

InvContextToMsg looks up a specified method call, including the types and values of any arguments, from an invocation context, and returns an encoded version of that method call that can be transported to the application that executes it.

IntfMD represents the runtime type information (RTTI) from the interface whose method is called.

MethNum identifies the called method by its position in the interface's method table.

Con is the invocation context that contains details of the method call, including the parameter values passed in, the calling conventions, and any other temporary data used when making the call.

Headers is a list of TSOAPHeader (see page 4448) descendants that represent the headers of the SOAP envelope that contained the method call.

InvContextToMsg returns a stream from which an application can read the encoded version of the method call.

See Also

MsgToInvContext (see page 6174)

66.1.2.4.2 TOPToSoapDomConvert.MakeFault Method

Encodes an exception that was raised when trying to execute a method on an invokable interface.

Pascal

```
procedure MakeFault(const Ex: Exception; EStream: TStream); virtual;
```

C++

```
virtual __fastcall MakeFault(const Exception Ex, TStream EStream);
```

Description

MakeFault encodes an exception that a Web Service application catches when trying to execute a method on an invokable interface. It generates an encoded exception packet, which the client can decode and use to raise the exception on the client application.

Ex is the exception object that represents the exception that occurred.

EStream is a stream to which MakeFault writes the encoded exception packet.

See Also

MakeResponse (see page 6173)

66.1.2.4.3 TOPToSoapDomConvert.MakeResponse Method

Encodes the results of successfully executing a method on an invokable interface.

Pascal

```
procedure MakeResponse(const IntfMD: TIntfMetaData; const MethNum: Integer; Context:
TInvContext; Response: TStream; Headers: THeaderLIst); virtual;
```

C++

```
virtual __fastcall MakeResponse(const TIntfMetaData IntfMD, const int MethNum, TInvContext
Context, TStream Response, THeaderLIst Headers);
```

Description

MakeResponse retrieves the results of executing a method on an invokable interface from an invocation context and packages them into a transportable string, which it writes to a stream. This string is passed back to the client, which can unpack it using the ProcessResponse (see page 6175) method.

IntfMD represents the runtime type information (RTTI) from the interface whose method was executed.

MethNum identifies the called method by its position in the interface's method table.

Context is the invocation context that contains details of the method call.

Headers is a list of TSOAPHeader (see page 4448) descendants that should be converted to headers on the encoded response.

Response is a stream to which MakeResponse writes the encoded version of the method result and any output parameters.

Headers is a list of TSOAPHeader (see page 4448) descendants that represent the headers that should be added to the response message.

See Also

MakeFault (see page 6172)

ProcessResponse (see page 6175)

66.1.2.4.4 MsgToInvContext Method

This is the overview for the MsgToInvContext method overload.

Overload List

	Name	Description
	TOPToSoapDomConvert.MsgToInvContext (InvString, TIntfMetaData, Integer, TInvContext) (see page 6174)	Unpacks an encoded method call into an invocation context so that it can be executed.
	TOPToSoapDomConvert.MsgToInvContext (TStream, TIntfMetaData, Integer, TInvContext, THeaderList) (see page 6174)	Unpacks an encoded method call into an invocation context so that it can be executed.

66.1.2.4.4.1 TOPToSoapDomConvert.MsgToInvContext Method (InvString, TIntfMetaData, Integer, TInvContext)

Unpacks an encoded method call into an invocation context so that it can be executed.

Pascal

```
procedure MsgToInvContext(const Request: InvString; const IntfMD: TIntfMetaData; var MethNum:
Integer; Context: TInvContext); virtual; overload;
procedure MsgToInvContext(const Request: TStream; const IntfMD: TIntfMetaData; var MethNum:
Integer; Context: TInvContext; Headers: THeaderList); virtual; overload;
```

C++

```
virtual __fastcall MsgToInvContext(const InvString Request, const TIntfMetaData IntfMD, int
MethNum, TInvContext Context);
virtual __fastcall MsgToInvContext(const TStream Request, const TIntfMetaData IntfMD, int
MethNum, TInvContext Context, THeaderList Headers);
```

Description

MsgToInvContext takes an encoded message that a server application receives and uses it to fill out an invocation context, which can then be used to execute the method call.

Request is the encoded method call, or a stream from which to read that method call. It is generated on the client by a call to InvContextToMsg (see page 6172).

IntfMD represents the runtime type information (RTTI) from the interface whose method is called.

MethNum returns the position of the called method in the interface's method table.

Context is the invocation context to which this method adds the information encoded in Request.

Headers is an object list to which MsgToInvContext adds TSOAPHeader (see page 4448) descendants to represent every header in the encoded message.

See Also

InvContextToMsg (see page 6172)

66.1.2.4.5 TOPToSoapDomConvert.NewXMLDocument Method

Creates a new empty XML document to hold the SOAP representation and returns its interface.

Pascal

```
function NewXMLDocument: IXMLDocument;
```

C++

```
__fastcall IXMLDocument NewXMLDocument();
```

Description

TOPToSoapDomConvert (see page 6167) uses NewXMLDocument internally to create the object that holds the SOAP representation of a message. It returns an interface for working with this representation. Note that the XML document that NewXMLDocument returns is empty. TOPToSoapDomConvert (see page 6167) subsequently uses the methods of the interface to fill out the body of this document.

66.1.2.4.6 ProcessResponse Method

This is the overview for the ProcessResponse method overload.

Overload List

	Name	Description
	TOPToSoapDomConvert.ProcessResponse (InvString, TIntfMetaData, TIntfMethEntry, TInvContext) (see page 6175)	Unpacks the response packet from a method call into an invocation context.
	TOPToSoapDomConvert.ProcessResponse (IXMLDocument, TIntfMetaData, TIntfMethEntry, TInvContext, THeaderList) (see page 6175)	Unpacks the response packet from a method call into an invocation context.
	TOPToSoapDomConvert.ProcessResponse (TStream, TIntfMetaData, TIntfMethEntry, TInvContext, THeaderList) (see page 6175)	Unpacks the response packet from a method call into an invocation context.

66.1.2.4.6.1 TOPToSoapDomConvert.ProcessResponse Method (IXMLDocument, TIntfMetaData, TIntfMethEntry, TInvContext, THeaderList)

Unpacks the response packet from a method call into an invocation context.

Pascal

```
procedure ProcessResponse(const Resp: InvString; const IntfMD: TIntfMetaData; const MD:
TIntfMethEntry; Context: TInvContext); virtual; overload;
procedure ProcessResponse(const Resp: TStream; const IntfMD: TIntfMetaData; const MD:
TIntfMethEntry; Context: TInvContext; Headers: THeaderList); virtual; overload;
procedure ProcessResponse(const XMLDoc: IXMLDocument; const IntfMD: TIntfMetaData; const MD:
TIntfMethEntry; Context: TInvContext; Headers: THeaderList); virtual; overload;
```

C++

```
virtual __fastcall ProcessResponse(const InvString Resp, const TIntfMetaData IntfMD, const
TIntfMethEntry MD, TInvContext Context);
virtual __fastcall ProcessResponse(const TStream Resp, const TIntfMetaData IntfMD, const
TIntfMethEntry MD, TInvContext Context, THeaderList Headers);
virtual __fastcall ProcessResponse(const IXMLDocument XMLDoc, const TIntfMetaData IntfMD,
const TIntfMethEntry MD, TInvContext Context, THeaderList Headers);
```

Description

ProcessResponse takes the encoded results of executing a method on an invokable interface from an invocation context and unpacks them into an invocation context.

Response is the encoded results of executing a method on the invokable interface, or a stream from which those results can be read. It is generated on the server by the MakeResponse (see page 6173) method if the call was successful, or the MakeFault (see page 6172) method if the call was unsuccessful.

XMLDoc is the interface to an XML document that represents the results of executing a method on the invokable interface. The values of its nodes come from the MakeResponse (see page 6173) method if the call was successful, or the MakeFault (see page 6172) method if the call was unsuccessful.

IntfMD describes the runtime type information (RTTI) of the interface whose method was called.

MD describes the runtime type information (RTTI) of the method that was called.

Context is the invocation context that ProcessResponse fills out based on the contents of Response.

Headers is a list that ProcessResponse fills with TSOAPHeader (see page 4448) descendants that represent the headers of the encoded result message.

See Also

MakeFault (see page 6172)

MakeResponse (see page 6173)

66.1.2.5 TOPToSoapDomConvert Properties

The properties of the TOPToSoapDomConvert class are listed here.

Public Properties

	Name	Description
	Attachments (see page 6176)	Lists the objects that encapsulate the attachments included with the SOAP request or its response.

Published Properties

	Name	Description
	Encoding (see page 6177)	Indicates the character set to use for encoded method calls.
	TempDir (see page 6177)	Specifies the directory where temporary files for attachments are saved.
	WSDLView (see page 6178)	Provides access to information in a WSDL document that represents the SOAP request.

66.1.2.5.1 TOPToSoapDomConvert.Attachments Property

Lists the objects that encapsulate the attachments included with the SOAP request or its response.

Pascal

```
property Attachments: TSOAPDataList;
```

C++

```
__property TSOAPDataList Attachments;
```

Description

When a method on an invokable interface requires the user to send or receive attachments, these attachments are each represented by a TSoapAttachment object. Attachments lists the TSoapAttachment objects for each attachment of the current method.

Note: When the application that contains TOPToSoapDomConvert (see page 6167) receives attachments, it writes them to a temporary file rather than storing them in memory. The location for these temporary files is specified by the TempDir (see page 6177) property.

See Also

TempDir (see page 6177)

TSOAPAttachment (see page 4435)

66.1.2.5.2 TOPToSoapDomConvert.Encoding Property

Indicates the character set to use for encoded method calls.

Pascal

```
property Encoding: DOMString;
```

C++

```
__property DOMString Encoding;
```

Description

Use Encoding to indicate the character set that is used for encoded method calls. Encoding causes the converter to make character set conversions using the DOM, rather than at the transport level. This approach is more efficient than transport-level encoding. If you set Encoding, the Options (see page 6201) property should not include soUTF8EncodeXML and soUTF8InHeader.

If you do not specify an encoding (that is, if Encoding is an empty string), TOPToSoapDomConvert (see page 6167) converts characters at the transport level assuming UTF-8.

TOPToSoapDomConvert (see page 6167) uses the DOM parser identified by the global DefaultDOMVendor variable to perform its conversions. Encoding must indicate an encoding that this default DOM parser supports.

Note: Some Web Services (such as Apache or .NET) require transport level encoding rather than DOM level encoding. In such cases, it is possible that setting Encoding can cause problems because the Web Service converts characters at the transport level and then converts a second time because of the encoding attribute that Encoding adds to the XML representation. If a Web Service requires transport-level encoding and assumes UTF8, Encoding should be an empty string and the Options (see page 6201) property should include soUTF8EncodeXML and soUTF8InHeader.

See Also

DefaultDOMVendor

Encoding

Options (see page 6201)

66.1.2.5.3 TOPToSoapDomConvert.TempDir Property

Specifies the directory where temporary files for attachments are saved.

Pascal

```
property TempDir: string;
```

C++

```
__property UnicodeString TempDir;
```

Description

When the application that includes this TOPToSoapDomConvert (see page 6167) instance receives an attachment as the value of a parameter (or the return value) of the current method, TOPToSoapDomConvert (see page 6167) writes the attachment to a temporary file. This temporary file becomes the value of the CacheFile property on the TSoapAttachment object that represents the attachment.

Use TempDir to specify the directory where TOPToSoapDomConvert (see page 6167) writes the temporary files for attachments.

Note: If TempDir is not set, the application uses the default temporary directory. On Windows, this is the directory that the Windows API GetTempPath returns. On Linux, this is obtained from the TMPDIR environment setting (or, if TMPDIR is not set, /tmp/)

See Also

Attachments (see page 6176)

CacheFile (see page 4444)

66.1.2.5.4 TOPToSoapDomConvert.WSDLView Property

Provides access to information in a WSDL document that represents the SOAP request.

Pascal

```
property WSDLView: TWSDLView;
```

C++

```
__property TWSDLView WSDLView;
```

Description

WSDLView represents information about the SOAP request when the application uses a WSDL document to define information about the interface. If the application does not use a WSDL document, WSDLView is nil (Delphi) or NULL (C++).

WSDL includes the parsed WSDL document, as well as properties to identify the target method call.

66.1.3 TSOAPDomConv Class

TSOAPDomConv is the base class for components that use a DOM to interpret and create SOAP method calls.

Class Hierarchy

Pascal

```
TSOAPDomConv = class(TSOAPDOMProcessor, IObjConverter);
```

C++

```
class TSOAPDomConv : public TSOAPDOMProcessor, public IObjConverter;
```

File

OPToSOAPDomConv

Description

TSOAPDomConv is the base class for DOM-based components that interpret and create SOAP method calls. It handles the logic of converting between the SOAP representation of a type and its native representation. TSOAPDomConv uses the remotable type registry (RemTypeRegistry (see page 4472)) to look up the native type or class that corresponds to a type from a SOAP method call and to generate an instance of that type to represent an incoming value. It uses runtime type information (RTTI) to convert a native type or remotable class to its SOAP representation.

TSOAPDomConv implements the IObjConverter (see page 4461) interface.

Do not create instances of TSOAPDomConv. It is intended only as a base class for components that interpret or create SOAP

method calls.

RemTypeRegistry

IObjConverter (see page 4461)

66.1.3.1 TSOAPDomConv Members

The following tables list the members exposed by TSOAPDomConv.

Protected Methods

	Name	Description
	AddAttachment (see page 6183)	Stores information about a SOAP attachment so that it is included in the final message that is created.
	AddMultiRefNode (see page 6183)	This is AddMultiRefNode, a member of class TSOAPDomConv.
	AddNamespaceDecl (see page 6183)	This is AddNamespaceDecl, a member of class TSOAPDomConv.
	AddObjectAsWriting (see page 6184)	This is AddObjectAsWriting, a member of class TSOAPDomConv.
	CheckEncodingStyle (see page 6184)	This is CheckEncodingStyle, a member of class TSOAPDomConv.
	ChildNodesAreNull (see page 6184)	This is ChildNodesAreNull, a member of class TSOAPDomConv.
	ConvertByteArrayToSoap (see page 6184)	This is ConvertByteArrayToSoap, a member of class TSOAPDomConv.
	ConvertEnumToSoap (see page 6184)	This is ConvertEnumToSoap, a member of class TSOAPDomConv.
	ConvertNativeArrayToSoap (see page 6185)	This is ConvertNativeArrayToSoap, a member of class TSOAPDomConv.
	ConvertObjectToSOAP (see page 6186)	This is ConvertObjectToSOAP, a member of class TSOAPDomConv.
	ConvertSoapToEnum (see page 6186)	This is ConvertSoapToEnum, a member of class TSOAPDomConv.
	ConvertSoapToNativeArray (see page 6186)	This is ConvertSoapToNativeArray, a member of class TSOAPDomConv.
	ConvertSoapToNativeArrayElem (see page 6186)	This is ConvertSoapToNativeArrayElem, a member of class TSOAPDomConv.
	ConvertSOAPToObject (see page 6187)	This is ConvertSOAPToObject, a member of class TSOAPDomConv.
	ConvertSoapToVariant (see page 6187)	This is ConvertSoapToVariant, a member of class TSOAPDomConv.
	ConvertVariantToSoap (see page 6188)	This is ConvertVariantToSoap, a member of class TSOAPDomConv.
	CreateMultiRefNode (see page 6188)	This is CreateMultiRefNode, a member of class TSOAPDomConv.
	CreateNULLNode (see page 6188)	This is CreateNULLNode, a member of class TSOAPDomConv.
	CreateObjectNode (see page 6188)	This is CreateObjectNode, a member of class TSOAPDomConv.
	CreateScalarNodeXS (see page 6189)	This is CreateScalarNodeXS, a member of class TSOAPDomConv.
	CreateTypedNode (see page 6189)	This is CreateTypedNode, a member of class TSOAPDomConv.
	FinalizeMultiRefNodes (see page 6189)	This is FinalizeMultiRefNodes, a member of class TSOAPDomConv.
	FindAttachment (see page 6189)	Returns a TSOAPAttachment instance that represent the attachment with a specified ID.
	FindMultiRefNodeByID (see page 6190)	This is FindMultiRefNodeByID, a member of class TSOAPDomConv.
	FindMultiRefNodeByInstance (see page 6190)	This is FindMultiRefNodeByInstance, a member of class TSOAPDomConv.
	FindNodeByHREF (see page 6190)	This is FindNodeByHREF, a member of class TSOAPDomConv.
	FindPrefixForURI (see page 6190)	This is FindPrefixForURI, a member of class TSOAPDomConv.
	GetDataNode (see page 6191)	This is GetDataNode, a member of class TSOAPDomConv.
	GetElementType (see page 6191)	This is GetElementType, a member of class TSOAPDomConv.
	GetNewID (see page 6191)	This is GetNewID, a member of class TSOAPDomConv.
	GetNodeAsText (see page 6191)	This is GetNodeAsText, a member of class TSOAPDomConv.
	GetObjectPropAsText (see page 6192)	This is GetObjectPropAsText, a member of class TSOAPDomConv.
	GetOptions (see page 6192)	This is GetOptions, a member of class TSOAPDomConv.
	GetTypeBySchemaNS (see page 6192)	This is GetTypeBySchemaNS, a member of class TSOAPDomConv.
	InitObjectFromSOAP (see page 6192)	Initializes an instance of a remotable object to reflect the values in its SOAP representation.
	IsNodeAVarArray (see page 6193)	This is IsNodeAVarArray, a member of class TSOAPDomConv.
	IsObjectWriting (see page 6193)	This is IsObjectWriting, a member of class TSOAPDomConv.

	LoadObject (see page 6193)	This is LoadObject, a member of class TSOAPDomConv.
	MakeArrayNode (see page 6193)	This is the overview for the MakeArrayNode method overload.
	MultiRefObject (see page 6194)	This is MultiRefObject, a member of class TSOAPDomConv.
	NodeIsNULL (see page 6194)	This is NodeIsNULL, a member of class TSOAPDomConv.
	ObjectMemberNoShow (see page 6195)	This is ObjectMemberNoShow, a member of class TSOAPDomConv.
	ObjInstanceToSOAP (see page 6195)	Returns the SOAP representation of a remotable object.
	ReadHeader (see page 6195)	This is ReadHeader, a member of class TSOAPDomConv.
	ReadRectDynArray (see page 6196)	This is ReadRectDynArray, a member of class TSOAPDomConv.
	ReadRectDynArrayElem (see page 6196)	This is ReadRectDynArrayElem, a member of class TSOAPDomConv.
	ReadRow (see page 6196)	This is ReadRow, a member of class TSOAPDomConv.
	ReadVarArrayDim (see page 6196)	This is ReadVarArrayDim, a member of class TSOAPDomConv.
	ReadVariant (see page 6197)	This is ReadVariant, a member of class TSOAPDomConv.
	RemoveObjectAsWriting (see page 6197)	This is RemoveObjectAsWriting, a member of class TSOAPDomConv.
	ResetMultiRef (see page 6197)	This is ResetMultiRef, a member of class TSOAPDomConv.
	SerializationOptions (see page 6197)	This is the overview for the SerializationOptions method overload.
	SetNodeType (see page 6198)	This is SetNodeType, a member of class TSOAPDomConv.
	SetObjectPropFromText (see page 6198)	This is SetObjectPropFromText, a member of class TSOAPDomConv.
	SetOptions (see page 6199)	This is SetOptions, a member of class TSOAPDomConv.
	UnhandledNode (see page 6199)	This is UnhandledNode, a member of class TSOAPDomConv.
	WriteHeader (see page 6199)	This is WriteHeader, a member of class TSOAPDomConv.
	WriteNonRectDynArray (see page 6199)	This is WriteNonRectDynArray, a member of class TSOAPDomConv.
	WriteNonRectDynArrayElem (see page 6200)	This is WriteNonRectDynArrayElem, a member of class TSOAPDomConv.
	WriteRectDynArray (see page 6200)	This is WriteRectDynArray, a member of class TSOAPDomConv.
	WriteRectDynArrayElem (see page 6200)	This is WriteRectDynArrayElem, a member of class TSOAPDomConv.
	WriteVarArray (see page 6200)	This is WriteVarArray, a member of class TSOAPDomConv.
	WriteVarArrayAsB64 (see page 6201)	This is WriteVarArrayAsB64, a member of class TSOAPDomConv.
	WriteVariant (see page 6201)	This is WriteVariant, a member of class TSOAPDomConv.

Public Methods

	Name	Description
	ConvertNativeDataToSoap (see page 6185)	Converts a native type to its SOAP representation.
	ConvertSoapToNativeData (see page 6187)	Converts the SOAP representation of a value to a pointer to the corresponding native representation.
	Create (see page 6180)	Creates a new TSOAPDomConv (see page 6178) object.
	Destroy (see page 6181)	Frees the memory associated with the TSOAPDomConv (see page 6178) object.

Published Events

	Name	Description
	OnMemberDataNotReceived (see page 6202)	Occurs when converting a SOAP representation to a remotable object and an expected class member was not found.
	OnUnhandledNode (see page 6202)	Occurs when a SOAP representation includes an XML node that the converter does not know how to handle.

Published Properties

	Name	Description
	Options (see page 6201)	Controls how the TSOAPDomConv (see page 6178) object performs certain types of conversions.

66.1.3.2 TSOAPDomConv.Create Constructor

Creates a new TSOAPDomConv (see page 6178) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TSOAPDomConv(TComponent * AOwner);
```

Description

Typically, applications do not need to create instances of TSOAPDomConv (see page 6178). Instead, it is created and used by THTTPRio on client applications and THTTPSoapPascalInvoker or THTTPSoapCppInvoker on server applications.

The AOwner parameter specifies the component that is responsible for freeing the TSOAPDomConv (see page 6178) instance.

See Also

Owner

THTTPRio

THTTPSoapPascalInvoker

THTTPSoapCppInvoker

66.1.3.3 TSOAPDomConv.Destroy Destructor

Frees the memory associated with the TSOAPDomConv (see page 6178) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TSOAPDomConv();
```

Description

Do not call Destroy to free an instance of TSOAPDomConv (see page 6178). Instead, use the Free method, which first checks for a nil reference before calling Destroy.

See Also

System::TObject::Free

66.1.3.4 TSOAPDomConv Methods

The methods of the TSOAPDomConv class are listed here.

Protected Methods

	Name	Description
	AddAttachment (see page 6183)	Stores information about a SOAP attachment so that it is included in the final message that is created.
	AddMultiRefNode (see page 6183)	This is AddMultiRefNode, a member of class TSOAPDomConv.
	AddNamespaceDecl (see page 6183)	This is AddNamespaceDecl, a member of class TSOAPDomConv.
	AddObjectAsWriting (see page 6184)	This is AddObjectAsWriting, a member of class TSOAPDomConv.
	CheckEncodingStyle (see page 6184)	This is CheckEncodingStyle, a member of class TSOAPDomConv.
	ChildNodesAreNull (see page 6184)	This is ChildNodesAreNull, a member of class TSOAPDomConv.
	ConvertByteArrayToSoap (see page 6184)	This is ConvertByteArrayToSoap, a member of class TSOAPDomConv.
	ConvertEnumToSoap (see page 6184)	This is ConvertEnumToSoap, a member of class TSOAPDomConv.
	ConvertNativeArrayToSoap (see page 6185)	This is ConvertNativeArrayToSoap, a member of class TSOAPDomConv.
	ConvertObjectToSOAP (see page 6186)	This is ConvertObjectToSOAP, a member of class TSOAPDomConv.
	ConvertSoapToEnum (see page 6186)	This is ConvertSoapToEnum, a member of class TSOAPDomConv.

	ConvertSoapToNativeArray (see page 6186)	This is ConvertSoapToNativeArray, a member of class TSOAPDomConv.
	ConvertSoapToNativeArrayElem (see page 6186)	This is ConvertSoapToNativeArrayElem, a member of class TSOAPDomConv.
	ConvertSOAPToObject (see page 6187)	This is ConvertSOAPToObject, a member of class TSOAPDomConv.
	ConvertSoapToVariant (see page 6187)	This is ConvertSoapToVariant, a member of class TSOAPDomConv.
	ConvertVariantToSoap (see page 6188)	This is ConvertVariantToSoap, a member of class TSOAPDomConv.
	CreateMultiRefNode (see page 6188)	This is CreateMultiRefNode, a member of class TSOAPDomConv.
	CreateNULLNode (see page 6188)	This is CreateNULLNode, a member of class TSOAPDomConv.
	CreateObjectNode (see page 6188)	This is CreateObjectNode, a member of class TSOAPDomConv.
	CreateScalarNodeXS (see page 6189)	This is CreateScalarNodeXS, a member of class TSOAPDomConv.
	CreateTypedNode (see page 6189)	This is CreateTypedNode, a member of class TSOAPDomConv.
	FinalizeMultiRefNodes (see page 6189)	This is FinalizeMultiRefNodes, a member of class TSOAPDomConv.
	FindAttachment (see page 6189)	Returns a TSOAPAttachment instance that represent the attachment with a specified ID.
	FindMultiRefNodeByID (see page 6190)	This is FindMultiRefNodeByID, a member of class TSOAPDomConv.
	FindMultiRefNodeByInstance (see page 6190)	This is FindMultiRefNodeByInstance, a member of class TSOAPDomConv.
	FindNodeByHREF (see page 6190)	This is FindNodeByHREF, a member of class TSOAPDomConv.
	FindPrefixForURI (see page 6190)	This is FindPrefixForURI, a member of class TSOAPDomConv.
	GetDataNode (see page 6191)	This is GetDataNode, a member of class TSOAPDomConv.
	GetElementType (see page 6191)	This is GetElementType, a member of class TSOAPDomConv.
	GetNewID (see page 6191)	This is GetNewID, a member of class TSOAPDomConv.
	GetNodeAsText (see page 6191)	This is GetNodeAsText, a member of class TSOAPDomConv.
	GetObjectPropAsText (see page 6192)	This is GetObjectPropAsText, a member of class TSOAPDomConv.
	GetOptions (see page 6192)	This is GetOptions, a member of class TSOAPDomConv.
	GetTypeBySchemaNS (see page 6192)	This is GetTypeBySchemaNS, a member of class TSOAPDomConv.
	InitObjectFromSOAP (see page 6192)	Initializes an instance of a remotable object to reflect the values in its SOAP representation.
	IsNodeAVarArray (see page 6193)	This is IsNodeAVarArray, a member of class TSOAPDomConv.
	IsObjectWriting (see page 6193)	This is IsObjectWriting, a member of class TSOAPDomConv.
	LoadObject (see page 6193)	This is LoadObject, a member of class TSOAPDomConv.
	MakeArrayNode (see page 6193)	This is the overview for the MakeArrayNode method overload.
	MultiRefObject (see page 6194)	This is MultiRefObject, a member of class TSOAPDomConv.
	NodeIsNULL (see page 6194)	This is NodeIsNULL, a member of class TSOAPDomConv.
	ObjectMemberNoShow (see page 6195)	This is ObjectMemberNoShow, a member of class TSOAPDomConv.
	ObjInstanceToSOAP (see page 6195)	Returns the SOAP representation of a remotable object.
	ReadHeader (see page 6195)	This is ReadHeader, a member of class TSOAPDomConv.
	ReadRectDynArray (see page 6196)	This is ReadRectDynArray, a member of class TSOAPDomConv.
	ReadRectDynArrayElem (see page 6196)	This is ReadRectDynArrayElem, a member of class TSOAPDomConv.
	ReadRow (see page 6196)	This is ReadRow, a member of class TSOAPDomConv.
	ReadVarArrayDim (see page 6196)	This is ReadVarArrayDim, a member of class TSOAPDomConv.
	ReadVariant (see page 6197)	This is ReadVariant, a member of class TSOAPDomConv.
	RemoveObjectAsWriting (see page 6197)	This is RemoveObjectAsWriting, a member of class TSOAPDomConv.
	ResetMultiRef (see page 6197)	This is ResetMultiRef, a member of class TSOAPDomConv.
	SerializationOptions (see page 6197)	This is the overview for the SerializationOptions method overload.
	SetNodeType (see page 6198)	This is SetNodeType, a member of class TSOAPDomConv.
	SetObjectPropFromText (see page 6198)	This is SetObjectPropFromText, a member of class TSOAPDomConv.
	SetOptions (see page 6199)	This is SetOptions, a member of class TSOAPDomConv.
	UnhandledNode (see page 6199)	This is UnhandledNode, a member of class TSOAPDomConv.
	WriteHeader (see page 6199)	This is WriteHeader, a member of class TSOAPDomConv.
	WriteNonRectDynArray (see page 6199)	This is WriteNonRectDynArray, a member of class TSOAPDomConv.
	WriteNonRectDynArrayElem (see page 6200)	This is WriteNonRectDynArrayElem, a member of class TSOAPDomConv.
	WriteRectDynArray (see page 6200)	This is WriteRectDynArray, a member of class TSOAPDomConv.
	WriteRectDynArrayElem (see page 6200)	This is WriteRectDynArrayElem, a member of class TSOAPDomConv.
	WriteVarArray (see page 6200)	This is WriteVarArray, a member of class TSOAPDomConv.
	WriteVarArrayAsB64 (see page 6201)	This is WriteVarArrayAsB64, a member of class TSOAPDomConv.
	WriteVariant (see page 6201)	This is WriteVariant, a member of class TSOAPDomConv.

Public Methods

	Name	Description
	ConvertNativeDataToSoap (see page 6185)	Converts a native type to its SOAP representation.
	ConvertSoapToNativeData (see page 6187)	Converts the SOAP representation of a value to a pointer to the corresponding native representation.

66.1.3.4.1 TSOAPDomConv.AddAttachment Method

Stores information about a SOAP attachment so that it is included in the final message that is created.

Pascal

```
procedure AddAttachment(Attachment: TSOAPAttachment; const AContentId: string);
```

C++

```
__fastcall AddAttachment(TSOAPAttachment Attachment, const UnicodeString AContentId);
```

Description

AddAttachment stores a SOAP attachment so that it can be used to generate part of the multipart form that includes the SOAP envelope as another of its parts.

Attachment is the attachment that should be added to the multipart form.

AContentId is a string that uniquely identifies the attachment. It is added as a header to the part of the form that contains the attachment so that XML in the SOAP envelope can refer to the attachment. When interpreting the encoded SOAP envelope, this value is passed to the FindAttachment method so that the information in the attachment part can be used to recreate the TSOAPAttachment instance.

See Also

FindAttachment (see page 4463)

66.1.3.4.2 TSOAPDomConv.AddMultiRefNode Method

Pascal

```
procedure AddMultiRefNode(const ID: string; Instance: Pointer);
```

C++

```
__fastcall AddMultiRefNode(const UnicodeString ID, void * Instance);
```

Description

This is AddMultiRefNode, a member of class TSOAPDomConv.

66.1.3.4.3 TSOAPDomConv.AddNamespaceDecl Method

Pascal

```
function AddNamespaceDecl(Node: IXMLNode; const URI: InvString): InvString;
```

C++

```
__fastcall InvString AddNamespaceDecl(IXMLNode Node, const InvString URI);
```

Description

This is AddNamespaceDecl, a member of class TSOAPDomConv.

66.1.3.4.4 TSOAPDomConv.AddObjectAsWriting Method

Pascal

```
procedure AddObjectAsWriting(Instance: TObject);
```

C++

```
__fastcall AddObjectAsWriting(TObject * Instance);
```

Description

This is AddObjectAsWriting, a member of class TSOAPDomConv.

66.1.3.4.5 TSOAPDomConv.CheckEncodingStyle Method

Pascal

```
procedure CheckEncodingStyle(Node: IXMLNode);
```

C++

```
__fastcall CheckEncodingStyle(IXMLNode Node);
```

Description

This is CheckEncodingStyle, a member of class TSOAPDomConv.

66.1.3.4.6 TSOAPDomConv.ChildNodesAreNull Method

Pascal

```
function ChildNodesAreNull(Node: IXMLNode): Boolean;
```

C++

```
__fastcall Boolean ChildNodesAreNull(IXMLNode Node);
```

Description

This is ChildNodesAreNull, a member of class TSOAPDomConv.

66.1.3.4.7 TSOAPDomConv.ConvertByteArrayToSoap Method

Pascal

```
procedure ConvertByteArrayToSoap(RootNode: IXMLNode; Node: IXMLNode; const Name: InvString;
Info: PTypeInfo; P: Pointer);
```

C++

```
__fastcall ConvertByteArrayToSoap(IXMLNode RootNode, IXMLNode Node, const InvString Name,
PTypeInfo Info, void * P);
```

Description

This is ConvertByteArrayToSoap, a member of class TSOAPDomConv.

66.1.3.4.8 TSOAPDomConv.ConvertEnumToSoap Method

Pascal

```
function ConvertEnumToSoap(Info: PTypeInfo; P: Pointer; NumIndirect: Integer): InvString;
```

C++

```
__fastcall InvString ConvertEnumToSoap(PTypeInfo Info, void * P, int NumIndirect);
```

Description

This is ConvertEnumToSoap, a member of class TSOAPDomConv.

66.1.3.4.9 TSOAPDomConv.ConvertNativeArrayToSoap Method

Pascal

```
procedure ConvertNativeArrayToSoap(RootNode: IXMLNode; Node: IXMLNode; const Name: InvString;
Info: PTypeInfo; P: Pointer; NumIndirect: Integer; InlineElements: Boolean = False);
```

C++

```
__fastcall ConvertNativeArrayToSoap(IXMLNode RootNode, IXMLNode Node, const InvString Name,
PTypeInfo Info, void * P, int NumIndirect, Boolean InlineElements = False);
```

Description

This is ConvertNativeArrayToSoap, a member of class TSOAPDomConv.

66.1.3.4.10 TSOAPDomConv.ConvertNativeDataToSoap Method

Converts a native type to its SOAP representation.

Pascal

```
procedure ConvertNativeDataToSoap(RootNode: IXMLNode; Node: IXMLNode; const Name: InvString;
Info: PTypeInfo; P: Pointer; NumIndirect: Integer); dynamic;
```

C++

```
__fastcall ConvertNativeDataToSoap(IXMLNode RootNode, IXMLNode Node, const InvString Name,
PTypeInfo Info, void * P, int NumIndirect);
```

Description

ConvertNativeDataToSoap performs the conversion from a native type to its SOAP representation and adds that to the emerging DOM representation of a SOAP packet. It uses the options specified by the Options (see page 6201) property to determine whether to include type data and how to handle multiple references to the same remotable object.

RootNode is the node in the emerging SOAP representation that acts as a parent to any elements that represent an object that has multiple references.

Node is the parent node to which ConvertNativeDataToSoap adds a new child node that represents the native value.

Name is the type name of the SOAP encoding of the native type.

Info is a TypeInfo pointer that indicates the type in which the native data appears.

P is a pointer to the value to convert. It points (possibly with additional levels of indirection) to a value of the type indicated by Info.

NumIndirect indicates the number of levels of indirection by which P points to a value of the type indicated by Info.

See Also

ConvertSoapToNativeData (see page 6187)

Options (see page 6201)

66.1.3.4.11 TSOAPDomConv.ConvertObjectToSOAP Method

Pascal

```
procedure ConvertObjectToSOAP(const Name: InvString; ObjP: Pointer; RootNode: IXMLNOde; Node:
IXMLNOde; NumIndirect: Integer);
```

C++

```
__fastcall ConvertObjectToSOAP(const InvString Name, void * ObjP, IXMLNOde RootNode, IXMLNOde
Node, int NumIndirect);
```

Description

This is ConvertObjectToSOAP, a member of class TSOAPDomConv.

66.1.3.4.12 TSOAPDomConv.ConvertSoapToEnum Method

Pascal

```
function ConvertSoapToEnum(Info: PTypeInfo; S: InvString; IsNull: Boolean): Integer;
```

C++

```
__fastcall int ConvertSoapToEnum(PTypeInfo Info, InvString S, Boolean IsNull);
```

Description

This is ConvertSoapToEnum, a member of class TSOAPDomConv.

66.1.3.4.13 TSOAPDomConv.ConvertSoapToNativeArray Method

Pascal

```
function ConvertSoapToNativeArray(DataP: Pointer; TypeInfo: PTypeInfo; RootNode: IXMLNode;
Node: IXMLNode): Pointer;
```

C++

```
__fastcall void * ConvertSoapToNativeArray(void * DataP, PTypeInfo TypeInfo, IXMLNode
RootNode, IXMLNode Node);
```

Description

This is ConvertSoapToNativeArray, a member of class TSOAPDomConv.

66.1.3.4.14 TSOAPDomConv.ConvertSoapToNativeArrayElem Method

Pascal

```
function ConvertSoapToNativeArrayElem(ArrayInfo: PTypeInfo; ElemInfo: PTypeInfo; RootNode:
IXMLNode; Node: IXMLNode; ArrayDesc: TSOAPArrayDesc; Dims: Integer; CurDim: Integer; DataP:
Pointer): Pointer;
```

C++

```
__fastcall void * ConvertSoapToNativeArrayElem(PTypeInfo ArrayInfo, PTypeInfo ElemInfo,
IXMLNode RootNode, IXMLNode Node, TSOAPArrayDesc ArrayDesc, int Dims, int CurDim, void *
DataP);
```

Description

This is ConvertSoapToNativeArrayElem, a member of class TSOAPDomConv.

66.1.3.4.15 TSOAPDomConv.ConvertSoapToNativeData Method

Converts the SOAP representation of a value to a pointer to the corresponding native representation.

Pascal

```
procedure ConvertSoapToNativeData(DataP: Pointer; TypeInfo: PTypeInfo; Context: TDataContext;
RootNode: IXMLNode; Node: IXMLNode; Translate: Boolean; ByRef: Boolean; NumIndirect: Integer);
dynamic;
```

C++

```
__fastcall ConvertSoapToNativeData(void * DataP, PTypeInfo TypeInfo, TDataContext Context,
IXMLNode RootNode, IXMLNode Node, Boolean Translate, Boolean ByRef, int NumIndirect);
```

Description

ConvertSoapToNativeData performs the conversion from a DOM node that represents a SOAP encoding of a value to the corresponding native representation.

DataP is a pointer to the memory allocated to hold the native representation of the value, and points to the results of the conversion.

TypeInfo is the typeinfo pointer that describes the native type that will represent the value.

Context is the TDataContext (see page 4354) object that stores the value.

RootNode is the node in the SOAP packet that acts as a parent to any elements to which there are multiple references.

Node is the node in the SOAP packet whose value is to be translated.

Translate indicates whether Node represents a value to be translated, as opposed to a reference to value that is found elsewhere in the SOAP packet.

ByRef indicates whether the node corresponds to a parameter that is passed by reference.

NumIndirect indicates the number of levels of indirection by which DataP points to its value.

See Also

ConvertNativeDataToSoap (see page 6185)

Options (see page 6201)

66.1.3.4.16 TSOAPDomConv.ConvertSOAPToObject Method

Pascal

```
function ConvertSOAPToObject(RootNode: IXMLNode; Node: IXMLNode; AClass: TClass; const URI:
InvString; const TypeName: InvString; ObjP: Pointer; NumIndirect: Integer): TObject;
```

C++

```
__fastcall TObject * ConvertSOAPToObject(IXMLNode RootNode, IXMLNode Node, TClass AClass,
const InvString URI, const InvString TypeName, void * ObjP, int NumIndirect);
```

Description

This is ConvertSOAPToObject, a member of class TSOAPDomConv.

66.1.3.4.17 TSOAPDomConv.ConvertSoapToVariant Method

Pascal

```
procedure ConvertSoapToVariant(Node: IXMLNode; InvData: Pointer);
```

C++

```
__fastcall ConvertSoapToVariant(IXMLNode Node, void * InvData);
```

Description

This is ConvertSoapToVariant, a member of class TSOAPDomConv.

66.1.3.4.18 TSOAPDomConv.ConvertVariantToSoap Method

Pascal

```
procedure ConvertVariantToSoap(RootNode: IXMLNode; Node: IXMLNode; const Name: InvString;
Info: PTypeInfo; P: PVarData; NumIndirect: Integer; V: Variant; UseVariant: Boolean);
```

C++

```
__fastcall ConvertVariantToSoap(IXMLNode RootNode, IXMLNode Node, const InvString Name,
PTypeInfo Info, PVarData P, int NumIndirect, Variant V, Boolean UseVariant);
```

Description

This is ConvertVariantToSoap, a member of class TSOAPDomConv.

66.1.3.4.19 TSOAPDomConv.CreateMultiRefNode Method

Pascal

```
function CreateMultiRefNode(RootNode: IXMLNode; const Name: InvString; const ID: InvString):
IXMLNode;
```

C++

```
__fastcall IXMLNode CreateMultiRefNode(IXMLNode RootNode, const InvString Name, const
InvString ID);
```

Description

This is CreateMultiRefNode, a member of class TSOAPDomConv.

66.1.3.4.20 TSOAPDomConv.CreateNULLNode Method

Pascal

```
function CreateNULLNode(RootNode: IXMLNode; ParentNode: IXMLNode; const Name: InvString;
UseParentNode: Boolean = False): IXMLNode;
```

C++

```
__fastcall IXMLNode CreateNULLNode(IXMLNode RootNode, IXMLNode ParentNode, const InvString
Name, Boolean UseParentNode = False);
```

Description

This is CreateNULLNode, a member of class TSOAPDomConv.

66.1.3.4.21 TSOAPDomConv.CreateObjectNode Method

Pascal

```
function CreateObjectNode(Instance: TObject; RootNode: IXMLNode; ParentNode: IXMLNode; const
Name: InvString; const URI: InvString; ObjConvOpts: TObjectConvertOptions): InvString;
```

C++

```
__fastcall InvString CreateObjectNode(TObject * Instance, IXMLNode RootNode, IXMLNode
ParentNode, const InvString Name, const InvString URI, TObjectConvertOptions ObjConvOpts);
```

Description

This is CreateObjectNode, a member of class TSOAPDomConv.

66.1.3.4.22 TSOAPDomConv.CreateScalarNodeXS Method

Pascal

```
function CreateScalarNodeXS(RootNode: IXMLNode; ParentNode: IXMLNode; const NodeName:
InvString; const URI: InvString; const TypeName: InvString; const Value: InvString; GenPre:
Boolean = False): IXMLNode;
```

C++

```
__fastcall IXMLNode CreateScalarNodeXS(IXMLNode RootNode, IXMLNode ParentNode, const InvString
NodeName, const InvString URI, const InvString TypeName, const InvString Value, Boolean GenPre
= False);
```

Description

This is CreateScalarNodeXS, a member of class TSOAPDomConv.

66.1.3.4.23 TSOAPDomConv.CreateTypedNode Method

Pascal

```
function CreateTypedNode(RootNode: IXMLNode; ParentNode: IXMLNode; const NodeName: InvString;
const URI: InvString; TypeName: InvString; GenPre: Boolean = False): IXMLNode;
```

C++

```
__fastcall IXMLNode CreateTypedNode(IXMLNode RootNode, IXMLNode ParentNode, const InvString
NodeName, const InvString URI, InvString TypeName, Boolean GenPre = False);
```

Description

This is CreateTypedNode, a member of class TSOAPDomConv.

66.1.3.4.24 TSOAPDomConv.FinalizeMultiRefNodes Method

Pascal

```
procedure FinalizeMultiRefNodes;
```

C++

```
__fastcall FinalizeMultiRefNodes();
```

Description

This is FinalizeMultiRefNodes, a member of class TSOAPDomConv.

66.1.3.4.25 TSOAPDomConv.FindAttachment Method

Returns a TSOAPAttachment instance that represent the attachment with a specified ID.

Pascal

```
function FindAttachment(const AContentId: string): TSOAPAttachment;
```

C++

```
__fastcall TSOAPAttachment FindAttachment(const UnicodeString AContentId);
```

Description

FindAttachment locates the attachment that is identified by a specified content ID (HREF).

AContentId is the unique identifier for the attachment that was supplied to the AddAttachment method when the attachment was first added to the multipart form.

FindAttachment returns a TSOAPAttachment instance that represents the attachment.

See Also

AddAttachment (see page 4462)

66.1.3.4.26 TSOAPDomConv.FindMultiRefNodeByID Method

Pascal

```
function FindMultiRefNodeByID(const ID: string): Pointer;
```

C++

```
__fastcall void * FindMultiRefNodeByID(const UnicodeString ID);
```

Description

This is FindMultiRefNodeByID, a member of class TSOAPDomConv.

66.1.3.4.27 TSOAPDomConv.FindMultiRefNodeByInstance Method

Pascal

```
function FindMultiRefNodeByInstance(Instance: Pointer): string;
```

C++

```
__fastcall UnicodeString FindMultiRefNodeByInstance(void * Instance);
```

Description

This is FindMultiRefNodeByInstance, a member of class TSOAPDomConv.

66.1.3.4.28 TSOAPDomConv.FindNodeByHREF Method

Pascal

```
function FindNodeByHREF(RootNode: IXMLNode; const HREF: InvString): IXMLNode;
```

C++

```
__fastcall IXMLNode FindNodeByHREF(IXMLNode RootNode, const InvString HREF);
```

Description

This is FindNodeByHREF, a member of class TSOAPDomConv.

66.1.3.4.29 TSOAPDomConv.FindPrefixForURI Method

Pascal

```
function FindPrefixForURI(RootNode: IXMLNode; Node: IXMLNode; const URI: InvString;
DeclIfNone: Boolean = False): InvString;
```

C++

```
__fastcall InvString FindPrefixForURI(IXMLNode RootNode, IXMLNode Node, const InvString URI,
Boolean DeclIfNone = False);
```

Description

This is FindPrefixForURI, a member of class TSOAPDomConv.

66.1.3.4.30 TSOAPDomConv.GetDataNode Method

Pascal

```
function GetDataNode(RootNode: IXMLNode; Node: IXMLNode; var ID: InvString): IXMLNode;
```

C++

```
__fastcall IXMLNode GetDataNode(IXMLNode RootNode, IXMLNode Node, InvString ID);
```

Description

This is GetDataNode, a member of class TSOAPDomConv.

66.1.3.4.31 TSOAPDomConv.GetElementType Method

Pascal

```
function GetElementType(Node: IXMLNode; var TypeURI: InvString; var TypeName: InvString):
Boolean;
```

C++

```
__fastcall Boolean GetElementType(IXMLNode Node, InvString TypeURI, InvString TypeName);
```

Description

This is GetElementType, a member of class TSOAPDomConv.

66.1.3.4.32 TSOAPDomConv.GetNewID Method

Pascal

```
function GetNewID: string;
```

C++

```
__fastcall UnicodeString GetNewID();
```

Description

This is GetNewID, a member of class TSOAPDomConv.

66.1.3.4.33 TSOAPDomConv.GetNodeAsText Method

Pascal

```
function GetNodeAsText(Node: IXMLNode): InvString;
```

C++

```
__fastcall InvString GetNodeAsText(IXMLNode Node);
```

Description

This is GetNodeAsText, a member of class TSOAPDomConv.

66.1.3.4.34 TSOAPDomConv.GetObjectPropAsText Method

Pascal

```
function GetObjectPropAsText(Instance: TObject; PropInfo: PPropInfo): InvString;
```

C++

```
__fastcall InvString GetObjectPropAsText(TObject * Instance, PPropInfo PropInfo);
```

Description

This is GetObjectPropAsText, a member of class TSOAPDomConv.

66.1.3.4.35 TSOAPDomConv.GetOptions Method

Pascal

```
function GetOptions: TSOAPConvertOptions;
```

C++

```
__fastcall TSOAPConvertOptions GetOptions();
```

Description

This is GetOptions, a member of class TSOAPDomConv.

66.1.3.4.36 TSOAPDomConv.GetTypeBySchemaNS Method

Pascal

```
function GetTypeBySchemaNS(Node: IXMLNode; const URI: InvString): Variant;
```

C++

```
__fastcall Variant GetTypeBySchemaNS(IXMLNode Node, const InvString URI);
```

Description

This is GetTypeBySchemaNS, a member of class TSOAPDomConv.

66.1.3.4.37 TSOAPDomConv.InitObjectFromSOAP Method

Initializes an instance of a remotable object to reflect the values in its SOAP representation.

Pascal

```
procedure InitObjectFromSOAP(Instance: TObject; RootNode: IXMLNode; Node: IXMLNode);
```

C++

```
__fastcall InitObjectFromSOAP(TObject * Instance, IXMLNode RootNode, IXMLNode Node);
```

Description

InitObjectFromSOAP assigns values to the published properties of a remotable object that represents a node from the SOAP envelope.

Instance is the remotable object to initialize from its SOAP representation.

RootNode is an ancestor node of the node for the remotable object that can contain information needed for initializing the remotable object.

Node is the node in the SOAP envelope that represents the remotable object.

See Also

ObjInstanceToSOAP (see page 4463)

66.1.3.4.38 TSOAPDomConv.IsNodeAVarArray Method

Pascal

```
function IsNodeAVarArray(const Node: IXMLNode; var VT: TVarType): Boolean;
```

C++

```
__fastcall Boolean IsNodeAVarArray(const IXMLNode Node, TVarType VT);
```

Description

This is IsNodeAVarArray, a member of class TSOAPDomConv.

66.1.3.4.39 TSOAPDomConv.IsObjectWriting Method

Pascal

```
function IsObjectWriting(Instance: TObject): Boolean;
```

C++

```
__fastcall Boolean IsObjectWriting(TObject * Instance);
```

Description

This is IsObjectWriting, a member of class TSOAPDomConv.

66.1.3.4.40 TSOAPDomConv.LoadObject Method

Pascal

```
procedure LoadObject(Instance: TObject; RootNode: IXMLNode; Node: IXMLNode);
```

C++

```
__fastcall LoadObject(TObject * Instance, IXMLNode RootNode, IXMLNode Node);
```

Description

This is LoadObject, a member of class TSOAPDomConv.

66.1.3.4.41 MakeArrayNode Method

This is the overview for the MakeArrayNode method overload.

Overload List

	Name	Description
	TSOAPDomConv.MakeArrayNode (IXMLNode, IXMLNode, InvString, InvString, InvString, array of Integer) (see page 6194)	This is MakeArrayNode, a member of class TSOAPDomConv.
	TSOAPDomConv.MakeArrayNode (IXMLNode, IXMLNode, InvString, InvString, InvString, Integer, Integer) (see page 6194)	This is MakeArrayNode, a member of class TSOAPDomConv.

66.1.3.4.41.1 TSOAPDomConv.MakeArrayNode Method (IXMLNode, IXMLNode, InvString, InvString, InvString, Integer, Integer)

Pascal

```
function MakeArrayNode(RootNode: IXMLNode; Node: IXMLNode; const Name: InvString; const URI:
InvString; const TypeName: InvString; Dim: Integer; Len: Integer): IXMLNode; overload;
```

C++

```
__fastcall IXMLNode MakeArrayNode(IXMLNode RootNode, IXMLNode Node, const InvString Name,
const InvString URI, const InvString TypeName, int Dim, int Len);
```

Description

This is MakeArrayNode, a member of class TSOAPDomConv.

66.1.3.4.41.2 TSOAPDomConv.MakeArrayNode Method (IXMLNode, IXMLNode, InvString, InvString, InvString, array of Integer)

Pascal

```
function MakeArrayNode(RootNode: IXMLNode; Node: IXMLNode; const Name: InvString; const URI:
InvString; const TypeName: InvString; Indices: array of Integer): IXMLNode; overload;
```

C++

```
__fastcall IXMLNode MakeArrayNode(IXMLNode RootNode, IXMLNode Node, const InvString Name,
const InvString URI, const InvString TypeName, array of Integer Indices);
```

Description

This is MakeArrayNode, a member of class TSOAPDomConv.

66.1.3.4.42 TSOAPDomConv.MultiRefObject Method

Pascal

```
function MultiRefObject(Cls: TClass): Boolean;
```

C++

```
__fastcall Boolean MultiRefObject(TClass Cls);
```

Description

This is MultiRefObject, a member of class TSOAPDomConv.

66.1.3.4.43 TSOAPDomConv.NodeIsNULL Method

Pascal

```
function NodeIsNULL(Node: IXMLNode): Boolean;
```

C++

```
__fastcall Boolean NodeIsNULL(IXMLNode Node);
```

Description

This is NodeIsNULL, a member of class TSOAPDomConv.

66.1.3.4.44 TSOAPDomConv.ObjectMemberNoShow Method

Pascal

```
procedure ObjectMemberNoShow(const ClassName: string; const MemberName: string);
```

C++

```
__fastcall ObjectMemberNoShow(const UnicodeString ClassName, const UnicodeString MemberName);
```

Description

This is ObjectMemberNoShow, a member of class TSOAPDomConv.

66.1.3.4.45 TSOAPDomConv.ObjInstanceToSOAP Method

Returns the SOAP representation of a remotable object.

Pascal

```
function ObjInstanceToSOAP(Instance: TObject; RootNode: IXMLNode; ParentNode: IXMLNode; const
NodeName: InvString; const NodeNamespace: InvString; ObjConvOpts: TObjectConvertOptions; out
RefID: InvString): IXMLNode;
```

C++

```
__fastcall IXMLNode ObjInstanceToSOAP(TObject * Instance, IXMLNode RootNode, IXMLNode
ParentNode, const InvString NodeName, const InvString NodeNamespace, TObjectConvertOptions
ObjConvOpts, InvString RefID);
```

Description

ObjInstanceToSOAP adds a node to represent the value of a remotable object.

Instance is the remotable object to encode as its SOAP representation.

RootNode is an ancestor of the node to which information about the node can be added as attributes.

ParentNode is the node in the SOAP representation that should act as a parent to the node that ObjInstanceToSOAP generates.

NodeName is the name of the node that is generated.

NodeNamespace is the URI for the namespace in which NodeName is defined.

ObjConvOpts are flags that customize the way the node is serialized.

RefID returns a reference ID for the node. This is used if the node is multi-referenced.

ObjInstanceToSOAP returns the XML for the newly generated node.

See Also

InitObjectFromSOAP (see page 4463)

66.1.3.4.46 TSOAPDomConv.ReadHeader Method

Pascal

```
procedure ReadHeader(const EnvNode: IXMLNode; const HdrNode: IXMLNode; Headers: THeaderList);
```

C++

```
__fastcall ReadHeader(const IXMLNode EnvNode, const IXMLNode HdrNode, THeaderList Headers);
```

Description

This is ReadHeader, a member of class TSOAPDomConv.

66.1.3.4.47 TSOAPDomConv.ReadRectDynArray Method

Pascal

```
procedure ReadRectDynArray(RootNode: IXMLNode; Node: IXMLNode; Info: PTypeInfo; Dims: Integer;
P: Pointer; CurElem: Integer);
```

C++

```
__fastcall ReadRectDynArray(IXMLNode RootNode, IXMLNode Node, PTypeInfo Info, int Dims, void *
P, int CurElem);
```

Description

This is ReadRectDynArray, a member of class TSOAPDomConv.

66.1.3.4.48 TSOAPDomConv.ReadRectDynArrayElem Method

Pascal

```
procedure ReadRectDynArrayElem(RootNode: IXMLNode; Node: IXMLNode; Info: PTypeInfo; Size:
Integer; Dim: Integer; P: Pointer; var CurElem: Integer);
```

C++

```
__fastcall ReadRectDynArrayElem(IXMLNode RootNode, IXMLNode Node, PTypeInfo Info, int Size,
int Dim, void * P, int CurElem);
```

Description

This is ReadRectDynArrayElem, a member of class TSOAPDomConv.

66.1.3.4.49 TSOAPDomConv.ReadRow Method

Pascal

```
procedure ReadRow(RootNode: IXMLNode; Node: IXMLNode; var CurElem: Integer; Size: Integer; P:
Pointer; Info: PTypeInfo);
```

C++

```
__fastcall ReadRow(IXMLNode RootNode, IXMLNode Node, int CurElem, int Size, void * P,
PTypeInfo Info);
```

Description

This is ReadRow, a member of class TSOAPDomConv.

66.1.3.4.50 TSOAPDomConv.ReadVarArrayDim Method

Pascal

```
function ReadVarArrayDim(Node: IXMLNode; IsVarVArray: Boolean = False; VT: TVarType = 0):
Variant;
```

C++

```
__fastcall Variant ReadVarArrayDim(IXMLNode Node, Boolean IsVarVArray = False, TVarType VT =
0);
```

Description

This is ReadVarArrayDim, a member of class TSOAPDomConv.

66.1.3.4.51 TSOAPDomConv.ReadVariant Method

Pascal

```
procedure ReadVariant(Node: IXMLNode; P: Pointer);
```

C++

```
__fastcall ReadVariant(IXMLNode Node, void * P);
```

Description

This is ReadVariant, a member of class TSOAPDomConv.

66.1.3.4.52 TSOAPDomConv.RemoveObjectAsWriting Method

Pascal

```
procedure RemoveObjectAsWriting(Instance: TObject);
```

C++

```
__fastcall RemoveObjectAsWriting(TObject * Instance);
```

Description

This is RemoveObjectAsWriting, a member of class TSOAPDomConv.

66.1.3.4.53 TSOAPDomConv.ResetMultiRef Method

Pascal

```
procedure ResetMultiRef;
```

C++

```
__fastcall ResetMultiRef();
```

Description

This is ResetMultiRef, a member of class TSOAPDomConv.

66.1.3.4.54 SerializationOptions Method

This is the overview for the SerializationOptions method overload.

Overload List

	Name	Description
	TSOAPDomConv.SerializationOptions (PTypeInfo) (see page 6198)	This is SerializationOptions, a member of class TSOAPDomConv.
	TSOAPDomConv.SerializationOptions (TClass) (see page 6198)	This is SerializationOptions, a member of class TSOAPDomConv.
	TSOAPDomConv.SerializationOptions (TObject) (see page 6198)	This is SerializationOptions, a member of class TSOAPDomConv.

66.1.3.4.54.1 TSOAPDomConv.SerializationOptions Method (PTypeInfo)

Pascal

```
function SerializationOptions(ATypeInfo: PTypeInfo): TSerializationOptions; overload;
```

C++

```
__fastcall TSerializationOptions SerializationOptions(PTypeInfo ATypeInfo);
```

Description

This is SerializationOptions, a member of class TSOAPDomConv.

66.1.3.4.54.2 TSOAPDomConv.SerializationOptions Method (TClass)

Pascal

```
function SerializationOptions(Cls: TClass): TSerializationOptions; overload;
```

C++

```
__fastcall TSerializationOptions SerializationOptions(TClass Cls);
```

Description

This is SerializationOptions, a member of class TSOAPDomConv.

66.1.3.4.54.3 TSOAPDomConv.SerializationOptions Method (TObject)

Pascal

```
function SerializationOptions(Obj: TObject): TSerializationOptions; overload;
```

C++

```
__fastcall TSerializationOptions SerializationOptions(TObject * Obj);
```

Description

This is SerializationOptions, a member of class TSOAPDomConv.

66.1.3.4.55 TSOAPDomConv.SetNodeType Method

Pascal

```
procedure SetNodeType(RootNode: IXMLNode; InstNode: IXMLNode; const ElemURI: InvString; const
TypeName: InvString);
```

C++

```
__fastcall SetNodeType(IXMLNode RootNode, IXMLNode InstNode, const InvString ElemURI, const
InvString TypeName);
```

Description

This is SetNodeType, a member of class TSOAPDomConv.

66.1.3.4.56 TSOAPDomConv.SetObjectPropFromText Method

Pascal

```
procedure SetObjectPropFromText(Instance: TObject; PropInfo: PPropInfo; const SoapData:
InvString);
```

C++

```
__fastcall SetObjectPropFromText(TObject * Instance, PPropInfo PropInfo, const InvString
SoapData);
```

Description

This is SetObjectPropFromText, a member of class TSOAPDomConv.

66.1.3.4.57 TSOAPDomConv.SetOptions Method

Pascal

```
procedure SetOptions(const Value: TSOAPConvertOptions);
```

C++

```
__fastcall SetOptions(const TSOAPConvertOptions Value);
```

Description

This is SetOptions, a member of class TSOAPDomConv.

66.1.3.4.58 TSOAPDomConv.UnhandledNode Method

Pascal

```
procedure UnhandledNode(const Name: string; NodeXML: InvString);
```

C++

```
__fastcall UnhandledNode(const UnicodeString Name, InvString NodeXML);
```

Description

This is UnhandledNode, a member of class TSOAPDomConv.

66.1.3.4.59 TSOAPDomConv.WriteHeader Method

Pascal

```
procedure WriteHeader(const Header: TObject; RootNode: IXMLNode; ParentNode: IXMLNode);
```

C++

```
__fastcall WriteHeader(const TObject * Header, IXMLNode RootNode, IXMLNode ParentNode);
```

Description

This is WriteHeader, a member of class TSOAPDomConv.

66.1.3.4.60 TSOAPDomConv.WriteNonRectDynArray Method

Pascal

```
procedure WriteNonRectDynArray(RootNode: IXMLNode; Node: IXMLNode; const Name: InvString;
Info: PTypeInfo; const URI: InvString; const TypeName: InvString; P: Pointer; Dim: Integer);
```

C++

```
__fastcall WriteNonRectDynArray(IXMLNode RootNode, IXMLNode Node, const InvString Name,
PTypeInfo Info, const InvString URI, const InvString TypeName, void * P, int Dim);
```

Description

This is WriteNonRectDynArray, a member of class TSOAPDomConv.

66.1.3.4.61 TSOAPDomConv.WriteNonRectDynArrayElem Method

Pascal

```
function WriteNonRectDynArrayElem(RootNode: IXMLNode; Node: IXMLNode; Info: PTypeInfo; const
URI: InvString; const TypeName: InvString; P: Pointer; Dim: Integer): Integer;
```

C++

```
__fastcall int WriteNonRectDynArrayElem(IXMLNode RootNode, IXMLNode Node, PTypeInfo Info,
const InvString URI, const InvString TypeName, void * P, int Dim);
```

Description

This is WriteNonRectDynArrayElem, a member of class TSOAPDomConv.

66.1.3.4.62 TSOAPDomConv.WriteRectDynArray Method

Pascal

```
procedure WriteRectDynArray(RootNode: IXMLNode; Node: IXMLNode; Info: PTypeInfo; Dims:
Integer; P: Pointer; const TypeName: InvString);
```

C++

```
__fastcall WriteRectDynArray(IXMLNode RootNode, IXMLNode Node, PTypeInfo Info, int Dims, void
* P, const InvString TypeName);
```

Description

This is WriteRectDynArray, a member of class TSOAPDomConv.

66.1.3.4.63 TSOAPDomConv.WriteRectDynArrayElem Method

Pascal

```
procedure WriteRectDynArrayElem(RootNode: IXMLNode; Node: IXMLNode; Info: PTypeInfo; Size:
Integer; Dim: Integer; P: Pointer; const TypeName: InvString);
```

C++

```
__fastcall WriteRectDynArrayElem(IXMLNode RootNode, IXMLNode Node, PTypeInfo Info, int Size,
int Dim, void * P, const InvString TypeName);
```

Description

This is WriteRectDynArrayElem, a member of class TSOAPDomConv.

66.1.3.4.64 TSOAPDomConv.WriteVarArray Method

Pascal

```
procedure WriteVarArray(RootNode: IXMLNode; Node: IXMLNode; const Name: InvString; V: Variant);
```

C++

```
__fastcall WriteVarArray(IXMLNode RootNode, IXMLNode Node, const InvString Name, Variant V);
```

Description

This is WriteVarArray, a member of class TSOAPDomConv.

66.1.3.4.65 TSOAPDomConv.WriteVarArrayAsB64 Method

Pascal

```
procedure WriteVarArrayAsB64(RootNode: IXMLNode; Node: IXMLNode; const Name: InvString; V:
Variant);
```

C++

```
__fastcall WriteVarArrayAsB64(IXMLNode RootNode, IXMLNode Node, const InvString Name, Variant
V);
```

Description

This is WriteVarArrayAsB64, a member of class TSOAPDomConv.

66.1.3.4.66 TSOAPDomConv.WriteVariant Method

Pascal

```
procedure WriteVariant(RootNode: IXMLNode; Node: IXMLNode; const Name: InvString; V: Variant);
```

C++

```
__fastcall WriteVariant(IXMLNode RootNode, IXMLNode Node, const InvString Name, Variant V);
```

Description

This is WriteVariant, a member of class TSOAPDomConv.

66.1.3.5 TSOAPDomConv Properties

The properties of the TSOAPDomConv class are listed here.

Published Properties

	Name	Description
	Options (see page 6201)	Controls how the TSOAPDomConv (see page 6178) object performs certain types of conversions.

66.1.3.5.1 TSOAPDomConv.Options Property

Controls how the TSOAPDomConv (see page 6178) object performs certain types of conversions.

Pascal

```
property Options: TSOAPConvertOptions;
```

C++

```
__property TSOAPConvertOptions Options;
```

Description

Set Options to indicate how you want the TSOAPDomConv (see page 6178) object to handle various types of conversions. This set can include zero or more of the TSOAPConvertOption (see page 6162) flags.

See Also

ConvertNativeDataToSoap (see page 6185)

ClassOptions (see page 4417)

ConvertSoapToNativeData (see page 6187)

66.1.3.6 TSOAPDomConv Events

The events of the TSOAPDomConv class are listed here.

Published Events

	Name	Description
	OnMemberDataNotReceived (see page 6202)	Occurs when converting a SOAP representation to a remotable object and an expected class member was not found.
	OnUnhandledNode (see page 6202)	Occurs when a SOAP representation includes an XML node that the converter does not know how to handle.

66.1.3.6.1 TSOAPDomConv.OnMemberDataNotReceived Event

Occurs when converting a SOAP representation to a remotable object and an expected class member was not found.

Pascal

```
property OnMemberDataNotReceived: TMemberDataNotReceivedEvent;
```

C++

```
__property TMemberDataNotReceivedEvent OnMemberDataNotReceived;
```

Description

Write an OnMemberDataNotReceived to detect cases where the converter does not receive the information it excepts When a method on an invokable interface requires the user to send or receive OnMemberDataNotReceived, these for deserializing a remotable type (a TRemotable (see page 4408) descendant). This event is especially useful during debugging. Typically, after detecting a problem using OnMemberDataNotReceived, the problem is then handled by changing the code that declares or registers the remotable type.

See Also

TRemotable (see page 4408)

66.1.3.6.2 TSOAPDomConv.OnUnhandledNode Event

Occurs when a SOAP representation includes an XML node that the converter does not know how to handle.

Pascal

```
property OnUnhandledNode: TUnhandledNodeEvent;
```

C++

```
__property TUnhandledNodeEvent OnUnhandledNode;
```

Description

Write an OnUnhandledNode to detect and, possibly, fix cases where the converter can't correctly generate the native code corresponding to a node in a SOAP packet.

66.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	GetOrdPropEx (see page 6203)	This is function OPToSOAPDomConv.GetOrdPropEx.

66.2.1 OPToSOAPDomConv.GetOrdPropEx Function

Pascal

```
function GetOrdPropEx(Instance: TObject; PropInfo: PPropInfo): Longint;
```

C++

```
Longint GetOrdPropEx(TObject * Instance, PPropInfo PropInfo);
```

File

OPToSOAPDomConv

Description

This is function OPToSOAPDomConv.GetOrdPropEx.

66.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	ConvNodeState (see page 6204)	This is record OPToSOAPDomConv.ConvNodeState.

Records

	Name	Description
	TMultiRefNodeElem (see page 6204)	This is record OPToSOAPDomConv.TMultiRefNodeElem.
	TMultiRefNodeMapElem (see page 6205)	This is record OPToSOAPDomConv.TMultiRefNodeMapElem.
	TSOAPArrayElemDesc (see page 6205)	This is record OPToSOAPDomConv.TSOAPArrayElemDesc.

66.3.1 OPToSOAPDomConv.ConvNodeState Enumeration

Pascal

```
ConvNodeState = (
  nsClientSend,
  nsServerReceive,
  nsServerSend,
  nsClientReceive
);
```

C++

```
enum ConvNodeState {
  nsClientSend,
  nsServerReceive,
  nsServerSend,
  nsClientReceive
};
```

File

OPToSOAPDomConv

Description

This is record OPToSOAPDomConv.ConvNodeState.

66.3.2 OPToSOAPDomConv.TMultiRefNodeElem Record

Pascal

```
TMultiRefNodeElem = record
  Node: IXMLNode;
  MultiRefChildren: TXMLNodeArray;
end;
```

C++

```
struct TMultiRefNodeElem {
  IXMLNode Node;
  TXMLNodeArray MultiRefChildren;
};
```

File

OPToSOAPDomConv

Description

This is record OPToSOAPDomConv.TMultiRefNodeElem.

66.3.3 OPToSOAPDomConv.TMultiRefNodeMapElem Record

Pascal

```
TMultiRefNodeMapElem = record
  Instance: Pointer;
  ID: string;
end;
```

C++

```
struct TMultiRefNodeMapElem {
  void * Instance;
  UnicodeString ID;
};
```

File

OPToSOAPDomConv

Description

This is record OPToSOAPDomConv.TMultiRefNodeMapElem.

66.3.4 OPToSOAPDomConv.TSOAPArrayElemDesc Record

Pascal

```
TSOAPArrayElemDesc = record
  MultiDim: Boolean;
  Dims: TIntegerDynArray;
end;
```

C++

```
struct TSOAPArrayElemDesc {
  Boolean MultiDim;
  TIntegerDynArray Dims;
};
```

File

OPToSOAPDomConv

Description

This is record OPToSOAPDomConv.TSOAPArrayElemDesc.

66.4 Types

The following table lists types in this documentation.

Types

Name	Description
TMemberDataNotReceivedEvent (see page 6206)	This is type OPToSOAPDomConv.TMemberDataNotReceivedEvent.
TMultiRefNodeMap (see page 6206)	This is type OPToSOAPDomConv.TMultiRefNodeMap.
TMultiRefNodes (see page 6207)	This is type OPToSOAPDomConv.TMultiRefNodes.
TSOAPArrayDesc (see page 6207)	This is type OPToSOAPDomConv.TSOAPArrayDesc.
TUnhandledNodeEvent (see page 6207)	This is type OPToSOAPDomConv.TUnhandledNodeEvent.
TXMLNodeArray (see page 6208)	This is type OPToSOAPDomConv.TXMLNodeArray.

66.4.1 OPToSOAPDomConv.TMemberDataNotReceivedEvent Type

Pascal

```
TMemberDataNotReceivedEvent = procedure (const ClassName: string; const Member: string) of object;
```

C++

```
(const ClassName: string; const Member: string) ( TMemberDataNotReceivedEvent)();
```

File

OPToSOAPDomConv

Description

This is type OPToSOAPDomConv.TMemberDataNotReceivedEvent.

66.4.2 OPToSOAPDomConv.TMultiRefNodeMap Type

Pascal

```
TMultiRefNodeMap = array of TMultiRefNodeMapElem;
```

C++

```
array of TMultiRefNodeMapElem TMultiRefNodeMap;
```

File

OPToSOAPDomConv

Description

This is type OPToSOAPDomConv.TMultiRefNodeMap.

66.4.3 OPToSOAPDomConv.TMultiRefNodes Type

Pascal

```
TMultiRefNodes = array of TMultiRefNodeElem;
```

C++

```
array of TMultiRefNodeElem TMultiRefNodes;
```

File

OPToSOAPDomConv

Description

This is type OPToSOAPDomConv.TMultiRefNodes.

66.4.4 OPToSOAPDomConv.TSOAPArrayDesc Type

Pascal

```
TSOAPArrayDesc = array of TSOAPArrayElemDesc;
```

C++

```
array of TSOAPArrayElemDesc TSOAPArrayDesc;
```

File

OPToSOAPDomConv

Description

This is type OPToSOAPDomConv.TSOAPArrayDesc.

66.4.5 OPToSOAPDomConv.TUnhandledNodeEvent Type

Pascal

```
TUnhandledNodeEvent = procedure (const Name: string; NodeXML: InvString) of object;
```

C++

```
(const Name: string; NodeXML: InvString) ( TUnhandledNodeEvent)();
```

File

OPToSOAPDomConv

Description

This is type OPToSOAPDomConv.TUnhandledNodeEvent.

66.4.6 OPToSOAPDomConv.TXMLNodeArray Type

Pascal

```
TXMLNodeArray = array of IXMLNode;
```

C++

```
array of IXMLNode TXMLNodeArray;
```

File

OPToSOAPDomConv

Description

This is type OPToSOAPDomConv.TXMLNodeArray.

66.5 Variables

The following table lists variables in this documentation.

Variables

Name	Description
DefArrayElemName (see page 6209)	This is variable OPToSOAPDomConv.DefArrayElemName.

66.5.1 OPToSOAPDomConv.DefArrayElemName Variable

Pascal

```
DefArrayElemName: string = 'item';
```

C++

```
UnicodeString DefArrayElemName = 'item';
```

File

OPToSOAPDomConv

Description

This is variable OPToSOAPDomConv.DefArrayElemName.

66.6 Constants

The following table lists constants in this documentation.

Constants

Name	Description
SVarArrayType (see page 6210)	This is constant OPToSOAPDomConv.SVarArrayType.

66.6.1 OPToSOAPDomConv.SVarArrayType Constant

Pascal

```
SVarArrayType = 'VarArrayType';
```

C++

```
SVarArrayType = 'VarArrayType';
```

File

OPToSOAPDomConv

Description

This is constant OPToSOAPDomConv.SVarArrayType.

67 OrbPas Namespace

This is namespace OrbPas.

Topics

Name	Description
Interfaces (see page 6213)	The following table lists interfaces in this documentation.
Functions (see page 6241)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 6246)	The following table lists structs, records, enums in this documentation.
Types (see page 6248)	The following table lists types in this documentation.

Functions

	Name	Description
	AnyToVariant (see page 6241)	This is function OrbPas.AnyToVariant.
	BindStub (see page 6241)	This is function OrbPas.BindStub.
	CorbaAnyType (see page 6242)	This is function OrbPas.CorbaAnyType.
	CorbaDuplicateAny (see page 6242)	This is function OrbPas.CorbaDuplicateAny.
	CorbaReleaseAny (see page 6242)	This is function OrbPas.CorbaReleaseAny.
	CorbaStringFree (see page 6243)	This is function OrbPas.CorbaStringFree.
	CorbaWStringFree (see page 6243)	This is function OrbPas.CorbaWStringFree.
	CreateSkeleton (see page 6243)	This is function OrbPas.CreateSkeleton.
	CreateUserException (see page 6244)	This is function OrbPas.CreateUserException.
	InitORB (see page 6244)	This is function OrbPas.InitORB.
	RegisterUserException (see page 6244)	This is function OrbPas.RegisterUserException.
	SequenceToVariant (see page 6245)	This is function OrbPas.SequenceToVariant.
	UnRegisterUserException (see page 6245)	This is function OrbPas.UnRegisterUserException.
	VariantToAny (see page 6245)	This is function OrbPas.VariantToAny.

Interfaces

	Name	Description
	IBOA (see page 6213)	This is class OrbPas.IBOA.
	ICorbaObj (see page 6215)	This is class OrbPas.ICorbaObj.
	IMarshalInBuffer (see page 6216)	This is class OrbPas.IMarshalInBuffer.
	IMarshalOutBuffer (see page 6220)	This is class OrbPas.IMarshalOutBuffer.
	IORB (see page 6225)	This is class OrbPas.IORB.
	ISkeleton (see page 6229)	This is class OrbPas.ISkeleton.
	ISkeletonObject (see page 6230)	This is class OrbPas.ISkeletonObject.

	IStub (see page 6232)	This is class OrbPas.IStub.
	IStubObject (see page 6235)	This is class OrbPas.IStubObject.
	ITypeCode (see page 6236)	This is class OrbPas.ITypeCode.

Structs, Records, Enums

	Name	Description
	TCKind (see page 6246)	This is record OrbPas.TCKind.
	TStructMember (see page 6247)	This is record OrbPas.TStructMember.

Types

Name	Description
CorbaBoolean (see page 6248)	This is type OrbPas.CorbaBoolean.
CorbaULong (see page 6248)	This is type OrbPas.CorbaULong.
PCorbaAny (see page 6249)	This is type OrbPas.PCorbaAny.
PCorbaInterfaceDef (see page 6249)	This is type OrbPas.PCorbaInterfaceDef.
PCorbaObject (see page 6249)	This is type OrbPas.PCorbaObject.
PCorbaOrb (see page 6250)	This is type OrbPas.PCorbaOrb.
PExceptionDescription (see page 6250)	This is type OrbPas.PExceptionDescription.
PMarshalInbuffer (see page 6250)	This is type OrbPas.PMarshalInbuffer.
PMarshalOutbuffer (see page 6251)	This is type OrbPas.PMarshalOutbuffer.
PUserExceptionProxy (see page 6251)	This is type OrbPas.PUserExceptionProxy.
TArgv (see page 6251)	This is type OrbPas.TArgv.
TCopyUserExceptionProc (see page 6252)	This is type OrbPas.TCopyUserExceptionProc.
TStructMembers (see page 6252)	This is type OrbPas.TStructMembers.
TThrowUserExceptionProc (see page 6252)	This is type OrbPas.TThrowUserExceptionProc.
TUserExceptionFactoryProc (see page 6253)	This is type OrbPas.TUserExceptionFactoryProc.

67.1 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IBOA (see page 6213)	This is class OrbPas.IBOA.
	ICorbaObj (see page 6215)	This is class OrbPas.ICorbaObj.
	IMarshalInBuffer (see page 6216)	This is class OrbPas.IMarshalInBuffer.
	IMarshalOutBuffer (see page 6220)	This is class OrbPas.IMarshalOutBuffer.
	IORB (see page 6225)	This is class OrbPas.IORB.
	ISkeleton (see page 6229)	This is class OrbPas.ISkeleton.
	ISkeletonObject (see page 6230)	This is class OrbPas.ISkeletonObject.
	IStub (see page 6232)	This is class OrbPas.IStub.
	IStubObject (see page 6235)	This is class OrbPas.IStubObject.
	ITypeCode (see page 6236)	This is class OrbPas.ITypeCode.

67.1.1 IBOA Interface

Class Hierarchy

OrbPas.IBOA

Pascal

```
IBOA = interface;
```

C++

```
__interface IBOA;
```

File

OrbPas

Description

This is class OrbPas.IBOA.

67.1.1.1 IBOA Members

The following tables list the members exposed by IBOA.

Public Methods

	Name	Description
	Deactivate (see page 6214)	This is Deactivate, a member of class IBOA.
	GetPrincipal (see page 6214)	This is GetPrincipal, a member of class IBOA.
	GetPrincipalLength (see page 6214)	This is GetPrincipalLength, a member of class IBOA.
	ImplIsReady (see page 6214)	This is ImplIsReady, a member of class IBOA.
	ObjIsReady (see page 6215)	This is ObjIsReady, a member of class IBOA.

67.1.1.2 IBOA Methods

The methods of the IBOA class are listed here.

Public Methods

	Name	Description
	Deactivate (see page 6214)	This is Deactivate, a member of class IBOA.
	GetPrincipal (see page 6214)	This is GetPrincipal, a member of class IBOA.
	GetPrincipalLength (see page 6214)	This is GetPrincipalLength, a member of class IBOA.
	ImplIsReady (see page 6214)	This is ImplIsReady, a member of class IBOA.
	ObjIsReady (see page 6215)	This is ObjIsReady, a member of class IBOA.

67.1.1.2.1 IBOA.Deactivate Method

Pascal

```
procedure Deactivate(const Skeleton: ISkeleton); stdcall;
```

C++

```
__fastcall __stdcall Deactivate(const ISkeleton Skeleton);
```

Description

This is Deactivate, a member of class IBOA.

67.1.1.2.2 IBOA.GetPrincipal Method

Pascal

```
function GetPrincipal(Skeleton: ISkeleton; Bytes: Pointer): Integer; stdcall;
```

C++

```
__fastcall __stdcall int GetPrincipal(ISkeleton Skeleton, void * Bytes);
```

Description

This is GetPrincipal, a member of class IBOA.

67.1.1.2.3 IBOA.GetPrincipalLength Method

Pascal

```
function GetPrincipalLength(Skeleton: ISkeleton): Integer; stdcall;
```

C++

```
__fastcall __stdcall int GetPrincipalLength(ISkeleton Skeleton);
```

Description

This is GetPrincipalLength, a member of class IBOA.

67.1.1.2.4 IBOA.ImplIsReady Method

Pascal

```
procedure ImplIsReady; stdcall;
```

C++

```
__fastcall __stdcall ImplIsReady();
```

Description

This is ImplIsReady, a member of class IBOA.

67.1.1.2.5 IBOA.ObjIsReady Method

Pascal

```
procedure ObjIsReady(const Skeleton: ISkeleton); stdcall;
```

C++

```
__fastcall __stdcall ObjIsReady(const ISkeleton Skeleton);
```

Description

This is ObjIsReady, a member of class IBOA.

67.1.2 ICorbaObj Interface

Class Hierarchy

Pascal

```
ICorbaObj = interface;
```

C++

```
__interface ICorbaObj;
```

File

OrbPas

Description

This is class OrbPas.ICorbaObj.

67.1.2.1 ICorbaObj Members

The following tables list the members exposed by ICorbaObj.

Public Methods

	Name	Description
	CorbaObject (see page 6216)	This is CorbaObject, a member of class ICorbaObj.
	IsLocal (see page 6216)	This is IsLocal, a member of class ICorbaObj.

67.1.2.2 ICorbaObj Methods

The methods of the ICorbaObj class are listed here.

Public Methods

	Name	Description
	CorbaObject (see page 6216)	This is CorbaObject, a member of class ICorbaObj.
	IsLocal (see page 6216)	This is IsLocal, a member of class ICorbaObj.

67.1.2.2.1 ICorbaObj.CorbaObject Method

Pascal

```
function CorbaObject: PCorbaObject; stdcall;
```

C++

```
__fastcall __stdcall PCorbaObject CorbaObject();
```

Description

This is CorbaObject, a member of class ICorbaObj.

67.1.2.2.2 ICorbaObj.IsLocal Method

Pascal

```
function IsLocal: CorbaBoolean; stdcall;
```

C++

```
__fastcall __stdcall CorbaBoolean IsLocal();
```

Description

This is IsLocal, a member of class ICorbaObj.

67.1.3 IMarshalInBuffer Interface

Class Hierarchy

OrbPas.IMarshalInBuffer

Pascal

```
IMarshalInBuffer = interface;
```

C++

```
__interface IMarshalInBuffer;
```

File

OrbPas

Description

This is class OrbPas.IMarshalInBuffer.

67.1.3.1 IMarshalInBuffer Members

The following tables list the members exposed by IMarshalInBuffer.

Public Methods

	Name	Description
	Buffer (see page 6217)	This is Buffer, a member of class IMarshalInBuffer.
	GetAny (see page 6218)	This is GetAny, a member of class IMarshalInBuffer.
	GetChar (see page 6218)	This is GetChar, a member of class IMarshalInBuffer.
	GetDouble (see page 6218)	This is GetDouble, a member of class IMarshalInBuffer.
	GetFloat (see page 6218)	This is GetFloat, a member of class IMarshalInBuffer.
	GetLong (see page 6218)	This is GetLong, a member of class IMarshalInBuffer.
	GetObject (see page 6219)	This is GetObject, a member of class IMarshalInBuffer.
	GetShort (see page 6219)	This is GetShort, a member of class IMarshalInBuffer.
	GetText (see page 6219)	This is GetText, a member of class IMarshalInBuffer.
	GetUnsignedChar (see page 6219)	This is GetUnsignedChar, a member of class IMarshalInBuffer.
	GetUnsignedLong (see page 6220)	This is GetUnsignedLong, a member of class IMarshalInBuffer.
	GetUnsignedShort (see page 6220)	This is GetUnsignedShort, a member of class IMarshalInBuffer.
	GetWidechar (see page 6220)	This is GetWidechar, a member of class IMarshalInBuffer.
	GetWideText (see page 6220)	This is GetWideText, a member of class IMarshalInBuffer.

67.1.3.2 IMarshalInBuffer Methods

The methods of the IMarshalInBuffer class are listed here.

Public Methods

	Name	Description
	Buffer (see page 6217)	This is Buffer, a member of class IMarshalInBuffer.
	GetAny (see page 6218)	This is GetAny, a member of class IMarshalInBuffer.
	GetChar (see page 6218)	This is GetChar, a member of class IMarshalInBuffer.
	GetDouble (see page 6218)	This is GetDouble, a member of class IMarshalInBuffer.
	GetFloat (see page 6218)	This is GetFloat, a member of class IMarshalInBuffer.
	GetLong (see page 6218)	This is GetLong, a member of class IMarshalInBuffer.
	GetObject (see page 6219)	This is GetObject, a member of class IMarshalInBuffer.
	GetShort (see page 6219)	This is GetShort, a member of class IMarshalInBuffer.
	GetText (see page 6219)	This is GetText, a member of class IMarshalInBuffer.
	GetUnsignedChar (see page 6219)	This is GetUnsignedChar, a member of class IMarshalInBuffer.
	GetUnsignedLong (see page 6220)	This is GetUnsignedLong, a member of class IMarshalInBuffer.
	GetUnsignedShort (see page 6220)	This is GetUnsignedShort, a member of class IMarshalInBuffer.
	GetWidechar (see page 6220)	This is GetWidechar, a member of class IMarshalInBuffer.
	GetWideText (see page 6220)	This is GetWideText, a member of class IMarshalInBuffer.

67.1.3.2.1 IMarshalInBuffer.Buffer Method

Pascal

```
function Buffer: PMarshalInbuffer; stdcall;
```

C++

```
__fastcall __stdcall PMarshalInbuffer Buffer();
```

Description

This is Buffer, a member of class IMarshalInBuffer.

67.1.3.2.2 IMarshalInBuffer.GetAny Method

Pascal

```
function GetAny: PCorbaAny; stdcall;
```

C++

```
__fastcall __stdcall PCorbaAny GetAny();
```

Description

This is GetAny, a member of class IMarshalInBuffer.

67.1.3.2.3 IMarshalInBuffer.GetChar Method

Pascal

```
function GetChar: Shortint; stdcall;
```

C++

```
__fastcall __stdcall Shortint GetChar();
```

Description

This is GetChar, a member of class IMarshalInBuffer.

67.1.3.2.4 IMarshalInBuffer.GetDouble Method

Pascal

```
function GetDouble: Double; stdcall;
```

C++

```
__fastcall __stdcall Double GetDouble();
```

Description

This is GetDouble, a member of class IMarshalInBuffer.

67.1.3.2.5 IMarshalInBuffer.GetFloat Method

Pascal

```
function GetFloat: Single; stdcall;
```

C++

```
__fastcall __stdcall Single GetFloat();
```

Description

This is GetFloat, a member of class IMarshalInBuffer.

67.1.3.2.6 IMarshalInBuffer.GetLong Method

Pascal

```
function GetLong: Integer; stdcall;
```

C++

```
__fastcall __stdcall int GetLong();
```

Description

This is GetLong, a member of class IMarshalInBuffer.

67.1.3.2.7 IMarshalInBuffer.GetObject Method

Pascal

```
procedure GetObject(out Obj: ICorbaObj; ref_cnt: CorbaBoolean = True); stdcall;
```

C++

```
__fastcall __stdcall GetObject(ICorbaObj Obj, CorbaBoolean ref_cnt = True);
```

Description

This is GetObject, a member of class IMarshalInBuffer.

67.1.3.2.8 IMarshalInBuffer.GetShort Method

Pascal

```
function GetShort: Smallint; stdcall;
```

C++

```
__fastcall __stdcall Smallint GetShort();
```

Description

This is GetShort, a member of class IMarshalInBuffer.

67.1.3.2.9 IMarshalInBuffer.GetText Method

Pascal

```
function GetText: PChar; stdcall;
```

C++

```
__fastcall __stdcall const char * GetText();
```

Description

This is GetText, a member of class IMarshalInBuffer.

67.1.3.2.10 IMarshalInBuffer.GetUnsignedChar Method

Pascal

```
function GetUnsignedChar: Byte; stdcall;
```

C++

```
__fastcall __stdcall Byte GetUnsignedChar();
```

Description

This is GetUnsignedChar, a member of class IMarshalInBuffer.

67.1.3.2.11 IMarshalInBuffer.GetUnsignedLong Method

Pascal

```
function GetUnsignedLong: UINT; stdcall;
```

C++

```
__fastcall __stdcall UINT GetUnsignedLong();
```

Description

This is GetUnsignedLong, a member of class IMarshalInBuffer.

67.1.3.2.12 IMarshalInBuffer.GetUnsignedShort Method

Pascal

```
function GetUnsignedShort: Word; stdcall;
```

C++

```
__fastcall __stdcall Word GetUnsignedShort();
```

Description

This is GetUnsignedShort, a member of class IMarshalInBuffer.

67.1.3.2.13 IMarshalInBuffer.GetWidechar Method

Pascal

```
function GetWidechar: Word; stdcall;
```

C++

```
__fastcall __stdcall Word GetWidechar();
```

Description

This is GetWidechar, a member of class IMarshalInBuffer.

67.1.3.2.14 IMarshalInBuffer.GetWideText Method

Pascal

```
function GetWideText: PWideChar; stdcall;
```

C++

```
__fastcall __stdcall PWideChar GetWideText();
```

Description

This is GetWideText, a member of class IMarshalInBuffer.

67.1.4 IMarshalOutBuffer Interface

Class Hierarchy

Pascal

```
IMarshalOutBuffer = interface;
```

C++

```
__interface IMarshalOutBuffer;
```

File

OrbPas

Description

This is class OrbPas.IMarshalOutBuffer.

67.1.4.1 IMarshalOutBuffer Members

The following tables list the members exposed by IMarshalOutBuffer.

Public Methods

	Name	Description
	Buffer (see page 6222)	This is Buffer, a member of class IMarshalOutBuffer.
	PutAny (see page 6222)	This is PutAny, a member of class IMarshalOutBuffer.
	PutChar (see page 6222)	This is PutChar, a member of class IMarshalOutBuffer.
	PutDouble (see page 6222)	This is PutDouble, a member of class IMarshalOutBuffer.
	PutFloat (see page 6222)	This is PutFloat, a member of class IMarshalOutBuffer.
	PutLong (see page 6223)	This is PutLong, a member of class IMarshalOutBuffer.
	PutObject (see page 6223)	This is PutObject, a member of class IMarshalOutBuffer.
	PutShort (see page 6223)	This is PutShort, a member of class IMarshalOutBuffer.
	PutText (see page 6223)	This is PutText, a member of class IMarshalOutBuffer.
	PutUnsignedChar (see page 6224)	This is PutUnsignedChar, a member of class IMarshalOutBuffer.
	PutUnsignedLong (see page 6224)	This is PutUnsignedLong, a member of class IMarshalOutBuffer.
	PutUnsignedShort (see page 6224)	This is PutUnsignedShort, a member of class IMarshalOutBuffer.
	PutWidechar (see page 6224)	This is PutWidechar, a member of class IMarshalOutBuffer.
	PutWideText (see page 6224)	This is PutWideText, a member of class IMarshalOutBuffer.

67.1.4.2 IMarshalOutBuffer Methods

The methods of the IMarshalOutBuffer class are listed here.

Public Methods

	Name	Description
	Buffer (see page 6222)	This is Buffer, a member of class IMarshalOutBuffer.
	PutAny (see page 6222)	This is PutAny, a member of class IMarshalOutBuffer.
	PutChar (see page 6222)	This is PutChar, a member of class IMarshalOutBuffer.
	PutDouble (see page 6222)	This is PutDouble, a member of class IMarshalOutBuffer.
	PutFloat (see page 6222)	This is PutFloat, a member of class IMarshalOutBuffer.
	PutLong (see page 6223)	This is PutLong, a member of class IMarshalOutBuffer.
	PutObject (see page 6223)	This is PutObject, a member of class IMarshalOutBuffer.
	PutShort (see page 6223)	This is PutShort, a member of class IMarshalOutBuffer.
	PutText (see page 6223)	This is PutText, a member of class IMarshalOutBuffer.
	PutUnsignedChar (see page 6224)	This is PutUnsignedChar, a member of class IMarshalOutBuffer.
	PutUnsignedLong (see page 6224)	This is PutUnsignedLong, a member of class IMarshalOutBuffer.
	PutUnsignedShort (see page 6224)	This is PutUnsignedShort, a member of class IMarshalOutBuffer.
	PutWidechar (see page 6224)	This is PutWidechar, a member of class IMarshalOutBuffer.

	PutWideText (see page 6224)	This is PutWideText, a member of class IMarshalOutBuffer.

67.1.4.2.1 IMarshalOutBuffer.Buffer Method

Pascal

```
function Buffer: PMarshalOutbuffer; stdcall;
```

C++

```
__fastcall __stdcall PMarshalOutbuffer Buffer();
```

Description

This is Buffer, a member of class IMarshalOutBuffer.

67.1.4.2.2 IMarshalOutBuffer.PutAny Method

Pascal

```
procedure PutAny(Value: PCorbaAny); stdcall;
```

C++

```
__fastcall __stdcall PutAny(PCorbaAny Value);
```

Description

This is PutAny, a member of class IMarshalOutBuffer.

67.1.4.2.3 IMarshalOutBuffer.PutChar Method

Pascal

```
procedure PutChar(Value: Shortint); stdcall;
```

C++

```
__fastcall __stdcall PutChar(Shortint Value);
```

Description

This is PutChar, a member of class IMarshalOutBuffer.

67.1.4.2.4 IMarshalOutBuffer.PutDouble Method

Pascal

```
procedure PutDouble(Value: Double); stdcall;
```

C++

```
__fastcall __stdcall PutDouble(Double Value);
```

Description

This is PutDouble, a member of class IMarshalOutBuffer.

67.1.4.2.5 IMarshalOutBuffer.PutFloat Method

Pascal

```
procedure PutFloat(Value: Single); stdcall;
```

C++

```
__fastcall __stdcall PutFloat(Single Value);
```

Description

This is PutFloat, a member of class IMarshalOutBuffer.

67.1.4.2.6 IMarshalOutBuffer.PutLong Method

Pascal

```
procedure PutLong(Value: Integer); stdcall;
```

C++

```
__fastcall __stdcall PutLong(int Value);
```

Description

This is PutLong, a member of class IMarshalOutBuffer.

67.1.4.2.7 IMarshalOutBuffer.PutObject Method

Pascal

```
procedure PutObject(const Value: ICorbaObj); stdcall;
```

C++

```
__fastcall __stdcall PutObject(const ICorbaObj Value);
```

Description

This is PutObject, a member of class IMarshalOutBuffer.

67.1.4.2.8 IMarshalOutBuffer.PutShort Method

Pascal

```
procedure PutShort(Value: Smallint); stdcall;
```

C++

```
__fastcall __stdcall PutShort(Smallint Value);
```

Description

This is PutShort, a member of class IMarshalOutBuffer.

67.1.4.2.9 IMarshalOutBuffer.PutText Method

Pascal

```
procedure PutText(Value: PChar); stdcall;
```

C++

```
__fastcall __stdcall PutText(const char * Value);
```

Description

This is PutText, a member of class IMarshalOutBuffer.

67.1.4.2.10 IMarshalOutBuffer.PutUnsignedChar Method

Pascal

```
procedure PutUnsignedChar(Value: Byte); stdcall;
```

C++

```
__fastcall __stdcall PutUnsignedChar(Byte Value);
```

Description

This is PutUnsignedChar, a member of class IMarshalOutBuffer.

67.1.4.2.11 IMarshalOutBuffer.PutUnsignedLong Method

Pascal

```
procedure PutUnsignedLong(Value: UINT); stdcall;
```

C++

```
__fastcall __stdcall PutUnsignedLong(UINT Value);
```

Description

This is PutUnsignedLong, a member of class IMarshalOutBuffer.

67.1.4.2.12 IMarshalOutBuffer.PutUnsignedShort Method

Pascal

```
procedure PutUnsignedShort(Value: Word); stdcall;
```

C++

```
__fastcall __stdcall PutUnsignedShort(Word Value);
```

Description

This is PutUnsignedShort, a member of class IMarshalOutBuffer.

67.1.4.2.13 IMarshalOutBuffer.PutWidechar Method

Pascal

```
procedure PutWidechar(Value: Word); stdcall;
```

C++

```
__fastcall __stdcall PutWidechar(Word Value);
```

Description

This is PutWidechar, a member of class IMarshalOutBuffer.

67.1.4.2.14 IMarshalOutBuffer.PutWideText Method

Pascal

```
procedure PutWideText(Value: PWideChar); stdcall;
```

C++

```
__fastcall __stdcall PutWideText(PWideChar Value);
```

Description

This is PutWideText, a member of class IMarshalOutBuffer.

67.1.5 IORB Interface

Class Hierarchy

Pascal

```
IORB = interface;
```

C++

```
__interface IORB;
```

File

OrbPas

Description

This is class OrbPas.IORB.

67.1.5.1 IORB Members

The following tables list the members exposed by IORB.

Public Methods

	Name	Description
	BOAInit (see page 6226)	This is BOAInit, a member of class IORB.
	CreateAliasTC (see page 6226)	This is CreateAliasTC, a member of class IORB.
	CreateArrayTC (see page 6226)	This is CreateArrayTC, a member of class IORB.
	CreateObjRefTC (see page 6227)	This is CreateObjRefTC, a member of class IORB.
	CreateSequenceTC (see page 6227)	This is CreateSequenceTC, a member of class IORB.
	CreateStructTC (see page 6227)	This is CreateStructTC, a member of class IORB.
	CreateTC (see page 6227)	This is CreateTC, a member of class IORB.
	DispatchStruct (see page 6227)	This is DispatchStruct, a member of class IORB.
	FindRepositoryTC (see page 6228)	This is FindRepositoryTC, a member of class IORB.
	MakeAny (see page 6228)	This is MakeAny, a member of class IORB.
	ObjectToString (see page 6228)	This is ObjectToString, a member of class IORB.
	Orb (see page 6228)	This is Orb, a member of class IORB.
	Shutdown (see page 6229)	This is Shutdown, a member of class IORB.
	StringToObject (see page 6229)	This is StringToObject, a member of class IORB.

67.1.5.2 IORB Methods

The methods of the IORB class are listed here.

Public Methods

	Name	Description
	BOAInit (see page 6226)	This is BOAInit, a member of class IORB.

	CreateAliasTC (see page 6226)	This is CreateAliasTC, a member of class IORB.
	CreateArrayTC (see page 6226)	This is CreateArrayTC, a member of class IORB.
	CreateObjRefTC (see page 6227)	This is CreateObjRefTC, a member of class IORB.
	CreateSequenceTC (see page 6227)	This is CreateSequenceTC, a member of class IORB.
	CreateStructTC (see page 6227)	This is CreateStructTC, a member of class IORB.
	CreateTC (see page 6227)	This is CreateTC, a member of class IORB.
	DispatchStruct (see page 6227)	This is DispatchStruct, a member of class IORB.
	FindRepositoryTC (see page 6228)	This is FindRepositoryTC, a member of class IORB.
	MakeAny (see page 6228)	This is MakeAny, a member of class IORB.
	ObjectToString (see page 6228)	This is ObjectToString, a member of class IORB.
	Orb (see page 6228)	This is Orb, a member of class IORB.
	Shutdown (see page 6229)	This is Shutdown, a member of class IORB.
	StringToObject (see page 6229)	This is StringToObject, a member of class IORB.

67.1.5.2.1 IORB.BOAInit Method

Pascal

```
procedure BOAInit(Argc: Integer; const Argv: TArgv; out BOA: IBOA); stdcall;
```

C++

```
__fastcall __stdcall BOAInit(int Argc, const TArgv Argv, IBOA BOA);
```

Description

This is BOAInit, a member of class IORB.

67.1.5.2.2 IORB.CreateAliasTC Method

Pascal

```
procedure CreateAliasTC(RepID: PChar; TypeName: PChar; const TC: ITypeCode; out Result:
ITypeCode); stdcall;
```

C++

```
__fastcall __stdcall CreateAliasTC(const char * RepID, const char * TypeName, const ITypeCode
TC, ITypeCode Result);
```

Description

This is CreateAliasTC, a member of class IORB.

67.1.5.2.3 IORB.CreateArrayTC Method

Pascal

```
procedure CreateArrayTC(Bound: CorbaULong; const TC: ITypeCode; out Result: ITypeCode);
stdcall;
```

C++

```
__fastcall __stdcall CreateArrayTC(CorbaULong Bound, const ITypeCode TC, ITypeCode Result);
```

Description

This is CreateArrayTC, a member of class IORB.

67.1.5.2.4 IORB.CreateObjRefTC Method

Pascal

```
procedure CreateObjRefTC(RepId: PChar; Name: PChar; out Result: ITypeCode); stdcall;
```

C++

```
__fastcall __stdcall CreateObjRefTC(const char * RepId, const char * Name, ITypeCode Result);
```

Description

This is CreateObjRefTC, a member of class IORB.

67.1.5.2.5 IORB.CreateSequenceTC Method

Pascal

```
procedure CreateSequenceTC(Bound: CorbaULong; const TC: ITypeCode; out Result: ITypeCode);
stdcall;
```

C++

```
__fastcall __stdcall CreateSequenceTC(CorbaULong Bound, const ITypeCode TC, ITypeCode Result);
```

Description

This is CreateSequenceTC, a member of class IORB.

67.1.5.2.6 IORB.CreateStructTC Method

Pascal

```
procedure CreateStructTC(Kind: TCKind; RepId: PChar; Name: PChar; Members: TStructMembers;
nMember: Integer; out Result: ITypeCode); stdcall;
```

C++

```
__fastcall __stdcall CreateStructTC(TCKind Kind, const char * RepId, const char * Name,
TStructMembers Members, int nMember, ITypeCode Result);
```

Description

This is CreateStructTC, a member of class IORB.

67.1.5.2.7 IORB.CreateTC Method

Pascal

```
procedure CreateTC(Kind: TCKind; out TC: ITypeCode); stdcall;
```

C++

```
__fastcall __stdcall CreateTC(TCKind Kind, ITypeCode TC);
```

Description

This is CreateTC, a member of class IORB.

67.1.5.2.8 IORB.DispatchStruct Method

Pascal

```
function DispatchStruct(Any: PCorbaAny; CallDesc: PCallDesc; Params: Pointer; out Result:
```

```
  Variant): Integer; stdcall;
```

C++

```
  __fastcall __stdcall int DispatchStruct(PCorbaAny Any, PCallDesc CallDesc, void * Params,
  Variant Result);
```

Description

This is DispatchStruct, a member of class IORB.

67.1.5.2.9 IORB.FindRepositoryTC Method

Pascal

```
  procedure FindRepositoryTC(RepID: PChar; out TC: ITypeCode); stdcall;
```

C++

```
  __fastcall __stdcall FindRepositoryTC(const char * RepID, ITypeCode TC);
```

Description

This is FindRepositoryTC, a member of class IORB.

67.1.5.2.10 IORB.MakeAny Method

Pascal

```
  function MakeAny(const TC: ITypeCode; VS: array of Variant): PCorbaAny; stdcall;
```

C++

```
  __fastcall __stdcall PCorbaAny MakeAny(const ITypeCode TC, array of Variant VS);
```

Description

This is MakeAny, a member of class IORB.

67.1.5.2.11 IORB.ObjectToString Method

Pascal

```
  function ObjectToString(const Obj: IStub): PChar; stdcall;
```

C++

```
  __fastcall __stdcall const char * ObjectToString(const IStub Obj);
```

Description

This is ObjectToString, a member of class IORB.

67.1.5.2.12 IORB.Orb Method

Pascal

```
  function Orb: PCorbaOrb;
```

C++

```
  __fastcall PCorbaOrb Orb();
```

Description

This is Orb, a member of class IORB.

67.1.5.2.13 IORB.Shutdown Method

Pascal

```
procedure Shutdown; stdcall;
```

C++

```
__fastcall __stdcall Shutdown();
```

Description

This is Shutdown, a member of class IORB.

67.1.5.2.14 IORB.StringToObject Method

Pascal

```
procedure StringToObject(Str: PChar; out Obj: IStub); stdcall;
```

C++

```
__fastcall __stdcall StringToObject(const char * Str, IStub Obj);
```

Description

This is StringToObject, a member of class IORB.

67.1.6 ISkeleton Interface

Class Hierarchy

Pascal

```
ISkeleton = interface(ICorbaObj);
```

C++

```
__interface ISkeleton : public ICorbaObj;
```

File

OrbPas

Description

This is class OrbPas.ISkeleton.

67.1.6.1 ISkeleton Members

The following tables list the members exposed by ISkeleton.

Public Methods

	Name	Description
	CorbaObject (see page 6216)	This is CorbaObject, a member of class ICorbaObj.
	GetImplementation (see page 6230)	This is GetImplementation, a member of class ISkeleton.
	GetReplyBuffer (see page 6230)	This is GetReplyBuffer, a member of class ISkeleton.

	IsLocal (see page 6216)	This is IsLocal, a member of class ICorbaObj.

67.1.6.2 ISkeleton Methods

The methods of the ISkeleton class are listed here.

Public Methods

	Name	Description
	GetImplementation (see page 6230)	This is GetImplementation, a member of class ISkeleton.
	GetReplyBuffer (see page 6230)	This is GetReplyBuffer, a member of class ISkeleton.

67.1.6.2.1 ISkeleton.GetImplementation Method

Pascal

```
procedure GetImplementation(out Impl: IUnknown); stdcall;
```

C++

```
__fastcall __stdcall GetImplementation(IUnknown Impl);
```

Description

This is GetImplementation, a member of class ISkeleton.

67.1.6.2.2 ISkeleton.GetReplyBuffer Method

Pascal

```
procedure GetReplyBuffer(cookie: Pointer; out Outbuf: IMarshalOutBuffer); stdcall;
```

C++

```
__fastcall __stdcall GetReplyBuffer(void * cookie, IMarshalOutBuffer Outbuf);
```

Description

This is GetReplyBuffer, a member of class ISkeleton.

67.1.7 ISkeletonObject Interface

Class Hierarchy

OrbPas.ISkeletonObject

Pascal

```
ISkeletonObject = interface;
```

C++

```
__interface ISkeletonObject;
```

File

OrbPas

Description

This is class OrbPas.ISkeletonObject.

67.1.7.1 ISkeletonObject Members

The following tables list the members exposed by ISkeletonObject.

Public Methods

	Name	Description
	Execute (see page 6231)	This is Execute, a member of class ISkeletonObject.
	GetImplementation (see page 6231)	This is GetImplementation, a member of class ISkeletonObject.
	GetSkeleton (see page 6231)	This is GetSkeleton, a member of class ISkeletonObject.

67.1.7.2 ISkeletonObject Methods

The methods of the ISkeletonObject class are listed here.

Public Methods

	Name	Description
	Execute (see page 6231)	This is Execute, a member of class ISkeletonObject.
	GetImplementation (see page 6231)	This is GetImplementation, a member of class ISkeletonObject.
	GetSkeleton (see page 6231)	This is GetSkeleton, a member of class ISkeletonObject.

67.1.7.2.1 ISkeletonObject.Execute Method

Pascal

```
function Execute(Operation: PAnsiChar; const Strm: IMarshalInBuffer; Cookie: Pointer):
CorbaBoolean; stdcall;
```

C++

```
__fastcall __stdcall CorbaBoolean Execute(PAnsiChar Operation, const IMarshalInBuffer Strm,
void * Cookie);
```

Description

This is Execute, a member of class ISkeletonObject.

67.1.7.2.2 ISkeletonObject.GetImplementation Method

Pascal

```
procedure GetImplementation(out Impl: IUnknown); stdcall;
```

C++

```
__fastcall __stdcall GetImplementation(IUnknown Impl);
```

Description

This is GetImplementation, a member of class ISkeletonObject.

67.1.7.2.3 ISkeletonObject.GetSkeleton Method

Pascal

```
procedure GetSkeleton(out Skeleton: ISkeleton); stdcall;
```

C++

```
__fastcall __stdcall GetSkeleton(ISkeleton Skeleton);
```

Description

This is GetSkeleton, a member of class ISkeletonObject.

67.1.8 IStub Interface

Class Hierarchy

Pascal

```
IStub = interface(ICorbaObj);
```

C++

```
__interface IStub : public ICorbaObj;
```

File

OrbPas

Description

This is class OrbPas.IStub.

67.1.8.1 IStub Members

The following tables list the members exposed by IStub.

Public Methods

	Name	Description
	CorbaObject (see page 6216)	This is CorbaObject, a member of class ICorbaObj.
	CreateRequest (see page 6233)	This is CreateRequest, a member of class IStub.
	Dispatch (see page 6233)	This is Dispatch, a member of class IStub.
	GetInterface (see page 6233)	This is GetInterface, a member of class IStub.
	Hash (see page 6233)	This is Hash, a member of class IStub.
	Invoke (see page 6234)	This is Invoke, a member of class IStub.
	IsA (see page 6234)	This is IsA, a member of class IStub.
	IsLocal (see page 6216)	This is IsLocal, a member of class ICorbaObj.
	NonExistent (see page 6234)	This is NonExistent, a member of class IStub.
	RepositoryID (see page 6234)	This is RepositoryID, a member of class IStub.
	SetPrincipal (see page 6235)	This is SetPrincipal, a member of class IStub.

67.1.8.2 IStub Methods

The methods of the IStub class are listed here.

Public Methods

	Name	Description
	CreateRequest (see page 6233)	This is CreateRequest, a member of class IStub.

	Dispatch (see page 6233)	This is Dispatch, a member of class IStub.
	GetInterface (see page 6233)	This is GetInterface, a member of class IStub.
	Hash (see page 6233)	This is Hash, a member of class IStub.
	Invoke (see page 6234)	This is Invoke, a member of class IStub.
	IsA (see page 6234)	This is IsA, a member of class IStub.
	NonExistent (see page 6234)	This is NonExistent, a member of class IStub.
	RepositoryID (see page 6234)	This is RepositoryID, a member of class IStub.
	SetPrincipal (see page 6235)	This is SetPrincipal, a member of class IStub.

67.1.8.2.1 IStub.CreateRequest Method

Pascal

```
procedure CreateRequest(Operation: PChar; ResponseExpected: CorbaBoolean; out Outbuf:
IMarshalOutBuffer); stdcall;
```

C++

```
__fastcall __stdcall CreateRequest(const char * Operation, CorbaBoolean ResponseExpected,
IMarshalOutBuffer Outbuf);
```

Description

This is CreateRequest, a member of class IStub.

67.1.8.2.2 IStub.Dispatch Method

Pascal

```
function Dispatch(CallDesc: PCallDesc; Params: Pointer; out Result: Variant): Integer; stdcall;
```

C++

```
__fastcall __stdcall int Dispatch(PCallDesc CallDesc, void * Params, Variant Result);
```

Description

This is Dispatch, a member of class IStub.

67.1.8.2.3 IStub.GetInterface Method

Pascal

```
function GetInterface: PCorbaInterfaceDef; stdcall;
```

C++

```
__fastcall __stdcall PCorbaInterfaceDef GetInterface();
```

Description

This is GetInterface, a member of class IStub.

67.1.8.2.4 IStub.Hash Method

Pascal

```
function Hash(Maximum: CorbaULong): CorbaULong; stdcall;
```

C++

```
__fastcall __stdcall CorbaULong Hash(CorbaULong Maximum);
```

Description

This is Hash, a member of class IStub.

67.1.8.2.5 IStub.Invoke Method

Pascal

```
procedure Invoke(const Outbuf: IMarshalOutBuffer; out Inbuf: IMarshalInBuffer); stdcall;
```

C++

```
__fastcall __stdcall Invoke(const IMarshalOutBuffer Outbuf, IMarshalInBuffer Inbuf);
```

Description

This is Invoke, a member of class IStub.

67.1.8.2.6 IStub.IsA Method

Pascal

```
function IsA(LogicalTypeId: PChar): CorbaBoolean; stdcall;
```

C++

```
__fastcall __stdcall CorbaBoolean IsA(const char * LogicalTypeId);
```

Description

This is IsA, a member of class IStub.

67.1.8.2.7 IStub.NonExistent Method

Pascal

```
function NonExistent: CorbaBoolean; stdcall;
```

C++

```
__fastcall __stdcall CorbaBoolean NonExistent();
```

Description

This is NonExistent, a member of class IStub.

67.1.8.2.8 IStub.RepositoryID Method

Pascal

```
function RepositoryID: PChar; stdcall;
```

C++

```
__fastcall __stdcall const char * RepositoryID();
```

Description

This is RepositoryID, a member of class IStub.

67.1.8.2.9 IStub.SetPrincipal Method

Pascal

```
procedure SetPrincipal(Bytes: Pointer; Length: CorbaULong); stdcall;
```

C++

```
__fastcall __stdcall SetPrincipal(void * Bytes, CorbaULong Length);
```

Description

This is SetPrincipal, a member of class IStub.

67.1.9 IStubObject Interface

Class Hierarchy

Pascal

```
IStubObject = interface;
```

C++

```
__interface IStubObject;
```

File

OrbPas

Description

This is class OrbPas.IStubObject.

67.1.9.1 IStubObject Members

The following tables list the members exposed by IStubObject.

Public Methods

	Name	Description
	GetStub (see page 6236)	This is GetStub, a member of class IStubObject.

67.1.9.2 IStubObject Methods

The methods of the IStubObject class are listed here.

Public Methods

	Name	Description
	GetStub (see page 6236)	This is GetStub, a member of class IStubObject.

67.1.9.2.1 IStubObject.GetStub Method

Pascal

```
procedure GetStub(out stub: IStub); stdcall;
```

C++

```
__fastcall __stdcall GetStub(IStub stub);
```

Description

This is GetStub, a member of class IStubObject.

67.1.10 ITypeCode Interface

Class Hierarchy

Pascal

```
ITypeCode = interface;
```

C++

```
__interface ITypeCode;
```

File

OrbPas

Description

This is class OrbPas.ITypeCode.

67.1.10.1 ITypeCode Members

The following tables list the members exposed by ITypeCode.

Public Methods

	Name	Description
	ContentType (see page 6237)	This is ContentType, a member of class ITypeCode.
	DefaultIndex (see page 6237)	This is DefaultIndex, a member of class ITypeCode.
	DiscriminatorType (see page 6237)	This is DiscriminatorType, a member of class ITypeCode.
	Equal (see page 6238)	This is Equal, a member of class ITypeCode.
	Id (see page 6238)	This is Id, a member of class ITypeCode.
	Kind (see page 6238)	This is Kind, a member of class ITypeCode.
	Length (see page 6238)	This is Length, a member of class ITypeCode.
	MemberCount (see page 6239)	This is MemberCount, a member of class ITypeCode.
	MemberLabel (see page 6239)	This is MemberLabel, a member of class ITypeCode.
	MemberName (see page 6239)	This is MemberName, a member of class ITypeCode.
	MemberType (see page 6239)	This is MemberType, a member of class ITypeCode.
	Name (see page 6239)	This is Name, a member of class ITypeCode.
	Parameter (see page 6240)	This is Parameter, a member of class ITypeCode.
	ParameterCount (see page 6240)	This is ParameterCount, a member of class ITypeCode.

67.1.10.2 ITypeCode Methods

The methods of the ITypeCode class are listed here.

Public Methods

	Name	Description
	ContentType (see page 6237)	This is ContentType, a member of class ITypeCode.
	DefaultIndex (see page 6237)	This is DefaultIndex, a member of class ITypeCode.
	DiscriminatorType (see page 6237)	This is DiscriminatorType, a member of class ITypeCode.
	Equal (see page 6238)	This is Equal, a member of class ITypeCode.
	Id (see page 6238)	This is Id, a member of class ITypeCode.
	Kind (see page 6238)	This is Kind, a member of class ITypeCode.
	Length (see page 6238)	This is Length, a member of class ITypeCode.
	MemberCount (see page 6239)	This is MemberCount, a member of class ITypeCode.
	MemberLabel (see page 6239)	This is MemberLabel, a member of class ITypeCode.
	MemberName (see page 6239)	This is MemberName, a member of class ITypeCode.
	MemberType (see page 6239)	This is MemberType, a member of class ITypeCode.
	Name (see page 6239)	This is Name, a member of class ITypeCode.
	Parameter (see page 6240)	This is Parameter, a member of class ITypeCode.
	ParameterCount (see page 6240)	This is ParameterCount, a member of class ITypeCode.

67.1.10.2.1 ITypeCode.ContentType Method

Pascal

```
procedure ContentType(out tc: ITypeCode); stdcall;
```

C++

```
__fastcall __stdcall ContentType(ITypeCode tc);
```

Description

This is ContentType, a member of class ITypeCode.

67.1.10.2.2 ITypeCode.DefaultIndex Method

Pascal

```
function DefaultIndex: Integer; stdcall;
```

C++

```
__fastcall __stdcall int DefaultIndex();
```

Description

This is DefaultIndex, a member of class ITypeCode.

67.1.10.2.3 ITypeCode.DiscriminatorType Method

Pascal

```
procedure DiscriminatorType(out tc: ITypeCode); stdcall;
```

C++

```
__fastcall __stdcall DiscriminatorType(ITypeCode tc);
```

Description

This is DiscriminatorType, a member of class ITypeCode.

67.1.10.2.4 ITypeCode.Equal Method

Pascal

```
function Equal(const tc: ITypeCode): CorbaBoolean; stdcall;
```

C++

```
__fastcall __stdcall CorbaBoolean Equal(const ITypeCode tc);
```

Description

This is Equal, a member of class ITypeCode.

67.1.10.2.5 ITypeCode.Id Method

Pascal

```
function Id: PChar; stdcall;
```

C++

```
__fastcall __stdcall const char * Id();
```

Description

This is Id, a member of class ITypeCode.

67.1.10.2.6 ITypeCode.Kind Method

Pascal

```
function Kind: TCKind; stdcall;
```

C++

```
__fastcall __stdcall TCKind Kind();
```

Description

This is Kind, a member of class ITypeCode.

67.1.10.2.7 ITypeCode.Length Method

Pascal

```
function Length: CorbaULong; stdcall;
```

C++

```
__fastcall __stdcall CorbaULong Length();
```

Description

This is Length, a member of class ITypeCode.

67.1.10.2.8 ITypeCode.MemberCount Method

Pascal

```
function MemberCount: CorbaULong; stdcall;
```

C++

```
__fastcall __stdcall CorbaULong MemberCount();
```

Description

This is MemberCount, a member of class ITypeCode.

67.1.10.2.9 ITypeCode.MemberLabel Method

Pascal

```
function MemberLabel(index: CorbaULong): PCorbaAny; stdcall;
```

C++

```
__fastcall __stdcall PCorbaAny MemberLabel(CorbaULong index);
```

Description

This is MemberLabel, a member of class ITypeCode.

67.1.10.2.10 ITypeCode.MemberName Method

Pascal

```
function MemberName(index: CorbaULong): PChar; stdcall;
```

C++

```
__fastcall __stdcall const char * MemberName(CorbaULong index);
```

Description

This is MemberName, a member of class ITypeCode.

67.1.10.2.11 ITypeCode.MemberType Method

Pascal

```
procedure MemberType(index: CorbaULong; out tc: ITypeCode); stdcall;
```

C++

```
__fastcall __stdcall MemberType(CorbaULong index, ITypeCode tc);
```

Description

This is MemberType, a member of class ITypeCode.

67.1.10.2.12 ITypeCode.Name Method

Pascal

```
function Name: PChar; stdcall;
```

C++

```
__fastcall __stdcall const char * Name();
```

Description

This is Name, a member of class ITypeCode.

67.1.10.2.13 ITypeCode.Parameter Method

Pascal

```
function Parameter(index: Integer): PCorbaAny; stdcall;
```

C++

```
__fastcall __stdcall PCorbaAny Parameter(int index);
```

Description

This is Parameter, a member of class ITypeCode.

67.1.10.2.14 ITypeCode.ParameterCount Method

Pascal

```
function ParameterCount: Integer; stdcall;
```

C++

```
__fastcall __stdcall int ParameterCount();
```

Description

This is ParameterCount, a member of class ITypeCode.

67.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	AnyToVariant (see page 6241)	This is function OrbPas.AnyToVariant.
	BindStub (see page 6241)	This is function OrbPas.BindStub.
	CorbaAnyType (see page 6242)	This is function OrbPas.CorbaAnyType.
	CorbaDuplicateAny (see page 6242)	This is function OrbPas.CorbaDuplicateAny.
	CorbaReleaseAny (see page 6242)	This is function OrbPas.CorbaReleaseAny.
	CorbaStringFree (see page 6243)	This is function OrbPas.CorbaStringFree.
	CorbaWStringFree (see page 6243)	This is function OrbPas.CorbaWStringFree.
	CreateSkeleton (see page 6243)	This is function OrbPas.CreateSkeleton.
	CreateUserException (see page 6244)	This is function OrbPas.CreateUserException.
	InitORB (see page 6244)	This is function OrbPas.InitORB.
	RegisterUserException (see page 6244)	This is function OrbPas.RegisterUserException.
	SequenceToVariant (see page 6245)	This is function OrbPas.SequenceToVariant.
	UnRegisterUserException (see page 6245)	This is function OrbPas.UnRegisterUserException.
	VariantToAny (see page 6245)	This is function OrbPas.VariantToAny.

67.2.1 OrbPas.AnyToVariant Function

Pascal

```
function AnyToVariant(Value: PCorbaAny; OV: PVariant): Boolean;
```

C++

```
Boolean AnyToVariant(PCorbaAny Value, PVariant OV);
```

File

OrbPas

Description

This is function OrbPas.AnyToVariant.

67.2.2 OrbPas.BindStub Function

Pascal

```
procedure BindStub(RepositoryID: PChar; InstanceName: PChar; HostName: PChar; const Orb: IORB;
RefCountServer: CorbaBoolean; out Stub: IStub);
```

C++

```
BindStub(const char * RepositoryID, const char * InstanceName, const char * HostName, const
IORB Orb, CorbaBoolean RefCountServer, IStub Stub);
```

File

OrbPas

Description

This is function OrbPas.BindStub.

67.2.3 OrbPas.CorbaAnyType Function

Pascal

```
procedure CorbaAnyType(Any: PCorbaAny; out TypeCode: ITypeCode);
```

C++

```
CorbaAnyType(PCorbaAny Any, ITypeCode TypeCode);
```

File

OrbPas

Description

This is function OrbPas.CorbaAnyType.

67.2.4 OrbPas.CorbaDuplicateAny Function

Pascal

```
function CorbaDuplicateAny(Any: PCorbaAny): PCorbaAny;
```

C++

```
PCorbaAny CorbaDuplicateAny(PCorbaAny Any);
```

File

OrbPas

Description

This is function OrbPas.CorbaDuplicateAny.

67.2.5 OrbPas.CorbaReleaseAny Function

Pascal

```
procedure CorbaReleaseAny(Any: PCorbaAny);
```

C++

```
CorbaReleaseAny(PCorbaAny Any);
```

File

OrbPas

Description

This is function OrbPas.CorbaReleaseAny.

67.2.6 OrbPas.CorbaStringFree Function

Pascal

```
procedure CorbaStringFree(Str: PChar);
```

C++

```
CorbaStringFree(const char * Str);
```

File

OrbPas

Description

This is function OrbPas.CorbaStringFree.

67.2.7 OrbPas.CorbaWStringFree Function

Pascal

```
procedure CorbaWStringFree(Str: PWideChar);
```

C++

```
CorbaWStringFree(PWideChar Str);
```

File

OrbPas

Description

This is function OrbPas.CorbaWStringFree.

67.2.8 OrbPas.CreateSkeleton Function

Pascal

```
procedure CreateSkeleton(InterfaceName: PChar; const DelphiObject: ISkeletonObject; Serialize:
CorbaBoolean; InstanceName: PChar; RepositoryID: PChar; ClientRefCount: CorbaBoolean; out
Skeleton: ISkeleton);
```

C++

```
CreateSkeleton(const char * InterfaceName, const ISkeletonObject DelphiObject, CorbaBoolean
Serialize, const char * InstanceName, const char * RepositoryID, CorbaBoolean ClientRefCount,
ISkeleton Skeleton);
```

File

OrbPas

Description

This is function OrbPas.CreateSkeleton.

67.2.9 OrbPas.CreateUserException Function

Pascal

```
function CreateUserException(copy: TCopyUserExceptionProc; throwobj: TThrowUserExceptionProc):
PUserExceptionProxy;
```

C++

```
PUserExceptionProxy CreateUserException(TCopyUserExceptionProc copy, TThrowUserExceptionProc
throwobj);
```

File

OrbPas

Description

This is function OrbPas.CreateUserException.

67.2.10 OrbPas.InitORB Function

Pascal

```
procedure InitORB(const Argv: TArgv; out Orb: IORB);
```

C++

```
InitORB(const TArgv Argv, IORB Orb);
```

File

OrbPas

Description

This is function OrbPas.InitORB.

67.2.11 OrbPas.RegisterUserException Function

Pascal

```
function RegisterUserException(Name: PChar; RepositoryID: PChar; Factory:
TUserExceptionFactoryProc): PExceptionDescription;
```

C++

```
PExceptionDescription RegisterUserException(const char * Name, const char * RepositoryID,
TUserExceptionFactoryProc Factory);
```

File

OrbPas

Description

This is function OrbPas.RegisterUserException.

67.2.12 OrbPas.SequenceToVariant Function

Pascal

```
function SequenceToVariant(Value: PCorbaAny; OV: PVariant): Boolean;
```

C++

```
Boolean SequenceToVariant(PCorbaAny Value, PVariant OV);
```

File

OrbPas

Description

This is function OrbPas.SequenceToVariant.

67.2.13 OrbPas.UnRegisterUserException Function

Pascal

```
procedure UnRegisterUserException(Description: PExceptionDescription);
```

C++

```
UnRegisterUserException(PExceptionDescription Description);
```

File

OrbPas

Description

This is function OrbPas.UnRegisterUserException.

67.2.14 OrbPas.VariantToAny Function

Pascal

```
function VariantToAny(Value: PVariant): PCorbaAny;
```

C++

```
PCorbaAny VariantToAny(PVariant Value);
```

File

OrbPas

Description

This is function OrbPas.VariantToAny.

67.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TCKind (see page 6246)	This is record OrbPas.TCKind.

Records

	Name	Description
	TStructMember (see page 6247)	This is record OrbPas.TStructMember.

67.3.1 OrbPas.TCKind Enumeration

Pascal

```
TCKind = (
  tk_null,
  tk_void,
  tk_short,
  tk_long,
  tk_ushort,
  tk_ulong,
  tk_float,
  tk_double,
  tk_boolean,
  tk_char,
  tk_octet,
  tk_any,
  tk_TypeCode,
  tk_Principal,
  tk_objref,
  tk_struct,
  tk_union,
  tk_enum,
  tk_string,
  tk_sequence,
  tk_array,
  tk_alias,
  tk_except,
  tk_longlong,
  tk_ulonglong,
  tk_longdouble,
  tk_wchar,
  tk_wstring,
  tk_fixed
);
```

C++

```
enum TCKind {
  tk_null,
  tk_void,
  tk_short,
  tk_long,
  tk_ushort,
```

```
    tk_ulong,
    tk_float,
    tk_double,
    tk_boolean,
    tk_char,
    tk_octet,
    tk_any,
    tk_TypeCode,
    tk_Principal,
    tk_objref,
    tk_struct,
    tk_union,
    tk_enum,
    tk_string,
    tk_sequence,
    tk_array,
    tk_alias,
    tk_except,
    tk_longlong,
    tk_ulonglong,
    tk_longdouble,
    tk_wchar,
    tk_wstring,
    tk_fixed
  };
```

File

OrbPas

Description

This is record OrbPas.TCKind.

67.3.2 OrbPas.TStructMember Record

Pascal

```
  TStructMember = record
    Name: string;
    TC: ITypeCode;
  end;
```

C++

```
  struct TStructMember {
    UnicodeString Name;
    ITypeCode TC;
  };
```

File

OrbPas

Description

This is record OrbPas.TStructMember.

67.4 Types

The following table lists types in this documentation.

Types

Name	Description
CorbaBoolean (see page 6248)	This is type OrbPas.CorbaBoolean.
CorbaULong (see page 6248)	This is type OrbPas.CorbaULong.
PCorbaAny (see page 6249)	This is type OrbPas.PCorbaAny.
PCorbaInterfaceDef (see page 6249)	This is type OrbPas.PCorbaInterfaceDef.
PCorbaObject (see page 6249)	This is type OrbPas.PCorbaObject.
PCorbaOrb (see page 6250)	This is type OrbPas.PCorbaOrb.
PExceptionDescription (see page 6250)	This is type OrbPas.PExceptionDescription.
PMarshalInbuffer (see page 6250)	This is type OrbPas.PMarshalInbuffer.
PMarshalOutbuffer (see page 6251)	This is type OrbPas.PMarshalOutbuffer.
PUserExceptionProxy (see page 6251)	This is type OrbPas.PUserExceptionProxy.
TArgv (see page 6251)	This is type OrbPas.TArgv.
TCopyUserExceptionProc (see page 6252)	This is type OrbPas.TCopyUserExceptionProc.
TStructMembers (see page 6252)	This is type OrbPas.TStructMembers.
TThrowUserExceptionProc (see page 6252)	This is type OrbPas.TThrowUserExceptionProc.
TUserExceptionFactoryProc (see page 6253)	This is type OrbPas.TUserExceptionFactoryProc.

67.4.1 OrbPas.CorbaBoolean Type

Pascal

```
CorbaBoolean = ByteBool;
```

C++

```
ByteBool CorbaBoolean;
```

File

OrbPas

Description

This is type OrbPas.CorbaBoolean.

67.4.2 OrbPas.CorbaULong Type

Pascal

```
CorbaULong = Integer;
```

C++

```
int CorbaULong;
```

File

OrbPas

Description

This is type OrbPas.CorbaULong.

67.4.3 OrbPas.PCorbaAny Type

Pascal

```
PCorbaAny = type Pointer;
```

C++

```
type Pointer PCorbaAny;
```

File

OrbPas

Description

This is type OrbPas.PCorbaAny.

67.4.4 OrbPas.PCorbaInterfaceDef Type

Pascal

```
PCorbaInterfaceDef = type Pointer;
```

C++

```
type Pointer PCorbaInterfaceDef;
```

File

OrbPas

Description

This is type OrbPas.PCorbaInterfaceDef.

67.4.5 OrbPas.PCorbaObject Type

Pascal

```
PCorbaObject = type Pointer;
```

C++

```
type Pointer PCorbaObject;
```

File

OrbPas

Description

This is type OrbPas.PCorbaObject.

67.4.6 OrbPas.PCorbaOrb Type

Pascal

```
PCorbaOrb = type Pointer;
```

C++

```
type Pointer PCorbaOrb;
```

File

OrbPas

Description

This is type OrbPas.PCorbaOrb.

67.4.7 OrbPas.PExceptionDescription Type

Pascal

```
PExceptionDescription = type Pointer;
```

C++

```
type Pointer PExceptionDescription;
```

File

OrbPas

Description

This is type OrbPas.PExceptionDescription.

67.4.8 OrbPas.PMarshalInbuffer Type

Pascal

```
PMarshalInbuffer = type Pointer;
```

C++

```
type Pointer PMarshalInbuffer;
```

File

OrbPas

Description

This is type OrbPas.PMarshalInbuffer.

67.4.9 OrbPas.PMarshalOutbuffer Type

Pascal

```
PMarshalOutbuffer = type Pointer;
```

C++

```
type Pointer PMarshalOutbuffer;
```

File

OrbPas

Description

This is type OrbPas.PMarshalOutbuffer.

67.4.10 OrbPas.PUserExceptionProxy Type

Pascal

```
PUserExceptionProxy = type Pointer;
```

C++

```
type Pointer PUserExceptionProxy;
```

File

OrbPas

Description

This is type OrbPas.PUserExceptionProxy.

67.4.11 OrbPas.TArgv Type

Pascal

```
TArgv = array of string;
```

C++

```
array of string TArgv;
```

File

OrbPas

Description

This is type OrbPas.TArgv.

67.4.12 OrbPas.TCopyUserExceptionProc Type

Pascal

```
TCopyUserExceptionProc = procedure (const InBuf: IMarshalInBuffer) of object;
```

C++

```
(const InBuf: IMarshalInBuffer) ( TCopyUserExceptionProc)();
```

File

OrbPas

Description

This is type OrbPas.TCopyUserExceptionProc.

67.4.13 OrbPas.TStructMembers Type

Pascal

```
TStructMembers = array of TStructMember;
```

C++

```
array of TStructMember TStructMembers;
```

File

OrbPas

Description

This is type OrbPas.TStructMembers.

67.4.14 OrbPas.TThrowUserExceptionProc Type

Pascal

```
TThrowUserExceptionProc = procedure of object;
```

C++

```
( TThrowUserExceptionProc)();
```

File

OrbPas

Description

This is type OrbPas.TThrowUserExceptionProc.

67.4.15 OrbPas.TUserExceptionFactoryProc Type

Pascal

```
TUserExceptionFactoryProc = function : PUserExceptionProxy;
```

C++

```
: PUserExceptionProxy ( TUserExceptionFactoryProc)();
```

File

OrbPas

Description

This is type OrbPas.TUserExceptionFactoryProc.

68 Outline Namespace

This is namespace Outline.

Topics

Name	Description
Classes (see page 6257)	The following table lists classes in this documentation.
Structs, Records, Enums (see page 6380)	The following table lists structs, records, enums in this documentation.
Types (see page 6385)	The following table lists types in this documentation.

Classes

	Name	Description
	EOutlineError (see page 6257)	EOutlineError is the exception class for outline components.
	OutlineError (see page 6258)	OutlineError is a special exception class for invalid outline-node indexes.
	TCustomOutline (see page 6258)	TCustomOutline is the base class for controls that display outline nodes (TOutlineNode (see page 6363) objects).
	TOutline (see page 6296)	TOutline is a multilevel outline that displays the values of TOutlineNode (see page 6363) objects.
	TOutlineNode (see page 6363)	TOutlineNode represents a node in a TCustomOutline (see page 6258) object.

Structs, Records, Enums

	Name	Description
	TAttachMode (see page 6380)	TAttachMode indicates how an outline node should be inserted into an outline.
	TOutlineBitmap (see page 6381)	This is record Outline.TOutlineBitmap.
	TOutlineNodeCompare (see page 6381)	This is record Outline.TOutlineNodeCompare.
	TOutlineOption (see page 6382)	TOutlineOptions (see page 6387) represents the style in which an outline is drawn.
	TOutlineStyle (see page 6382)	TOutlineStyle determines how the nodes of an outline are drawn.
	TOutlineType (see page 6383)	TOutlineType indicates whether an outline is owner-drawn.

Types

Name	Description
EOutlineChange (see page 6385)	EOutlineChange is the type of event handlers that respond when the nodes in an outline control change.
TBitmapArray (see page 6385)	This is type Outline.TBitmapArray.
TBitmapArrayRange (see page 6386)	This is type Outline.TBitmapArrayRange.
TChangeRange (see page 6386)	TChangeRange indicates the direction in which a node is moved.
TOutlineBitmaps (see page 6386)	This is type Outline.TOutlineBitmaps.

TOutlineOptions (see page 6387)	TOutlineOptions represents the style in which an outline is drawn.

68.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EOutlineError (see page 6257)	EOutlineError is the exception class for outline components.
	OutlineError (see page 6258)	OutlineError is a special exception class for invalid outline-node indexes.
	TCustomOutline (see page 6258)	TCustomOutline is the base class for controls that display outline nodes (TOutlineNode (see page 6363) objects).
	TOutline (see page 6296)	TOutline is a multilevel outline that displays the values of TOutlineNode (see page 6363) objects.
	TOutlineNode (see page 6363)	TOutlineNode represents a node in a TCustomOutline (see page 6258) object.

68.1.1 EOutlineError Class

EOutlineError is the exception class for outline components.

Class Hierarchy

Pascal

```
EOutlineError = class(Exception);
```

C++

```
class EOutlineError : public Exception;
```

File

Outline

Description

EOutlineError is raised when an error occurs as an application works with an outline component. For example, an EOutlineError exception occurs when an application

Attempts to access an outline using an invalid node index.

Attempts to expand a node whose parent isn't expanded.

Attempts to load items from a file using an invalid file extension.

Note: EOutlineError is raised by the TOutline (see page 6296) component, which is maintained for backward compatibility.

See Also

OutlineError (see page 6258)

68.1.2 OutlineError Class

OutlineError is a special exception class for invalid outline-node indexes.

Class Hierarchy

Pascal

```
OutlineError = class(TObject);
```

C++

```
class OutlineError : public TObject;
```

File

Outline

Description

OutlineError is raised when an application cannot access a specified outline node. In most cases, this occurs because the index used is invalid.

OutlineError is raised internally to abort look-ups of outline components. Because it does not descend from Exception, it never appears at runtime—even if the debugger is set to break on exceptions. Thus it is a useful tool for aborting deep recursions.

Note: OutlineError is raised by the TOutline (see page 6296) component, which is maintained for backward compatibility.

EOutlineError (see page 6257)

Exception

68.1.3 TCustomOutline Class

TCustomOutline is the base class for controls that display outline nodes (TOutlineNode (see page 6363) objects).

Class Hierarchy

Pascal

```
TCustomOutline = class(TCustomGrid);
```

C++

```
class TCustomOutline : public TCustomGrid;
```

File

Outline

Description

Use TCustomOutline as a base class when defining a control that displays outline nodes in a two-dimensional layout. TCustomOutline introduces the ability to manage a hierarchy of outline nodes, including the ability to control the appearance and layout of those nodes and to expand or collapse branches of the outline tree.

Do not create instances of TCustomOutline. To add an outline control to a form, use the TOutline (see page 6296) object, which publishes many of the properties, events, and methods of TCustomOutline, or TTreeView, which wraps the Windows control that performs the same function.

See Also

TOutline (see page 6296)

TOutlineNode (see page 6363)

TTreeView

68.1.3.1 TCustomOutline Members

The following tables list the members exposed by TCustomOutline.

Protected Events

	Name	Description
	OnCollapse (see page 6295)	Occurs immediately after a node in the outline is collapsed.
	OnDrawItem (see page 6295)	Occurs when a node must be drawn in an owner-draw outline.
	OnExpand (see page 6296)	Occurs immediately after a node in the outline is expanded.

Protected Fields

	Name	Description
	DesignOptionsBoost (see page 3031)	This is DesignOptionsBoost, a member of class TCustomGrid.
	FGridState (see page 3031)	This is FGridState, a member of class TCustomGrid.
	FSaveCellExtents (see page 3032)	This is FSaveCellExtents, a member of class TCustomGrid.
	VirtualView (see page 3032)	This is VirtualView, a member of class TCustomGrid.

Protected Methods

	Name	Description
	AdjustSize (see page 3034)	Adds or deletes rows or columns from the grid.
	BadIndex (see page 6267)	Indicates whether a node's index is up to date.
	BeginColumnDrag (see page 3034)	Starts the dragging of a column in the grid.
	BeginRowDrag (see page 3034)	Starts the dragging of a row in the grid.
	BoxRect (see page 3035)	Returns the screen coordinates of a specified set of cells.
	CalcDrawInfo (see page 3035)	Calculates the pixel locations of the grid boundaries.
	CalcFixedInfo (see page 3036)	Calculates the pixel locations of the fixed cells.
V	CalcSizingState (see page 3036)	Determines the appearance of the mouse cursor during resizing.
	CanEditAcceptKey (see page 3036)	Indicates whether the Key parameter can be entered into the current cell.
	CanEditModify (see page 3037)	Indicates whether the current cell in the grid can be edited.
V	CanEditShow (see page 3037)	Indicates whether the inplace edit control can be created to allow editing.
	CanGridAcceptKey (see page 3037)	Indicates whether the grid should respond to a given key combination.
	CellRect (see page 3038)	Returns the screen coordinates of a cell in the grid.
	ChangeGridOrientation (see page 3038)	Prepares the grid's canvas for painting to reflect a right-to-left or left-to-right orientation.
	CheckColumnDrag (see page 3039)	CheckColumnDrag validates whether the column currently selected for dragging can be dropped at the current location.
	CheckRowDrag (see page 3039)	CheckRowDrag validates whether the row currently selected for dragging can be dropped at the current location.
V	Click (see page 6268)	Updates the SelectedItem (see page 6294) property.
	Collapse (see page 6269)	Generates an OnCollapse (see page 6295) event.
	ColumnMoved (see page 3039)	Provides the interface for a method that responds when the position of a column changes.
	ColWidthsChanged (see page 3040)	Responds when the column widths change.
V	CreateEditor (see page 3040)	Creates the inplace editor control.

	CreateParams (see page 3041)	Initializes the window-creation parameter record.
	DblClick (see page 6269)	Expands or collapses the selected node.
	DefineProperties (see page 6269)	Creates a binary property for customized bitmap values.
	DeleteColumn (see page 3041)	Deletes a specified column from the grid.
	DeleteNode (see page 6270)	Fixes up the outline after a node has been deleted.
	DeleteRow (see page 3042)	Deletes a specified from the grid.
	DoExit (see page 3042)	Hides the inplace editor when selection moves to another control in a form.
	DoMouseWheelDown (see page 3042)	Performs tasks when the mouse wheel is rotated downward.
	DoMouseWheelUp (see page 3043)	Performs tasks when the mouse wheel is rotated upward.
	DrawCell (see page 6271)	Draws a node in the outline.
	EndColumnDrag (see page 3044)	Ends the dragging of a column in the grid.
	EndRowDrag (see page 3044)	Ends the dragging of a row in the grid.
	Expand (see page 6272)	Generates an OnExpand (see page 6296) event.
	FocusCell (see page 3044)	Changes the current cell to a specified cell.
	GetEditLimit (see page 3045)	Provides the interface for a method that limits the number of characters the user can type into cells.
	GetEditMask (see page 3045)	Provides the interface for a method that returns an input mask for the specified cell.
	GetEditStyle (see page 3046)	Indicates whether a specified cell has an ellipsis button or drop-down arrow.
	GetEditText (see page 3046)	Returns the value of the indicated cell formatted for editing.
	GetGridHeight (see page 3046)	Returns the value of the GridHeight (see page 3068) property.
	GetGridWidth (see page 3047)	Returns the value of the GridWidth (see page 3070) property.
	HideEdit (see page 3047)	Hides the inplace editor.
	HideEditor (see page 3048)	Hides the inplace editor when it is not in use.
	InvalidateCell (see page 6276)	Invalidates the region occupied by a cell so that it will be repainted with the next Windows paint message.
	InvalidateCol (see page 3048)	Invalidates the region occupied by a column so that it will be repainted with the next Windows paint message.
	InvalidateEditor (see page 3049)	Causes the inplace editor to repaint itself, moving to a new location if necessary.
	InvalidateGrid (see page 3049)	Tells Windows to repaint the grid after other important Windows messages are handled.
	InvalidateRow (see page 3050)	Invalidates the region occupied by a row so that it will be repainted with the next Windows paint message.
	KeyDown (see page 6277)	Provides special processing when the user presses a key.
	KeyPress (see page 6277)	Provides special processing when a key is pressed.
	Loaded (see page 6278)	Sets up the outline after it has been streamed in.
	MouseDown (see page 6280)	Updates the SelectedItem (see page 6294) property.
	MouseMove (see page 3052)	Provides special processing when the user moves the mouse.
	MouseUp (see page 3052)	Provides special processing when the user releases the mouse button.
	Move (see page 6280)	Repositions a node in the outline.
	MoveColRow (see page 3053)	Selects the cell indicated by the ACol and ARow parameters.
	MoveColumn (see page 3053)	Moves a column to a new position.
	MoveRow (see page 3053)	Moves a row to a new position.
	Paint (see page 3054)	Draws the image of the grid control on the screen.
	RowHeightsChanged (see page 3054)	Responds when the row heights change.
	RowMoved (see page 3055)	Provides the interface for a method that responds when the position of a row changes.
	ScrollData (see page 3055)	Scrolls the visual image of the cells in the grid.
	SelectCell (see page 3055)	Determines whether a particular cell in the grid can be selected.
	SetDisplayWidth (see page 6282)	Sets the display width of the outline.
	SetEditText (see page 3056)	Provides the interface for a method that updates the text associated with a cell.
	SetGoodIndex (see page 6282)	Returns the first node in the Items (see page 6287) array that must be reindexed to make the index of the Value parameter correct.
	SetLevel (see page 6283)	Sets the level of an outline node.
	ShowEditor (see page 3056)	Displays the inplace editor when the grid enters edit mode.
	ShowEditorChar (see page 3057)	Displays the inplace editor, with its text set to the specified character.
	SizeChanged (see page 3057)	Responds to changes in the size of the grid.

	Sizing (see page 3057)	Indicates whether the indicated coordinates are on one of the resize hot zones of the graph.
	TimedScroll (see page 3058)	Extends a move, resize, or selection out of the scrollable region when the user drags the mouse in a direction where the grid is scrolled.
	TopLeftChanged (see page 3058)	Updates the position of the inplace editor when the grid scrolls.
	UpdateDesigner (see page 3059)	Notifies the designer when rows and columns of the grid are moved or resized.

Protected Properties

	Name	Description
	BorderStyle (see page 3060)	Determines whether a single line border is drawn around the grid.
	Col (see page 3060)	Specifies the index of the column that contains the selected cell.
	ColCount (see page 3062)	Specifies the number of columns in the grid.
	Color (see page 3063)	Specifies the background color of the control.
	ColWidths (see page 3063)	Indicates the width (in pixels) of all the columns in the grid.
	DefaultColWidth (see page 3064)	Determines the width (in pixels) of all columns that have not been explicitly resized.
	DefaultDrawing (see page 3066)	Determines whether the Cells are painted when the grid is drawn.
	DefaultRowHeight (see page 3066)	Specifies the height (in pixels) of all rows that have not been explicitly resized.
	EditorMode (see page 3066)	Determines whether the current cell can be edited.
	FixedColor (see page 3067)	Specifies the background color of the fixed rows and columns in the grid.
	FixedCols (see page 3067)	Specifies the number of columns on the left of the grid that cannot be scrolled.
	FixedRows (see page 3068)	Specifies the number of rows on the top of the grid that cannot be scrolled.
R	GridHeight (see page 3068)	Specifies the height of the grid in pixels.
	GridLineWidth (see page 3069)	Specifies the width (in pixels) of the lines that separate the cells of the grid.
R	GridWidth (see page 3070)	Specifies the width of the grid in pixels.
R	HitTest (see page 3071)	Indicates the current position of the mouse cursor.
R	InplaceEditor (see page 3071)	Designates the edit control the grid uses to allow users to edit the contents of the selected cell.
	ItemHeight (see page 6286)	Specifies the height of each node in the outline.
	ItemSeparator (see page 6288)	Specifies a delimiting string for outline nodes.
	LeftCol (see page 3072)	Specifies the index of the first visible scrollable column in the grid.
	Lines (see page 6288)	Lists the Text property values of all nodes in the outline.
	Options (see page 6288)	Determines how the nodes in the outline are drawn.
	OutlineStyle (see page 6289)	Specifies how the outline tree is displayed.
	ParentColor (see page 3073)	Determines where a control looks for its color information.
	PictureClosed (see page 6290)	Specifies the bitmap used to represent a collapsed node that has subitems.
	PictureLeaf (see page 6291)	Specifies the bitmap used to represent an item that does not have subitems.
	PictureMinus (see page 6291)	Specifies the bitmap used to represent an expanded item that has subitems.
	PictureOpen (see page 6291)	Specifies the bitmap used to represent an expanded item that has subitems.
	PicturePlus (see page 6292)	Specifies the bitmap used to represent a collapsed item that has subitems.
	RowCount (see page 3075)	Specifies the number of rows in the grid.
	RowHeights (see page 3076)	Gives the height (in pixels) of all rows in the grid.
	ScrollBars (see page 3077)	Specifies whether the grid includes horizontal and vertical scroll bars.
	Selection (see page 3077)	Indicates the boundaries of the current selection.
	Style (see page 6294)	Determines whether the nodes and tree are drawn automatically.
	TabStops (see page 3079)	Indicates whether the user can tab to specified columns in the grid.
	TopRow (see page 3080)	Specifies the index of the first visible scrollable row in the grid.
R	VisibleColCount (see page 3082)	Indicates the number of scrollable columns visible in the grid.
R	VisibleRowCount (see page 3082)	Indicates the number of scrollable rows visible in the grid.

Public Methods

	Name	Description
	Add (see page 6264)	Adds a node to the outline.
	AddChild (see page 6265)	Adds a child node to a node in the outline.
	AddChildObject (see page 6266)	Adds a child node containing data to a node in the outline.
	AddObject (see page 6266)	Adds a node containing data to the outline.

	BeginUpdate (see page 6268)	Prevents the updating of the outline until the EndUpdate (see page 6271) method is called.
	Clear (see page 6268)	Removes all items from the outline.
V	Create (see page 6262)	Creates an instance of TCustomOutline (see page 6258).
	Delete (see page 6270)	Deletes a node from the outline.
V	Destroy (see page 6263)	Destroys an instance of TCustomOutline (see page 6258).
	EndUpdate (see page 6271)	Performs the reindexing and repaints deferred by a call to BeginUpdate (see page 6268).
	FullCollapse (see page 6272)	Causes all top-level nodes in the outline to collapse.
	FullExpand (see page 6272)	Expands every node in the outline.
	GetDataItem (see page 6273)	Returns the index of the first node in the outline that has the Value pointer as its Data property.
	GetItem (see page 6273)	Returns the index of the node at the position indicated by the X and Y parameters.
	GetNodeDisplayWidth (see page 6274)	Returns the length of the row containing a specified node.
	GetTextItem (see page 6274)	Returns the index of the first node in the outline with the Value parameter as its Text property.
	GetVisibleNode (see page 6274)	Returns the TOutlineNode (see page 6363) object for the node indicated by a position in the image of the outline.
	Insert (see page 6275)	Inserts a node at a specified position.
	InsertObject (see page 6275)	Inserts a node containing data at a specified position.
	LoadFromFile (see page 6278)	This is the overview for the LoadFromFile method overload.
	LoadFromStream (see page 6279)	This is the overview for the LoadFromStream method overload.
	MouseCoord (see page 3051)	Returns the row and column indexes of the cell that contains a point specified in screen coordinates.
	SaveToFile (see page 6280)	This is the overview for the SaveToFile method overload.
	SaveToStream (see page 6281)	This is the overview for the SaveToStream method overload.
	SetUpdateState (see page 6283)	Enables or disables the maintenance of the node indexes.

Public Properties

	Name	Description
	Canvas (see page 6284)	Specifies the TCanvas object that presents a drawing surface for the control.
R	ItemCount (see page 6286)	Indicates the number of nodes in the outline.
R	Items (see page 6287)	Lists the nodes in the outline.
	Row (see page 6292)	Specifies the index of the row that contains the selected cell.
	SelectedItem (see page 6294)	Specifies the index of the selected node.

Published Properties

	Name	Description
	TabStop (see page 3079)	Determines if the user can tab to a control.

68.1.3.2 TCustomOutline.Create Constructor

Creates an instance of TCustomOutline (see page 6258).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomOutline(TComponent * AOwner);
```

Description

Call Create to instantiate a TCustomOutline (see page 6258) object at runtime. Outlines placed on forms at design time are created automatically.

Create initializes the outline object, setting the values of some internal properties, as well as setting

Color to clWindow (see page 2965) and ParentColor to false.

Height to 97 and Width to 121.

ItemSeparator (see page 6288) to '\'.

Options (see page 6288) to [ooDrawTreeRoot, ooDrawFocusRect].

OutlineStyle (see page 6289) to osTreePictureText.

See Also

Height

ItemSeparator (see page 6288)

Options (see page 6288)

OutlineStyle (see page 6289)

Color

ParentColor

Create

Width

68.1.3.3 TCustomOutline.Destroy Destructor

Destroys an instance of TCustomOutline (see page 6258).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomOutline();
```

Description

Destroy frees all memory associated with the outline. While the destructor frees the TOutlineNode (see page 6363) objects that comprise the outline, any objects associated with those nodes are not freed.

68.1.3.4 TCustomOutline Methods

The methods of the TCustomOutline class are listed here.

Protected Methods

	Name	Description
	BadIndex (see page 6267)	Indicates whether a node's index is up to date.
V	Click (see page 6268)	Updates the SelectedItem (see page 6294) property.
	Collapse (see page 6269)	Generates an OnCollapse (see page 6295) event.
V	DblClick (see page 6269)	Expands or collapses the selected node.
V	DefineProperties (see page 6269)	Creates a binary property for customized bitmap values.
	DeleteNode (see page 6270)	Fixes up the outline after a node has been deleted.
V	DrawCell (see page 6271)	Draws a node in the outline.
	Expand (see page 6272)	Generates an OnExpand (see page 6296) event.
	InvalidateCell (see page 6276)	Invalidates the region occupied by a cell so that it will be repainted with the next Windows paint message.

	KeyDown (see page 6277)	Provides special processing when the user presses a key.
	KeyPress (see page 6277)	Provides special processing when a key is pressed.
	Loaded (see page 6278)	Sets up the outline after it has been streamed in.
	MouseDown (see page 6280)	Updates the SelectedItem (see page 6294) property.
	Move (see page 6280)	Repositions a node in the outline.
	SetDisplayWidth (see page 6282)	Sets the display width of the outline.
	SetGoodIndex (see page 6282)	Returns the first node in the Items (see page 6287) array that must be reindexed to make the index of the Value parameter correct.
	SetLevel (see page 6283)	Sets the level of an outline node.

Public Methods

	Name	Description
	Add (see page 6264)	Adds a node to the outline.
	AddChild (see page 6265)	Adds a child node to a node in the outline.
	AddChildObject (see page 6266)	Adds a child node containing data to a node in the outline.
	AddObject (see page 6266)	Adds a node containing data to the outline.
	BeginUpdate (see page 6268)	Prevents the updating of the outline until the EndUpdate (see page 6271) method is called.
	Clear (see page 6268)	Removes all items from the outline.
	Delete (see page 6270)	Deletes a node from the outline.
	EndUpdate (see page 6271)	Performs the reindexing and repaints deferred by a call to BeginUpdate (see page 6268).
	FullCollapse (see page 6272)	Causes all top-level nodes in the outline to collapse.
	FullExpand (see page 6272)	Expands every node in the outline.
	GetDataItem (see page 6273)	Returns the index of the first node in the outline that has the Value pointer as its Data property.
	GetItem (see page 6273)	Returns the index of the node at the position indicated by the X and Y parameters.
	GetNodeDisplayWidth (see page 6274)	Returns the length of the row containing a specified node.
	GetTextItem (see page 6274)	Returns the index of the first node in the outline with the Value parameter as its Text property.
	GetVisibleNode (see page 6274)	Returns the TOutlineNode (see page 6363) object for the node indicated by a position in the image of the outline.
	Insert (see page 6275)	Inserts a node at a specified position.
	InsertObject (see page 6275)	Inserts a node containing data at a specified position.
	LoadFromFile (see page 6278)	This is the overview for the LoadFromFile method overload.
	LoadFromStream (see page 6279)	This is the overview for the LoadFromStream method overload.
	SaveToFile (see page 6280)	This is the overview for the SaveToFile method overload.
	SaveToStream (see page 6281)	This is the overview for the SaveToStream method overload.
	SetUpdateState (see page 6283)	Enables or disables the maintenance of the node indexes.

68.1.3.4.1 TCustomOutline.Add Method

Adds a node to the outline.

Pascal

```
function Add(Index: LongInt; const Text: string): LongInt;
```

C++

```
__fastcall LongInt Add(LongInt Index, const UnicodeString Text);
```

Description

Use Add to add a TOutlineNode (see page 6363) object to the outline. Text specifies the Text property value of the new node.

Index specifies where to add the new node. The new node is positioned in the outline as the last sibling of the node identified by Index. To add nodes to the beginning of the outline, specify zero (0) as the Index parameter.

Nodes that appear after the new node are moved down one row and reindexed in the Items (see page 6287) property array with valid Index values. If BeginUpdate (see page 6268) has been called, the Items (see page 6287) array is not reindexed until the EndUpdate (see page 6271) method is called.

Add returns the Index property of the new node.

Text (see page 6378)

68.1.3.4.2 TCustomOutline.AddChild Method

Adds a child node to a node in the outline.

Pascal

```
function AddChild(Index: LongInt; const Text: string): LongInt;
```

C++

```
__fastcall LongInt AddChild(LongInt Index, const UnicodeString Text);
```

Description

Use AddChild to add a TOutlineNode (see page 6363) object as the child of a node in the outline. Text specifies the Text property value of the new node.

Index specifies where to add the new node. The new node is positioned in the outline as the last child of the node identified by Index. To add nodes to the top level of the outline (off the root), specify zero (0) as the Index parameter.

Nodes that appear after the new node are moved down one row and reindexed in the Items (see page 6287) property array with valid Index values. If BeginUpdate (see page 6268) has been called, the Items (see page 6287) array is not reindexed until the EndUpdate (see page 6271) method is called.

AddChild returns the Index property of the new node.

Text (see page 6378)

68.1.3.4.3 TCustomOutline.AddChildObject Method

Adds a child node containing data to a node in the outline.

Pascal

```
function AddChildObject(Index: LongInt; const Text: string; const Data: TCustomData): LongInt;
```

C++

```
__fastcall LongInt AddChildObject(LongInt Index, const UnicodeString Text, const TCustomData
Data);
```

Description

Use AddChildObject to add a TOutlineNode (see page 6363) object as the child of a node in the outline and assign it a data pointer. Text specifies the value of the Text property for the new node. Data specifies the value of the Data property for the new node.

Index specifies where to add the new node. The new node is positioned in the outline as the last child of the node identified by Index. To add nodes to the top level of the outline (off the root), specify zero (0) as the Index parameter.

Nodes that appear after the new node are moved down one row and reindexed in the Items (see page 6287) property array with valid Index values. If BeginUpdate (see page 6268) has been called, the Items (see page 6287) array is not reindexed until the EndUpdate (see page 6271) method is called.

AddChildObject returns the Index property of the new node.

See Also

AddChild (see page 6265)

Delete (see page 6270)

EndUpdate (see page 6271)

InsertObject (see page 6275)

Items (see page 6287)

Data (see page 6374)

Index (see page 6376)

Text (see page 6378)

68.1.3.4.4 TCustomOutline.AddObject Method

Adds a node containing data to the outline.

Pascal

```
function AddObject(Index: LongInt; const Text: string; const Data: TCustomData): LongInt;
```

C++

```
__fastcall LongInt AddObject(LongInt Index, const UnicodeString Text, const TCustomData Data);
```

Description

Use AddObject to add a TOutlineNode (see page 6363) object to the outline and assign it a data pointer. Text specifies the value of the Text property for the new node. Data specifies the value of the Data property for the new node.

Index specifies where to add the new node. The new node is positioned in the outline as the last sibling of the node identified by Index. To add nodes to the beginning of the outline, specify zero (0) as the Index parameter.

Nodes that appear after the new node are moved down one row and reindexed in the Items (see page 6287) property array with valid Index values. If BeginUpdate (see page 6268) has been called, the Items (see page 6287) array is not reindexed until the EndUpdate (see page 6271) method is called.

AddChild (see page 6265) returns the Index property of the new node.

See Also

Add (see page 6264)

AddChildObject (see page 6266)

BeginUpdate (see page 6268)

Delete (see page 6270)

EndUpdate (see page 6271)

InsertObject (see page 6275)

Items (see page 6287)

Data (see page 6374)

Index (see page 6376)

Text (see page 6378)

68.1.3.4.5 TCustomOutline.BadIndex Method

Indicates whether a node's index is up to date.

Pascal

```
function BadIndex(Value: TOutlineNode): Boolean;
```

C++

```
__fastcall Boolean BadIndex(TOutlineNode Value);
```

Description

Use BadIndex to determine whether the Index property of the TOutlineNode (see page 6363) object specified by the Value parameter accurately reflects the position of the node in the outline.

If nodes are added or removed after a call to BeginUpdate (see page 6268), the indexes may be out of date until the EndUpdate (see page 6271) method is called.

See Also

BeginUpdate (see page 6268)

EndUpdate (see page 6271)

Index (see page 6376)

68.1.3.4.6 TCustomOutline.BeginUpdate Method

Prevents the updating of the outline until the EndUpdate (see page 6271) method is called.

Pascal

```
procedure BeginUpdate;
```

C++

```
__fastcall BeginUpdate();
```

Description

Call BeginUpdate before adding, removing, or moving multiple outline items. BeginUpdate speeds processing time by deferring repaints and the adjustment of index values until EndUpdate (see page 6271) is called.

Note: Make sure that EndUpdate (see page 6271) is called after all changes have been made to the nodes in the Items (see page 6287) array.

See Also

BadIndex (see page 6267)

EndUpdate (see page 6271)

Items (see page 6287)

68.1.3.4.7 TCustomOutline.Clear Method

Removes all items from the outline.

Pascal

```
procedure Clear;
```

C++

```
__fastcall Clear();
```

Description

Call Clear to empty the outline of all its nodes. Clear frees the memory for the removed items but not any memory for associated data.

68.1.3.4.8 TCustomOutline.Click Method

Updates the SelectedItem (see page 6294) property.

Pascal

```
procedure Click; override;
```

C++

```
virtual __fastcall Click();
```

Description

Click is called automatically when the user clicks the mouse on a node in the outline. Click updates the SelectedItem (see page 6294) property before the OnClick event handler is called by the inherited method.

See Also

DblClick (see page 6269)

SelectedItem (see page 6294)

68.1.3.4.9 TCustomOutline.Collapse Method

Generates an OnCollapse (see page 6295) event.

Pascal

```
procedure Collapse(Index: LongInt); dynamic;
```

C++

```
__fastcall Collapse(LongInt Index);
```

Description

Collapse is called automatically after a node in the outline is collapsed. It calls the OnCollapse (see page 6295) event handler if it is assigned.

Override the Collapse method to provide additional processing after nodes in the outline have been collapsed, or to block the OnCollapse (see page 6295) event.

See Also

Expand (see page 6272)

OnCollapse (see page 6295)

68.1.3.4.10 TCustomOutline.DblClick Method

Expands or collapses the selected node.

Pascal

```
procedure DblClick; override;
```

C++

```
virtual __fastcall DblClick();
```

Description

DblClick is called automatically when the user double clicks the mouse on a node in the outline. After calling the OnDblClick event handler, DblClick updates the SelectedItem (see page 6294) property and expands the selected node if it is collapsed or collapses the selected node if it is expanded.

See Also

Click (see page 6268)

SelectedItem (see page 6294)

Expanded (see page 6375)

68.1.3.4.11 TCustomOutline.DefineProperties Method

Creates a binary property for customized bitmap values.

Pascal

```
procedure DefineProperties(Filer: TFiler); override;
```

C++

```
virtual __fastcall DefineProperties(TFiler Filer);
```

Description

The streaming system calls DefineProperties to allow the outline to define new properties that should be saved with the outline object. DefineProperties checks whether the outline uses any bitmaps other than the default values of PictureClosed (see page 6290), PictureLeaf (see page 6291), PictureMinus (see page 6291), PictureOpen (see page 6291), and PicturePlus (see page 6292). If the outline has customized any of these bitmaps, DefineProperties uses the DefineBinaryProperty method of the Filer parameter to create a binary property for the customized values.

See Also

PictureClosed (see page 6290)

PictureLeaf (see page 6291)

PictureMinus (see page 6291)

PictureOpen (see page 6291)

PicturePlus (see page 6292)

TWriter

DefineBinaryProperty

68.1.3.4.12 TCustomOutline.Delete Method

Deletes a node from the outline.

Pascal

```
procedure Delete(Index: LongInt);
```

C++

```
__fastcall Delete(LongInt Index);
```

Description

Call Delete to remove a node and all its descendants from the outline. Index is the index of the node to delete.

Delete removes the node and its children, frees all associated memory, and then calls DeleteNode (see page 6270) to update the indexes and make sure that SelectedItem (see page 6294) is valid.

See Also

Add (see page 6264)

DeleteNode (see page 6270)

SelectedItem (see page 6294)

68.1.3.4.13 TCustomOutline.DeleteNode Method

Fixes up the outline after a node has been deleted.

Pascal

```
procedure DeleteNode(Node: TOutlineNode; CurIndex: LongInt);
```

C++

```
__fastcall DeleteNode(TOutlineNode Node, LongInt CurIndex);
```

Description

DeleteNode is called automatically whenever a node in the outline is destroyed. It fixes up the index and makes sure that the

SelectedItem (see page 6294) property is valid.

To Delete (see page 6270) a node from the outline, call the Delete (see page 6270) method of the outline or free the TOulineNode object.

See Also

Delete (see page 6270)

SelectedItem (see page 6294)

68.1.3.4.14 TCustomOutline.DrawCell Method

Draws a node in the outline.

Pascal

```
procedure DrawCell(ACol: Longint; ARow: Longint; ARect: TRect; AState: TGridDrawState);
override;
```

C++

```
virtual __fastcall DrawCell(Longint ACol, Longint ARow, TRect ARect, TGridDrawState AState);
```

Description

DrawCell is called automatically whenever the outline needs to draw a node. If the Style (see page 6294) property is otOwnerDraw and an OnDrawItem (see page 6295) event handler has been supplied, DrawCell generates an OnDrawItem (see page 6295) event. Otherwise, DrawCell draws the node in the manner indicated by the OutlineStyle (see page 6289) property.

See Also

OnDrawItem (see page 6295)

OutlineStyle (see page 6289)

68.1.3.4.15 TCustomOutline.EndUpdate Method

Performs the reindexing and repaints deferred by a call to BeginUpdate (see page 6268).

Pascal

```
procedure EndUpdate;
```

C++

```
__fastcall EndUpdate();
```

Description

Call EndUpdate at the end of a segment of code that began with a call to BeginUpdate (see page 6268). Every time BeginUpdate (see page 6268) is called, an internal counter is incremented. When EndUpdate is called, the counter is decremented. When every call to BeginUpdate (see page 6268) has been matched by a call to EndUpdate, EndUpdate fixes up the indexes and repaints the outline.

See Also

BeginUpdate (see page 6268)

Items (see page 6287)

68.1.3.4.16 TCustomOutline.Expand Method

Generates an OnExpand (see page 6296) event.

Pascal

```
procedure Expand(Index: LongInt); dynamic;
```

C++

```
__fastcall Expand(LongInt Index);
```

Description

Expand is called automatically after a node in the outline is expanded. It calls the OnExpand (see page 6296) event handler if it is assigned.

Override the Expand method to provide additional processing after nodes in the outline have been expanded, or to block the OnExpand (see page 6296) event.

See Also

Collapse (see page 6269)

OnExpand (see page 6296)

68.1.3.4.17 TCustomOutline.FullCollapse Method

Causes all top-level nodes in the outline to collapse.

Pascal

```
procedure FullCollapse;
```

C++

```
__fastcall FullCollapse();
```

Description

Call FullCollapse to shrink the outline as much as possible. FullCollapse sets the Expanded property of each TOutlineNode (see page 6363) that is a direct descendant of the root of the outline to false. This causes all the descendants of these top-level nodes to be hidden. Depending on the value of OutlineStyle (see page 6289), each collapsed top-level node is then represented with the PictureClosed (see page 6290) bitmap and/or the PicturePlus (see page 6292) bitmap.

See Also

OutlineStyle (see page 6289)

PictureClosed (see page 6290)

PicturePlus (see page 6292)

Expanded (see page 6375)

68.1.3.4.18 TCustomOutline.FullExpand Method

Expands every node in the outline.

Pascal

```
procedure FullExpand;
```

C++

```
__fastcall FullExpand();
```

Description

Call FullExpand to show all nodes in the outline. FullExpand calls the FullExpand method of the root node. This causes the Expanded property of all nodes in the outline to be set to true. Every node in the Items (see page 6287) array appears fully expanded in the outline. Depending on the value of OutlineStyle (see page 6289), each node that has descendants is then represented with the PictureOpen (see page 6291) bitmap and/or the PictureMinus (see page 6291) bitmap. The appearance of leaf nodes is unaffected.

See Also

OutlineStyle (see page 6289)

PictureMinus (see page 6291)

PictureOpen (see page 6291)

FullExpand (see page 6368)

68.1.3.4.19 TCustomOutline.GetDataItem Method

Returns the index of the first node in the outline that has the Value pointer as its Data property.

Pascal

```
function GetDataItem(Value: TCustomData): Longint;
```

C++

```
__fastcall Longint GetDataItem(TCustomData Value);
```

Description

Call GetDataItem to locate the node that corresponds to the Value parameter. GetDataItem returns an index into the Items (see page 6287) property array.

See Also

Items (see page 6287)

Data (see page 6374)

68.1.3.4.20 TCustomOutline.GetItem Method

Returns the index of the node at the position indicated by the X and Y parameters.

Pascal

```
function GetItem(X: Integer; Y: Integer): LongInt;
```

C++

```
__fastcall LongInt GetItem(int X, int Y);
```

Description

Call GetItem to locate the node at the specified screen pixel coordinates. GetItem returns an index into the Items (see page 6287) property array.

See Also

Items (see page 6287)

68.1.3.4.21 TCustomOutline.GetNodeDisplayWidth Method

Returns the length of the row containing a specified node.

Pascal

```
function GetNodeDisplayWidth(Node: TOutlineNode): Integer;
```

C++

```
__fastcall int GetNodeDisplayWidth(TOutlineNode Node);
```

Description

Call GetNodeDisplayWidth to determine the length, in pixels, of the line in the outline that contains the node specified by the Node parameter. GetNodeDisplayWidth adjusts for the lines and bitmaps specified by the OutlineStyle (see page 6289) property.

See Also

ItemHeight (see page 6286)

OutlineStyle (see page 6289)

68.1.3.4.22 TCustomOutline.GetTextItem Method

Returns the index of the first node in the outline with the Value parameter as its Text property.

Pascal

```
function GetTextItem(const Value: string): Longint;
```

C++

```
__fastcall Longint GetTextItem(const UnicodeString Value);
```

Description

Call GetTextItem to locate the node that corresponds to the Value parameter. GetTextItem returns an index into the Items (see page 6287) property array.

See Also

Items (see page 6287)

Text (see page 6378)

68.1.3.4.23 TCustomOutline.GetVisibleNode Method

Returns the TOutlineNode (see page 6363) object for the node indicated by a position in the image of the outline.

Pascal

```
function GetVisibleNode(Index: LongInt): TOutlineNode;
```

C++

```
__fastcall TOutlineNode GetVisibleNode(LongInt Index);
```

Description

Call GetVisibleNode to locate a node with the position given by the Index parameter, where all nodes that are hidden because their parent node is collapsed are ignored. An Index of 0 indicates the first visible node, an Index of 1 indicates the second visible node, and so on. If the outline is fully expanded, GetVisibleNode returns the value of Items (see page 6287)[Index+1].

See Also

Items (see page 6287)

68.1.3.4.24 TCustomOutline.Insert Method

Inserts a node at a specified position.

Pascal

```
function Insert(Index: LongInt; const Text: string): LongInt;
```

C++

```
__fastcall LongInt Insert(LongInt Index, const UnicodeString Text);
```

Description

Use Insert to add a TOutlineNode (see page 6363) object to the outline. Text specifies the Text property value of the new node.

Index specifies where to add the new node. The new node is positioned in the outline in the position currently occupied by the node identified by Index. The new node is inserted at the same level as the node currently identified by Index, so that the original node and the new node are siblings and share the same parent. To add nodes to the beginning of the outline, specify zero (0) as the Index parameter.

Nodes that appear after the new node, including the one specified by Index before Insert is called, are moved down one row and reindexed in the Items (see page 6287) property array with valid Index values. If BeginUpdate (see page 6268) has been called, the Items (see page 6287) array is not reindexed until the EndUpdate (see page 6271) method is called.

Insert returns the Index property of the new node.

See Also

Add (see page 6264)

AddChild (see page 6265)

BeginUpdate (see page 6268)

Delete (see page 6270)

EndUpdate (see page 6271)

InsertObject (see page 6275)

Items (see page 6287)

Index (see page 6376)

Text (see page 6378)

68.1.3.4.25 TCustomOutline.InsertObject Method

Inserts a node containing data at a specified position.

Pascal

```
function InsertObject(Index: LongInt; const Text: string; const Data: TCustomData): LongInt;
```

C++

```
__fastcall LongInt InsertObject(LongInt Index, const UnicodeString Text, const TCustomData
Data);
```

Description

Use InsertObject to add a TOutlineNode (see page 6363) object to the outline and assign it a data pointer. Text specifies the value of the Text property for the new node. Data specifies the value of the Data property for the new node.

Index specifies where to add the new node. The new node is positioned in the outline in the position currently occupied by the node identified by Index. The new node is inserted at the same level as the node currently identified by Index, so that the original node and the new node are siblings and share the same parent. To add nodes to the beginning of the outline, specify zero (0) as the Index parameter.

Nodes that appear after the new node, including the one specified by Index before Insert (see page 6275) is called, are moved down one row and reindexed in the Items (see page 6287) property array with valid Index values. If BeginUpdate (see page 6268) has been called, the Items (see page 6287) array is not reindexed until the EndUpdate (see page 6271) method is called.

Insert (see page 6275) returns the Index property of the new node.

See Also

AddObject (see page 6266)

AddChildObject (see page 6266)

BeginUpdate (see page 6268)

Delete (see page 6270)

EndUpdate (see page 6271)

Insert (see page 6275)

Items (see page 6287)

Data (see page 6374)

Index (see page 6376)

Text (see page 6378)

68.1.3.4.26 TCustomOutline.InvalidateCell Method

Invalidates the region occupied by a cell so that it will be repainted with the next Windows paint message.

Pascal

```
procedure InvalidateCell(ACol: Longint; ARow: Longint);
```

C++

```
__fastcall InvalidateCell(Longint ACol, Longint ARow);
```

Description

Call InvalidateCell when the contents of a cell change so that the cell will need to be repainted. The ACol parameter is the column index of the cell, and the ARow parameter is the row index.

See Also

CellRect (see page 3038)

InvalidateCol (see page 3048)

InvalidateEditor (see page 3049)

InvalidateRow (see page 3050)

68.1.3.4.27 TCustomOutline.KeyDown Method

Provides special processing when the user presses a key.

Pascal

```
procedure KeyDown(var Key: Word; Shift: TShiftState); override;
```

C++

```
virtual __fastcall KeyDown(Word Key, TShiftState Shift);
```

Description

KeyDown is called automatically when the user presses a key. After calling the inherited method, which generates an OnKeyDown event, KeyDown processes the following keystrokes:

Key	Behavior
Home	Selects the first node in the outline.
End	Selects the last node in the outline.
Return	Toggles the selected node between its collapsed and expanded states.
Ctrl+*	Fully expands the outline.
Right arrow	Selects the first child of the selected node.
Left arrow	Selects the parent of the selected node.
Ctrl+Up arrow	Selects the node following the selected node.
Ctrl+Down arrow	Selects the node preceding the selected node.

See Also

KeyPress (see page 6277)

SelectedItem (see page 6294)

KeyDown (see page 3050)

68.1.3.4.28 TCustomOutline.KeyPress Method

Provides special processing when a key is pressed.

Pascal

```
procedure KeyPress(var Key: Char); override;
```

C++

```
virtual __fastcall KeyPress(Char Key);
```

Description

KeyPress is called automatically after the user presses a key but before it is released. After calling the inherited method, which generates an OnKeyPress event, KeyPress processes the following characters :

Key	Behavior
+	Expands the selected node.
-	Collapses the selected node.
*	Fully expands the outline.

See Also

KeyDown (see page 6277)

KeyPress (see page 3050)

68.1.3.4.29 TCustomOutline.Loaded Method

Sets up the outline after it has been streamed in.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

The streaming system calls Loaded after the outline has been fully loaded into memory. Loaded makes sure that all indexes are correct, loads any custom bitmaps that replaced the default values, and selects the first node in the outline.

See Also

DefineProperties (see page 6269)

SelectedItem (see page 6294)

SetGoodIndex (see page 6282)

68.1.3.4.30 LoadFromFile Method

This is the overview for the LoadFromFile method overload.

Overload List

	Name	Description
	TCustomOutline.LoadFromFile (string) (see page 6278)	Loads the outline from a text image stored in a file.
	TCustomOutline.LoadFromFile (string, TEncoding) (see page 6278)	Loads the outline from a text image stored in a file.

68.1.3.4.30.1 TCustomOutline.LoadFromFile Method (string)

Loads the outline from a text image stored in a file.

Pascal

```
procedure LoadFromFile(const FileName: string); overload;
procedure LoadFromFile(const FileName: string; Encoding: TEncoding); overload;
```

C++

```
__fastcall LoadFromFile(const UnicodeString FileName);
__fastcall LoadFromFile(const UnicodeString FileName, TEncoding Encoding);
```

Description

Call LoadFromFile to fill an outline from the file specified by the FileName parameter. Each line in the file represents a node in the outline. The file does not include the root node.

Leading tabs and spaces are converted into levels of the outline. Text without any leading tabs or spaces becomes level 1 items.

For example, the following set of strings represents an outline with three first level children descended from the root, and an additional, second level child on the first and third nodes:

```
ChildA
 ChildA1
ChildB
ChildC
 ChildC1
```

To fill the outline from a text image read from a stream, use the LoadFromStream (see page 6279) method. To fill the outline from a text image represented as a TStrings object, use the Lines (see page 6288) property.

See Also

Lines (see page 6288)

LoadFromStream (see page 6279)

SaveToFile (see page 6281)

68.1.3.4.31 LoadFromStream Method

This is the overview for the LoadFromStream method overload.

Overload List

	Name	Description
	TCustomOutline.LoadFromStream (TStream) (see page 6279)	Loads the outline from a text image read from a stream.
	TCustomOutline.LoadFromStream (TStream, TEncoding) (see page 6279)	Loads the outline from a text image read from a stream.

68.1.3.4.31.1 TCustomOutline.LoadFromStream Method (TStream)

Loads the outline from a text image read from a stream.

Pascal

```
procedure LoadFromStream(Stream: TStream); overload;
procedure LoadFromStream(Stream: TStream; Encoding: TEncoding); overload;
```

C++

```
__fastcall LoadFromStream(TStream Stream);
__fastcall LoadFromStream(TStream Stream, TEncoding Encoding);
```

Description

Call LoadFromStream to fill an outline from the stream specified by the Stream parameter. For example, use LoadFromStream to load an outline from an image stored in a database table, using a TBlobStream object. Each node in the outline is separated by a newline character. The stream does not provide the root node.

Leading tabs and spaces are converted into levels of the outline. Text without any leading tabs or spaces becomes level 1 items. For example, the following set of strings represents an outline with three first level children descended from the root, and an additional, second level child on the first and third nodes:

```
ChildA
 ChildA1
ChildB
ChildC
 ChildC1
```

To fill the outline from a text image read from a file, use the LoadFromFile (see page 6278) method. To fill the outline from a

text image represented as a TStrings object, use the Lines (see page 6288) property.

See Also

Lines (see page 6288)

LoadFromFile (see page 6278)

SaveToStream (see page 6281)

68.1.3.4.32 TCustomOutline.MouseDown Method

Updates the SelectedItem (see page 6294) property.

Pascal

```
procedure MouseDown(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer);
override;
```

C++

```
virtual __fastcall MouseDown(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

After calling the inherited method to generate an OnMouseDown event and locate the line under the mouse, MouseDown sets the SelectedItem (see page 6294) property to the node in the line under the mouse.

See Also

SelectedItem (see page 6294)

68.1.3.4.33 TCustomOutline.Move Method

Repositions a node in the outline.

Pascal

```
procedure Move(Destination: LongInt; Source: LongInt; AttachMode: TAttachMode);
```

C++

```
__fastcall Move(LongInt Destination, LongInt Source, TAttachMode AttachMode);
```

Description

Call Move to reposition the node with the index specified by the Source parameter to the position indicated by the Destination parameter. The meaning of the Destination parameter depends on the value of the AttachMode parameter.

See Also

Add (see page 6264)

AddChild (see page 6265)

Insert (see page 6275)

Items (see page 6287)

68.1.3.4.34 SaveToFile Method

This is the overview for the SaveToFile method overload.

Overload List

	Name	Description
	TCustomOutline.SaveToFile (string) (see page 6281)	Saves the Lines (see page 6288) property to a file.
	TCustomOutline.SaveToFile (string, TEncoding) (see page 6281)	Saves the Lines (see page 6288) property to a file.

68.1.3.4.34.1 TCustomOutline.SaveToFile Method (string)

Saves the Lines (see page 6288) property to a file.

Pascal

```
procedure SaveToFile(const FileName: string); overload;
procedure SaveToFile(const FileName: string; Encoding: TEncoding); overload;
```

C++

```
__fastcall SaveToFile(const UnicodeString FileName);
__fastcall SaveToFile(const UnicodeString FileName, TEncoding Encoding);
```

Description

Call SaveToFile to save a text image of the outline to the file specified by the FileName parameter. The image saved is the value of the Lines (see page 6288) property, where each line of the file represents a node, and each level of the outline is represented by a tab character.

To write the outline to an arbitrary stream, use the SaveToStream (see page 6281) method.

See Also

Lines (see page 6288)

LoadFromFile (see page 6278)

SaveToStream (see page 6281)

68.1.3.4.35 SaveToStream Method

This is the overview for the SaveToStream method overload.

Overload List

	Name	Description
	TCustomOutline.SaveToStream (TStream) (see page 6281)	Writes the Lines (see page 6288) property to a stream.
	TCustomOutline.SaveToStream (TStream, TEncoding) (see page 6281)	Writes the Lines (see page 6288) property to a stream.

68.1.3.4.35.1 TCustomOutline.SaveToStream Method (TStream)

Writes the Lines (see page 6288) property to a stream.

Pascal

```
procedure SaveToStream(Stream: TStream); overload;
procedure SaveToStream(Stream: TStream; Encoding: TEncoding); overload;
```

C++

```
__fastcall SaveToStream(TStream Stream);
__fastcall SaveToStream(TStream Stream, TEncoding Encoding);
```

Description

Call SaveToStream to write a text image of the outline to the stream specified by the Stream parameter. The image saved is the value of the Lines (see page 6288) property, where each line of text represents a node, and each level of the outline is represented by a tab character.

To write the outline to a file, use the SaveToFile (see page 6281) method.

See Also

Lines (see page 6288)

LoadFromStream (see page 6279)

SaveToFile (see page 6281)

68.1.3.4.36 TCustomOutline.SetDisplayWidth Method

Sets the display width of the outline.

Pascal

```
procedure SetDisplayWidth(Value: Integer);
```

C++

```
__fastcall SetDisplayWidth(int Value);
```

Description

Call SetDisplayWidth to set the width of the image of the outline to the number of pixels specified by the Value parameter. Value should large enough to display the most deeply nested node. Use the GetNodeDisplayWidth (see page 6274) method to determine the size needed to display the visible nodes.

If the display width is greater than the client width of the control, users can scroll the image to view the entire width.

See Also

ClientWidth

GetVisibleNode (see page 6274)

68.1.3.4.37 TCustomOutline.SetGoodIndex Method

Returns the first node in the Items (see page 6287) array that must be reindexed to make the index of the Value parameter correct.

Pascal

```
function SetGoodIndex(Value: TOutlineNode): TOutlineNode;
```

C++

```
__fastcall TOutlineNode SetGoodIndex(TOutlineNode Value);
```

Description

Call SetGoodIndex to determine how much of the Items (see page 6287) array must be reindexed after changing the nodes in the outline. All nodes from the root to the value returned by SetGoodIndex do not need to be reindexed.

See Also

BadIndex (see page 6267)

68.1.3.4.38 TCustomOutline.SetLevel Method

Sets the level of an outline node.

Pascal

```
procedure SetLevel(Node: TOutlineNode; CurLevel: Cardinal; NewLevel: Cardinal);
```

C++

```
__fastcall SetLevel(TOutlineNode Node, unsigned CurLevel, unsigned NewLevel);
```

Description

Call SetLevel to change the nesting depth of the node specified by the Node parameter. CurLevel is the node's current level and NewLevel is the node's new level.

For example, consider the outline specified by the following value of Lines (see page 6288):

```
NodeA
 NodeB
  NodeC
 NodeD
```

Calling SetLevel for NodeD with CurLevel set to 2 and NewLevel set to 4 results in the outline with the following value of Lines (see page 6288):

```
NodeA
 NodeB
  NodeC
   NodeD
```

That is, the parent of NodeD was changed from NodeA to NodeC.

See Also

Lines (see page 6288)

68.1.3.4.39 TCustomOutline.SetUpdateState Method

Enables or disables the maintenance of the node indexes.

Pascal

```
procedure SetUpdateState(Value: Boolean);
```

C++

```
__fastcall SetUpdateState(Boolean Value);
```

Description

Call SetUpdateState with Value set to true to block the recomputation of indexes. Call SetUpdateState with Value set to false to recompute all indexes in the outline and enable the maintenance of indexes with every change to the nodes in the outline.

Unlike calls to BeginUpdate (see page 6268) and EndUpdate (see page 6271), calls to SetUpdateState do not nest: Calling SetUpdateState with Value set to false always recomputes the indexes regardless of the number of previous calls to SetUpdateState with Value set to true.

Note: Calling SetUpdateState takes precedence over any enabling or disabling of index maintenance provided by BeginUpdate (see page 6268) or EndUpdate (see page 6271).

See Also

BeginUpdate (see page 6268)

EndUpdate (see page 6271)

68.1.3.5 TCustomOutline Properties

The properties of the TCustomOutline class are listed here.

Protected Properties

	Name	Description
	ItemHeight (see page 6286)	Specifies the height of each node in the outline.
	ItemSeparator (see page 6288)	Specifies a delimiting string for outline nodes.
	Lines (see page 6288)	Lists the Text property values of all nodes in the outline.
	Options (see page 6288)	Determines how the nodes in the outline are drawn.
	OutlineStyle (see page 6289)	Specifies how the outline tree is displayed.
	PictureClosed (see page 6290)	Specifies the bitmap used to represent a collapsed node that has subitems.
	PictureLeaf (see page 6291)	Specifies the bitmap used to represent an item that does not have subitems.
	PictureMinus (see page 6291)	Specifies the bitmap used to represent an expanded item that has subitems.
	PictureOpen (see page 6291)	Specifies the bitmap used to represent an expanded item that has subitems.
	PicturePlus (see page 6292)	Specifies the bitmap used to represent a collapsed item that has subitems.
	Style (see page 6294)	Determines whether the nodes and tree are drawn automatically.

Public Properties

	Name	Description
	Canvas (see page 6284)	Specifies the TCanvas object that presents a drawing surface for the control.
R	ItemCount (see page 6286)	Indicates the number of nodes in the outline.
R	Items (see page 6287)	Lists the nodes in the outline.
	Row (see page 6292)	Specifies the index of the row that contains the selected cell.
	SelectedItem (see page 6294)	Specifies the index of the selected node.

68.1.3.5.1 TCustomOutline.Canvas Property

Specifies the TCanvas object that presents a drawing surface for the control.

Pascal

```
property Canvas;
```

C++

```
__property Canvas;
```

Description

Use the properties of the TCanvas object to draw or paint on the surface of the control. Canvas encapsulates a Windows device context, providing all the tools and methods needed for drawing and painting.

Canvas is a protected property that is usually redeclared as public in descendants of TCustomControl.

C++ Examples:

```
/*
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
```

```
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
*/
void __fastcall TForm1::DrawGrid1DrawCell(
  TObject *Sender, int ACol, int ARow, TRect &Rect, TGridDrawState State)
{
  long index = ARow * DrawGrid1->ColCount + ACol;
  DrawGrid1->Canvas->Brush->Color = clBackground;
  DrawGrid1->Canvas->FillRect(Rect);
  if (State.Contains(gdFocused))
  {
    DrawGrid1->Canvas->DrawFocusRect(Rect);
    Label1->Caption = "Cell " + IntToStr(int(index)) + " has the focus.";
  }
  ImageList1->Draw(
    DrawGrid1->Canvas, Rect.Left, Rect.Top, index, True);
}

void __fastcall TForm1::DrawGrid1SelectCell(TObject *Sender, int ACol, int ARow,
      bool &CanSelect)
{
  CanSelect= True;
}
/*
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
*/
{
  TPoint APoint = Point(X, Y);
  int Index = ListBox1->ItemAtPos(APoint, True);
  TStringGrid *myStringGrid;
  TClass ClassRef = ListBox1->Items->Objects[Index]->ClassType();
  if (String(ClassRef->ClassName()) == "TStringGrid")
  {
    myStringGrid = dynamic_cast<TStringGrid *>(ListBox1->Items->Objects[Index]);
    // make sure we are using the TControls canvas and not the from's!
    myStringGrid->Canvas->MoveTo(myStringGrid->ClientRect.Left, myStringGrid->ClientRect.Top);
    myStringGrid->Canvas->LineTo(myStringGrid->ClientRect.Right,
myStringGrid->ClientRect.Bottom);
    myStringGrid = NULL;
  }
}
```

Delphi Examples:

```
{
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
}
procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
  Rect: TRect; State: TGridDrawState);
var
  index: Integer;
begin
  index := ARow * DrawGrid1.ColCount + ACol;
  DrawGrid1.Canvas.Brush.Color := clWhite;
  DrawGrid1.Canvas.FillRect(Rect);
  if (gdFocused in State) then
  begin
```

```
    DrawGrid1.Canvas.DrawFocusRect(Rect);
    Label1.Caption:= 'Cell ' + InttoStr(index) + ' has the focus.';
  end;
  ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
end;

procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
  var CanSelect: Boolean);
begin
  CanSelect:= True;
end;
{
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
}
  if (ListBox1.Items.Objects[Index] is TStringGrid) then
  begin
    myStringGrid:= (ListBox1.Items.Objects[Index] as TStringGrid);
    with myStringGrid.ClientRect do
    begin // make sure we are using the TControl's canvas and not the form's!
      myStringGrid.Canvas.MoveTo(Left, Top);
      myStringGrid.Canvas.LineTo(Right, Bottom);
    end;
  myStringGrid:= nil;
  end;
```

Paint

68.1.3.5.2 TCustomOutline.ItemCount Property

Indicates the number of nodes in the outline.

Pascal

```
property ItemCount: LongInt;
```

C++

```
__property LongInt ItemCount;
```

Description

Read ItemCount to determine the number of nodes in the outline. Use ItemCount with the Items (see page 6287) property array to iterate over all nodes in the outline.

Note: Reading ItemCount can be computationally expensive, as it causes all the indexes used by the outline to be updated.

See Also

Items (see page 6287)

68.1.3.5.3 TCustomOutline.ItemHeight Property

Specifies the height of each node in the outline.

Pascal

```
property ItemHeight: Integer;
```

C++

```
__property int ItemHeight;
```

Description

Set ItemHeight to the height, in pixels, of each node in the outline. Changing the ItemHeight property also changes the font used to display the nodes.

See Also

ItemCount (see page 6286)

Items (see page 6287)

68.1.3.5.4 TCustomOutline.Items Property

Lists the nodes in the outline.

Pascal

```
property Items [Index: LongInt]: TOutlineNode;
```

C++

```
__property TOutlineNode Items[LongInt Index];
```

Description

Use Items to access a node in the outline. Each item is a TOutlineNode (see page 6363) object.

Index is a number specifying the node to return, where Items[0] refers to the root, Items[1] is the first (topmost) node, and so on.

Note: Items is the default property of TCustomOutline (see page 6258). This means that the name of the property may be omitted in code. Thus the line

Note: Outline1.Items[1].Text := Edit1.Text;

Note: can also be written

Note: Outline1[1].Text := Edit1.Text;

Note: In C++, Items can be accessed using the [] operator, to achieve an affect similar to the default property in Delphi.

See Also

ItemCount (see page 6286)

ItemHeight (see page 6286)

ItemSeparator (see page 6288)

Lines (see page 6288)

operator_[]

68.1.3.5.5 TCustomOutline.ItemSeparator Property

Specifies a delimiting string for outline nodes.

Pascal

```
property ItemSeparator: string;
```

C++

```
__property UnicodeString ItemSeparator;
```

Description

Set ItemSeparator to the string that should appear between node names in the path description of any individual node in the outline. ItemSeparator is used to implement the FullPath read method of TOutlineNode (see page 6363).

ItemSeparator is initialized to the backslash (\) character when the TCustomOutline (see page 6258) object is created.

See Also

Items (see page 6287)

FullPath (see page 6375)

68.1.3.5.6 TCustomOutline.Lines Property

Lists the Text property values of all nodes in the outline.

Pascal

```
property Lines: TStrings;
```

C++

```
__property TStrings Lines;
```

Description

Read Lines to obtain a text representation of the outline. Set Lines to fill the outline from a set of text strings. Each string in the Lines property represents a node in the outline. Lines does not include the root node.

Leading tabs and spaces are converted into levels of the outline. Text without any leading tabs or spaces becomes level 1 items. For example, the following set of strings represents an outline with three first level children descended from the root, and an additional, second level child on the first and third nodes:

```
ChildA
 ChildA1
ChildB
ChildC
 ChildC1
```

The Lines property is primarily useful for filling an outline with items at design time. While Lines can be used to access the individual nodes at run time, it is much quicker to access an item with the Items (see page 6287) property.

See Also

Items (see page 6287)

Text (see page 6378)

68.1.3.5.7 TCustomOutline.Options Property

Determines how the nodes in the outline are drawn.

Pascal

```
property Options: TOutlineOptions;
```

C++

```
__property TOutlineOptions Options;
```

Description

Set Options to any combination of the following values:

Value	Meaning
ooDrawTreeRoot	The first item (Index value of 1) is connected to the root item by the outline tree. This means that the tree will extend from the top of the outline to all the first level items. Without ooDrawTreeRoot, all first level items appear leftmost in the outline, not connected by the tree.
ooDrawFocusRect	The outline draws a focus rectangle around the selected item.
ooStretchBitmaps	The outline stretches the standard bitmaps (PictureLeaf (see page 6291), PictureOpen (see page 6291), PictureClosed (see page 6290), PicturePlus (see page 6292), PictureMinus (see page 6291)) to fit in the size of the item, determined by the size of the Font of the Text. Without ooStretchBitmaps, the bitmaps will be cropped if larger than the height of the item text, or won't fill up the entire item space if smaller than the text.

See Also

Items (see page 6287)

OutlineStyle (see page 6289)

PictureClosed (see page 6290)

PictureLeaf (see page 6291)

PictureMinus (see page 6291)

PictureOpen (see page 6291)

PicturePlus (see page 6292)

SelectedItem (see page 6294)

68.1.3.5.8 TCustomOutline.OutlineStyle Property

Specifies how the outline tree is displayed.

Pascal

```
property OutlineStyle: TOutlineStyle;
```

C++

```
__property TOutlineStyle OutlineStyle;
```

Description

Set OutlineStyle to one of the following values:

Value	Meaning
osText	Displays node text (specified in Text) only.
osPlusMinusText	Displays plus picture (specified in PicturePlus (see page 6292)), minus picture (specified in PictureMinus (see page 6291)), and node text (specified in Text).

osPictureText	Displays open picture (specified in PictureOpen (see page 6291)), closed picture (specified in PictureClosed (see page 6290)), leaf picture (specified in PictureLeaf (see page 6291)) and node text (specified in Text).
osPlusMinusPictureText	Displays plus picture (specified in PicturePlus (see page 6292)), minus picture (specified in PictureMinus (see page 6291)), open picture (specified in PictureOpen (see page 6291)), closed picture (specified in PictureClosed (see page 6290)), leaf picture (specified in PictureLeaf (see page 6291)), and node text (specified in Text).
osTreeText	Displays lines connecting outline nodes and node text (specified in Text).
osTreePictureText	Displays lines connecting outline nodes, open picture (specified in PictureOpen (see page 6291)), closed picture (specified in PictureClosed (see page 6290)), leaf picture (specified in PictureLeaf (see page 6291)), and node text (specified in Text).

Note: If the Style (see page 6294) property is otOwnerDraw, the value of OutlineStyle is ignored. The connecting lines, node bitmaps, and node text must all be drawn in an OnDrawItem (see page 6295) event handler.

See Also

Options (see page 6288)

PictureClosed (see page 6290)

PictureLeaf (see page 6291)

PictureMinus (see page 6291)

PictureOpen (see page 6291)

PicturePlus (see page 6292)

Style (see page 6294)

Text (see page 6378)

68.1.3.5.9 TCustomOutline.PictureClosed Property

Specifies the bitmap used to represent a collapsed node that has subitems.

Pascal

```
property PictureClosed: TBitmap;
```

C++

```
__property TBitmap PictureClosed;
```

Description

By default, PictureClosed is a closed file folder bitmap. Set PictureClosed to change the bitmap used for collapsed nodes.

Note: The bitmap is not displayed in the outline unless the OutlineStyle (see page 6289) property is set to osPictureText, osPlusMinusPictureText, or osTreePictureText.

See Also

OutlineStyle (see page 6289)

PictureLeaf (see page 6291)

PictureMinus (see page 6291)

PictureOpen (see page 6291)

68.1.3.5.10 TCustomOutline.PictureLeaf Property

Specifies the bitmap used to represent an item that does not have subitems.

Pascal

```
property PictureLeaf: TBitmap;
```

C++

```
__property TBitmap PictureLeaf;
```

Description

By default, PictureLeaf is a document bitmap. Set PictureLeaf to change the bitmap used for leaf nodes.

Note: The bitmap is not displayed in the outline unless the OutlineStyle (see page 6289) property is set to osPictureText, osPlusMinusPictureText, or osTreePictureText.

See Also

OutlineStyle (see page 6289)

PictureClosed (see page 6290)

PictureOpen (see page 6291)

68.1.3.5.11 TCustomOutline.PictureMinus Property

Specifies the bitmap used to represent an expanded item that has subitems.

Pascal

```
property PictureMinus: TBitmap;
```

C++

```
__property TBitmap PictureMinus;
```

Description

By default, PictureMinus is a minus sign (-). Set PictureMinus to change the bitmap used for collapsible nodes.

Note: The bitmap is not displayed in the outline unless the OutlineStyle (see page 6289) property is set to osPlusMinusPictureText or osPlusMinusText.

See Also

OutlineStyle (see page 6289)

PictureOpen (see page 6291)

PicturePlus (see page 6292)

68.1.3.5.12 TCustomOutline.PictureOpen Property

Specifies the bitmap used to represent an expanded item that has subitems.

Pascal

```
property PictureOpen: TBitmap;
```

C++

```
__property TBitmap PictureOpen;
```

Description

By default, the PictureOpen property is an open file folder. Set PictureOpen to change the bitmap used for expanded nodes.

Note: The bitmap is not displayed in the outline unless the OutlineStyle (see page 6289) property is set to osPictureText, osPlusMinusPictureText, or osTreePictureText.

See Also

OutlineStyle (see page 6289)

PictureClosed (see page 6290)

PictureLeaf (see page 6291)

PicturePlus (see page 6292)

68.1.3.5.13 TCustomOutline.PicturePlus Property

Specifies the bitmap used to represent a collapsed item that has subitems.

Pascal

```
property PicturePlus: TBitmap;
```

C++

```
__property TBitmap PicturePlus;
```

Description

By default, the PicturePlus property is a plus sign (+). Set PicturePlus to change the bitmap used for collapsed nodes.

Note: The bitmap will not be displayed in the outline unless the OutlineStyle (see page 6289) property is set to osPlusMinusPictureText or osPlusMinusText.

See Also

OutlineStyle (see page 6289)

PictureClosed (see page 6290)

PictureMinus (see page 6291)

68.1.3.5.14 TCustomOutline.Row Property

Specifies the index of the row that contains the selected cell.

Pascal

```
property Row: Longint;
```

C++

```
__property Longint Row;
```

Description

Use Row at runtime to determine the current row in the grid. Setting Row moves focus to the cell in the current column that is in the new row. The first row has an index of 0, the second row an index of 1, and so on.

The selected cell in the grid can be located by reading the Row property and the Col property to obtain the indexes of its row and column. When focus moves to the grid, the selected cell gets input focus.

C++ Examples:

```
/*
This example displays a string grid, a list box, and a
button on a form. When the application runs, strings are put
in the cells of row 1 of the string grid. When the user
clicks the button, The strings in the current row of the
grid are displayed in the list box.
Note that when the grid contains an empty cell, the list box
has a corresponding empty string.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  ListBox1->Items = StringGrid1->Rows[StringGrid1->Row];
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{

  StringGrid1->Cells[1][0] = "Column 1";
  StringGrid1->Cells[2][0] = "Column 2";
  StringGrid1->Cells[3][0] = "Column 3";
  StringGrid1->Cells[4][0] = "Column 4";
  StringGrid1->Cells[0][1] = "Row 1";
  StringGrid1->Cells[1][1] = "Object";
  StringGrid1->Cells[2][1] = "Pascal";
  StringGrid1->Cells[3][1] = "is";
  StringGrid1->Cells[4][1] = "excellent";
  StringGrid1->Cells[0][2] = "Row 2";
  StringGrid1->Cells[1][2] = "Delphi";
  StringGrid1->Cells[2][2] = "is";
  StringGrid1->Cells[4][2] = "RAD";

}
```

Delphi Examples:

```
{
This example displays a string grid, a list box, and a
button on a form. When the application runs, strings are put
in the cells of row 1 of the string grid. When the user
clicks the button, The strings in the current row of the
grid are displayed in the list box.
Note that when the grid contains an empty cell, the list box
has a corresponding empty string.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  ListBox1.Items := StringGrid1.Rows[StringGrid1.Row];
end;
procedure TForm1.FormCreate(Sender: TObject);
begin
  with StringGrid1 do
  begin
    Cells[1,0] := 'Column 1';
    Cells[2,0] := 'Column 2';
    Cells[3,0] := 'Column 3';
    Cells[4,0] := 'Column 4';
    Cells[0,1] := 'Row 1';
    Cells[1,1] := 'Object';
    Cells[2,1] := 'Pascal';
    Cells[3,1] := 'is';
    Cells[4,1] := 'excellent';
    Cells[0,2] := 'Row 2';
    Cells[1,2] := 'Delphi';
    Cells[2,2] := 'is';
    Cells[4,2] := 'RAD';
  end;
end;
```

See Also

Col (see page 3060)

68.1.3.5.15 TCustomOutline.SelectedItem Property

Specifies the index of the selected node.

Pascal

```
property SelectedItem: Longint;
```

C++

```
__property Longint SelectedItem;
```

Description

Read SelectedItem to determine the Index of the selected node. If no node is selected, SelectedItem is 0. Set SelectedItem to set focus to a particular node in the outline.

See Also

Items (see page 6287)

68.1.3.5.16 TCustomOutline.Style Property

Determines whether the nodes and tree are drawn automatically.

Pascal

```
property Style: TOutlineType;
```

C++

```
__property TOutlineType Style;
```

Description

By default, Style is osStandard, meaning that the outline displays items in the style determined by the OutlineStyle (see page 6289) property. Set Style to otOwnerDraw to create owner-draw outlines, meaning that items must be drawn on the canvas of the outline by code in an OnDrawItem (see page 6295) event handler.

Owner-draw outlines can display items other than the Text of a node and the standard bitmaps specified in the PictureClosed (see page 6290), PictureOpen (see page 6291), PictureMinus (see page 6291), PicturePlus (see page 6292), and PictureLeaf (see page 6291) properties. Owner-draw outlines require more programming, however, as the application must specify how to render the image for each node in an OnDrawItem (see page 6295) event handler.

See Also

Canvas

OnDrawItem (see page 6295)

OutlineStyle (see page 6289)

68.1.3.6 TCustomOutline Events

The events of the TCustomOutline class are listed here.

Protected Events

	Name	Description
	OnCollapse (see page 6295)	Occurs immediately after a node in the outline is collapsed.
	OnDrawItem (see page 6295)	Occurs when a node must be drawn in an owner-draw outline.
	OnExpand (see page 6296)	Occurs immediately after a node in the outline is expanded.

68.1.3.6.1 TCustomOutline.OnCollapse Event

Occurs immediately after a node in the outline is collapsed.

Pascal

```
property OnCollapse: EOutlineChange;
```

C++

```
__property EOutlineChange OnCollapse;
```

Description

Write an OnCollapse event handler to perform special processing when a node in the outline is collapsed. The event handler supplies the index of the node that collapsed.

See Also

OnExpand (see page 6296)

68.1.3.6.2 TCustomOutline.OnDrawItem Event

Occurs when a node must be drawn in an owner-draw outline.

Pascal

```
property OnDrawItem: TDrawItemEvent;
```

C++

```
__property TDrawItemEvent OnDrawItem;
```

Description

When the Style (see page 6294) property is set to otOwnerDraw, specify an OnDrawItem event handler to render the image of each node in the outline. An OnDrawItem event handler can display items other than the Text of a node and the standard bitmaps specified in the PictureClosed (see page 6290), PictureOpen (see page 6291), PictureMinus (see page 6291), PicturePlus (see page 6292), and PictureLeaf (see page 6291) properties.

Draw the image of the node specified by the Index parameter onto the canvas of the outline.

See Also

Canvas

PictureClosed (see page 6290)

PictureLeaf (see page 6291)

PictureMinus (see page 6291)

PictureOpen (see page 6291)

PicturePlus (see page 6292)

Style (see page 6294)

Text (see page 6378)

68.1.3.6.3 TCustomOutline.OnExpand Event

Occurs immediately after a node in the outline is expanded.

Pascal

```
property OnExpand: EOutlineChange;
```

C++

```
__property EOutlineChange OnExpand;
```

Description

Write an OnExpand event handler to perform special processing when a node in the outline is expanded. The event handler identifies the node that was just expanded.

See Also

OnCollapse (see page 6295)

68.1.4 TOutline Class

TOutline is a multilevel outline that displays the values of TOutlineNode (see page 6363) objects.

Class Hierarchy

Pascal

```
TOutline = class(TCustomOutline);
```

C++

```
class TOutline : public TCustomOutline;
```

File

Outline

Description

Use an outline to visually organize information in a hierarchical tree. Each item in an outline is contained in a TOutlineNode (see page 6363) object. Outline (see page 6255) controls allow an application to manage a hierarchy of outline nodes, including the ability to control the appearance and layout of those nodes and the ability to expand or collapse branches of the outline tree.

TOutline is provided primarily for backward compatibility. New applications should use TTreeView instead.

See Also

TOutlineNode (see page 6363)

TTreeView

68.1.4.1 TOutline Members

The following tables list the members exposed by TOutline.

Protected Fields

	Name	Description
	DesignOptionsBoost (see page 3031)	This is DesignOptionsBoost, a member of class TCustomGrid.
	FGridState (see page 3031)	This is FGridState, a member of class TCustomGrid.
	FSaveCellExtents (see page 3032)	This is FSaveCellExtents, a member of class TCustomGrid.
	VirtualView (see page 3032)	This is VirtualView, a member of class TCustomGrid.

Protected Methods

	Name	Description
	AdjustSize (see page 3034)	Adds or deletes rows or columns from the grid.
	BadIndex (see page 6267)	Indicates whether a node's index is up to date.
	BeginColumnDrag (see page 3034)	Starts the dragging of a column in the grid.
	BeginRowDrag (see page 3034)	Starts the dragging of a row in the grid.
	BoxRect (see page 3035)	Returns the screen coordinates of a specified set of cells.
	CalcDrawInfo (see page 3035)	Calculates the pixel locations of the grid boundaries.
	CalcFixedInfo (see page 3036)	Calculates the pixel locations of the fixed cells.
V	CalcSizingState (see page 3036)	Determines the appearance of the mouse cursor during resizing.
	CanEditAcceptKey (see page 3036)	Indicates whether the Key parameter can be entered into the current cell.
	CanEditModify (see page 3037)	Indicates whether the current cell in the grid can be edited.
V	CanEditShow (see page 3037)	Indicates whether the inplace edit control can be created to allow editing.
	CanGridAcceptKey (see page 3037)	Indicates whether the grid should respond to a given key combination.
	CellRect (see page 3038)	Returns the screen coordinates of a cell in the grid.
	ChangeGridOrientation (see page 3038)	Prepares the grid's canvas for painting to reflect a right-to-left or left-to-right orientation.
	CheckColumnDrag (see page 3039)	CheckColumnDrag validates whether the column currently selected for dragging can be dropped at the current location.
	CheckRowDrag (see page 3039)	CheckRowDrag validates whether the row currently selected for dragging can be dropped at the current location.
V	Click (see page 6268)	Updates the SelectedItem (see page 6294) property.
	Collapse (see page 6269)	Generates an OnCollapse (see page 6295) event.
	ColumnMoved (see page 3039)	Provides the interface for a method that responds when the position of a column changes.
	ColWidthsChanged (see page 3040)	Responds when the column widths change.
V	CreateEditor (see page 3040)	Creates the inplace editor control.
V	CreateParams (see page 3041)	Initializes the window-creation parameter record.
V	DblClick (see page 6269)	Expands or collapses the selected node.
V	DefineProperties (see page 3041)	Adds the ColWidths (see page 3063) and RowHeights (see page 3076) properties to the values saved with the grid.
V	DefineProperties (see page 6269)	Creates a binary property for customized bitmap values.
V	DeleteColumn (see page 3041)	Deletes a specified column from the grid.
	DeleteNode (see page 6270)	Fixes up the outline after a node has been deleted.
V	DeleteRow (see page 3042)	Deletes a specified from the grid.
V	DoExit (see page 3042)	Hides the inplace editor when selection moves to another control in a form.
V	DoMouseWheelDown (see page 3042)	Performs tasks when the mouse wheel is rotated downward.
V	DoMouseWheelUp (see page 3043)	Performs tasks when the mouse wheel is rotated upward.
A	DrawCell (see page 3043)	Provides the prototype for a method that draws the contents of a cell in the grid.
V	DrawCell (see page 6271)	Draws a node in the outline.
	EndColumnDrag (see page 3044)	Ends the dragging of a column in the grid.
	EndRowDrag (see page 3044)	Ends the dragging of a row in the grid.
	Expand (see page 6272)	Generates an OnExpand (see page 6296) event.
	FocusCell (see page 3044)	Changes the current cell to a specified cell.
	GetEditLimit (see page 3045)	Provides the interface for a method that limits the number of characters the user can type into cells.
	GetEditMask (see page 3045)	Provides the interface for a method that returns an input mask for the specified cell.
	GetEditStyle (see page 3046)	Indicates whether a specified cell has an ellipsis button or drop-down arrow.

	GetEditText (see page 3046)	Returns the value of the indicated cell formatted for editing.
	GetGridHeight (see page 3046)	Returns the value of the GridHeight (see page 3068) property.
	GetGridWidth (see page 3047)	Returns the value of the GridWidth (see page 3070) property.
	HideEdit (see page 3047)	Hides the inplace editor.
	HideEditor (see page 3048)	Hides the inplace editor when it is not in use.
	InvalidateCell (see page 3048)	Invalidates the region occupied by a cell so that it will be repainted with the next Windows paint message.
	InvalidateCell (see page 6276)	Invalidates the region occupied by a cell so that it will be repainted with the next Windows paint message.
	InvalidateCol (see page 3048)	Invalidates the region occupied by a column so that it will be repainted with the next Windows paint message.
	InvalidateEditor (see page 3049)	Causes the inplace editor to repaint itself, moving to a new location if necessary.
	InvalidateGrid (see page 3049)	Tells Windows to repaint the grid after other important Windows messages are handled.
	InvalidateRow (see page 3050)	Invalidates the region occupied by a row so that it will be repainted with the next Windows paint message.
V	KeyDown (see page 3050)	Provides special processing when the user presses a key.
V	KeyDown (see page 6277)	Provides special processing when the user presses a key.
V	KeyPress (see page 3050)	Provides special processing when the user presses a key.
V	KeyPress (see page 6277)	Provides special processing when a key is pressed.
V	Loaded (see page 6278)	Sets up the outline after it has been streamed in.
V	MouseDown (see page 3051)	Provides special processing when the user presses a mouse button.
V	MouseDown (see page 6280)	Updates the SelectedItem (see page 6294) property.
V	MouseMove (see page 3052)	Provides special processing when the user moves the mouse.
V	MouseUp (see page 3052)	Provides special processing when the user releases the mouse button.
	Move (see page 6280)	Repositions a node in the outline.
	MoveColRow (see page 3053)	Selects the cell indicated by the ACol and ARow parameters.
	MoveColumn (see page 3053)	Moves a column to a new position.
	MoveRow (see page 3053)	Moves a row to a new position.
V	Paint (see page 3054)	Draws the image of the grid control on the screen.
	RowHeightsChanged (see page 3054)	Responds when the row heights change.
	RowMoved (see page 3055)	Provides the interface for a method that responds when the position of a row changes.
	ScrollData (see page 3055)	Scrolls the visual image of the cells in the grid.
V	SelectCell (see page 3055)	Determines whether a particular cell in the grid can be selected.
	SetDisplayWidth (see page 6282)	Sets the display width of the outline.
	SetEditText (see page 3056)	Provides the interface for a method that updates the text associated with a cell.
	SetGoodIndex (see page 6282)	Returns the first node in the Items (see page 6287) array that must be reindexed to make the index of the Value parameter correct.
	SetLevel (see page 6283)	Sets the level of an outline node.
	ShowEditor (see page 3056)	Displays the inplace editor when the grid enters edit mode.
	ShowEditorChar (see page 3057)	Displays the inplace editor, with its text set to the specified character.
	SizeChanged (see page 3057)	Responds to changes in the size of the grid.
	Sizing (see page 3057)	Indicates whether the indicated coordinates are on one of the resize hot zones of the graph.
	TimedScroll (see page 3058)	Extends a move, resize, or selection out of the scrollable region when the user drags the mouse in a direction where the grid is scrolled.
	TopLeftChanged (see page 3058)	Updates the position of the inplace editor when the grid scrolls.
	UpdateDesigner (see page 3059)	Notifies the designer when rows and columns of the grid are moved or resized.

Protected Properties

	Name	Description
	Col (see page 3060)	Specifies the index of the column that contains the selected cell.
	ColCount (see page 3062)	Specifies the number of columns in the grid.
	ColWidths (see page 3063)	Indicates the width (in pixels) of all the columns in the grid.
	DefaultColWidth (see page 3064)	Determines the width (in pixels) of all columns that have not been explicitly resized.

	DefaultDrawing (see page 3066)	Determines whether the Cells are painted when the grid is drawn.
	DefaultRowHeight (see page 3066)	Specifies the height (in pixels) of all rows that have not been explicitly resized.
	EditorMode (see page 3066)	Determines whether the current cell can be edited.
	FixedColor (see page 3067)	Specifies the background color of the fixed rows and columns in the grid.
	FixedCols (see page 3067)	Specifies the number of columns on the left of the grid that cannot be scrolled.
	FixedRows (see page 3068)	Specifies the number of rows on the top of the grid that cannot be scrolled.
R	GridHeight (see page 3068)	Specifies the height of the grid in pixels.
	GridLineWidth (see page 3069)	Specifies the width (in pixels) of the lines that separate the cells of the grid.
R	GridWidth (see page 3070)	Specifies the width of the grid in pixels.
R	HitTest (see page 3071)	Indicates the current position of the mouse cursor.
R	InplaceEditor (see page 3071)	Designates the edit control the grid uses to allow users to edit the contents of the selected cell.
	LeftCol (see page 3072)	Specifies the index of the first visible scrollable column in the grid.
	Row (see page 3074)	Specifies the index of the row that contains the selected cell.
	RowCount (see page 3075)	Specifies the number of rows in the grid.
	RowHeights (see page 3076)	Gives the height (in pixels) of all rows in the grid.
	Selection (see page 3077)	Indicates the boundaries of the current selection.
	TabStops (see page 3079)	Indicates whether the user can tab to specified columns in the grid.
	TopRow (see page 3080)	Specifies the index of the first visible scrollable row in the grid.
R	VisibleColCount (see page 3082)	Indicates the number of scrollable columns visible in the grid.
R	VisibleRowCount (see page 3082)	Indicates the number of scrollable rows visible in the grid.

Public Methods

	Name	Description
	Add (see page 6264)	Adds a node to the outline.
	AddChild (see page 6265)	Adds a child node to a node in the outline.
	AddChildObject (see page 6266)	Adds a child node containing data to a node in the outline.
	AddObject (see page 6266)	Adds a node containing data to the outline.
	BeginUpdate (see page 6268)	Prevents the updating of the outline until the EndUpdate (see page 6271) method is called.
	Clear (see page 6268)	Removes all items from the outline.
V	Create (see page 3030)	Creates an instance of TCustomGrid (see page 3027).
V	Create (see page 6262)	Creates an instance of TCustomOutline (see page 6258).
	Delete (see page 6270)	Deletes a node from the outline.
V	Destroy (see page 3031)	Destroys an instance of TCustomGrid (see page 3027).
V	Destroy (see page 6263)	Destroys an instance of TCustomOutline (see page 6258).
	EndUpdate (see page 6271)	Performs the reindexing and repaints deferred by a call to BeginUpdate (see page 6268).
	FullCollapse (see page 6272)	Causes all top-level nodes in the outline to collapse.
	FullExpand (see page 6272)	Expands every node in the outline.
	GetDataItem (see page 6273)	Returns the index of the first node in the outline that has the Value pointer as its Data property.
	GetItem (see page 6273)	Returns the index of the node at the position indicated by the X and Y parameters.
	GetNodeDisplayWidth (see page 6274)	Returns the length of the row containing a specified node.
	GetTextItem (see page 6274)	Returns the index of the first node in the outline with the Value parameter as its Text property.
	GetVisibleNode (see page 6274)	Returns the TOutlineNode (see page 6363) object for the node indicated by a position in the image of the outline.
	Insert (see page 6275)	Inserts a node at a specified position.
	InsertObject (see page 6275)	Inserts a node containing data at a specified position.
	LoadFromFile (see page 6278)	This is the overview for the LoadFromFile method overload.
	LoadFromStream (see page 6279)	This is the overview for the LoadFromStream method overload.
	MouseCoord (see page 3051)	Returns the row and column indexes of the cell that contains a point specified in screen coordinates.
	SaveToFile (see page 6280)	This is the overview for the SaveToFile method overload.
	SaveToStream (see page 6281)	This is the overview for the SaveToStream method overload.

	SetUpdateState (see page 6283)	Enables or disables the maintenance of the node indexes.

Public Properties

	Name	Description
	Canvas (see page 6284)	Specifies the TCanvas object that presents a drawing surface for the control.
R	ItemCount (see page 6286)	Indicates the number of nodes in the outline.
R	Items (see page 6287)	Lists the nodes in the outline.
	Row (see page 6292)	Specifies the index of the row that contains the selected cell.
	SelectedItem (see page 6294)	Specifies the index of the selected node.

Published Events

	Name	Description
	OnClick (see page 6330)	Occurs when the user clicks the control.
	OnCollapse (see page 6332)	Occurs immediately after a node in the outline is collapsed.
	OnContextPopup (see page 6332)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 6333)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 6333)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 6336)	Occurs when the user drags an object over a control.
	OnDrawItem (see page 6340)	Occurs when a node must be drawn in an owner-draw outline.
	OnEndDock (see page 6340)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 6341)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6342)	Occurs when a control receives the input focus.
	OnExit (see page 6344)	Occurs when the input focus shifts away from one control to another.
	OnExpand (see page 6347)	Occurs immediately after a node in the outline is expanded.
	OnKeyDown (see page 6347)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6351)	Occurs when a key is pressed.
	OnKeyUp (see page 6352)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 6354)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 6355)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 6357)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 6357)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 6357)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 6360)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 6362)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 6362)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 6302)	Determines how the control aligns within its container (parent control).
	BorderStyle (see page 6305)	Determines whether a single line border is drawn around the grid.
	Color (see page 6306)	Specifies the background color of the control.
	Ctl3D (see page 6306)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 6307)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 6309)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 6309)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 6309)	Determines how the control initiates drag-and-drop or drag-and-dock operations.

	Enabled (see page 6311)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 6311)	Controls the attributes of text written on or in the control.
	ItemHeight (see page 6313)	Specifies the height of each node in the outline.
	ItemSeparator (see page 6313)	Specifies a delimiting string for outline nodes.
	Lines (see page 6313)	Lists the Text property values of all nodes in the outline.
	Options (see page 6314)	Determines how the nodes in the outline are drawn.
	OutlineStyle (see page 6315)	Specifies how the outline tree is displayed.
	ParentColor (see page 6315)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6316)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 6316)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 6316)	Determines where a control looks for its font information.
	ParentShowHint (see page 6317)	Determines where a control looks to find out if its Help Hint should be shown.
	PictureClosed (see page 6318)	Specifies the bitmap used to represent a collapsed node that has subitems.
	PictureLeaf (see page 6318)	Specifies the bitmap used to represent an item that does not have subitems.
	PictureMinus (see page 6318)	Specifies the bitmap used to represent an expanded item that has subitems.
	PictureOpen (see page 6319)	Specifies the bitmap used to represent an expanded item that has subitems.
	PicturePlus (see page 6319)	Specifies the bitmap used to represent a collapsed item that has subitems.
	PopupMenu (see page 6320)	Identifies the pop-up menu associated with the control.
	ScrollBars (see page 6325)	Specifies whether the grid includes horizontal and vertical scroll bars.
	ShowHint (see page 6325)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Style (see page 6327)	Determines whether the nodes and tree are drawn automatically.
	TabOrder (see page 6327)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6328)	Determines if the user can tab to a control.
	Visible (see page 6328)	Determines whether the component appears onscreen.

68.1.4.2 TOutline Properties

The properties of the TOutline class are listed here.

Published Properties

	Name	Description
	Align (see page 6302)	Determines how the control aligns within its container (parent control).
	BorderStyle (see page 6305)	Determines whether a single line border is drawn around the grid.
	Color (see page 6306)	Specifies the background color of the control.
	Ctl3D (see page 6306)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 6307)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 6309)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 6309)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 6309)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 6311)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 6311)	Controls the attributes of text written on or in the control.
	ItemHeight (see page 6313)	Specifies the height of each node in the outline.
	ItemSeparator (see page 6313)	Specifies a delimiting string for outline nodes.
	Lines (see page 6313)	Lists the Text property values of all nodes in the outline.
	Options (see page 6314)	Determines how the nodes in the outline are drawn.
	OutlineStyle (see page 6315)	Specifies how the outline tree is displayed.
	ParentColor (see page 6315)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6316)	Determines where a component looks to determine if it should appear three dimensional.

	ParentDoubleBuffered (see page 6316)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 6316)	Determines where a control looks for its font information.
	ParentShowHint (see page 6317)	Determines where a control looks to find out if its Help Hint should be shown.
	PictureClosed (see page 6318)	Specifies the bitmap used to represent a collapsed node that has subitems.
	PictureLeaf (see page 6318)	Specifies the bitmap used to represent an item that does not have subitems.
	PictureMinus (see page 6318)	Specifies the bitmap used to represent an expanded item that has subitems.
	PictureOpen (see page 6319)	Specifies the bitmap used to represent an expanded item that has subitems.
	PicturePlus (see page 6319)	Specifies the bitmap used to represent a collapsed item that has subitems.
	PopupMenu (see page 6320)	Identifies the pop-up menu associated with the control.
	ScrollBars (see page 6325)	Specifies whether the grid includes horizontal and vertical scroll bars.
	ShowHint (see page 6325)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Style (see page 6327)	Determines whether the nodes and tree are drawn automatically.
	TabOrder (see page 6327)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6328)	Determines if the user can tab to a control.
	Visible (see page 6328)	Determines whether the component appears onscreen.

68.1.4.2.1 TOutline.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
```

```
  Note that when creating a splitter dynamically at runtime,
  it is important to set its position to the appropriate side
  of the control it will resize.
  */

  void __fastcall TForm1::FormCreate(TObject *Sender)
  {
    TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
  (Form1).
    TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
  objects.
    TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

    // Line up the directory list box on the left of the form.
    pdlb->Parent = Form1;
    pdlb->Align = alLeft;
    pdlb->Width = Form1->ClientWidth/3;

    // Now use the splitter to divide the directory pane from the file pane.
    ps->Parent = Form1;
    ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
    ps->Align = pdlb->Align; // Give same alignment as directory list.

    // Each pane must be at least one quarter of the form's width.
    ps->MinSize = Form1->ClientWidth/4;

    // Finally, create the last pane - a file list box.
    pflb->Parent = Form1;
    pflb->Align = alClient;
    pdlb->FileList = pflb; // Link the file list box to the directory list box.
  }
  /*
  Dynamically create a TProgressBar control and align it to
  the bottom of the form.
  */

  #include <ComCtrls.hpp>
  #include <Controls.hpp>

  void __fastcall TForm1::Button1Click(TObject *Sender)
  {
    TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
    ProgressBar->Parent = this;
    ProgressBar->Align = alBottom;
    TButton *Button1 = new TButton(this);  // The owner will clean this up.
    Button1->Parent = this;
  }
  /*
  This example dynamically creates a Page Control, then a
  series of Tab Sheets on the Page Control.
  */
  #include <Comctrls.hpp>
  TPageControl* ppc;
  const int MAXTABS = 3;
  TTabSheet* pts[MAXTABS];
  const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
  int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
  const TColor colorPalette[12] = {
    clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
    clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

  void __fastcall TForm1::FormCreate(TObject *Sender)
  {
      ppc = new TPageControl(this); // The owner (this) will clean this up.
      ppc->Parent = this;
      ppc->Align = alClient;
```

```
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane – a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
}

var
  I: Integer;

procedure TForm1.Button1Click(Sender: TObject);
var
  ProgressBar: TProgressBar;
begin
  ProgressBar := TProgressBar.Create(Self);
  with ProgressBar do
  begin
    Parent := Self;
    Align := alBottom;
  end;
end;
```

```
{
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
}
var
  PageControl1: TPageControl;
  pts: array[0..3] of TTabSheet;
const
  TabTitles: array[0..3] of ShortString = ('Customer', 'Orders', 'Items', 'Parts' );

procedure TForm1.FormCreate(Sender: TObject);
const
  colorpalette: Array[0..11] of TColor = (
    clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia, clTeal,
    clNavy, clMaroon, clLime, clOlive, clPurple);
var
  i: Integer;
begin
  PageControl1 := TPageControl.Create(Self);
  PageControl1.Parent := Self;
  PageControl1.Align := alClient;
  for i := Low(TabTitles) to High(TabTitles) do
  begin
    pts[i]:= TTabSheet.Create(PageControl1);
    with pts[i] do
    begin
      PageControl := PageControl1;
      Name := 'ts' + TabTitles[i];
      Caption := TabTitles[i];
      Brush.Color := colorPalette[i];
   end;
  end;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  i: Integer;
begin
  for i := Low(TabTitles) to High(TabTitles) do
  begin
    pts[i].Free;
  end;
  PageControl1.Free;
end;
```

Anchors

68.1.4.2.2 TOutline.BorderStyle Property

Determines whether a single line border is drawn around the grid.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Set BorderStyle to bsSingle to add a single line border around the grid's image. Set BorderStyle to bsNone to omit the border.

68.1.4.2.3 TOutline.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

ParentColor

68.1.4.2.4 TOutline.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

BorderWidth

68.1.4.2.5 TOutline.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}
```

```
/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
```

```
end;

68.1.4.2.6 TOutline.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

68.1.4.2.7 TOutline.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

68.1.4.2.8 TOutline.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
```

```
      else if htNowhere in HT then AttachMode := naAdd
      else if htOnIndent in HT then AttachMode := naInsert;
      TreeView1.Selected.MoveTo(AnItem, AttachMode);
    end;
  end;

68.1.4.2.9 TOutline.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

68.1.4.2.10 TOutline.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

Displaying and Editing Text in a Memo Control

68.1.4.2.11 TOutline.ItemHeight Property

Specifies the height of each node in the outline.

Pascal

```
property ItemHeight: Integer;
```

C++

```
__property int ItemHeight;
```

Description

Set ItemHeight to the height, in pixels, of each node in the outline. Changing the ItemHeight property also changes the font used to display the nodes.

See Also

ItemCount (see page 6286)

Items (see page 6287)

68.1.4.2.12 TOutline.ItemSeparator Property

Specifies a delimiting string for outline nodes.

Pascal

```
property ItemSeparator: string;
```

C++

```
__property UnicodeString ItemSeparator;
```

Description

Set ItemSeparator to the string that should appear between node names in the path description of any individual node in the outline. ItemSeparator is used to implement the FullPath read method of TOutlineNode.

ItemSeparator is initialized to the backslash (\) character when the TCustomOutline object is created.

See Also

Items (see page 6287)

FullPath (see page 6375)

68.1.4.2.13 TOutline.Lines Property

Lists the Text property values of all nodes in the outline.

Pascal

```
property Lines: TStrings;
```

C++

```
__property TStrings Lines;
```

Description

Read Lines to obtain a text representation of the outline. Set Lines to fill the outline from a set of text strings. Each string in the Lines property represents a node in the outline. Lines does not include the root node.

Leading tabs and spaces are converted into levels of the outline. Text without any leading tabs or spaces becomes level 1 items.

For example, the following set of strings represents an outline with three first level children descended from the root, and an additional, second level child on the first and third nodes:

```
ChildA
 ChildA1
ChildB
ChildC
 ChildC1
```

The Lines property is primarily useful for filling an outline with items at design time. While Lines can be used to access the individual nodes at run time, it is much quicker to access an item with the Items property.

See Also

Items (see page 6287)

Text (see page 6378)

68.1.4.2.14 TOutline.Options Property

Determines how the nodes in the outline are drawn.

Pascal

```
property Options: TGridOptions;
```

C++

```
__property TOutlineOptions Options;__property TGridOptions Options;
```

Description

Set Options to any combination of the following values:

Value	Meaning
ooDrawTreeRoot	The first item (Index value of 1) is connected to the root item by the outline tree. This means that the tree will extend from the top of the outline to all the first level items. Without ooDrawTreeRoot, all first level items appear leftmost in the outline, not connected by the tree.
ooDrawFocusRect	The outline draws a focus rectangle around the selected item.
ooStretchBitmaps	The outline stretches the standard bitmaps (PictureLeaf, PictureOpen, PictureClosed, PicturePlus, PictureMinus) to fit in the size of the item, determined by the size of the Font of the Text. Without ooStretchBitmaps, the bitmaps will be cropped if larger than the height of the item text, or won't fill up the entire item space if smaller than the text.

See Also

Items (see page 6287)

PictureClosed (see page 6290)

PictureLeaf (see page 6291)

PictureMinus (see page 6291)

PictureOpen (see page 6291)

PicturePlus (see page 6292)

SelectedItem (see page 6294)

68.1.4.2.15 TOutline.OutlineStyle Property

Specifies how the outline tree is displayed.

Pascal

```
property OutlineStyle: TOutlineStyle;
```

C++

```
__property TOutlineStyle OutlineStyle;
```

Description

Set OutlineStyle to one of the following values:

Value	Meaning
osText	Displays node text (specified in Text) only.
osPlusMinusText	Displays plus picture (specified in PicturePlus), minus picture (specified in PictureMinus), and node text (specified in Text).
osPictureText	Displays open picture (specified in PictureOpen), closed picture (specified in PictureClosed), leaf picture (specified in PictureLeaf) and node text (specified in Text).
osPlusMinusPictureText	Displays plus picture (specified in PicturePlus), minus picture (specified in PictureMinus), open picture (specified in PictureOpen), closed picture (specified in PictureClosed), leaf picture (specified in PictureLeaf), and node text (specified in Text).
osTreeText	Displays lines connecting outline nodes and node text (specified in Text).
osTreePictureText	Displays lines connecting outline nodes, open picture (specified in PictureOpen), closed picture (specified in PictureClosed), leaf picture (specified in PictureLeaf), and node text (specified in Text).

Note: If the Style property is otOwnerDraw, the value of OutlineStyle is ignored. The connecting lines, node bitmaps, and node text must all be drawn in an OnDrawItem event handler.

68.1.4.2.16 TOutline.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

68.1.4.2.17 TOutline.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

68.1.4.2.18 TOutline.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

68.1.4.2.19 TOutline.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

Font

Parent

ParentColor

ParentShowHint

68.1.4.2.20 TOutline.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

68.1.4.2.21 TOutline.PictureClosed Property

Specifies the bitmap used to represent a collapsed node that has subitems.

Pascal

```
property PictureClosed: TBitmap;
```

C++

```
__property TBitmap PictureClosed;
```

Description

By default, PictureClosed is a closed file folder bitmap. Set PictureClosed to change the bitmap used for collapsed nodes.

Note: The bitmap is not displayed in the outline unless the OutlineStyle property is set to osPictureText, osPlusMinusPictureText, or osTreePictureText.

See Also

OutlineStyle (see page 6289)

PictureLeaf (see page 6291)

PictureMinus (see page 6291)

PictureOpen (see page 6291)

68.1.4.2.22 TOutline.PictureLeaf Property

Specifies the bitmap used to represent an item that does not have subitems.

Pascal

```
property PictureLeaf: TBitmap;
```

C++

```
__property TBitmap PictureLeaf;
```

Description

By default, PictureLeaf is a document bitmap. Set PictureLeaf to change the bitmap used for leaf nodes.

Note: The bitmap is not displayed in the outline unless the OutlineStyle property is set to osPictureText, osPlusMinusPictureText, or osTreePictureText.

See Also

OutlineStyle (see page 6289)

PictureClosed (see page 6290)

PictureOpen (see page 6291)

68.1.4.2.23 TOutline.PictureMinus Property

Specifies the bitmap used to represent an expanded item that has subitems.

Pascal

```
property PictureMinus: TBitmap;
```

C++

```
__property TBitmap PictureMinus;
```

Description

By default, PictureMinus is a minus sign (-). Set PictureMinus to change the bitmap used for collapsible nodes.

Note: The bitmap is not displayed in the outline unless the OutlineStyle property is set to osPlusMinusPictureText or osPlusMinusText.

See Also

OutlineStyle (see page 6289)

PictureOpen (see page 6291)

PicturePlus (see page 6292)

68.1.4.2.24 TOutline.PictureOpen Property

Specifies the bitmap used to represent an expanded item that has subitems.

Pascal

```
property PictureOpen: TBitmap;
```

C++

```
__property TBitmap PictureOpen;
```

Description

By default, the PictureOpen property is an open file folder. Set PictureOpen to change the bitmap used for expanded nodes.

Note: The bitmap is not displayed in the outline unless the OutlineStyle property is set to osPictureText, osPlusMinusPictureText, or osTreePictureText.

See Also

OutlineStyle (see page 6289)

PictureClosed (see page 6290)

PictureLeaf (see page 6291)

Specifies the bitmap used to represent a collapsed item that has subitems.

Pascal

```
property PicturePlus: TBitmap;
```

C++

```
__property TBitmap PicturePlus;
```

Description

By default, the PicturePlus property is a plus sign (+). Set PicturePlus to change the bitmap used for collapsed nodes.

Note: The bitmap will not be displayed in the outline unless the OutlineStyle property is set to osPlusMinusPictureText or osPlusMinusText.

See Also

OutlineStyle (see page 6289)

68.1.4.2.26 TOutline.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
```

```
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
```

```
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
```

```
  Note: only the selected portion of the string in the edit box will
  be copied, cut or replaced.
  }
  procedure TForm1.Copy1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
     Edit1.CopyToClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.CopyToClipboard
    else
      Beep;
  end;

  procedure TForm1.Cut1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
      Edit1.CutToClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.CutToClipboard
    else
      Beep;
  end;

  procedure TForm1.Paste1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
      Edit1.PasteFromClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.PasteFromClipboard
    else
      Beep;
  end;
  {
  This example demonstrates how to add and delete menu items
  to a popup menu at runtime and assign an event handler to
  the OnClick event.  Place a TPopupMenu and three buttons on
  the form named "AddButton", "EditButton",  and
  "DestroyButton" and add OnClick events to all three buttons.
  Put the TPopupMenu in the PopupMenu property of the form.
  Place the PopupMenuItemsClick procedure in the TForm1 type
  declaration so that it can be used as the method call for
  the menu item OnClick event.
  }

  type
    TForm1 = class(TForm)

OnContextPopup

68.1.4.2.27 TOutline.ScrollBars Property

Specifies whether the grid includes horizontal and vertical scroll bars.

Pascal

```
property ScrollBars: TScrollStyle;
```

C++

```
__property TScrollStyle ScrollBars;
```

Description

Use ScrollBars to give the grid horizontal or vertical scroll bars.

Note: If all the cells in the grid fit in the ClientWidth, no horizontal scroll bar appears, even if ScrollBars is ssHorizontal or ssBoth. If all the cells fit in the ClientHeight, no vertical scroll bar appears, even if ScrollBars is ssVertical or ssBoth.

ClientHeight

ClientWidth

68.1.4.2.28 TOutline.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
```

```
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

Displaying Fly-over Help

68.1.4.2.29 TOutline.Style Property

Determines whether the nodes and tree are drawn automatically.

Pascal

```
property Style: TOutlineType;
```

C++

```
__property TOutlineType Style;
```

Description

By default, Style is osStandard, meaning that the outline displays items in the style determined by the OutlineStyle property. Set Style to otOwnerDraw to create owner-draw outlines, meaning that items must be drawn on the canvas of the outline by code in an OnDrawItem event handler.

Owner-draw outlines can display items other than the Text of a node and the standard bitmaps specified in the PictureClosed, PictureOpen, PictureMinus, PicturePlus, and PictureLeaf properties. Owner-draw outlines require more programming, however, as the application must specify how to render the image for each node in an OnDrawItem event handler.

OnDrawItem (see page 6295)

OutlineStyle (see page 6289)

68.1.4.2.30 TOutline.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

68.1.4.2.31 TOutline.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

68.1.4.2.32 TOutline.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
```

```
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;

68.1.4.3 TOutline Events

The events of the TOutline class are listed here.

Published Events

	Name	Description
	OnClick (see page 6330)	Occurs when the user clicks the control.
	OnCollapse (see page 6332)	Occurs immediately after a node in the outline is collapsed.
	OnContextPopup (see page 6332)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 6333)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 6333)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 6336)	Occurs when the user drags an object over a control.
	OnDrawItem (see page 6340)	Occurs when a node must be drawn in an owner-draw outline.
	OnEndDock (see page 6340)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 6341)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6342)	Occurs when a control receives the input focus.
	OnExit (see page 6344)	Occurs when the input focus shifts away from one control to another.
	OnExpand (see page 6347)	Occurs immediately after a node in the outline is expanded.
	OnKeyDown (see page 6347)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6351)	Occurs when a key is pressed.
	OnKeyUp (see page 6352)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 6354)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 6355)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 6357)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 6357)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 6357)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 6360)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 6362)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 6362)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

68.1.4.3.1 TOutline.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
```

```
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;

68.1.4.3.2 TOutline.OnCollapse Event

Occurs immediately after a node in the outline is collapsed.

Pascal

```
property OnCollapse: EOutlineChange;
```

C++

```
__property EOutlineChange OnCollapse;
```

Description

Write an OnCollapse event handler to perform special processing when a node in the outline is collapsed. The event handler supplies the index of the node that collapsed.

See Also

OnExpand (see page 6296)

68.1.4.3.3 TOutline.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

68.1.4.3.4 TOutline.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

OnClick

Responding to User Actions at Runtime

68.1.4.3.5 TOutline.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

68.1.4.3.6 TOutline.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.

68.1.4.3.7 TOutline.OnDrawItem Event

Occurs when a node must be drawn in an owner-draw outline.

Pascal

```
property OnDrawItem: TDrawItemEvent;
```

C++

```
__property TDrawItemEvent OnDrawItem;
```

Description

When the Style property is set to otOwnerDraw, specify an OnDrawItem event handler to render the image of each node in the outline. An OnDrawItem event handler can display items other than the Text of a node and the standard bitmaps specified in the PictureClosed, PictureOpen, PictureMinus, PicturePlus, and PictureLeaf properties.

Draw the image of the node specified by the Index parameter onto the canvas of the outline.

68.1.4.3.8 TOutline.OnEndDock Event

Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

Pascal

```
property OnEndDock;
```

C++

```
__property OnEndDock;
```

Description

Use OnEndDock to specify actions or special processing that when a drag-and-dock operation stops.

68.1.4.3.9 TOutline.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;

DragKind

68.1.4.3.10 TOutline.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   (dynamic_cast<TEdit *>(myActiveControl))->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    (dynamic_cast<TRichEdit *>(myActiveControl))->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
```

```
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{

68.1.4.3.11 TOutline.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
```

```
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

ActiveControl (see page 2145)

68.1.4.3.12 TOutline.OnExpand Event

Occurs immediately after a node in the outline is expanded.

Pascal

```
property OnExpand: EOutlineChange;
```

C++

```
__property EOutlineChange OnExpand;
```

Description

Write an OnExpand event handler to perform special processing when a node in the outline is expanded. The event handler identifies the node that was just expanded.

OnCollapse (see page 6295)

68.1.4.3.13 TOutline.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown;
```

C++

```
__property OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/

OnKeyPress

OnKeyUp

68.1.4.3.14 TOutline.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress;
```

C++

```
__property OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;

OnKeyDown

OnKeyPress

68.1.4.3.16 TOutline.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

MouseCapture

68.1.4.3.17 TOutline.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
```

```
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer);
begin
  StartX := X;
  StartY := Y;
end;

procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer);
begin

68.1.4.3.21 TOutline.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp;
```

C++

```
__property OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.

OnMouseDown

OnMouseMove

Responding to a Mouse-up Action

68.1.4.3.22 TOutline.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

TDragDockObjectEx

DragKind

OnDragOver

OnDockDrop

68.1.4.3.23 TOutline.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

68.1.5 TOutlineNode Class

TOutlineNode represents a node in a TCustomOutline (see page 6258) object.

Class Hierarchy

Pascal

```
TOutlineNode = class(TPersistent);
```

C++

```
class TOutlineNode : public TPersistent;
```

File

Outline

Description

Use TOutlineNode to describe a node in a Win 3.1 outline. Each outline node appears as a line, or row, of the outline. An outline node can have from 0 to 16368 subnodes, which are subordinate to the parent node in the outline structure.

See Also

TOutline (see page 6296)

68.1.5.1 TOutlineNode Members

The following tables list the members exposed by TOutlineNode.

Protected Methods

	Name	Description
	AddNode (see page 6366)	This is AddNode, a member of class TOutlineNode.
	GetDataItem (see page 6368)	This is GetDataItem, a member of class TOutlineNode.
	GetNodeAtIndex (see page 6370)	This is GetNodeAtIndex, a member of class TOutlineNode.
	GetRowOfNode (see page 6371)	This is GetRowOfNode, a member of class TOutlineNode.
	GetTextItem (see page 6371)	This is GetTextItem, a member of class TOutlineNode.
	GetVisibleNode (see page 6371)	This is GetVisibleNode, a member of class TOutlineNode.
	HasAsParent (see page 6372)	This is HasAsParent, a member of class TOutlineNode.
	InsertNode (see page 6372)	This is InsertNode, a member of class TOutlineNode.
	InternalRemove (see page 6372)	This is InternalRemove, a member of class TOutlineNode.
	Remove (see page 6373)	This is Remove, a member of class TOutlineNode.
	WriteNode (see page 6373)	This is the overview for the WriteNode method overload.

Protected Properties

	Name	Description
R	ExpandCount (see page 6374)	This is ExpandCount, a member of class TOutlineNode.
R	Items (see page 6377)	This is Items, a member of class TOutlineNode.
R	List (see page 6378)	This is List, a member of class TOutlineNode.
R	Outline (see page 6378)	This is Outline, a member of class TOutlineNode.

Public Methods

	Name	Description
	ChangeLevelBy (see page 6367)	Changes the level of an outline node.
	Collapse (see page 6367)	Collapses an outline item.
	Create (see page 6365)	Creates a new TOutlineNode (see page 6363) object.
V	Destroy (see page 6365)	Frees the memory associated with the TOutlineNode (see page 6363) object.
	Expand (see page 6368)	Expands an outline item.
	FullExpand (see page 6368)	Expands an outline node and all its descendants.
	GetDisplayWidth (see page 6369)	Returns the distance, in pixels, from the left edge of the outline to the right edge of the outline node.
	getFirstChild (see page 6369)	This is getFirstChild, a member of class TOutlineNode.
	GetLastChild (see page 6369)	Returns the Index (see page 6376) value of the last subnode.
	GetNextChild (see page 6370)	Returns the Index (see page 6376) value of the next child of an outline node.
	GetPrevChild (see page 6370)	Returns the Index (see page 6376) value of the previous child of an outline node.
	MoveTo (see page 6372)	Moves an outline node from one location within the outline to another.

Public Properties

	Name	Description
	Data (see page 6374)	Points to application-specific data associated with the node.
	Expanded (see page 6375)	Determines whether descendants of the outline node are displayed.
R	FullPath (see page 6375)	Describes an outline node, using its text and the text of all ancestor nodes in the outline.
R	HasItems (see page 6376)	Indicates whether the outline node has any subnodes.
R	Index (see page 6376)	Identifies the node in the Items (see page 6377) array maintained by the outline.

R	IsVisible (see page 6376)	Indicates whether the outline node is visible in the outline.
	Level (see page 6377)	Indicates the level of indentation of a node within the outline.
R	Parent (see page 6378)	Identifies the immediate ancestor of the node.
	Text (see page 6378)	Specifies the string that identifies the outline node.
R	TopItem (see page 6379)	Indicates which outline node is the topmost ancestor of a node.

68.1.5.2 TOutlineNode.Create Constructor

Creates a new TOutlineNode (see page 6363) object.

Pascal

```
constructor Create(AOwner: TCustomOutline);
```

C++

```
__fastcall TOutlineNode(TCustomOutline AOwner);
```

Description

Do not call the constructor for TOutlineNode (see page 6363) directly. Instead, use one of the methods of the outline component in which the node should appear. These methods are as follows:

Method	Action
Add	Creates the node as the last sibling of a specified node.
AddObject	Same as Add, but also initializing the node's Data (see page 6374) property.
AddChild	Creates the node as the last child of a specified node.
AddChildObject	Same as AddChild, but also initializing the node's Data (see page 6374) property.
Insert	Creates the node in the current position of an existing node.
InsertObject	Same as Insert, but also initializing the node's Data (see page 6374) property.

See Also

Data (see page 6374)

Add (see page 6264)

AddObject (see page 6266)

AddChild (see page 6265)

Insert (see page 6275)

AddChildObject (see page 6266)

InsertObject (see page 6275)

68.1.5.3 TOutlineNode.Destroy Destructor

Frees the memory associated with the TOutlineNode (see page 6363) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TOutlineNode();
```

Description

Do not call Destroy directly. The preferred method of deleting nodes is to use the Delete method of the containing outline component.

See Also

System::TObject::Free

Delete (see page 6270)

68.1.5.4 TOutlineNode Methods

The methods of the TOutlineNode class are listed here.

Protected Methods

	Name	Description
	AddNode (see page 6366)	This is AddNode, a member of class TOutlineNode.
	GetDataItem (see page 6368)	This is GetDataItem, a member of class TOutlineNode.
	GetNodeAtIndex (see page 6370)	This is GetNodeAtIndex, a member of class TOutlineNode.
	GetRowOfNode (see page 6371)	This is GetRowOfNode, a member of class TOutlineNode.
	GetTextItem (see page 6371)	This is GetTextItem, a member of class TOutlineNode.
	GetVisibleNode (see page 6371)	This is GetVisibleNode, a member of class TOutlineNode.
	HasAsParent (see page 6372)	This is HasAsParent, a member of class TOutlineNode.
	InsertNode (see page 6372)	This is InsertNode, a member of class TOutlineNode.
	InternalRemove (see page 6372)	This is InternalRemove, a member of class TOutlineNode.
	Remove (see page 6373)	This is Remove, a member of class TOutlineNode.
	WriteNode (see page 6373)	This is the overview for the WriteNode method overload.

Public Methods

	Name	Description
	ChangeLevelBy (see page 6367)	Changes the level of an outline node.
	Collapse (see page 6367)	Collapses an outline item.
	Expand (see page 6368)	Expands an outline item.
	FullExpand (see page 6368)	Expands an outline node and all its descendants.
	GetDisplayWidth (see page 6369)	Returns the distance, in pixels, from the left edge of the outline to the right edge of the outline node.
	getFirstChild (see page 6369)	This is getFirstChild, a member of class TOutlineNode.
	GetLastChild (see page 6369)	Returns the Index (see page 6376) value of the last subnode.
	GetNextChild (see page 6370)	Returns the Index (see page 6376) value of the next child of an outline node.
	GetPrevChild (see page 6370)	Returns the Index (see page 6376) value of the previous child of an outline node.
	MoveTo (see page 6372)	Moves an outline node from one location within the outline to another.

68.1.5.4.1 TOutlineNode.AddNode Method

Pascal

```
function AddNode(Value: TOutlineNode): LongInt;
```

C++

```
__fastcall LongInt AddNode(TOutlineNode Value);
```

Description

This is AddNode, a member of class TOutlineNode.

68.1.5.4.2 TOutlineNode.ChangeLevelBy Method

Changes the level of an outline node.

Pascal

```
procedure ChangeLevelBy(Value: TChangeRange);
```

C++

```
__fastcall ChangeLevelBy(TChangeRange Value);
```

Description

Call ChangeLevelBy to move a node up or down a branch in the outline. Specify a Value parameter value of -1 to move up (toward the root) one level. Specify a Value parameter value of 1 to move down (away from the root) one level.

When moving up one level, an item becomes the next sibling of its former parent. When moving down one level, an item becomes the last child of its former prior sibling.

Nodes at the first level can not be moved up, as they have no parent. The first node in the outline can not be moved down either, as it has no prior sibling.

Note: Before calling ChangeLevelBy, be sure that the node has the appropriate number of parents or that the appropriate prior siblings exist.

See Also

Level (see page 6377)

MoveTo (see page 6372)

Parent (see page 6378)

68.1.5.4.3 TOutlineNode.Collapse Method

Collapses an outline item.

Pascal

```
procedure Collapse;
```

C++

```
__fastcall Collapse();
```

Description

Collapse sets the Expanded (see page 6375) property to false. When an outline node is collapsed, its descendants are hidden and, depending on the OutlineStyle property of the outline in which the node is contained, the plus picture or closed picture is displayed.

Collapse does nothing to nodes that have no descendants.

See Also

Expand (see page 6368)

Expanded (see page 6375)

OutlineStyle (see page 6289)

68.1.5.4.4 TOutlineNode.Expand Method

Expands an outline item.

Pascal

```
procedure Expand;
```

C++

```
__fastcall Expand();
```

Description

Expand sets the Expanded (see page 6375) property to true. When an outline node is expanded, its descendants are displayed and, depending on the OutlineStyle property of the outline in which the node is contained, the minus picture or open picture is displayed.

Expand does nothing to nodes that have no descendants.

Note: Expand only ensures that the immediate children of a node are visible. To expand all descendants of a node, use the FullExpand (see page 6368) method.

See Also

Collapse (see page 6367)

Expanded (see page 6375)

FullExpand (see page 6368)

OutlineStyle (see page 6289)

68.1.5.4.5 TOutlineNode.FullExpand Method

Expands an outline node and all its descendants.

Pascal

```
procedure FullExpand;
```

C++

```
__fastcall FullExpand();
```

Description

Use FullExpand to expand all the nodes in the subtree of the outline rooted at the outline node. FullExpand sets the Expanded (see page 6375) property of the node and all its descendants to true.

See Also

Collapse (see page 6367)

Expand (see page 6368)

Expanded (see page 6375)

68.1.5.4.6 TOutlineNode.GetDataItem Method

Pascal

```
function GetDataItem(Value: TCustomData): LongInt;
```

C++

```
__fastcall LongInt GetDataItem(TCustomData Value);
```

Description

This is GetDataItem, a member of class TOutlineNode.

68.1.5.4.7 TOutlineNode.GetDisplayWidth Method

Returns the distance, in pixels, from the left edge of the outline to the right edge of the outline node.

Pascal

```
function GetDisplayWidth: Integer;
```

C++

```
__fastcall int GetDisplayWidth();
```

Description

Call GetDisplayWidth to determine the length of the line in the outline that contains the outline node. GetDisplayWidth adjusts for the lines and bitmaps specified by the OutlineStyle property of the outline.

See Also

GetNodeDisplayWidth (see page 6274)

OutlineStyle (see page 6289)

68.1.5.4.8 TOutlineNode.getFirstChild Method

Pascal

```
function getFirstChild: LongInt;
```

C++

```
__fastcall LongInt getFirstChild();
```

Description

This is getFirstChild, a member of class TOutlineNode.

68.1.5.4.9 TOutlineNode.GetLastChild Method

Returns the Index (see page 6376) value of the last subnode.

Pascal

```
function GetLastChild: LongInt;
```

C++

```
__fastcall LongInt GetLastChild();
```

Description

Call GetLastChild to locate the last subnode of a node. If the node has no descendants, GetLastChild returns -1.

See Also

GetFirstChild (see page 6369)

GetNextChild (see page 6370)

GetPrevChild (see page 6370)

HasItems (see page 6376)

Index (see page 6376)

68.1.5.4.10 TOutlineNode.GetNextChild Method

Returns the Index (see page 6376) value of the next child of an outline node.

Pascal

```
function GetNextChild(Value: LongInt): LongInt;
```

C++

```
__fastcall LongInt GetNextChild(LongInt Value);
```

Description

Call GetNextChild to obtain the index of the next immediate descendant of a node, following the child node with the index given by the Value parameter. If the child node indicated by Value has no next sibling, or if the child node indicated by Value is not an immediate descendant of the outline node, GetNextChild returns -1.

Index (see page 6376) values reflect a depth-first traversal of the outline. Thus, the node returned by GetNextChild is not simply the node with an index of Value+1, unless the node with index Value has no descendants. GetNextChild allows a breadth-first traversal of the outline.

See Also

GetFirstChild (see page 6369)

GetLastChild (see page 6369)

GetPrevChild (see page 6370)

Index (see page 6376)

68.1.5.4.11 TOutlineNode.GetNodeAtIndex Method

Pascal

```
function GetNodeAtIndex(TargetIndex: LongInt): TOutlineNode;
```

C++

```
__fastcall TOutlineNode GetNodeAtIndex(LongInt TargetIndex);
```

Description

This is GetNodeAtIndex, a member of class TOutlineNode.

68.1.5.4.12 TOutlineNode.GetPrevChild Method

Returns the Index (see page 6376) value of the previous child of an outline node.

Pascal

```
function GetPrevChild(Value: LongInt): LongInt;
```

C++

```
__fastcall LongInt GetPrevChild(LongInt Value);
```

Description

Call GetPrevChild to obtain the index of the previous immediate descendant of a node, preceding the child node with the index given by the Value parameter. If the child node indicated by Value has no prior sibling, or if the child node indicated by Value is not an immediate descendant of the outline node, GetPrevChild returns -1.

Index (see page 6376) values reflect a depth-first traversal of the outline. Thus, the previous sibling of the child node indicated by Value is not simply one less than Value, unless that previous sibling has no descendants.

See Also

GetFirstChild (see page 6369)

GetLastChild (see page 6369)

GetNextChild (see page 6370)

Index (see page 6376)

68.1.5.4.13 TOutlineNode.GetRowOfNode Method

Pascal

```
function GetRowOfNode(TargetNode: TOutlineNode; var RowCount: Longint): Boolean;
```

C++

```
__fastcall Boolean GetRowOfNode(TOutlineNode TargetNode, Longint RowCount);
```

Description

This is GetRowOfNode, a member of class TOutlineNode.

68.1.5.4.14 TOutlineNode.GetTextItem Method

Pascal

```
function GetTextItem(const Value: string): LongInt;
```

C++

```
__fastcall LongInt GetTextItem(const UnicodeString Value);
```

Description

This is GetTextItem, a member of class TOutlineNode.

68.1.5.4.15 TOutlineNode.GetVisibleNode Method

Pascal

```
function GetVisibleNode(TargetCount: LongInt): TOutlineNode;
```

C++

```
__fastcall TOutlineNode GetVisibleNode(LongInt TargetCount);
```

Description

This is GetVisibleNode, a member of class TOutlineNode.

68.1.5.4.16 TOutlineNode.HasAsParent Method

Pascal

```
function HasAsParent(Value: TOutlineNode): Boolean;
```

C++

```
__fastcall Boolean HasAsParent(TOutlineNode Value);
```

Description

This is HasAsParent, a member of class TOutlineNode.

68.1.5.4.17 TOutlineNode.InsertNode Method

Pascal

```
function InsertNode(Index: LongInt; Value: TOutlineNode): LongInt;
```

C++

```
__fastcall LongInt InsertNode(LongInt Index, TOutlineNode Value);
```

Description

This is InsertNode, a member of class TOutlineNode.

68.1.5.4.18 TOutlineNode.InternalRemove Method

Pascal

```
procedure InternalRemove(Value: TOutlineNode; Index: Integer);
```

C++

```
__fastcall InternalRemove(TOutlineNode Value, int Index);
```

Description

This is InternalRemove, a member of class TOutlineNode.

68.1.5.4.19 TOutlineNode.MoveTo Method

Moves an outline node from one location within the outline to another.

Pascal

```
procedure MoveTo(Destination: LongInt; AttachMode: TAttachMode);
```

C++

```
__fastcall MoveTo(LongInt Destination, TAttachMode AttachMode);
```

Description

Call MoveTo to reposition the node to the position indicated by the Destination parameter. Destination is the Index (see page 6376) value of another outline node. The AttachMode parameter specifies how to attach the moved node to the destination position.

Note: To change only the level of a node, use the ChangeLevelBy (see page 6367) method.

See Also

ChangeLevelBy (see page 6367)

Index (see page 6376)

Add (see page 6264)

AddChild (see page 6265)

Insert (see page 6275)

68.1.5.4.20 TOutlineNode.Remove Method

Pascal

```
procedure Remove(Value: TOutlineNode);
```

C++

```
__fastcall Remove(TOutlineNode Value);
```

Description

This is Remove, a member of class TOutlineNode.

68.1.5.4.21 WriteNode Method

This is the overview for the WriteNode method overload.

Overload List

	Name	Description
	TOutlineNode.WriteNode (PChar, TStream) (see page 6373)	This is WriteNode, a member of class TOutlineNode.
	TOutlineNode.WriteNode (TStream, TEncoding) (see page 6373)	This is WriteNode, a member of class TOutlineNode.

68.1.5.4.21.1 TOutlineNode.WriteNode Method (PChar, TStream)

Pascal

```
procedure WriteNode(Buffer: PChar; Stream: TStream); overload; deprecated;
```

C++

```
__fastcall WriteNode(const char * Buffer, TStream Stream);
```

Description

This is WriteNode, a member of class TOutlineNode.

68.1.5.4.21.2 TOutlineNode.WriteNode Method (TStream, TEncoding)

Pascal

```
procedure WriteNode(Stream: TStream; Encoding: TEncoding); overload;
```

C++

```
__fastcall WriteNode(TStream Stream, TEncoding Encoding);
```

Description

This is WriteNode, a member of class TOutlineNode.

68.1.5.5 TOutlineNode Properties

The properties of the TOutlineNode class are listed here.

Protected Properties

	Name	Description
	ExpandCount (see page 6374)	This is ExpandCount, a member of class TOutlineNode.
	Items (see page 6377)	This is Items, a member of class TOutlineNode.
	List (see page 6378)	This is List, a member of class TOutlineNode.
	Outline (see page 6378)	This is Outline, a member of class TOutlineNode.

Public Properties

	Name	Description
	Data (see page 6374)	Points to application-specific data associated with the node.
	Expanded (see page 6375)	Determines whether descendants of the outline node are displayed.
	FullPath (see page 6375)	Describes an outline node, using its text and the text of all ancestor nodes in the outline.
	HasItems (see page 6376)	Indicates whether the outline node has any subnodes.
	Index (see page 6376)	Identifies the node in the Items (see page 6377) array maintained by the outline.
	IsVisible (see page 6376)	Indicates whether the outline node is visible in the outline.
	Level (see page 6377)	Indicates the level of indentation of a node within the outline.
	Parent (see page 6378)	Identifies the immediate ancestor of the node.
	Text (see page 6378)	Specifies the string that identifies the outline node.
	TopItem (see page 6379)	Indicates which outline node is the topmost ancestor of a node.

68.1.5.5.1 TOutlineNode.Data Property

Points to application-specific data associated with the node.

Pascal

```
property Data: TCustomData;
```

C++

```
__property TCustomData Data;
```

Description

Use Data to associate an arbitrary value with a node in an outline. For example, if the outline represents the table of contents to an electronic document, Data could point to an object that provides jump information for accessing the section of the document named by the node.

The Data property is usually described by the Text (see page 6378) property, which is displayed in the rendered image of the node.

See Also

Text (see page 6378)

68.1.5.5.2 TOutlineNode.ExpandCount Property

Pascal

```
property ExpandCount: LongInt;
```

C++

```
__property LongInt ExpandCount;
```

Description

This is ExpandCount, a member of class TOutlineNode.

68.1.5.5.3 TOutlineNode.Expanded Property

Determines whether descendants of the outline node are displayed.

Pascal

```
property Expanded: Boolean;
```

C++

```
__property Boolean Expanded;
```

Description

Set Expanded to true to display all subnodes of a node. When an outline node is expanded, its descendants are displayed and, depending on the OutlineStyle property of the outline in which the node is contained, the minus picture or open picture is displayed.

Set Expanded to false to collapse the node. When an outline node is collapsed, its descendants are hidden and, depending on the OutlineStyle property of the outline in which the node is contained, the plus picture or closed picture is displayed.

Expanded is not meaningful for nodes that have no descendants.

See Also

HasItems (see page 6376)

OutlineStyle (see page 6289)

68.1.5.5.4 TOutlineNode.FullPath Property

Describes an outline node, using its text and the text of all ancestor nodes in the outline.

Pascal

```
property FullPath: string;
```

C++

```
__property UnicodeString FullPath;
```

Description

Read FullPath to obtain a description of the entire branch of the outline leading to the outline node. FullPath consists of the values of the Text (see page 6378) properties of all outline items, starting with the text of the node at the first level and traversing the outline down to the outline node. The string specified as the ItemSeparator property of the outline separates the text for each node in the path.

See Also

Level (see page 6377)

Parent (see page 6378)

ItemSeparator (see page 6288)

Text (see page 6378)

TopItem (see page 6379)

68.1.5.5.5 TOutlineNode.HasItems Property

Indicates whether the outline node has any subnodes.

Pascal

```
property HasItems: Boolean;
```

C++

```
__property Boolean HasItems;
```

Description

Read HasItem to determine whether the outline node is a leaf node. Depending on the OutlineStyle property of the outline that contains the node, leaf nodes may appear with the leaf bitmap. If the node is not a leaf, subnodes appear below and indented from the node when it is expanded.

HasItem returns true if the node has any descendants, even if the node is collapsed and the descendants are not visible. HasItem returns false if the node is a leaf node.

See Also

Expanded (see page 6375)

Parent (see page 6378)

OutlineStyle (see page 6289)

68.1.5.5.6 TOutlineNode.Index Property

Identifies the node in the Items (see page 6377) array maintained by the outline.

Pascal

```
property Index: LongInt;
```

C++

```
__property LongInt Index;
```

Description

Read Index to determine the row of the outline where the node appears. The first node has an Index value of 1, and subsequent nodes are indexed sequentially. If a node has subnodes, the Index value of the parent node is one less than the Index value of its first descendant.

When nodes in the outline are added, moved, or deleted, the values of the Index properties of all subsequent nodes must be recalculated to be valid. Sometimes, the recalculation of indexes is deferred until all changes to the nodes are complete. To ensure that the value of Index is valid, call the SetUpdateState method of the outline that contains the node.

See Also

Items (see page 6287)

SetUpdateState (see page 6283)

68.1.5.5.7 TOutlineNode.IsVisible Property

Indicates whether the outline node is visible in the outline.

Pascal

```
property IsVisible: Boolean;
```

C++

```
__property Boolean IsVisible;
```

Description

Read IsVisible to determine whether the node is part of the current image of the outline. A node is visible if it is on level 1 or if all its parents are expanded.

Note: Do not confuse IsVisible with the Visible property of TControl objects. Outline (see page 6378) nodes are not controls, but merely helper objects that describe nodes for an outline control. IsVisible indicates whether a node is visible because its parents are expanded or collapsed. It does not provide information about whether the node has been scrolled out of view, or even if the outline is not visible.

See Also

Expanded (see page 6375)

Visible

68.1.5.5.8 TOutlineNode.Items Property

Pascal

```
property Items [Index: LongInt]: TOutlineNode;
```

C++

```
__property TOutlineNode Items[LongInt Index];
```

Description

This is Items, a member of class TOutlineNode.

68.1.5.5.9 TOutlineNode.Level Property

Indicates the level of indentation of a node within the outline.

Pascal

```
property Level: Cardinal;
```

C++

```
__property unsigned Level;
```

Description

The value of Level is 1 for nodes that directly descend from the root of the outline (the top level). The value of Level is 2 for their children, and so on.

See Also

ChangeLevelBy (see page 6367)

Parent (see page 6378)

TopItem (see page 6379)

68.1.5.5.10 TOutlineNode.List Property

Pascal

```
property List: TList;
```

C++

```
__property TList List;
```

Description

This is List, a member of class TOutlineNode.

68.1.5.5.11 TOutlineNode.Outline Property

Pascal

```
property Outline: TCustomOutline;
```

C++

```
__property TCustomOutline Outline;
```

Description

This is Outline, a member of class TOutlineNode.

68.1.5.5.12 TOutlineNode.Parent Property

Identifies the immediate ancestor of the node.

Pascal

```
property Parent: TOutlineNode;
```

C++

```
__property TOutlineNode Parent;
```

Description

Read Parent to find the parent of an outline node. A parent node is one level higher and contains the child node as a subnode.

See Also

Level (see page 6377)

TopItem (see page 6379)

68.1.5.5.13 TOutlineNode.Text Property

Specifies the string that identifies the outline node.

Pascal

```
property Text: string;
```

C++

```
__property UnicodeString Text;
```

Description

Use Text to determine the string that is displayed in the outline to represent the node.

See Also

FullPath (see page 6375)

68.1.5.5.14 TOutlineNode.TopItem Property

Indicates which outline node is the topmost ancestor of a node.

Pascal

```
property TopItem: Longint;
```

C++

```
__property Longint TopItem;
```

Description

Read TopItem to determine the first node in the branch of the outline tree that contains the outline node. The TopItem property specifies the Index (see page 6376) value of the level 1 ancestor of the outline node. For a node on level 1, TopItem has the same value as the Index (see page 6376) property.

See Also

Index (see page 6376)

Level (see page 6377)

Parent (see page 6378)

68.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TAttachMode (see page 6380)	TAttachMode indicates how an outline node should be inserted into an outline.
	TOutlineBitmap (see page 6381)	This is record Outline.TOutlineBitmap.
	TOutlineNodeCompare (see page 6381)	This is record Outline.TOutlineNodeCompare.
	TOutlineOption (see page 6382)	TOutlineOptions (see page 6387) represents the style in which an outline is drawn.
	TOutlineStyle (see page 6382)	TOutlineStyle determines how the nodes of an outline are drawn.
	TOutlineType (see page 6383)	TOutlineType indicates whether an outline is owner-drawn.

68.2.1 Outline.TAttachMode Enumeration

TAttachMode indicates how an outline node should be inserted into an outline.

Pascal

```
TAttachMode = (
  oaAdd,
  oaAddChild,
  oaInsert
);
```

C++

```
enum TAttachMode {
  oaAdd,
  oaAddChild,
  oaInsert
};
```

File

Outline

Description

TAttachMode is used by methods that move outline nodes within an outline. It includes the following values:

Value	Description
oaAdd	The item is attached as if added with the Add method. The moved item becomes the last sibling of the item specified by the Destination parameter, sharing the same parent as the Destination item.
oaAddChild	The item is attached as if added with the AddChild method. The moved item becomes the last child of the item specified by the Destination parameter. The Destination item becomes the parent of the moved item.
oaInsert	The item is attached as if inserted with the Insert method. The moved item replaces the Destination item in the outline, while the Destination item and all other following items are moved down one row.

See Also

TCustomOutline

TOutlineNode

68.2.2 Outline.TOutlineBitmap Enumeration

Pascal

```
TOutlineBitmap = (
  obPlus,
  obMinus,
  obOpen,
  obClose,
  obLeaf
);
```

C++

```
enum TOutlineBitmap {
  obPlus,
  obMinus,
  obOpen,
  obClose,
  obLeaf
};
```

File

Outline

Description

This is record Outline.TOutlineBitmap.

68.2.3 Outline.TOutlineNodeCompare Enumeration

Pascal

```
TOutlineNodeCompare = (
  ocLess,
  ocSame,
  ocGreater,
  ocInvalid
);
```

C++

```
enum TOutlineNodeCompare {
  ocLess,
  ocSame,
  ocGreater,
  ocInvalid
};
```

File

Outline

Description

This is record Outline.TOutlineNodeCompare.

68.2.4 Outline.TOutlineOption Enumeration

TOutlineOptions (see page 6387) represents the style in which an outline is drawn.

Pascal

```
TOutlineOption = (
  ooDrawTreeRoot,
  ooDrawFocusRect,
  ooStretchBitmaps
);
```

C++

```
enum TOutlineOption {
  ooDrawTreeRoot,
  ooDrawFocusRect,
  ooStretchBitmaps
};
```

File

Outline

Description

TOutlineOptions (see page 6387) is a set of TOutlineOption values. Together they influence the way an outline is drawn. Each TOutlineOption value is described below:

Value	Meaning
ooDrawTreeRoot	The first item (Index value of 1) is connected to the root item by the outline tree. This means that the tree will extend from the top of the outline to all the first level items. Without ooDrawTreeRoot, all first level items appear leftmost in the outline, not connected by the tree.
ooDrawFocusRect	The outline draws a focus rectangle around the selected item.
ooStretchBitmaps	The outline stretches the standard bitmaps (PictureLeaf, PictureOpen, PictureClosed, PicturePlus, PictureMinus) to fit in the size of the item, determined by the size of the Font of the Text. Without ooStretchBitmaps, the bitmaps will be cropped if larger than the height of the item text, or won't fill up the entire item space if smaller than the text.

See Also

TCustomOutline (see page 6258)

68.2.5 Outline.TOutlineStyle Enumeration

TOutlineStyle determines how the nodes of an outline are drawn.

Pascal

```
TOutlineStyle = (
  osText,
  osPlusMinusText,
  osPictureText,
  osPlusMinusPictureText,
  osTreeText,
  osTreePictureText
);
```

C++

```
enum TOutlineStyle {
  osText,
  osPlusMinusText,
  osPictureText,
  osPlusMinusPictureText,
  osTreeText,
  osTreePictureText
};
```

File

Outline

Description

TOutlineStyle is the type of TCustomOutline (see page 6258).::OutlineStyle. It includes the following values:

Value	Meaning
osText	Only the text of nodes is drawn.
osPlusMinusText	In addition to the text, each node displays plus picture (when it can be expanded) or minus picture (when it can be collapsed).
osPictureText	In addition to the text, each node displays the open picture (when it is expanded), closed picture (when it is collapsed), or leaf picture (when it has no subnodes).
osPlusMinusPictureText	In addition to the text, each node displays the plus picture or minus picture (as in osPlusMinusText), and the open, closed or leaf picture (as in osPictureText).
osTreeText	Visible lines connect the outline nodes.
osTreePictureText	In addition to the text, each node displays the open picture (when it is expanded), closed picture (when it is collapsed), or leaf picture (when it has no subnodes). Visible lines connect the outline nodes.

See Also

TCustomOutline

68.2.6 Outline.TOutlineType Enumeration

TOutlineType indicates whether an outline is owner-drawn.

Pascal

```
TOutlineType = (
  otStandard,
  otOwnerDraw
);
```

C++

```
enum TOutlineType {
  otStandard,
  otOwnerDraw
};
```

File

Outline

Description

TOutlineType determines whether an outline is drawn automatically or by user code in an OnDrawItem event.

Value	Meaning
otStandardItems	Items are drawn automatically.
otOwnerDraw	Items are drawn on the Canvas by application code.

See Also

TCustomOutline

TCustomOutline

68.3 Types

The following table lists types in this documentation.

Types

Name	Description
EOutlineChange (see page 6385)	EOutlineChange is the type of event handlers that respond when the nodes in an outline control change.
TBitmapArray (see page 6385)	This is type Outline.TBitmapArray.
TBitmapArrayRange (see page 6386)	This is type Outline.TBitmapArrayRange.
TChangeRange (see page 6386)	TChangeRange indicates the direction in which a node is moved.
TOutlineBitmaps (see page 6386)	This is type Outline.TOutlineBitmaps.
TOutlineOptions (see page 6387)	TOutlineOptions represents the style in which an outline is drawn.

68.3.1 Outline.EOutlineChange Type

EOutlineChange is the type of event handlers that respond when the nodes in an outline control change.

Pascal

```
EOutlineChange = procedure (Sender: TObject; Index: LongInt) of object;
```

C++

```
(Sender: TObject; Index: LongInt) ( EOutlineChange)();
```

File

Outline

Description

Sender is the outline control whose node just changed.

Index is the index of the node that just changed.

68.3.2 Outline.TBitmapArray Type

Pascal

```
TBitmapArray = array[TBitmapArrayRange] of TBitmap;
```

C++

```
array[TBitmapArrayRange] of TBitmap TBitmapArray;
```

File

Outline

Description

This is type Outline.TBitmapArray.

68.3.3 Outline.TBitmapArrayRange Type

Pascal

```
TBitmapArrayRange = 0..4;
```

C++

```
0..4 TBitmapArrayRange;
```

File

Outline

Description

This is type Outline.TBitmapArrayRange.

68.3.4 Outline.TChangeRange Type

TChangeRange indicates the direction in which a node is moved.

Pascal

```
TChangeRange = -1..1;
```

C++

```
-1..1 TChangeRange;
```

File

Outline

Description

TChangeRange is the type of the Value parameter of an outline node's ChangeLevelBy method. It can take one of the following values:

Value	Meaning
-1	Move the node toward the root by one level.
1	Move the node toward the leaf by one level.

See Also

TOutlineNode (see page 6363)

68.3.5 Outline.TOutlineBitmaps Type

Pascal

```
TOutlineBitmaps = set of TOutlineBitmap;
```

C++

```
TOutlineBitmap TOutlineBitmaps;
```

File

Outline

Description

This is type Outline.TOutlineBitmaps.

68.3.6 Outline.TOutlineOptions Type

TOutlineOptions represents the style in which an outline is drawn.

Pascal

```
TOutlineOptions = set of TOutlineOption;
```

C++

```
TOutlineOption TOutlineOptions;
```

File

Outline

Description

TOutlineOptions is a set of TOutlineOption (see page 6382) values. Together they influence the way an outline is drawn. Each TOutlineOption (see page 6382) value is described below:

Value	Meaning
ooDrawTreeRoot	The first item (Index value of 1) is connected to the root item by the outline tree. This means that the tree will extend from the top of the outline to all the first level items. Without ooDrawTreeRoot, all first level items appear leftmost in the outline, not connected by the tree.
ooDrawFocusRect	The outline draws a focus rectangle around the selected item.
ooStretchBitmaps	The outline stretches the standard bitmaps (PictureLeaf, PictureOpen, PictureClosed, PicturePlus, PictureMinus) to fit in the size of the item, determined by the size of the Font of the Text. Without ooStretchBitmaps, the bitmaps will be cropped if larger than the height of the item text, or won't fill up the entire item space if smaller than the text.

TCustomOutline

69 PagItems Namespace

This is namespace PagItems.

Topics

Name	Description
Classes (see page 6390)	The following table lists classes in this documentation.

Classes

	Name	Description
	TBasePageItemsProducer (see page 6390)	TBasePageItemsProducer produces a string of HTML commands based on an input template.
	TPageItemsProducer (see page 6394)	TPageItemsProducer maintains a list of Web item components for producing a string of HTML commands based on an input template.

69.1 Classes

The following table lists classes in this documentation.

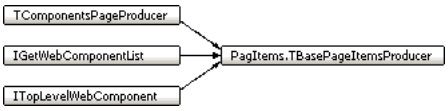
Classes

	Name	Description
	TBasePageItemsProducer (see page 6390)	TBasePageItemsProducer produces a string of HTML commands based on an input template.
	TPageItemsProducer (see page 6394)	TPageItemsProducer maintains a list of Web item components for producing a string of HTML commands based on an input template.

69.1.1 TBasePageItemsProducer Class

TBasePageItemsProducer produces a string of HTML commands based on an input template.

Class Hierarchy



Pascal

```
TBasePageItemsProducer = class(TComponentsPageProducer, IGetWebComponentList,
ITopLevelWebComponent);
```

C++

```
class TBasePageItemsProducer : public TComponentsPageProducer, public IGetWebComponentList,
public ITopLevelWebComponent;
```

File

PagItems

Description

Use TBasePageItemsProducer to convert an HTML template that includes content generated by other components into a string of HTML commands that can be interpreted by a client application such as a Web browser. HTML templates include HTML commands and HTML-transparent tags that are replaced with customized content by the components page producer in an OnHTMLTag event handler.

TBasePageItemsProducer differs from other page producer components in that it replaces special HTML-transparent tags of the format

```
<#COMPONENT Name=WebContentComponent>
```

with the HTML produced by the components named WebContentComponent. In addition, TBasePageItemsProducer stores a default value for WebContentComponent as the value of its WebPageItems (see page 6393) property.

IWebContent

TPageItemsProducer (see page 6394)

TInetXPageProducer (see page 5730)

TAdapterPageProducer

69.1.1.1 TBasePageItemsProducer Members

The following tables list the members exposed by TBasePageItemsProducer.

Protected Methods

	Name	Description
	GetChildren (see page 6392)	This is GetChildren, a member of class TBasePageItemsProducer.
	GetComponentList (see page 6392)	This is GetComponentList, a member of class TBasePageItemsProducer.
	GetDefaultComponentList (see page 6392)	This is GetDefaultComponentList, a member of class TBasePageItemsProducer.
	SetChildOrder (see page 6393)	This is SetChildOrder, a member of class TBasePageItemsProducer.

Public Methods

	Name	Description
	Create (see page 6391)	Creates an instance of a TBasePageItemsProducer (see page 6390).
	Destroy (see page 6391)	Destroys the instance of the TBasePageItemsProducer (see page 6390).

Public Properties

	Name	Description
	WebPageItems (see page 6393)	Maintains a list of components that generate HTML content for the producer.

69.1.1.2 TBasePageItemsProducer.Create Constructor

Creates an instance of a TBasePageItemsProducer (see page 6390).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TBasePageItemsProducer(TComponent * AOwner);
```

Description

Call Create to instantiate a TBasePageItemsProducer (see page 6390) component at runtime if it was not created at design time.

AOwner is the component, typically the Web module, that becomes the value of this page producer's Owner property. The Owner is responsible for freeing the TBasePageItemsProducer (see page 6390) instance.

See Also

Owner

69.1.1.3 TBasePageItemsProducer.Destroy Destructor

Destroys the instance of the TBasePageItemsProducer (see page 6390).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TBasePageItemsProducer();
```

Description

Do not call Destroy directly. Instead call Free, which checks that the TBasePageItemsProducer (see page 6390) reference is not nil before calling Destroy.

See Also

Create (see page 6391)

System::TObject::Free

69.1.1.4 TBasePageItemsProducer Methods

The methods of the TBasePageItemsProducer class are listed here.

Protected Methods

	Name	Description
	GetChildren (see page 6392)	This is GetChildren, a member of class TBasePageItemsProducer.
	GetComponentList (see page 6392)	This is GetComponentList, a member of class TBasePageItemsProducer.
	GetDefaultComponentList (see page 6392)	This is GetDefaultComponentList, a member of class TBasePageItemsProducer.
	SetChildOrder (see page 6393)	This is SetChildOrder, a member of class TBasePageItemsProducer.

69.1.1.4.1 TBasePageItemsProducer.GetChildren Method

Pascal

```
procedure GetChildren(Proc: TGetChildProc; Root: TComponent); override;
```

C++

```
virtual __fastcall GetChildren(TGetChildProc Proc, TComponent * Root);
```

Description

This is GetChildren, a member of class TBasePageItemsProducer.

69.1.1.4.2 TBasePageItemsProducer.GetComponentList Method

Pascal

```
function GetComponentList: TObject;
```

C++

```
__fastcall TObject * GetComponentList();
```

Description

This is GetComponentList, a member of class TBasePageItemsProducer.

69.1.1.4.3 TBasePageItemsProducer.GetDefaultComponentList Method

Pascal

```
function GetDefaultComponentList: TObject;
```

C++

```
__fastcall TObject * GetDefaultComponentList();
```

Description

This is GetDefaultComponentList, a member of class TBasePageItemsProducer.

69.1.1.4.4 TBasePageItemsProducer.SetChildOrder Method

Pascal

```
procedure SetChildOrder(Component: TComponent; Order: Integer); override;
```

C++

```
virtual __fastcall SetChildOrder(TComponent * Component, int Order);
```

Description

This is SetChildOrder, a member of class TBasePageItemsProducer.

69.1.1.5 TBasePageItemsProducer Properties

The properties of the TBasePageItemsProducer class are listed here.

Public Properties

	Name	Description
	WebPageItems (see page 6393)	Maintains a list of components that generate HTML content for the producer.

69.1.1.5.1 TBasePageItemsProducer.WebPageItems Property

Maintains a list of components that generate HTML content for the producer.

Pascal

```
property WebPageItems: TWebComponentList;
```

C++

```
__property TWebComponentList WebPageItems;
```

Description

WebPageItems lists the components that generate content for the page items producer. Each of these components supports the IWebContent interface, and can contain its own list of Web items that help it generate its content.

The type of items that can be added to the WebPageItems list are restricted by a protected method that is abstract or, in C++ terminology, pure virtual in TBasePageItemsProducer (see page 6390). Descendant classes implement this protected method to indicate what types of items can be added to the list.

At design time, use the Web page editor to add components to the WebPageItems property.

Note: Typically, WebPageItems lists all the components that generate content for the page items producer, in the order that the generated content appears in the final HTML document. However, the page items producer can transform COMPONENT tags in its template using components that are not in this list, as long as they have the same owner as the page items producer..

IWebContent

Creating Web Pages with an InternetExpress Page Producer

69.1.2 TPageItemsProducer Class

TPageItemsProducer maintains a list of Web item components for producing a string of HTML commands based on an input template.

Class Hierarchy

Pascal

```
TPageItemsProducer = class(TBasePageItemsProducer);
```

C++

```
class TPageItemsProducer : public TBasePageItemsProducer;
```

File

PagItems

Description

Use TPageItemsProducer as the base class for components that convert an HTML template that includes content generated by other components into a string of HTML commands that can be interpreted by a client application such as a Web browser. HTML templates include HTML commands and HTML-transparent tags that are replaced with customized content by the page items producer in an OnHTMLTag event handler.

Page item producers differ from other page producer components in that they replace special HTML-transparent tags of the format

```
<#COMPONENT Name=WebContentComponent>
```

with the HTML produced by the component named WebContentComponent. WebContentComponent must have the same Owner as the page item producer and support the IWebContent interface, which the page item producer uses to obtain the replacement HTML for the COMPONENT tag.

TPageItemsProducer introduces the WebPageItems (see page 6393) property to maintain a hierarchical list of these Web content components, where each component produces content for its parent component.

69.1.2.1 TPageItemsProducer Members

The following tables list the members exposed by TPageItemsProducer.

Protected Methods

	Name	Description
	GetChildren (see page 6392)	This is GetChildren, a member of class TBasePageItemsProducer.
	GetComponentList (see page 6392)	This is GetComponentList, a member of class TBasePageItemsProducer.
	GetDefaultComponentList (see page 6392)	This is GetDefaultComponentList, a member of class TBasePageItemsProducer.

	GetTemplateStream (see page 6396)	This is GetTemplateStream, a member of class TPageItemsProducer.
	SetChildOrder (see page 6393)	This is SetChildOrder, a member of class TBasePageItemsProducer.

Public Methods

	Name	Description
	Create (see page 6395)	Creates and initializes an instance of TPageItemsProducer (see page 6394).
	Destroy (see page 6395)	Frees an instance of TPageItemsProducer (see page 6394).

Public Properties

	Name	Description
	HTMLDoc (see page 6396)	Specifies the HTML template used to generate the value returned by the Content method.
	HTMLFile (see page 6397)	Specifies the name of a file that contains the HTML template used to generate the value returned by the Content method.
	WebPageItems (see page 6393)	Maintains a list of components that generate HTML content for the producer.

69.1.2.2 TPageItemsProducer.Create Constructor

Creates and initializes an instance of TPageItemsProducer (see page 6394).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TPageItemsProducer(TComponent * AOwner);
```

Description

Call Create to instantiate a page items producer at runtime.

69.1.2.3 TPageItemsProducer.Destroy Destructor

Frees an instance of TPageItemsProducer (see page 6394).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TPageItemsProducer();
```

Description

Do not call Destroy directly. Instead, call the Free method, which checks whether the TPageItemsProducer (see page 6394) reference is not nil before calling Destroy.

See Also

System::TObject::Free

69.1.2.4 TPageItemsProducer Methods

The methods of the TPageItemsProducer class are listed here.

Protected Methods

	Name	Description
	GetTemplateStream (see page 6396)	This is GetTemplateStream, a member of class TPageItemsProducer.

69.1.2.4.1 TPageItemsProducer.GetTemplateStream Method

Pascal

```
function GetTemplateStream(out AOwned: Boolean): TStream; override;
```

C++

```
virtual __fastcall TStream GetTemplateStream(Boolean AOwned);
```

Description

This is GetTemplateStream, a member of class TPageItemsProducer.

69.1.2.5 TPageItemsProducer Properties

The properties of the TPageItemsProducer class are listed here.

Public Properties

	Name	Description
	HTMLDoc (see page 6396)	Specifies the HTML template used to generate the value returned by the Content method.
	HTMLFile (see page 6397)	Specifies the name of a file that contains the HTML template used to generate the value returned by the Content method.

69.1.2.5.1 TPageItemsProducer.HTMLDoc Property

Specifies the HTML template used to generate the value returned by the Content method.

Pascal

```
property HTMLDoc: TStrings;
```

C++

```
__property TStrings HTMLDoc;
```

Description

Set HTMLDoc to a set of strings that make up the HTML template. Each string is a sequence of one or more HTML commands or HTML-transparent tags. An HTML-transparent tag has the form

```
<#TagName Param1=Value1 Param2=Value2 ...>
```

A pound sign (#) immediately follows the opening angle bracket (<) with no spaces separating it from the angle bracket. The pound sign identifies the string to the page producer as an HTML-transparent tag. The tag name immediately follows the pound sign with no spaces separating it from the pound sign. The page producer converts the entire HTML-transparent tag into true HTML commands based on the value of the tag name. Following the tag name, the HTML-transparent tag can optionally include parameters that specify details of the conversion to be performed. Each parameter is of the form ParamName=Value, where there is no space between the parameter name, the equals symbol (=) and the value. Each parameter is delimited by white space.

The angle brackets (< >) make the tag transparent to HTML browsers that do not recognize the #TagName construct.

Note: Setting HTMLDoc clears the HTMLFile (see page 6397) property.

See Also

Content (see page 3466)

HTMLFile (see page 6397)

69.1.2.5.2 TPageItemsProducer.HTMLFile Property

Specifies the name of a file that contains the HTML template used to generate the value returned by the Content method.

Pascal

```
property HTMLFile: TFileName;
```

C++

```
__property TFileName HTMLFile;
```

Description

Set HTMLFile to the name of the file that contains an HTML template. The HTML template is a sequence of HTML commands and HTML-transparent tags. An HTML-transparent tag has the form

```
<#TagName Param1=Value1 Param2=Value2 ...>
```

A pound sign (#) immediately follows the opening angle bracket (<) with no spaces separating it from the angle bracket. The pound sign identifies the string to the page producer as an HTML-transparent tag. The tag name immediately follows the pound sign with no spaces separating it from the pound sign. The page producer converts the entire HTML-transparent tag into true HTML commands based on the value of the tag name. Following the tag name, the HTML-transparent tag can optionally include parameters that specify details of the conversion to be performed. Each parameter is of the form ParamName=Value, where there is no space between the parameter name, the equals symbol (=) and the value. Each parameter is delimited by white space.

The angle brackets (< >) make the tag transparent to HTML browsers that do not recognize the #TagName construct.

Note: Setting HTMLFile clears the HTMLDoc (see page 6396) property.

Note: When distributing applications that contain page producers which use the HTMLFile property, be sure to distribute the file along with the application. Also, be sure that the value of HTMLFile does not include a hard-coded path name that will not be available on the user's disk.

70 PlatformDefaultStyleActnCtrls Namespace

This is namespace PlatformDefaultStyleActnCtrls.

Topics

Name	Description
Classes (see page 6400)	The following table lists classes in this documentation.
Variables (see page 6403)	The following table lists variables in this documentation.

Classes

	Name	Description
	TPlatformDefaultStyleActionBars (see page 6400)	This is class PlatformDefaultStyleActnCtrls.TPlatformDefaultStyleActionBars.

Variables

Name	Description
PlatformDefaultStyle (see page 6403)	This is variable PlatformDefaultStyleActnCtrls.PlatformDefaultStyle.

70.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TPlatformDefaultStyleActionBars (see page 6400)	This is class PlatformDefaultStyleActnCtrls.TPlatformDefaultStyleActionBars.

70.1.1 TPlatformDefaultStyleActionBars Class

Class Hierarchy

Pascal

```
TPlatformDefaultStyleActionBars = class(TActionBarStyleEx);
```

C++

```
class TPlatformDefaultStyleActionBars : public TActionBarStyleEx;
```

File

PlatformDefaultStyleActnCtrls

Description

This is class PlatformDefaultStyleActnCtrls.TPlatformDefaultStyleActionBars.

70.1.1.1 TPlatformDefaultStyleActionBars Members

The following tables list the members exposed by TPlatformDefaultStyleActionBars.

Public Methods

	Name	Description
	GetAddRemoveItemClass (see page 6401)	Returns the base class for ActionBand menus for customizing action bands.
	GetColorMapClass (see page 6401)	Returns the class type of the colormap for an action bar.
	GetControlClass (see page 6401)	Returns the control class type on an action bar item.
	GetPopupClass (see page 6402)	Returns the popup class added to a menu action band.
	GetScrollBtnClass (see page 6402)	This is GetScrollBtnClass, a member of class TPlatformDefaultStyleActionBars.
	GetStyleName (see page 6402)	Returns the style associated with action manager.

70.1.1.2 TPlatformDefaultStyleActionBars Methods

The methods of the TPlatformDefaultStyleActionBars class are listed here.

Public Methods

	Name	Description
	GetAddRemoveItemClass (see page 6401)	Returns the base class for ActionBand menus for customizing action bands.

	GetColorMapClass (see page 6401)	Returns the class type of the colormap for an action bar.
	GetControlClass (see page 6401)	Returns the control class type on an action bar item.
	GetPopupClass (see page 6402)	Returns the popup class added to a menu action band.
	GetScrollBtnClass (see page 6402)	This is GetScrollBtnClass, a member of class TPlatformDefaultStyleActionBars.
	GetStyleName (see page 6402)	Returns the style associated with action manager.

70.1.1.2.1 TPlatformDefaultStyleActionBars.GetAddRemoveItemClass Method

Returns the base class for ActionBand menus for customizing action bands.

Pascal

```
function GetAddRemoveItemClass(ActionBar: TCustomActionBar): TCustomAddRemoveItemClass;
override;
```

C++

```
virtual __fastcall TCustomAddRemoveItemClass GetAddRemoveItemClass(TCustomActionBar ActionBar);
```

Description

Call GetAddRemoveItemClass to customize action bands.

See Also

TCustomAddRemoveItem

70.1.1.2.2 TPlatformDefaultStyleActionBars.GetColorMapClass Method

Returns the class type of the colormap for an action bar.

Pascal

```
function GetColorMapClass(ActionBar: TCustomActionBar): TCustomColorMapClass; override;
```

C++

```
virtual __fastcall TCustomColorMapClass GetColorMapClass(TCustomActionBar ActionBar);
```

Description

Returns the class type TCustomActionBarColorMap, which is a colormap associated with an action bar. Override this method to customize the appearance of your applications.

70.1.1.2.3 TPlatformDefaultStyleActionBars.GetControlClass Method

Returns the control class type on an action bar item.

Pascal

```
function GetControlClass(ActionBar: TCustomActionBar; AnItem: TActionClientItem):
TCustomActionControlClass; override;
```

C++

```
virtual __fastcall TCustomActionControlClass GetControlClass(TCustomActionBar ActionBar,
TActionClientItem AnItem);
```

Description

Returns the control class type on an item in the action bar, such as a button or menu item.

70.1.1.2.4 TPlatformDefaultStyleActionBars.GetPopupClass Method

Returns the popup class added to a menu action band.

Pascal

```
function GetPopupClass(ActionBar: TCustomActionBar): TCustomPopupClass; override;
```

C++

```
virtual __fastcall TCustomPopupClass GetPopupClass(TCustomActionBar ActionBar);
```

Description

Call GetPopupClass to find the popup menu associated with a menu action band. Override GetPopupClass to change which popup class is associated with a menu action band depending on the state of the control.

See Also

TCustomActionPopupMenu

70.1.1.2.5 TPlatformDefaultStyleActionBars.GetScrollBtnClass Method

Pascal

```
function GetScrollBtnClass: TCustomToolScrollBtnClass; override;
```

C++

```
virtual __fastcall TCustomToolScrollBtnClass GetScrollBtnClass();
```

Description

This is GetScrollBtnClass, a member of class TPlatformDefaultStyleActionBars.

70.1.1.2.6 TPlatformDefaultStyleActionBars.GetStyleName Method

Returns the style associated with action manager.

Pascal

```
function GetStyleName: string; override;
```

C++

```
virtual __fastcall UnicodeString GetStyleName();
```

Description

Returns the value of the Style property.

70.2 Variables

The following table lists variables in this documentation.

Variables

Name	Description
PlatformDefaultStyle (see page 6403)	This is variable PlatformDefaultStyleActnCtrls.PlatformDefaultStyle.

70.2.1 PlatformDefaultStyleActnCtrls.PlatformDefaultStyle Variable

Pascal

```
PlatformDefaultStyle: TPlatformDefaultStyleActionBars;
```

C++

```
TPlatformDefaultStyleActionBars PlatformDefaultStyle;
```

File

PlatformDefaultStyleActnCtrls

Description

This is variable PlatformDefaultStyleActnCtrls.PlatformDefaultStyle.

71 Printers Namespace

This is namespace Printers.

Topics

Name	Description
Classes (see page 6406)	The following table lists classes in this documentation.
Functions (see page 6434)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 6438)	The following table lists structs, records, enums in this documentation.
Types (see page 6440)	The following table lists types in this documentation.

Classes

	Name	Description
	EPrinter (see page 6406)	EPrinter is the exception class for printing errors.
	TPrinter (see page 6406)	TPrinter encapsulates the Windows printer interface.

Functions

	Name	Description
	AssignPrn (see page 6434)	Assigns a text file variable to the printer.
	Printer (see page 6434)	Returns a global instance of TPrinter (see page 6406) to manage interaction with the printer.
	SetPrinter (see page 6436)	Replaces the global instance of TPrinter (see page 6406) that manages interaction with the printer.

Structs, Records, Enums

	Name	Description
	TPrinterCapability (see page 6438)	TPrinterCapability and TPrinterCapabilities (see page 6440) specify the capabilities of a printer device driver.
	TPrinterOrientation (see page 6438)	TPrinterOrientation indicates the orientation of pages when printing.
	TPrinterState (see page 6439)	This is record Printers.TPrinterState.

Types

Name	Description
TPrinterCapabilities (see page 6440)	This is type Printers.TPrinterCapabilities.

71.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EPrinter (see page 6406)	EPrinter is the exception class for printing errors.
	TPrinter (see page 6406)	TPrinter encapsulates the Windows printer interface.

71.1.1 EPrinter Class

EPrinter is the exception class for printing errors.

Class Hierarchy

Pascal

```
EPrinter = class(Exception);
```

C++

```
class EPrinter : public Exception;
```

File

Printers

Description

EPrinter is raised when a printing error occurs. For example, if an application attempts to use a printer that doesn't exist, or if a job can't be sent to the printer for some other reason, an EPrinter exception is raised.

See Also

TPrinter (see page 6406)

71.1.2 TPrinter Class

TPrinter encapsulates the Windows printer interface.

Class Hierarchy

Pascal

```
TPrinter = class(TObject);
```

C++

```
class TPrinter : public TObject;
```

File

Printers

Description

Use TPrinter to manage any printing performed by an application. Obtain an instance of TPrinter by calling the Printer (see page 6434) function in the Printers (see page 6430) unit.

To determine how the printed image of the form appears, use the PrintScale property of a TForm (see page 2241) component.

A print job is started by a call to BeginDoc (see page 6411). The application sends commands by rendering through a Text variable or the printer's canvas. You can move to a new page by calling the NewPage (see page 6415) method. The job stays open until the application calls EndDoc (see page 6413). If a problem occurs and you need to terminate a print job that was not sent to the printer successfully, call the Abort (see page 6409) method.

Use the TPrinter properties to configure the print job. For example, the title displayed in the Print Manager (and on network header pages) is determined by the Title (see page 6433) property. Copies (see page 6422) determines the number of copies to print, and Orientation (see page 6424) lets you specify whether to print in portrait or landscape mode.

TPrinter includes several read-only properties as well, that let you determine which page is currently being printed, the fonts available on the printer, the paper size, and so on.

When creating a TPrinter descendant, you must call the SetPrinter (see page 6418) routine in order for the TPrinter descendant object to work correctly.

See Also

Printer (see page 6434)

TCustomForm (see page 2103)

SetPrinter Routine

71.1.2.1 TPrinter Members

The following tables list the members exposed by TPrinter.

Public Methods

	Name	Description
	Abort (see page 6409)	Terminates the printing of a print job, dropping all unprinted data.
	BeginDoc (see page 6411)	Sends a print job to the printer.
	Create (see page 6408)	Creates a printer.
V	Destroy (see page 6408)	Destroys an instance of a printer.
	EndDoc (see page 6413)	Ends the current print job and closes the text file variable.
	GetPrinter (see page 6415)	Retrieves information about the current printer.
	NewPage (see page 6415)	Starts a new page and increments the PageNumber (see page 6427) property.
	Refresh (see page 6417)	Updates the Fonts (see page 6422) and Printers (see page 6430) properties.
	SetPrinter (see page 6418)	Specifies the current printer.

Public Properties

	Name	Description
R	Aborted (see page 6419)	Determines if the user aborted the print job.
R	Canvas (see page 6421)	Represents the surface of the currently printing page.
R	Capabilities (see page 6421)	Indicates the current settings of a printer device driver.
	Copies (see page 6422)	Specifies the number of copies to print.
R	Fonts (see page 6422)	Lists the fonts supported by the current printer.

R	Handle (see page 6422)	Provides access to the handle of the printer object.
	Orientation (see page 6424)	Determines if the print job prints vertically or horizontally on a page.
R	PageHeight (see page 6425)	Indicates the height (in pixels) of the currently printing page.
R	PageNumber (see page 6427)	Indicates the number of the page currently printing.
R	PageWidth (see page 6428)	Indicates the value of width (in pixels) of the currently printing page.
	PrinterIndex (see page 6430)	Specifies which printer listed in the Printers (see page 6430) property is the currently selected printer.
R	Printers (see page 6430)	Lists all printers installed in Windows.
R	Printing (see page 6430)	Indicates whether a print job is printing.
	Title (see page 6433)	Determines the text that is listed in the Print Manager and on network header pages.

71.1.2.2 TPrinter.Create Constructor

Creates a printer.

Pascal

```
constructor Create;
```

C++

```
__fastcall TPrinter();
```

Description

Never call Create directly. Create is called automatically by the Printer (see page 6434) function. Create allocates memory for a printer and calls the inherited Create. Then it sets the correct driver, device, and port.

See Also

System::TObject::Create

71.1.2.3 TPrinter.Destroy Destructor

Destroys an instance of a printer.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TPrinter();
```

Description

Do not call Destroy directly. The printer object is automatically created and destroyed.

When Destroy is called, it verifies that any currently printing job has ended, then frees resources such as the handle, fonts, and canvas, closes the printer, and calls the inherited Destroy method.

See Also

System::TObject::Destroy

System::TObject::Free

71.1.2.4 TPrinter Methods

The methods of the TPrinter class are listed here.

Public Methods

	Name	Description
	Abort (see page 6409)	Terminates the printing of a print job, dropping all unprinted data.
	BeginDoc (see page 6411)	Sends a print job to the printer.
	EndDoc (see page 6413)	Ends the current print job and closes the text file variable.
	GetPrinter (see page 6415)	Retrieves information about the current printer.
	NewPage (see page 6415)	Starts a new page and increments the PageNumber (see page 6427) property.
	Refresh (see page 6417)	Updates the Fonts (see page 6422) and Printers (see page 6430) properties.
	SetPrinter (see page 6418)	Specifies the current printer.

71.1.2.4.1 TPrinter.Abort Method

Terminates the printing of a print job, dropping all unprinted data.

Pascal

```
procedure Abort;
```

C++

```
__fastcall Abort();
```

Description

Use Abort to terminate the print job before it completes; otherwise, use the EndDoc (see page 6413) method.

When Abort is called, the device is then set for the next print job.

C++ Examples:

```
/*
The following code aborts a print job if the user presses
Esc. Note that you should set KeyPreview to true to ensure
that the OnKeyDown event handler of Form1 is called.
*/
#include <Printers.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
   KeyPreview = True;

}

void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key, TShiftState Shift)

{
  if (Key == VK_ESCAPE && Printer()->Printing)
  {
    Printer()->Abort();
    MessageDlg("Printing aborted", mtInformation,
               TMsgDlgButtons() << mbOK,0);
  }
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TMemo *Memo1 = new TMemo(Form1); // The parent (Form1) will clean up this object.
  Memo1->Parent = Form1;
  Memo1->Visible = True;
  Memo1->Width = 700;
  if (OpenDialog1->Execute())
  {
    Memo1->Lines->LoadFromFile(OpenDialog1->FileName);
```

```
    Printer()->BeginDoc();
    int X = 200;
    int Y = 200;
    for (int I = 0; I <= 10; I++)
      if (!Printer()->Aborted)
      {
        Printer()->Canvas->TextOut(X, Y, Memo1->Lines->Strings[I]);
        Y = Y + 80;
        if (Y > (Printer()->PageHeight - 300))
        {
          Y = 200;
          Printer()->NewPage();
          Sleep(1000);  // to give you time to abort!
        }
      }
    if (!Printer()->Aborted) Printer()->EndDoc();
  }
}
```

Delphi Examples:

```
{
The following code aborts a print job if the user presses
Esc. Note that you should set KeyPreview to true to ensure
that the OnKeyDown event handler of Form1 is called.
}

uses Printers;

procedure TForm1.Button1Click(Sender: TObject);
var
  I, X, Y: Integer;
  Memo1 : TMemo;
  r: TRect;
begin
  Memo1 := TMemo.Create(Form1);
  Memo1.Parent := Form1;
  Memo1.Visible := True;
  Memo1.Width := 700;
  if (OpenDialog1.Execute) then
  begin
    Memo1.Lines.LoadFromFile(OpenDialog1.FileName);

    Printer.BeginDoc;

71.1.2.4.2 TPrinter.BeginDoc Method

Sends a print job to the printer.

Pascal

```
procedure BeginDoc;
```

C++

```
__fastcall BeginDoc();
```

Description

Call BeginDoc to initiate a print job. If the print job is sent successfully, the application calls EndDoc (see page 6413) to end the print job. The print job won't actually start printing until EndDoc (see page 6413) is called.

C++ Examples:

```
{
This example uses a button, a Page Control, and a Print
dialog box on a form. When the user clicks the button, the
print dialog is displayed.  The user can select any subset
of the pages in the page control for printing.  The selected
pages are then printed.  To run this example successfully,
you must add the Printers unit to the uses clause of your
unit.  Right click on the PageControl to add at least one
page to the PageControl.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  PrintDialog1->Options.Clear();
  PrintDialog1->Options << poPageNums << poSelection;
  PrintDialog1->FromPage = 1;
  PrintDialog1->MinPage = 1;
  PrintDialog1->ToPage = PageControl1->PageCount;
  PrintDialog1->MaxPage = PageControl1->PageCount;
  if (PrintDialog1->Execute())
  {
    int Start, Stop;
    // determine the range the user wants to print
    switch (PrintDialog1->PrintRange)
    {
      case prSelection:
        Start = PageControl1->ActivePage->PageIndex;
        Stop = Start;
        break;
```

```
      case prPageNums:
        Start = PrintDialog1->FromPage - 1;
        Stop =  PrintDialog1->ToPage - 1;
        break;
      default:  // prAllPages
        Start = PrintDialog1->MinPage - 1;
        Stop = PrintDialog1->MaxPage - 1;
        break;
    }
    // now, print the pages
    Printer()->BeginDoc();
    for (int i = Start; i <= Stop; i++)
    {
      PageControl1->Pages[i]->PaintTo(Printer()->Handle, 10, 10);
      if (i != Stop)
        Printer()->NewPage();
    }
    Printer()->EndDoc();
  }
}
```

Delphi Examples:

Abort (see page 6409)

EndDoc (see page 6413)

Printing (see page 6430)

71.1.2.4.3 TPrinter.EndDoc Method

Ends the current print job and closes the text file variable.

Pascal

```
procedure EndDoc;
```

C++

```
__fastcall EndDoc();
```

Description

EndDoc terminates the print job (and closes the currently open Text). The print job will begin printing on the printer after a call to EndDoc.

After the application calls EndDoc, the printer begins printing. Use EndDoc after successfully sending a print job to the printer. If the print job isn't successful, use the Abort (see page 6409) method.

C++ Examples:

```
{
This example uses a button, a Page Control, and a Print
dialog box on a form. When the user clicks the button, the
print dialog is displayed.  The user can select any subset
of the pages in the page control for printing.  The selected
pages are then printed.  To run this example successfully,
you must add the Printers unit to the uses clause of your
unit.  Right click on the PageControl to add at least one
page to the PageControl.
*/

71.1.2.4.4 TPrinter.GetPrinter Method

Retrieves information about the current printer.

Pascal

```
procedure GetPrinter(ADevice: PChar; ADriver: PChar; APort: PChar; var ADeviceMode: THandle);
```

C++

```
__fastcall GetPrinter(const char * ADevice, const char * ADriver, const char * APort, THandle
ADeviceMode);
```

Description

Call GetPrinter to obtain information about the current printer.

ADevice is a buffer that receives the device name of the current printer. This is the name that appears in the Print Manager (for example, "Epson FX-80"). It is not the printer model name.

ADriver is a buffer that receives the driver name for the current printer. Some versions of Windows do not use printer driver names, in which case this buffer is unused. On versions of Windows that support printer driver names, this is the name of a printer driver (usually 'WINSPOOL').

APort is a buffer that receives the port used by the current printer. It is not used on 32-bit versions of Windows, but is included for backward compatibility.

DeviceMode returns the handle to a memory buffer containing device-specific initialization data for the device driver. Use the GlobalLock function to convert this handle into a pointer to a DeviceMode record (Delphi) or DEVMODE structure (C++).

See Also

Printers (see page 6430)

71.1.2.4.5 TPrinter.NewPage Method

Starts a new page and increments the PageNumber (see page 6427) property.

Pascal

```
procedure NewPage;
```

C++

```
__fastcall NewPage();
```

Description

NewPage forces the current print job to begin printing on a new page in the printer.

NewPage increments the value of the PageNumber (see page 6427) property. It also resets the value of the Pen property of the Canvas (see page 6421) back to (0, 0).

C++ Examples:

```
{
This example uses a button, a Page Control, and a Print
dialog box on a form. When the user clicks the button, the
print dialog is displayed.  The user can select any subset
of the pages in the page control for printing.  The selected
pages are then printed.  To run this example successfully,
you must add the Printers unit to the uses clause of your
unit.  Right click on the PageControl to add at least one
page to the PageControl.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  PrintDialog1->Options.Clear();
  PrintDialog1->Options << poPageNums << poSelection;
  PrintDialog1->FromPage = 1;
  PrintDialog1->MinPage = 1;
  PrintDialog1->ToPage = PageControl1->PageCount;
  PrintDialog1->MaxPage = PageControl1->PageCount;
  if (PrintDialog1->Execute())
  {
    int Start, Stop;
    // determine the range the user wants to print
    switch (PrintDialog1->PrintRange)
    {
      case prSelection:
        Start = PageControl1->ActivePage->PageIndex;
        Stop = Start;
        break;
      case prPageNums:
        Start = PrintDialog1->FromPage - 1;
        Stop =  PrintDialog1->ToPage - 1;
        break;
      default:  // prAllPages
        Start = PrintDialog1->MinPage - 1;
        Stop = PrintDialog1->MaxPage - 1;
        break;
    }
    // now, print the pages
    Printer()->BeginDoc();
    for (int i = Start; i <= Stop; i++)
    {
      PageControl1->Pages[i]->PaintTo(Printer()->Handle, 10, 10);
      if (i != Stop)
        Printer()->NewPage();
    }
    Printer()->EndDoc();
  }
}
```

Delphi Examples:

```
{
This example uses a button, a Page Control, and a Print
dialog box on a form. When the user clicks the button, the
```

```
  print dialog is displayed.  The user can select any subset
  of the pages in the page control for printing.  The selected
  pages are then printed.  To run this example successfully,
  you must add the Printers unit to the uses clause of your
  unit.  Right click on the PageControl to add at least one
  page to the PageControl.
  }
  procedure TForm1.Button1Click(Sender:TObject);
  var
    I, Start, Stop: Integer;
  begin
  PrintDialog1.Options := [poPageNums, poSelection];
  PrintDialog1.FromPage := 1;
  PrintDialog1.MinPage := 1;
  PrintDialog1.ToPage := PageControl1.PageCount;
  PrintDialog1.MaxPage := PageControl1.PageCount;

  if PrintDialog1.Execute() then
    begin
      { determine the range the user wants to print }
      with PrintDialog1 do
      begin
        if PrintRange = prAllPages then
          begin
          Start := MinPage - 1;
          Stop := MaxPage - 1;
        end
        else if PrintRange = prSelection then
        begin
          Start := PageControl1.ActivePage.PageIndex;
          Stop := Start;
          end
        else  { PrintRange = prPageNums }
        begin
          Start := FromPage - 1;
          Stop := ToPage - 1;
        end;
      end;
      { now, print the pages }
      with Printer do
      begin
        BeginDoc;
        for I := Start to Stop do
        begin
          PageControl1.Pages[I].PaintTo(Handle, 10, 10);
          if I <> Stop then
            NewPage;
        end;
        EndDoc;
      end;
    end;
  end;
```

See Also

PageNumber (see page 6427)

71.1.2.4.6 TPrinter.Refresh Method

Updates the Fonts (see page 6422) and Printers (see page 6430) properties.

Pascal

```
procedure Refresh;
```

C++

```
__fastcall Refresh();
```

Description

Call Refresh when the installed fonts or printers on the current system may have changed. Refresh clears the internal cache of installed fonts and printers, so that the Fonts (see page 6422) and Printers (see page 6430) properties are updated when they are next read.

See Also

Fonts (see page 6422)

Printers (see page 6430)

71.1.2.4.7 TPrinter.SetPrinter Method

Specifies the current printer.

Pascal

```
procedure SetPrinter(ADevice: PChar; ADriver: PChar; APort: PChar; ADeviceMode: THandle);
```

C++

```
__fastcall SetPrinter(const char * ADevice, const char * ADriver, const char * APort, THandle
ADeviceMode);
```

Description

Call SetPrinter to change the current printer.

ADevice specifies the device name of the new printer. This is the name that appears in the Print Manager (for example, "Epson FX-80"). It is not the printer model name.

ADriver specifies the driver name for the new printer (usually 'WINSPOOL').

APort is included for backward compatibility. It should be set to an empty string.

DeviceMode is the handle to a memory buffer device-specific initialization data for the device driver. This handle can be obtained by calling the GlobalAlloc function to allocate a DeviceMode record (Delphi) or DEVMODE structure (C++).

See Also

Printers (see page 6430)

71.1.2.5 TPrinter Properties

The properties of the TPrinter class are listed here.

Public Properties

	Name	Description
R	Aborted (see page 6419)	Determines if the user aborted the print job.
R	Canvas (see page 6421)	Represents the surface of the currently printing page.
R	Capabilities (see page 6421)	Indicates the current settings of a printer device driver.
	Copies (see page 6422)	Specifies the number of copies to print.
R	Fonts (see page 6422)	Lists the fonts supported by the current printer.
R	Handle (see page 6422)	Provides access to the handle of the printer object.
	Orientation (see page 6424)	Determines if the print job prints vertically or horizontally on a page.
R	PageHeight (see page 6425)	Indicates the height (in pixels) of the currently printing page.

R	PageNumber (see page 6427)	Indicates the number of the page currently printing.
R	PageWidth (see page 6428)	Indicates the value of width (in pixels) of the currently printing page.
	PrinterIndex (see page 6430)	Specifies which printer listed in the Printers (see page 6430) property is the currently selected printer.
R	Printers (see page 6430)	Lists all printers installed in Windows.
R	Printing (see page 6430)	Indicates whether a print job is printing.
	Title (see page 6433)	Determines the text that is listed in the Print Manager and on network header pages.

71.1.2.5.1 TPrinter.Aborted Property

Determines if the user aborted the print job.

Pascal

```
property Aborted: Boolean;
```

C++

```
__property Boolean Aborted;
```

Description

If Aborted is true, the print job was aborted. If it is false, the user did not abort the print job.

The Abort (see page 6409) method sets the Aborted property to true.

C++ Examples:

```
/*
The following code displays a dialog box if the print job
was aborted.  This code aborts a print job if the user
presses Esc. Note that you should set KeyPreview to true
to ensure that the OnKeyDown event handler of Form1 is called.
Also notice that the Button1Click routine continues to run
even after the print job has been aborted.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TMemo *Memo1 = new TMemo(Form1); // The parent (Form1) will clean up this object.
  Memo1->Parent = Form1;
  Memo1->Visible = True;
  Memo1->Width = 700;
  if (OpenDialog1->Execute())
  {
    Memo1->Lines->LoadFromFile(OpenDialog1->FileName);

    Printer()->BeginDoc();
    int X = 200;
    int Y = 200;
    for (int I = 0; I <= 140; I++)
      if (!Printer()->Aborted)
      {
        Printer()->Canvas->TextOut(X, Y, Memo1->Lines->Strings[I]);
        Y = Y + 80;
        if (Y > (Printer()->PageHeight - 300))
        {
          Y = 200;
          Printer()->NewPage();
          Sleep(1000);  // to give you time to abort!
        }
      }
    if (!Printer()->Aborted) Printer()->EndDoc();
  }
  if (Printer()->Aborted)
    MessageDlg(
```

```
      "The print job did not finish printing",
      mtInformation, TMsgDlgButtons() << mbOK, 0);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  KeyPreview = True;
}

void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key, TShiftState Shift)

{
  if (Key == VK_ESCAPE && Printer()->Printing)
  {
    Printer()->Abort();
    MessageDlg("Printing aborted", mtInformation,
               TMsgDlgButtons() << mbOK,0);
  }

}
```

Delphi Examples:

```
{
The following code displays a dialog box if the print job
was aborted.  This code aborts a print job if the user
presses Esc. Note that you should set KeyPreview to true
to ensure that the OnKeyDown event handler of Form1 is called.
Also notice that the Button1Click routine continues to run
even after the print job has been aborted.
}

if (Key=VK_ESCAPE) and Printer.Printing then
  begin
  Printer.Abort;
//  MessageDlg('Printing aborted', mtInformation, [mbOK],0);
  end;
end;
```

See Also

Abort (see page 6409)

71.1.2.5.2 TPrinter.Canvas Property

Represents the surface of the currently printing page.

Pascal

```
property Canvas: TCanvas;
```

C++

```
__property TCanvas Canvas;
```

Description

Canvas represents the printing surface of a page. Use the Brush, Font, and Pen properties of the Canvas object to determine how drawing or text appears on the page.

Note:

See Also

Brush (see page 2716)

CopyRect (see page 2683)

Draw (see page 2685)

Font (see page 2721)

Pen (see page 2725)

StretchDraw (see page 2704)

Handle (see page 2722)

71.1.2.5.3 TPrinter.Capabilities Property

Indicates the current settings of a printer device driver.

Pascal

```
property Capabilities: TPrinterCapabilities;
```

C++

```
__property TPrinterCapabilities Capabilities;
```

Description

Capabilities contains the capabilities for the printer, indicating the orientation, number of copies, and whether or not collated is selected.

71.1.2.5.4 TPrinter.Copies Property

Specifies the number of copies to print.

Pascal

```
property Copies: Integer;
```

C++

```
__property int Copies;
```

Description

Set Copies to indicate the number of copies to print.

Copies uses the device mode to determine the number of copies to print.

71.1.2.5.5 TPrinter.Fonts Property

Lists the fonts supported by the current printer.

Pascal

```
property Fonts: TStrings;
```

C++

```
__property TStrings Fonts;
```

Description

Read Fonts to get a list of the fonts supported by the printer. Each string in Fonts is the name of a typeface.

Fonts contains TrueType fonts even if the printer doesn't support them natively because the Windows Graphics (see page 2619) Device Interface (GDI) can draw TrueType fonts accurately when a print job uses them.

See Also

Name (see page 2743)

71.1.2.5.6 TPrinter.Handle Property

Provides access to the handle of the printer object.

Pascal

```
property Handle: HDC;
```

C++

```
__property HDC Handle;
```

Description

Use Handle to gain access to the handle of the printer object.

C++ Examples:

```
{
This example uses a button, a Page Control, and a Print
```

```
dialog box on a form. When the user clicks the button, the
print dialog is displayed.  The user can select any subset
of the pages in the page control for printing.  The selected
pages are then printed.  To run this example successfully,
you must add the Printers unit to the uses clause of your
unit.  Right click on the PageControl to add at least one
page to the PageControl.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  PrintDialog1->Options.Clear();
  PrintDialog1->Options << poPageNums << poSelection;
  PrintDialog1->FromPage = 1;
  PrintDialog1->MinPage = 1;
  PrintDialog1->ToPage = PageControl1->PageCount;
  PrintDialog1->MaxPage = PageControl1->PageCount;
  if (PrintDialog1->Execute())
  {
    int Start, Stop;
    // determine the range the user wants to print
    switch (PrintDialog1->PrintRange)
    {
      case prSelection:
        Start = PageControl1->ActivePage->PageIndex;
        Stop = Start;
        break;
      case prPageNums:
        Start = PrintDialog1->FromPage - 1;
        Stop =  PrintDialog1->ToPage - 1;
        break;
      default:  // prAllPages
        Start = PrintDialog1->MinPage - 1;
        Stop = PrintDialog1->MaxPage - 1;
        break;
    }
    // now, print the pages
    Printer()->BeginDoc();
    for (int i = Start; i <= Stop; i++)

      end;
      EndDoc;
    end;
  end;
end;
```

71.1.2.5.7 TPrinter.Orientation Property

Determines if the print job prints vertically or horizontally on a page.

Pascal

```
property Orientation: TPrinterOrientation;
```

C++

```
__property TPrinterOrientation Orientation;
```

Description

Use Orientation to determine if a print job prints in landscape or portrait.

C++ Examples:

```
/*
This example uses two radio buttons on a form named
Landscape and Portrait. The form also includes a button.
When the user selects an orientation by clicking one of the
radio buttons and then clicks the button to print one line
of text, the print job prints using the selected orientation:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Printer()->BeginDoc();
  Printer()->Canvas->TextOut(100,100,"Hi there!");
```

```
  Printer()->EndDoc();
}

void __fastcall TForm1::PortraitClick(TObject *Sender)
{
  Printer()->Orientation = poPortrait;
}

void __fastcall TForm1::LandscapeClick(TObject *Sender)
{
  Printer()->Orientation = poLandscape;
}
```

Delphi Examples:

```
{
This example uses two radio buttons on a form named
Landscape and Portrait. The form also includes a button.
When the user selects an orientation by clicking one of the
radio buttons and then clicks the button to print one line
of text, the print job prints using the selected orientation:
}
uses Printers;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Printer.BeginDoc;
  Printer.Canvas.TextOut(100,100,'Hi there');
  Printer.EndDoc;
end;

procedure TForm1.LandscapeClick(Sender: TObject);
begin
  Printer.Orientation := poLandscape;
end;

procedure TForm1.PortraitClick(Sender: TObject);
begin
  Printer.Orientation := poPortrait;
end;
```

71.1.2.5.8 TPrinter.PageHeight Property

Indicates the height (in pixels) of the currently printing page.

Pascal

```
property PageHeight: Integer;
```

C++

```
__property int PageHeight;
```

Description

Use PageHeight to find the height in pixels of the currently printing page.

C++ Examples:

```
/*
The following code aborts a print job if the user presses
Esc. Note that you should set KeyPreview to true to ensure
that the OnKeyDown event handler of Form1 is called.
*/
#include <Printers.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
```

```
    KeyPreview = True;

}

void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key, TShiftState Shift)

{
  if (Key == VK_ESCAPE && Printer()->Printing)
  {
    Printer()->Abort();
    MessageDlg("Printing aborted", mtInformation,
               TMsgDlgButtons() << mbOK,0);
  }
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TMemo *Memo1 = new TMemo(Form1); // The parent (Form1) will clean up this object.
  Memo1->Parent = Form1;
  Memo1->Visible = True;
  Memo1->Width = 700;
  if (OpenDialog1->Execute())
  {
    Memo1->Lines->LoadFromFile(OpenDialog1->FileName);

    Printer()->BeginDoc();
    int X = 200;
    int Y = 200;
    for (int I = 0; I <= 10; I++)
      if (!Printer()->Aborted)
      {
        Printer()->Canvas->TextOut(X, Y, Memo1->Lines->Strings[I]);
        Y = Y + 80;
        if (Y > (Printer()->PageHeight - 300))
        {
          Y = 200;
          Printer()->NewPage();
          Sleep(1000);  // to give you time to abort!
        }
      }
    if (!Printer()->Aborted) Printer()->EndDoc();
  }
}
```

Delphi Examples:

```
{
The following code aborts a print job if the user presses
Esc. Note that you should set KeyPreview to true to ensure
that the OnKeyDown event handler of Form1 is called.
}

uses Printers;

procedure TForm1.Button1Click(Sender: TObject);
var
  I, X, Y: Integer;
  Memo1 : TMemo;
  r: TRect;
begin
  Memo1 := TMemo.Create(Form1);
  Memo1.Parent := Form1;
  Memo1.Visible := True;
  Memo1.Width := 700;
  if (OpenDialog1.Execute) then
  begin
    Memo1.Lines.LoadFromFile(OpenDialog1.FileName);
```

```
      Printer.BeginDoc;
      X := 200;
      Y := 200;
      for I := 0 to 140 do
        if (not Printer.Aborted) then
        begin
          Printer.Canvas.TextOut(X, Y, Memo1.Lines[I]);
          Y := Y + 80;
          if (Y > (Printer.PageHeight - 300)) then
          begin
            Y := 200;
            Printer.NewPage;
            Sleep(1000);  // to give you time to abort!
          end;
        end;
      if (not Printer.Aborted) then Printer.EndDoc;
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
     KeyPreview := True;
  end;

  procedure TForm1.FormKeyDown(Sender: TObject; var Key: Word; Shift: TShiftState);
  begin
  if (Key=VK_ESCAPE) and Printer.Printing then
    begin
    Printer.Abort;
    MessageDlg('Printing aborted', mtInformation, [mbOK],0);
    end;
  end;
```

See Also

PageNumber (see page 6427)

PageWidth (see page 6428)

71.1.2.5.9 TPrinter.PageNumber Property

Indicates the number of the page currently printing.

Pascal

```
property PageNumber: Integer;
```

C++

```
__property int PageNumber;
```

Description

Use PageNumber to find the page number of the currently printing page.

PageNumber is incremented whenever the NewPage (see page 6415) method is called. It is also incremented when a Text variable is written and a CR is encountered on the last line of the page.

C++ Examples:

```
/*
This example uses a button and a status bar on a form. When
the user clicks the button, one line of text is printed on
six separate pages. As each page is printed, a message
indicating the number of the page being printed appears on
the status bar.  Notice that the SimplePanel property of the
```

```
status bar to must be set to true.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  StatusBar1->SimplePanel = True; // so that SimpleText will work
  Printer()->BeginDoc();
  for (int i = 1;i < 7;i++)
  {
    Printer()->Canvas->TextOut(100, 100, "C++Builder rules!");
    StatusBar1->SimpleText = AnsiString("Printing page ") + Printer()->PageNumber;
    Printer()->NewPage();
  }
  Printer()->EndDoc();
}
```

Delphi Examples:

```
{
This example uses a button and a status bar on a form. When
the user clicks the button, one line of text is printed on
six separate pages. As each page is printed, a message
indicating the number of the page being printed appears on
the status bar.  To run this example successfully, you must
add Printers to the uses clause of your unit and set the
SimplePanel property of the status bar to true.
}
uses Printers;

procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
begin
  StatusBar1.SimplePanel := True; { so that SimpleText will work }
  Printer.BeginDoc;
  for I := 1 to 6 do
  begin
    Printer.Canvas.TextOut(100, 100, 'Object Pascal is great');
    StatusBar1.SimpleText := 'Now printing page ' + IntToStr(Printer.PageNumber);
    Printer.NewPage;
  end;
  Printer.EndDoc;

end;
```

NewPage (see page 6415)

PageHeight (see page 6425)

PageWidth (see page 6428)

71.1.2.5.10 TPrinter.PageWidth Property

Indicates the value of width (in pixels) of the currently printing page.

Pascal

```
property PageWidth: Integer;
```

C++

```
__property int PageWidth;
```

Description

Use PageWidth to find the width in pixels of the currently printing page.

C++ Examples:

```
/*
This example uses a button and a memo on a form. When the
user clicks the button, the content of the memo is printed,
with a 200-pixel border around the page.
Note: The TMemo will wrap the lines of the text files, so to
see the TextRect clip, the memo width must be large and the
lines in the text file must be long.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Memo1->Width = 1000;
  Memo1->Lines->LoadFromFile("..\\readme.txt");
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Printer()->BeginDoc();
  int margin = 1000;
  int X = margin;
  int Y = margin;
  int I = 0;
  while(Y < Printer()->PageHeight)
  {
    Canvas->TextRect(Rect(X, Y, Printer()->PageWidth-margin, Printer()->PageHeight-margin),
                     X, Y, Memo1->Lines->Strings[I]);
    Y = Y + 100;
    I = I + 1;
  }
  Printer()->EndDoc();
}
```

Delphi Examples:

```
{
This example uses a button and a memo on a form. When the
user clicks the button, the content of the memo is printed,
with a 200-pixel border around the page. To run this example
successfully, include <Printers.hpp> in your unit file.
Note: The TMemo will wrap the lines of the text files, so to
see the TextRect clip, the memo width must be large and the
lines in the text file must be long.
}
uses Printers;

procedure TForm1.Button1Click(Sender: TObject);
var
  X, Y, I, margin: Integer;
begin
  with Printer do
  begin
    BeginDoc;
    margin := 1000;
    X := margin;
    Y := margin;
    I := 0;
    while(Y < PageHeight) do
    begin
      Canvas.TextRect(Rect(X, Y, PageWidth-margin, PageHeight-margin),
                      X, Y, Memo1.Lines[I]);
      Y := Y + 100;
      I := I + 1;
    end;
    EndDoc;
  end;
end;
```

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  Memo1.Width := 1000;
  Memo1.Lines.LoadFromFile('readme.txt');
end;
```

PageHeight (see page 6425)

PageNumber (see page 6427)

71.1.2.5.11 TPrinter.PrinterIndex Property

Specifies which printer listed in the Printers (see page 6430) property is the currently selected printer.

Pascal

```
property PrinterIndex: Integer;
```

C++

```
__property int PrinterIndex;
```

Description

The value of PrinterIndex is the currently selected printer. If this value is changed, EndDoc (see page 6413) is called automatically. To select the default printer, set the value of PrinterIndex to -1.

The list of installed printers is found in the Printers (see page 6430) property. The list of fonts supported by the current printer is found in the Fonts (see page 6422) property.

See Also

EndDoc (see page 6413)

Fonts (see page 6422)

Printers (see page 6430)

71.1.2.5.12 TPrinter.Printers Property

Lists all printers installed in Windows.

Pascal

```
property Printers: TStrings;
```

C++

```
__property TStrings Printers;
```

Description

The list of installed printers is found in the Printers property. The value of the PrinterIndex (see page 6430) property is the currently selected printer. The list of fonts supported by the current printer is found in the Fonts (see page 6422) property.

See Also

GetPrinter (see page 6415)

71.1.2.5.13 TPrinter.Printing Property

Indicates whether a print job is printing.

Pascal

```
property Printing: Boolean;
```

C++

```
__property Boolean Printing;
```

Description

Use Printing to determine if a job is printing.

Printing is true when the application has called the BeginDoc (see page 6411) method but the EndDoc (see page 6413) method (or the Abort (see page 6409) method) hasn't yet been called.

C++ Examples:

```
/*
The following code aborts a print job if the user presses
Esc. Note that you should set KeyPreview to true to ensure
that the OnKeyDown event handler of Form1 is called.
*/
#include <Printers.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
   KeyPreview = True;

}

void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key, TShiftState Shift)

{
  if (Key == VK_ESCAPE && Printer()->Printing)
  {
    Printer()->Abort();
    MessageDlg("Printing aborted", mtInformation,
               TMsgDlgButtons() << mbOK,0);
  }
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TMemo *Memo1 = new TMemo(Form1); // The parent (Form1) will clean up this object.
  Memo1->Parent = Form1;
  Memo1->Visible = True;
  Memo1->Width = 700;
  if (OpenDialog1->Execute())
  {
    Memo1->Lines->LoadFromFile(OpenDialog1->FileName);

    Printer()->BeginDoc();
    int X = 200;
    int Y = 200;
    for (int I = 0; I <= 10; I++)
      if (!Printer()->Aborted)
      {
        Printer()->Canvas->TextOut(X, Y, Memo1->Lines->Strings[I]);
        Y = Y + 80;
        if (Y > (Printer()->PageHeight - 300))
        {
          Y = 200;
          Printer()->NewPage();
          Sleep(1000);  // to give you time to abort!
        }
      }
    if (!Printer()->Aborted) Printer()->EndDoc();
```

```
  }
}
```

Delphi Examples:

```
{
The following code aborts a print job if the user presses
Esc. Note that you should set KeyPreview to true to ensure
that the OnKeyDown event handler of Form1 is called.
}

uses Printers;

procedure TForm1.Button1Click(Sender: TObject);
var
  I, X, Y: Integer;
  Memo1 : TMemo;
  r: TRect;
begin
  Memo1 := TMemo.Create(Form1);
  Memo1.Parent := Form1;
  Memo1.Visible := True;
  Memo1.Width := 700;
  if (OpenDialog1.Execute) then
  begin
    Memo1.Lines.LoadFromFile(OpenDialog1.FileName);

    Printer.BeginDoc;
    X := 200;
    Y := 200;
    for I := 0 to 140 do
      if (not Printer.Aborted) then
      begin
        Printer.Canvas.TextOut(X, Y, Memo1.Lines[I]);
        Y := Y + 80;
        if (Y > (Printer.PageHeight - 300)) then
        begin
          Y := 200;
          Printer.NewPage;
          Sleep(1000);  // to give you time to abort!
        end;
      end;
    if (not Printer.Aborted) then Printer.EndDoc;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
   KeyPreview := True;
end;

procedure TForm1.FormKeyDown(Sender: TObject; var Key: Word; Shift: TShiftState);
begin
if (Key=VK_ESCAPE) and Printer.Printing then
  begin
  Printer.Abort;
  MessageDlg('Printing aborted', mtInformation, [mbOK],0);
  end;
end;
```

See Also

Abort (see page 6409)

BeginDoc (see page 6411)

EndDoc (see page 6413)

71.1.2.5.14 TPrinter.Title Property

Determines the text that is listed in the Print Manager and on network header pages.

Pascal

```
property Title: string;
```

C++

```
__property UnicodeString Title;
```

Description

Title is used by Windows in the Print Manager and for network title pages.

71.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	AssignPrn (see page 6434)	Assigns a text file variable to the printer.
	Printer (see page 6434)	Returns a global instance of TPrinter (see page 6406) to manage interaction with the printer.
	SetPrinter (see page 6436)	Replaces the global instance of TPrinter (see page 6406) that manages interaction with the printer.

71.2.1 Printers.AssignPrn Function

Assigns a text file variable to the printer.

Pascal

```
procedure AssignPrn(var F: Text);
```

C++

```
AssignPrn(Text F);
```

File

Printers

Description

In Delphi code, Call AssignPrn to cause all information written to the text file variable F to be directed to the printer. After the variable is assigned, the application must call the Rewrite procedure.

See Also

Rewrite

71.2.2 Printers.Printer Function

Returns a global instance of TPrinter (see page 6406) to manage interaction with the printer.

Pascal

```
function Printer: TPrinter;
```

C++

```
TPrinter Printer();
```

File

Printers

Description

Printer creates an instance of a global TPrinter (see page 6406) object the first time it is called. Use the Printer function to print

using the TPrinter (see page 6406) object.

Printer is declared in the Printers (see page 6405) unit. To use the Printer function and the TPrinter (see page 6406) object, add Printers (see page 6405) to the uses clause of your unit (Delphi) or include Printers.hpp in the source file (C++).

C++ Examples:

```
{
This example uses a button, a Page Control, and a Print
dialog box on a form. When the user clicks the button, the
print dialog is displayed.  The user can select any subset
of the pages in the page control for printing.  The selected
pages are then printed.  To run this example successfully,
you must add the Printers unit to the uses clause of your
unit.  Right click on the PageControl to add at least one
page to the PageControl.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  PrintDialog1->Options.Clear();
  PrintDialog1->Options << poPageNums << poSelection;
  PrintDialog1->FromPage = 1;
  PrintDialog1->MinPage = 1;
  PrintDialog1->ToPage = PageControl1->PageCount;
  PrintDialog1->MaxPage = PageControl1->PageCount;
  if (PrintDialog1->Execute())
  {
    int Start, Stop;
    // determine the range the user wants to print
    switch (PrintDialog1->PrintRange)
    {
      case prSelection:
        Start = PageControl1->ActivePage->PageIndex;
        Stop = Start;
        break;
      case prPageNums:
        Start = PrintDialog1->FromPage - 1;
        Stop =  PrintDialog1->ToPage - 1;
        break;
      default:  // prAllPages
        Start = PrintDialog1->MinPage - 1;
        Stop = PrintDialog1->MaxPage - 1;
        break;
    }
    // now, print the pages
    Printer()->BeginDoc();
    for (int i = Start; i <= Stop; i++)
    {
      PageControl1->Pages[i]->PaintTo(Printer()->Handle, 10, 10);
      if (i != Stop)
        Printer()->NewPage();
    }
    Printer()->EndDoc();
  }
}
```

Delphi Examples:

```
{
This example uses a button, a Page Control, and a Print
dialog box on a form. When the user clicks the button, the
print dialog is displayed.  The user can select any subset
of the pages in the page control for printing.  The selected
pages are then printed.  To run this example successfully,
you must add the Printers unit to the uses clause of your
unit.  Right click on the PageControl to add at least one
page to the PageControl.
```

```
}

    begin
      BeginDoc;
      for I := Start to Stop do
      begin
        PageControl1.Pages[I].PaintTo(Handle, 10, 10);
        if I <> Stop then
          NewPage;
      end;
      EndDoc;
    end;
  end;
end;
```

See Also

SetPrinter (see page 6436)

71.2.3 Printers.SetPrinter Function

Replaces the global instance of TPrinter (see page 6406) that manages interaction with the printer.

Pascal

```
function SetPrinter(NewPrinter: TPrinter): TPrinter;
```

C++

```
TPrinter SetPrinter(TPrinter NewPrinter);
```

File

Printers

Description

SetPrinter replaces the global TPrinter (see page 6406) object with another TPrinter (see page 6406) object. This allows applications to change the way they handle printing by substituting a TPrinter (see page 6406) descendant for the default TPrinter (see page 6406) object.

NewPrinter is the new TPrinter (see page 6406) object that replaces the current global TPrinter (see page 6406) object.

SetPrinter returns the previous global TPrinter (see page 6406) object.

Note: The global TPrinter (see page 6406) object is freed automatically when the application shuts down. After a call to SetPrinter, the printer that is returned is not automatically freed. It is the caller's responsibility to either free the return value, or replace it using another call to SetPrinter and to free the substitute printer that the second SetPrinter call returns.

SetPrinter is declared in the Printers (see page 6405) unit. To use the SetPrinter function, add Printers (see page 6405) to the uses clause of your unit (Delphi) or include Printers.hpp in the source file (C++) .

Printer (see page 6434)

71.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TPrinterCapability (see page 6438)	TPrinterCapability and TPrinterCapabilities (see page 6440) specify the capabilities of a printer device driver.
	TPrinterOrientation (see page 6438)	TPrinterOrientation indicates the orientation of pages when printing.
	TPrinterState (see page 6439)	This is record Printers.TPrinterState.

71.3.1 Printers.TPrinterCapability Enumeration

TPrinterCapability and TPrinterCapabilities (see page 6440) specify the capabilities of a printer device driver.

Pascal

```
TPrinterCapability = (
  pcCopies,
  pcOrientation,
  pcCollation
);
```

C++

```
enum TPrinterCapability {
  pcCopies,
  pcOrientation,
  pcCollation
};
```

File

Printers

Description

TPrinterCapabilities (see page 6440) is a set of TPrinterCapability values. The possible values of TPrinterCapability are

Value	Meaning
pcCopies	The printer driver allows the user to specify the number of copies.
pcOrientation	The printer driver allows the user to specify portrait or landscape orientation.
pcCollation	The printer driver allows the user to specify whether copies should be collated.

71.3.2 Printers.TPrinterOrientation Enumeration

TPrinterOrientation indicates the orientation of pages when printing.

Pascal

```
TPrinterOrientation = (
```

```
    poPortrait,
    poLandscape
  );
```

C++

```
  enum TPrinterOrientation {
    poPortrait,
    poLandscape
  };
```

File

Printers

Description

These are the possible values for TPrinterOrientation:

Value	Meaning
poPortrait	The job prints vertically on the page.
poLandscape	The job prints horizontally on the page.

71.3.3 Printers.TPrinterState Enumeration

Pascal

```
  TPrinterState = (
    psNoHandle,
    psHandleIC,
    psHandleDC
  );
```

C++

```
  enum TPrinterState {
    psNoHandle,
    psHandleIC,
    psHandleDC
  };
```

File

Printers

Description

This is record Printers.TPrinterState.

71.4 Types

The following table lists types in this documentation.

Types

Name	Description
TPrinterCapabilities (see page 6440)	This is type Printers.TPrinterCapabilities.

71.4.1 Printers.TPrinterCapabilities Type

Pascal

```
TPrinterCapabilities = set of TPrinterCapability;
```

C++

```
TPrinterCapability TPrinterCapabilities;
```

File

Printers

Description

This is type Printers.TPrinterCapabilities.

72 Provider Namespace

This is namespace Provider.

Topics

Name	Description
Classes (see page 6443)	The following table lists classes in this documentation.
Interfaces (see page 6580)	The following table lists interfaces in this documentation.
Functions (see page 6582)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 6584)	The following table lists structs, records, enums in this documentation.
Types (see page 6589)	The following table lists types in this documentation.
Variables (see page 6595)	The following table lists variables in this documentation.
Constants (see page 6596)	The following table lists constants in this documentation.

Classes

	Name	Description
	EDSWriter (see page 6443)	EDSWriter is the exception class for errors that occur when creating data packets to represent the data or metadata in a dataset.
	TBaseProvider (see page 6445)	TBaseProvider is a base class for all providers that represent the data in a dataset.
	TCustomPacketWriter (see page 6460)	This is class Provider.TCustomPacketWriter.
	TCustomProvider (see page 6464)	TCustomProvider is the base class for data providers.
	TCustomResolver (see page 6491)	TCustomResolver is the base class for components that apply updates on behalf of a provider.
	TDataPacketWriter (see page 6501)	This is class Provider.TDataPacketWriter.
	TDataSetProvider (see page 6510)	TDataSetProvider provides data from a dataset and resolves updates to that dataset or its database server.
	TDataSetResolver (see page 6540)	TDataSetResolver applies updates to a dataset on behalf of a provider.
	TLocalAppServer (see page 6546)	This is class Provider.TLocalAppServer.
	TPacketDataSet (see page 6555)	TPacketDataSet represents a data packet or delta packet that is used by a provider.
	TProvider (see page 6563)	TProvider provides data to and applies updates from a client dataset.
	TSQLResolver (see page 6564)	TSQLResolver applies updates to a database server on behalf of a provider.
	TUpdateTree (see page 6572)	TUpdateTree stores information about a delta packet on behalf of a resolver.

Constants

Name	Description
MetaDataOption (see page 6596)	Specifies the options available when retrieving metadata from a target database.

ResetOption (see page 6597)	This is constant Provider.ResetOption.
XMLOption (see page 6597)	This is constant Provider.XMLOption.
XMLUTF8Option (see page 6598)	This is constant Provider.XMLUTF8Option.

Functions

	Name	Description
	GetObjectProperty (see page 6582)	This is function Provider.GetObjectProperty.
	GetStringProperty (see page 6582)	This is function Provider.GetStringProperty.
	VarArrayFromStrings (see page 6582)	Creates a Variant array that contains the strings in a TStrings object.
	VarArrayFromWideStrings (see page 6583)	This is function Provider.VarArrayFromWideStrings.

Interfaces

	Name	Description
	IProviderContainer (see page 6580)	This is class Provider.IProviderContainer.

Structs, Records, Enums

	Name	Description
	TGetRecordOption (see page 6584)	TGetRecordOption and TGetRecordOptions (see page 6591) influence what type of information is added to data packets.
	TProviderOption (see page 6585)	TProviderOption and TProviderOptions (see page 6593) influence what type of information is communicated between client datasets and provider components.
	TPutFieldInfo (see page 6587)	This is record Provider.TPutFieldInfo.
	TResolverResponse (see page 6587)	TResolverResponse indicates the action a resolver component should take after an OnUpdateError event handler handles an update error.

Types

Name	Description
PPutFieldInfo (see page 6589)	This is type Provider.PPutFieldInfo.
TAfterUpdateRecordEvent (see page 6589)	This is type Provider.TAfterUpdateRecordEvent.
TBeforeCommitEvent (see page 6590)	This is type Provider.TBeforeCommitEvent.
TBeforeUpdateRecordEvent (see page 6590)	This is type Provider.TBeforeUpdateRecordEvent.
TDataRequestEvent (see page 6590)	This is type Provider.TDataRequestEvent.
TGetDSProps (see page 6591)	This is type Provider.TGetDSProps.
TGetParamsEvent (see page 6591)	This is type Provider.TGetParamsEvent.
TGetRecordOptions (see page 6591)	This is type Provider.TGetRecordOptions.
TGetTableNameEvent (see page 6592)	This is type Provider.TGetTableNameEvent.
TInfoArray (see page 6592)	This is type Provider.TInfoArray.
TOnValidate (see page 6592)	This is type Provider.TOnValidate.
TProviderDataEvent (see page 6593)	This is type Provider.TProviderDataEvent.
TProviderOptions (see page 6593)	This is type Provider.TProviderOptions.
TPutFieldProc (see page 6593)	This is type Provider.TPutFieldProc.
TResolverErrorEvent (see page 6594)	This is type Provider.TResolverErrorEvent.

Variables

Name	Description
InformixLob (see page 6595)	This is variable Provider.InformixLob.

72.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EDSWriter (see page 6443)	EDSWriter is the exception class for errors that occur when creating data packets to represent the data or metadata in a dataset.
	TBaseProvider (see page 6445)	TBaseProvider is a base class for all providers that represent the data in a dataset.
	TCustomPacketWriter (see page 6460)	This is class Provider.TCustomPacketWriter.
	TCustomProvider (see page 6464)	TCustomProvider is the base class for data providers.
	TCustomResolver (see page 6491)	TCustomResolver is the base class for components that apply updates on behalf of a provider.
	TDataPacketWriter (see page 6501)	This is class Provider.TDataPacketWriter.
	TDataSetProvider (see page 6510)	TDataSetProvider provides data from a dataset and resolves updates to that dataset or its database server.
	TDataSetResolver (see page 6540)	TDataSetResolver applies updates to a dataset on behalf of a provider.
	TLocalAppServer (see page 6546)	This is class Provider.TLocalAppServer.
	TPacketDataSet (see page 6555)	TPacketDataSet represents a data packet or delta packet that is used by a provider.
	TProvider (see page 6563)	TProvider provides data to and applies updates from a client dataset.
	TSQLResolver (see page 6564)	TSQLResolver applies updates to a database server on behalf of a provider.
	TUpdateTree (see page 6572)	TUpdateTree stores information about a delta packet on behalf of a resolver.

72.1.1 EDSWriter Class

EDSWriter is the exception class for errors that occur when creating data packets to represent the data or metadata in a dataset.

Class Hierarchy

Pascal

```
EDSWriter = class(Exception);
```

C++

```
class EDSWriter : public Exception;
```

File

Provider

Description

EDSWriter is raised whenever a provider component encounters an error while trying to create a data packet from a dataset.

See Also

TDataSetProvider (see page 6510)

TCustomProvider (see page 6464)

72.1.1.1 EDSWriter Members

The following tables list the members exposed by EDSWriter.

Public Methods

	Name	Description
	Create (see page 6444)	Creates an instance of EDSWriter (see page 6443) using a specified error code and message string.

Public Properties

	Name	Description
	ErrorCode (see page 6444)	Indicates the error code that this exception represents.

72.1.1.2 EDSWriter.Create Constructor

Creates an instance of EDSWriter (see page 6443) using a specified error code and message string.

Pascal

```
constructor Create(ErrMsg: string; Status: Integer);
```

C++

```
__fastcall EDSWriter(UnicodeString ErrMsg, int Status);
```

Description

Create instantiates EDSWriter (see page 6443), setting the Message property to ErrMsg and the ErrorCode (see page 6444) property to Status.

See Also

Create

ErrorCode (see page 6444)

72.1.1.3 EDSWriter Properties

The properties of the EDSWriter class are listed here.

Public Properties

	Name	Description
	ErrorCode (see page 6444)	Indicates the error code that this exception represents.

72.1.1.3.1 EDSWriter.ErrorCode Property

Indicates the error code that this exception represents.

Pascal

```
property ErrorCode: Integer;
```

C++

```
__property int ErrorCode;
```

Description

Use ErrorCode to determine what error gave rise to this exception. ErrorCode is the value passed to the canonical EDSWriter (

see page 6443) constructor (C++) or Create (see page 6444) method (Delphi).

See Also

Create (see page 6444)

72.1.2 TBaseProvider Class

TBaseProvider is a base class for all providers that represent the data in a dataset.

Class Hierarchy

Pascal

```
TBaseProvider = class(TCustomProvider);
```

C++

```
class TBaseProvider : public TCustomProvider;
```

File

Provider

Description

TBaseProvider is the immediate ancestor of TDataSetProvider (see page 6510), which provides data from any dataset and applies updates back to that dataset or directly to an SQL server. Use TBaseProvider to derive other customized data provider objects, such as providers that apply updates directly to a database without using SQL.

Unlike its immediate ancestor (TCustomProvider (see page 6464)) TBaseProvider includes no abstract (Delphi) or pure virtual (C++) methods. However, applications should not create instances of TBaseProvider, as many of the methods are merely stubs that provide a backstop for specialized descendants that do not implement all the provider methods. To add a provider component to a form or data module, use TDataSetProvider (see page 6510) (or TXMLTransformProvider).

A provider derived from TBaseProvider is an intermediate link between a TClientDataSet or TXMLBroker object and a source dataset. The source dataset can reside in the same application as the client dataset or XML broker, or it can be part of a separate application server. The provider packages data from the source dataset and passes it in one or more transportable data packets to the client dataset or XML broker. The client dataset reconstructs the data in the data packet to create a local, in-memory copy for user access. When user access is complete, the client dataset repackages any changed data and sends the updates back to the provider. The provider applies the updates to the database or source dataset.

When the provider supplies data to a client dataset, the client dataset reconstructs the data in the data packet to create a local, in-memory copy for user access. When user access is complete, the client dataset repackages any changed data and sends the updates back to the provider. The provider applies the updates to the database or source dataset.

When the provider supplies data to an XML broker, the XML broker adds the data packet, in XML format, to an HTML document that is downloaded by a Web client. When the XML broker receives updates from the Web client, it sends the updates to the provider, which applies them to the database or source dataset.

Client datasets and XML brokers communicate with a provider through the IAppServer (see page 5222) interface. In multi-tiered applications, this is the interface of the remote data module that contains the provider. To enable the remote data module to pass calls to the provider, the provider's Exported (see page 6482) property must be true, and its Owner property must specify the remote data module.

TSoapDataModule

72.1.2.1 TBaseProvider Members

The following tables list the members exposed by TBaseProvider.

Protected Events

	Name	Description
	AfterApplyUpdates (see page 6483)	Occurs after the provider applies updates.
	AfterExecute (see page 6484)	Occurs after the provider passes an execute command to its dataset.
	AfterGetParams (see page 6485)	This is AfterGetParams, a member of class TCustomProvider.
	AfterGetRecords (see page 6485)	Occurs after the provider creates a data packet to send to the client dataset.
	AfterRowRequest (see page 6486)	Occurs after the provider fetches new information about the current record.
	BeforeApplyUpdates (see page 6487)	Occurs before the provider applies updates from a client dataset.
	BeforeExecute (see page 6487)	This is BeforeExecute, a member of class TCustomProvider.
	BeforeGetParams (see page 6488)	Occurs before the provider creates an OleVariant that encodes the current parameter values and sends them to a client dataset.
	BeforeGetRecords (see page 6488)	Occurs before the provider creates a data packet and sends it to a client dataset.
	BeforeRowRequest (see page 6490)	Occurs before the provider creates a delta packet with information about the current record.
	OnValidate (see page 6491)	This is OnValidate, a member of class TCustomProvider.

Protected Methods

	Name	Description
	CheckResolver (see page 6449)	Instantiates a resolver for the Resolver (see page 6456) property if it does not already exist.
V	CreateDataPacket (see page 6449)	Generates a data packet for the data associated with the provider.
V	CreateResolver (see page 6450)	Creates a resolver component for handling the application of updates.
V	DoAfterApplyUpdates (see page 6469)	Generates an AfterApplyUpdates (see page 6483) event.
V	DoAfterExecute (see page 6469)	Generates an AfterExecute (see page 6484) event.
V	DoAfterGetParams (see page 6470)	Generates an AfterGetParams (see page 6485) event.
V	DoAfterGetRecords (see page 6470)	Generates an AfterGetRecords (see page 6485) event.
V	DoAfterRowRequest (see page 6471)	Generates an AfterRowRequest (see page 6486) event.
V	DoAfterUpdateRecord (see page 6450)	Generates an AfterUpdateRecord (see page 6458) event.
V	DoApplyUpdates (see page 6471)	This is DoApplyUpdates, a member of class TCustomProvider.
V	DoBeforeApplyUpdates (see page 6471)	Generates a BeforeApplyUpdates (see page 6487) event.
V	DoBeforeCommit (see page 6450)	This is DoBeforeCommit, a member of class TBaseProvider.
V	DoBeforeExecute (see page 6472)	Generates a BeforeExecute (see page 6487) event.
V	DoBeforeGetParams (see page 6472)	Generates a BeforeGetParams (see page 6488) event.
V	DoBeforeGetRecords (see page 6473)	Generates a BeforeGetRecords (see page 6488) event.
V	DoBeforeRowRequest (see page 6474)	Generates a BeforeRowRequest (see page 6490) event.
V	DoBeforeUpdateRecord (see page 6451)	This is DoBeforeUpdateRecord, a member of class TBaseProvider.
V	DoGetRecords (see page 6474)	This is DoGetRecords, a member of class TCustomProvider.
V	DoOnGetData (see page 6451)	Generates an OnGetData (see page 6459) event.
V	DoOnUpdateData (see page 6451)	Generates an OnUpdateData (see page 6459) event.
V	FetchDetails (see page 6451)	Fills a delta dataset with all nested dataset field values.
	FreeResolver (see page 6452)	Frees the resolver specified by the Resolver (see page 6456) property.

	InternalApplyUpdates (see page 6452)	Provides the underlying implementation of the ApplyUpdates (see page 6468) method.
	InternalExecute (see page 6478)	Provides the underlying implementation of the Execute (see page 6474) method.
	InternalGetParams (see page 6478)	Returns the requested parameter values as a Variant array.
	InternalGetRecords (see page 6453)	Provides the underlying implementation of the GetRecords (see page 6476) method.
	InternalRowRequest (see page 6454)	Provides the underlying implementation of the RowRequest (see page 6480) method.
	LocateRecord (see page 6454)	Positions a data set on the record that corresponds to the current update in a specified delta packet.
	SetActiveUpdateException (see page 6481)	This is SetActiveUpdateException, a member of class TCustomProvider.
	UpdateRecord (see page 6455)	Retrieves specified data from a source dataset into a delta packet.

Protected Properties

	Name	Description
	ActiveUpdateException (see page 6482)	This is ActiveUpdateException, a member of class TCustomProvider.
	OwnerData (see page 6483)	This is OwnerData, a member of class TCustomProvider.
	PacketDataSet (see page 6456)	This is PacketDataSet, a member of class TBaseProvider.

Public Events

	Name	Description
	AfterUpdateRecord (see page 6458)	Occurs when the associated resolver has just updated a record.
	BeforeUpdateRecord (see page 6458)	This is BeforeUpdateRecord, a member of class TBaseProvider.
	OnDataRequest (see page 6458)	Occurs when a provider calls its DataRequest method.
	OnGetData (see page 6459)	Occurs after a provider retrieves data but before it is sent to the client.
	OnUpdateData (see page 6459)	Occurs when a provider begins to apply updates.
	OnUpdateError (see page 6460)	Occurs when a provider can't update a record because of an error condition.

Public Methods

	Name	Description
	ApplyUpdates (see page 6468)	This is the overview for the ApplyUpdates method overload.
	Create (see page 6447)	Creates and initializes a TBaseProvider (see page 6445) object.
	DataRequest (see page 6468)	Generates an OnDataRequest (see page 6490) event.
	Destroy (see page 6448)	Frees an instance of a provider object.
	Execute (see page 6474)	Executes a query, stored procedure, or custom SQL statement.
	GetParams (see page 6475)	Returns the current parameter values.
	GetRecords (see page 6476)	This is the overview for the GetRecords method overload.
	RowRequest (see page 6480)	Returns information from a specified record.

Public Properties

	Name	Description
	Data (see page 6482)	Denotes a data packet created by the provider.
	Exported (see page 6482)	Allows client applications to pass calls to the provider when it resides on an application server.
	Options (see page 6455)	Influences what is included in data packets and how the information in data packets is used.
	Resolver (see page 6456)	Provides access to the resolver component that applies updates and resolves update errors.
	UpdateMode (see page 6457)	Controls how the provider locates records when applying updates.

72.1.2.2 TBaseProvider.Create Constructor

Creates and initializes a TBaseProvider (see page 6445) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TBaseProvider(TComponent * AOwner);
```

Description

Call Create to instantiate a provider at runtime. Providers placed in forms or data modules at design time are created automatically.

AOwner specifies the component, typically a form or data module, that is responsible for freeing the provider.

See Also

Owner

72.1.2.3 TBaseProvider.Destroy Destructor

Frees an instance of a provider object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TBaseProvider();
```

Description

Do not call Destroy directly. Instead, call Free, which checks that the provider is not nil before calling the Destroy method.

See Also

System::TObject::Free

Resolver (see page 6456)

72.1.2.4 TBaseProvider Methods

The methods of the TBaseProvider class are listed here.

Protected Methods

	Name	Description
	CheckResolver (see page 6449)	Instantiates a resolver for the Resolver (see page 6456) property if it does not already exist.
V	CreateDataPacket (see page 6449)	Generates a data packet for the data associated with the provider.
V	CreateResolver (see page 6450)	Creates a resolver component for handling the application of updates.
V	DoAfterUpdateRecord (see page 6450)	Generates an AfterUpdateRecord (see page 6458) event.
V	DoBeforeCommit (see page 6450)	This is DoBeforeCommit, a member of class TBaseProvider.
V	DoBeforeUpdateRecord (see page 6451)	This is DoBeforeUpdateRecord, a member of class TBaseProvider.
V	DoOnGetData (see page 6451)	Generates an OnGetData (see page 6459) event.
V	DoOnUpdateData (see page 6451)	Generates an OnUpdateData (see page 6459) event.
V	FetchDetails (see page 6451)	Fills a delta dataset with all nested dataset field values.
	FreeResolver (see page 6452)	Frees the resolver specified by the Resolver (see page 6456) property.
V	InternalApplyUpdates (see page 6452)	Provides the underlying implementation of the ApplyUpdates (see page 6468) method.

	InternalGetRecords (see page 6453)	Provides the underlying implementation of the GetRecords (see page 6476) method.
	InternalRowRequest (see page 6454)	Provides the underlying implementation of the RowRequest (see page 6480) method.
	LocateRecord (see page 6454)	Positions a data set on the record that corresponds to the current update in a specified delta packet.
	UpdateRecord (see page 6455)	Retrieves specified data from a source dataset into a delta packet.

72.1.2.4.1 TBaseProvider.CheckResolver Method

Instantiates a resolver for the Resolver (see page 6456) property if it does not already exist.

Pascal

```
procedure CheckResolver;
```

C++

```
__fastcall CheckResolver();
```

Description

CheckResolver is called internally when the provider needs to use its resolver component. It checks whether Resolver (see page 6456) is nil (Delphi) or NULL (C++), and if so, calls CreateResolver (see page 6450) to assign a value.

See Also

Resolver (see page 6456)

CreateResolver (see page 6450)

72.1.2.4.2 TBaseProvider.CreateDataPacket Method

Generates a data packet for the data associated with the provider.

Pascal

```
procedure CreateDataPacket(PacketOpts: TGetRecordOptions; ProvOpts: TProviderOptions; var
RecsOut: Integer; var Data: OleVariant); virtual;
```

C++

```
virtual __fastcall CreateDataPacket(TGetRecordOptions PacketOpts, TProviderOptions ProvOpts,
int RecsOut, OleVariant Data);
```

Description

CreateDataPacket is used internally to generate data packets. As implemented in TBaseProvider (see page 6445), CreateDataPacket sets RecsOut to 0 and Data (see page 6482) to NULL. Descendants override this method to create the data packets that are returned by GetRecords (see page 6476).

The PacketOpts parameter indicates what information (other than record values) is included in the data packet. It reflects the Options (see page 6455) passed to the GetRecords (see page 6476) method.

The ProvOpts parameter reflects the current value of the Options (see page 6455) property.

The RecsOut parameter specifies the number of records desired in the packet and returns the actual number of records in the generated data packet.

The Data (see page 6482) parameter returns the generated data packet.

See Also

GetRecords (see page 6476)

Options (see page 6455)

72.1.2.4.3 TBaseProvider.CreateResolver Method

Creates a resolver component for handling the application of updates.

Pascal

```
function CreateResolver: TCustomResolver; virtual;
```

C++

```
virtual __fastcall TCustomResolver CreateResolver();
```

Description

CreateResolver is called automatically when a resolver is needed to implement one of TBaseProvider (see page 6445)'s methods. As implemented in TBaseProvider (see page 6445), CreateResolver always returns nil (Delphi) or NULL (C++). Descendants of TBaseProvider (see page 6445) override this method to create a TCustomResolver (see page 6491) descendant that applies updates in the desired manner.

See Also

Resolver (see page 6456)

FreeResolver (see page 6452)

72.1.2.4.4 TBaseProvider.DoAfterUpdateRecord Method

Generates an AfterUpdateRecord (see page 6458) event.

Pascal

```
procedure DoAfterUpdateRecord(SourceDS: TDataSet; DeltaDS: TCustomClientDataSet; UpdateKind:
TUpdateKind); virtual;
```

C++

```
virtual __fastcall DoAfterUpdateRecord(TDataSet SourceDS, TCustomClientDataSet DeltaDS,
TUpdateKind UpdateKind);
```

Description

DoAfterUpdateRecord is the protected implementation of the AfterUpdateRecord (see page 6458) event. Override this method to perform class-specific actions in response to data requests.

See Also

AfterUpdateRecord (see page 6458)

72.1.2.4.5 TBaseProvider.DoBeforeCommit Method

Pascal

```
procedure DoBeforeCommit(Delta: TPacketDataSet; ErrorCount: Integer; MaxErrors: Integer; const
ReturnVar: OleVariant); virtual;
```

C++

```
virtual __fastcall DoBeforeCommit(TPacketDataSet Delta, int ErrorCount, int MaxErrors, const
OleVariant ReturnVar);
```

Description

This is DoBeforeCommit, a member of class TBaseProvider.

72.1.2.4.6 TBaseProvider.DoBeforeUpdateRecord Method

Pascal

```
procedure DoBeforeUpdateRecord(SourceDS: TDataSet; DeltaDS: TCustomClientDataSet; UpdateKind:
TUpdateKind; var Applied: Boolean); virtual;
```

C++

```
virtual __fastcall DoBeforeUpdateRecord(TDataSet SourceDS, TCustomClientDataSet DeltaDS,
TUpdateKind UpdateKind, Boolean Applied);
```

Description

This is DoBeforeUpdateRecord, a member of class TBaseProvider.

72.1.2.4.7 TBaseProvider.DoOnGetData Method

Generates an OnGetData (see page 6459) event.

Pascal

```
procedure DoOnGetData(var Data: OleVariant); virtual;
```

C++

```
virtual __fastcall DoOnGetData(OleVariant Data);
```

Description

DoOnGetData is the protected implementation of the OnGetData (see page 6459) event. Override this method to perform class-specific actions in response to data requests.

See Also

OnGetData (see page 6459)

72.1.2.4.8 TBaseProvider.DoOnUpdateData Method

Generates an OnUpdateData (see page 6459) event.

Pascal

```
procedure DoOnUpdateData(Delta: TPacketDataSet); virtual;
```

C++

```
virtual __fastcall DoOnUpdateData(TPacketDataSet Delta);
```

Description

DoOnUpdateData is the protected implementation of the OnUpdateData (see page 6459) event. The Delta property contains the delta packet of records to update. It is passed to the OnUpdateData (see page 6459) event handler as a client dataset.

Override this method to perform class-specific actions in response to update requests.

See Also

OnUpdateData (see page 6459)

72.1.2.4.9 TBaseProvider.FetchDetails Method

Fills a delta dataset with all nested dataset field values.

Pascal

```
procedure FetchDetails(Source: TDataSet; Delta: TDataSet); virtual;
```

C++

```
virtual __fastcall FetchDetails(TDataSet Source, TDataSet Delta);
```

Description

FetchDetails is used internally to fetch the current values of any nested datasets when the provider is executing its RowRequest (see page 6480) method. As implemented in TBaseProvider (see page 6445), FetchDetails does nothing. Descendants override this method to add nested detail datasets to the delta packet specified by Delta.

Source is a source dataset that has the current values for all fields. Delta is a delta dataset that must be updated so that its nested detail fields match the values in Source.

See Also

RowRequest (see page 6480)

72.1.2.4.10 TBaseProvider.FreeResolver Method

Frees the resolver specified by the Resolver (see page 6456) property.

Pascal

```
procedure FreeResolver;
```

C++

```
__fastcall FreeResolver();
```

Description

Call FreeResolver to safely dispose of the component specified by the Resolver (see page 6456) property. FreeResolver sets the Resolver (see page 6456) property to nil (Delphi) or NULL (C++) after calling the resolver's Free method.

See Also

Resolver (see page 6456)

CreateResolver (see page 6450)

System::TObject::Free

72.1.2.4.11 TBaseProvider.InternalApplyUpdates Method

Provides the underlying implementation of the ApplyUpdates (see page 6468) method.

Pascal

```
function InternalApplyUpdates(const Delta: OleVariant; MaxErrors: Integer; out ErrorCount:
Integer): OleVariant; override;
```

C++

```
virtual __fastcall OleVariant InternalApplyUpdates(const OleVariant Delta, int MaxErrors, int
ErrorCount);
```

Description

The ApplyUpdates (see page 6468) method calls InternalApplyUpdates to apply the updates contained in a delta packet after generating the BeforeApplyUpdates (see page 6487) event and before generating the AfterApplyUpdates (see page 6483) event.

If the Options (see page 6455) property includes poReadOnly, InternalApplyUpdates raises an exception. Otherwise, it calls the ApplyUpdates (see page 6468) method of its Resolver (see page 6456) component to handle the actual update and resolving process. If the Resolver (see page 6456) property is nil (Delphi) or NULL (C++), ApplyUpdates (see page 6468) calls the CreateResolver (see page 6450) method and assigns the resulting resolver to the Resolver (see page 6456) property.

Delta is the delta packet containing insertions, deletions, and modifications to be applied.

MaxErrors indicates the maximum number of errors that can be applied before stopping the update operation. If MaxErrors is –1, the provider tries to apply all updates.

ErrorCount returns the number of errors encountered during the update operation.

InternalApplyUpdates returns a data packet of updates that could not be applied to the database as an OleVariant.

See Also

Resolver (see page 6456)

ApplyUpdates (see page 6494)

CreateResolver (see page 6450)

Options (see page 6455)

applyupdates (see page 6468)

72.1.2.4.12 TBaseProvider.InternalGetRecords Method

Provides the underlying implementation of the GetRecords (see page 6476) method.

Pascal

```
function InternalGetRecords(Count: Integer; out RecsOut: Integer; Options: TGetRecordOptions;
const CommandText: WideString; var Params: OleVariant): OleVariant; override;
```

C++

```
virtual __fastcall OleVariant InternalGetRecords(int Count, int RecsOut, TGetRecordOptions
Options, const BSTR CommandText, OleVariant Params);
```

Description

The GetRecords (see page 6476) method calls InternalGetRecords to assemble a data packet after calling DoBeforeGetRecords (see page 6473) to apply the CommandText and Params and generate a BeforeGetRecords (see page 6488) event. InternalGetRecords calls CreateDataPacket (see page 6449) to create a data packet that reflects the current property settings of the provider. It then generates an OnGetData (see page 6459) event.

Count indicates the number of records to retrieve. If Count is -1, all records are retrieved. If Count is 0, only metadata is retrieved. If Count is greater than 0, only the specified number of records are retrieved.

RecsOut returns the actual number of records retrieved.

Options (see page 6455) indicates what information should be added to the data packet in addition to data. It can include grMetaData (include metadata), grReset (start providing records with the first one in the dataset), and grXML (encode the datapacket in XML rather than as an OleVariant) or grXMLUTF8 (same as grXML except extended characters are encoded using UTF8).

CommandText specifies an optional SQL statement that replaces the SQL of an associated query, or the name of a table or stored procedure that replaces the associated table or stored procedure. This parameter is ignored if the Options (see page 6455) property does not include poAllowCommandText.

Params specifies any parameter values that should be applied to CommandText or to an associated query or stored procedure.

If the provider is associated with a table, Params specifies field values that filter the result set. On exit from GetRecords (see page 6476), Params returns any output parameters.

Records are returned as a data packet in a Variant.

See Also

Data (see page 6482)

CreateDataPacket (see page 6449)

GetRecords (see page 6476)

OnGetData (see page 6459)

72.1.2.4.13 TBaseProvider.InternalRowRequest Method

Provides the underlying implementation of the RowRequest (see page 6480) method.

Pascal

```
function InternalRowRequest(const Row: OleVariant; RequestType: TFetchOptions): OleVariant;
override;
```

C++

```
virtual __fastcall OleVariant InternalRowRequest(const OleVariant Row, TFetchOptions
RequestType);
```

Description

The RowRequest (see page 6480) method calls InternalRowRequest to assemble the specified information after generating a BeforeRowRequest (see page 6490) event and before generating an AfterRowRequest (see page 6486) event. InternalRowRequest passes this request on to its associated Resolver (see page 6456).

The Row parameter is an OleVariant that describes the record for which information is requested. The provider uses Row to locate the record before assembling the requested information.

InternalRowRequest returns the requested information in a delta packet.

See Also

RowRequest (see page 6480)

Resolver (see page 6456)

RowRequest (see page 6500)

72.1.2.4.14 TBaseProvider.LocateRecord Method

Positions a data set on the record that corresponds to the current update in a specified delta packet.

Pascal

```
procedure LocateRecord(Source: TDataSet; Delta: TDataSet); virtual;
```

C++

```
virtual __fastcall LocateRecord(TDataSet Source, TDataSet Delta);
```

Description

LocateRecord is called indirectly by the RowRequest (see page 6480) method to locate a record before fetching information about a specified record. The Source parameter is the dataset containing current record values. The Delta parameter is a delta packet that identifies the desired type of information and information identifying the desired record.

As implemented in TBaseProvider (see page 6445), LocateRecord does nothing. Descendants override this method to locate the specified record in Source and navigate to it.

See Also

RowRequest (see page 6480)

72.1.2.4.15 TBaseProvider.UpdateRecord Method

Retrieves specified data from a source dataset into a delta packet.

Pascal

```
procedure UpdateRecord(Source: TDataSet; Delta: TDataSet; BlobsOnly: Boolean; KeyOnly:
Boolean); virtual;
```

C++

```
virtual __fastcall UpdateRecord(TDataSet Source, TDataSet Delta, Boolean BlobsOnly, Boolean
KeyOnly);
```

Description

UpdateRecord is called indirectly by the RowRequest (see page 6480) method to fetch BLOB fields or nested detail sets. The Source parameter is the dataset containing the BLOB fields or the detail dataset. The Delta parameter is a delta packet that returns the requested data. BlobsOnly indicates whether all field values should be provided (BlobsOnly == false) or only Blob field values (BlobsOnly == true).

As implemented in TBaseProvider (see page 6445), UpdateRecord does nothing. Descendants override this method to fill the Delta parameter with the requested information.

See Also

RowRequest (see page 6480)

72.1.2.5 TBaseProvider Properties

The properties of the TBaseProvider class are listed here.

Protected Properties

	Name	Description
	PacketDataSet (see page 6456)	This is PacketDataSet, a member of class TBaseProvider.

Public Properties

	Name	Description
	Options (see page 6455)	Influences what is included in data packets and how the information in data packets is used.
R	Resolver (see page 6456)	Provides access to the resolver component that applies updates and resolves update errors.
	UpdateMode (see page 6457)	Controls how the provider locates records when applying updates.

72.1.2.5.1 TBaseProvider.Options Property

Influences what is included in data packets and how the information in data packets is used.

Pascal

```
property Options: TProviderOptions;
```

C++

```
__property TProviderOptions Options;
```

Description

Set Options to customize how the provider communicates with client datasets. Options is a set that specifies

Whether nested detail sets and BLOB data are included in data packets or fetched separately.

Whether data packets include field component properties such as formats, display names, and maximum & minimum values.

Whether data packets are provided on a read-only basis, and whether specific types of changes (insertions, edits, or deletions) are disabled.

Whether changes to master table fields should cause corresponding updates to detail tables.

Whether a single update can affect multiple server records.

Whether the client's records are refreshed when it applies updates.

Whether the client can send SQL statements that override the provider's dataset.

Note: Not all options are supported by an InternetExpress client. Specifically, InternetExpress clients don't support poFetchBlobsOnDemand, poFetchDetailsOnDemand, poDisableInserts, poDisableEdits, psDisableDeletes, poPropogateChanges, and poAllowCommandText.

Overriding the Dataset On the Application Server

Setting Options That Influence the Data Packets

72.1.2.5.2 TBaseProvider.PacketDataSet Property

Pascal

```
property PacketDataSet: TPacketDataSet;
```

C++

```
__property TPacketDataSet PacketDataSet;
```

Description

This is PacketDataSet, a member of class TBaseProvider.

72.1.2.5.3 TBaseProvider.Resolver Property

Provides access to the resolver component that applies updates and resolves update errors.

Pascal

```
property Resolver: TCustomResolver;
```

C++

```
__property TCustomResolver Resolver;
```

Description

Provider (see page 6441) components use a resolver to handle the details of applying updates and resolving update errors. Most applications do not need to use the resolver directly.

When any method that uses a resolver is called, the provider automatically creates a resolver component (using the CreateResolver (see page 6450) method) if the value of Resolver is nil (Delphi) or NULL (C++). Thus, this property is nil (Delphi) or NULL (C++) until the first method that requires a resolver is called.

See Also

applyupdates (see page 6468)

CreateResolver (see page 6450)

72.1.2.5.4 TBaseProvider.UpdateMode Property

Controls how the provider locates records when applying updates.

Pascal

```
property UpdateMode: TUpdateMode;
```

C++

```
__property TUpdateMode UpdateMode;
```

Description

Use UpdateMode to specify the criteria for locating a record in the dataset when applying updates. UpdateMode specifies whether modified records are located based on all columns (fields), on only the key fields, or on the key fields plus the original values of fields that have been modified.

Note: To control how the provider locates records by specifying individual fields, use the field components' ProviderFlags property.

See Also

applyupdates (see page 6468)

ProviderFlags

Influencing How Updates Are Applied

72.1.2.6 TBaseProvider Events

The events of the TBaseProvider class are listed here.

Public Events

	Name	Description
	AfterUpdateRecord (see page 6458)	Occurs when the associated resolver has just updated a record.
	BeforeUpdateRecord (see page 6458)	This is BeforeUpdateRecord, a member of class TBaseProvider.
	OnDataRequest (see page 6458)	Occurs when a provider calls its DataRequest method.
	OnGetData (see page 6459)	Occurs after a provider retrieves data but before it is sent to the client.
	OnUpdateData (see page 6459)	Occurs when a provider begins to apply updates.
	OnUpdateError (see page 6460)	Occurs when a provider can't update a record because of an error condition.

72.1.2.6.1 TBaseProvider.AfterUpdateRecord Event

Occurs when the associated resolver has just updated a record.

Pascal

```
property AfterUpdateRecord: TAfterUpdateRecordEvent;
```

C++

```
__property TAfterUpdateRecordEvent AfterUpdateRecord;
```

Description

Write an AfterUpdateRecord event handler to provide special processing immediately after a record has been successfully updated. For example, use AfterUpdateRecord to maintain a log of successful updates.

See Also

beforeupdaterecord (see page 6458)

AfterApplyUpdates (see page 6483)

72.1.2.6.2 TBaseProvider.BeforeUpdateRecord Event

Pascal

```
property BeforeUpdateRecord: TBeforeUpdateRecordEvent;
```

C++

```
__property TBeforeUpdateRecordEvent BeforeUpdateRecord;
```

Description

This is BeforeUpdateRecord, a member of class TBaseProvider.

72.1.2.6.3 TBaseProvider.OnDataRequest Event

Occurs when a provider calls its DataRequest method.

Pascal

```
property OnDataRequest: TDataRequestEvent;
```

C++

```
__property TDataRequestEvent OnDataRequest;
```

Description

Write an OnDataRequest event handler to do custom processing of data. OnDataRequest has no built-in use. Instead, it allows developers to augment the IAppServer interface so that clients in a multi-tiered application can communicate directly with an individual provider.

If an application does not provide an OnDataRequest event handler, calls to DataRequest return NULL.

Note: To provide the same sort of custom processing on the client side, use an automation method on the connection component.

See Also

DataRequest (see page 6468)

IAppServer (see page 5222)

Communicating with Providers Using Custom Events

Communicating with the Client Dataset

Responding to Client-generated Events

72.1.2.6.4 TBaseProvider.OnGetData Event

Occurs after a provider retrieves data but before it is sent to the client.

Pascal

```
property OnGetData: TProviderDataEvent;
```

C++

```
__property TProviderDataEvent OnGetData;
```

Description

Write an OnGetData event handler to perform any custom data processing the provider should handle before returning data to a client. The OnGetData event occurs after a provider fetches data from its dataset but before the data is sent on to the client. Using the methods of the DataSet parameter, data can be edited in the OnGetData event handler before sending it to the client dataset or XML broker.

Note: OnGetData occurs when the Data (see page 6482) property is read, as well as when the GetRecords (see page 6476) method is called.

See Also

GetRecords (see page 6476)

OnUpdateData (see page 6459)

BeforeGetRecords (see page 6488)

AfterGetRecords (see page 6485)

Responding to Client Data Requests

72.1.2.6.5 TBaseProvider.OnUpdateData Event

Occurs when a provider begins to apply updates.

Pascal

```
property OnUpdateData: TProviderDataEvent;
```

C++

```
__property TProviderDataEvent OnUpdateData;
```

Description

Write an OnUpdateData event to handle special processing before the provider begins applying updates received from the client dataset or XML broker. Using the methods belonging to the DataSet parameter, an application can

Examine data (for example, for values or data changes that should not permitted), and raise exceptions that cancel applying of updates before they occur.

Change data (for example encrypting or decrypting values) before it is sent on to the source dataset or database server.

See Also

applyupdates (see page 6468)

beforeupdaterecord (see page 6458)

Adding Custom Information to Data Packets

Editing Delta Packets Before Updating the Database

Influencing How Updates Are Applied

72.1.2.6.6 TBaseProvider.OnUpdateError Event

Occurs when a provider can't update a record because of an error condition.

Pascal

```
property OnUpdateError: TResolverErrorEvent;
```

C++

```
__property TResolverErrorEvent OnUpdateError;
```

Description

Write an OnUpdateError event handler to respond to error conditions that arise when the provider applies a client dataset's updates. The OnUpdateError event handler is called for each record that can't be updated.

Warning: The provider can't detect when an update conflicts with another user's changes to a memo field. This situation will not generate an OnUpdateError event.

72.1.3 TCustomPacketWriter Class

Class Hierarchy

Pascal

```
TCustomPacketWriter = class(TObject);
```

C++

```
class TCustomPacketWriter : public TObject;
```

File

Provider

Description

This is class Provider.TCustomPacketWriter.

72.1.3.1 TCustomPacketWriter Members

The following tables list the members exposed by TCustomPacketWriter.

Protected Fields

	Name	Description
	FBuffer (see page 6462)	This is FBuffer, a member of class TCustomPacketWriter.

Protected Methods

	Name	Description
V	AddAttribute (see page 6463)	This is AddAttribute, a member of class TCustomPacketWriter.
	Check (see page 6463)	This is Check, a member of class TCustomPacketWriter.
	SetDSWriter (see page 6463)	This is SetDSWriter, a member of class TCustomPacketWriter.

Protected Properties

	Name	Description
R	DSWriter (see page 6464)	This is DSWriter, a member of class TCustomPacketWriter.

Public Methods

	Name	Description
V	Create (see page 6461)	Constructs an object and initializes its data before the object is first used.
V	Destroy (see page 6461)	Disposes of an object instance.

72.1.3.2 TCustomPacketWriter.Create Constructor

Constructs an object and initializes its data before the object is first used.

Pascal

```
constructor Create; virtual;
```

C++

```
virtual __fastcall TCustomPacketWriter();
```

Description

System::TObject::Create constructs an object. The purpose, size, and behavior of objects differ greatly. The System::TObject::Create constructor defined by System::TObject::TObject allocates memory but does not initialize data.

Descendant objects usually define a constructor that creates the particular kind of object and initializes its data.

Note: If an exception escapes from a constructor, the object's destructor is called to clean up the failed instance.

See Also

System::TObject::Destroy

System::TObject::Free

72.1.3.3 TCustomPacketWriter.Destroy Destructor

Disposes of an object instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomPacketWriter();
```

Description

Do not call System::TObject::Destroy directly. Call System::TObject::Free instead. Free verifies that the object reference is not nil before calling System::TObject::Destroy.

The System::TObject::Destroy method defined by System::TObject::TObject deallocates memory. Descendant objects usually define a destructor that is customized for that particular kind of object.

When declaring a System::TObject::Destroy method in a descendant, always add the override directive to the declaration and call the inherited System::TObject::Destroy as the last statement in the overriding method. Since System::TObject::Destroy is a virtual method, overriding it ensures that the proper inherited behavior occurs.

Note: If an exception escapes from the constructor, the destructor is called to destroy the partially constructed object instance that failed to initialize completely. Therefore, destructors should check that allocated resources, such as handles, were actually allocated before trying to release them, since their value might be zero.

System::TObject::Destroy should be implemented so that it calls System::TObject::Free on all subobjects created within the object's constructor (that is, allocated by the constructor). Unlike System::TObject::Destroy, System::TObject::Free provides a safeguard when destroying objects that are nil.

See Also

System::TObject::Free

72.1.3.4 TCustomPacketWriter Fields

The fields of the TCustomPacketWriter class are listed here.

Protected Fields

	Name	Description
	FBuffer (see page 6462)	This is FBuffer, a member of class TCustomPacketWriter.

72.1.3.4.1 TCustomPacketWriter.FBuffer Field

Pascal

```
FBuffer: TBlobByteData;
```

C++

```
TBlobByteData FBuffer;
```

Description

This is FBuffer, a member of class TCustomPacketWriter.

72.1.3.5 TCustomPacketWriter Methods

The methods of the TCustomPacketWriter class are listed here.

Protected Methods

	Name	Description
	AddAttribute (see page 6463)	This is AddAttribute, a member of class TCustomPacketWriter.
	Check (see page 6463)	This is Check, a member of class TCustomPacketWriter.
	SetDSWriter (see page 6463)	This is SetDSWriter, a member of class TCustomPacketWriter.

72.1.3.5.1 TCustomPacketWriter.AddAttribute Method

Pascal

```
procedure AddAttribute(Area: TPcktAttrArea; const ParamName: string; const Value: OleVariant;
IncludeInDelta: Boolean); virtual;
```

C++

```
virtual __fastcall AddAttribute(TPcktAttrArea Area, const UnicodeString ParamName, const
OleVariant Value, Boolean IncludeInDelta);
```

Description

This is AddAttribute, a member of class TCustomPacketWriter.

72.1.3.5.2 TCustomPacketWriter.Check Method

Pascal

```
procedure Check(Status: Integer);
```

C++

```
__fastcall Check(int Status);
```

Description

This is Check, a member of class TCustomPacketWriter.

72.1.3.5.3 TCustomPacketWriter.SetDSWriter Method

Pascal

```
procedure SetDSWriter(const Value: IDSWriter);
```

C++

```
__fastcall SetDSWriter(const IDSWriter Value);
```

Description

This is SetDSWriter, a member of class TCustomPacketWriter.

72.1.3.6 TCustomPacketWriter Properties

The properties of the TCustomPacketWriter class are listed here.

Protected Properties

	Name	Description
	DSWriter (see page 6464)	This is DSWriter, a member of class TCustomPacketWriter.

72.1.3.6.1 TCustomPacketWriter.DSWriter Property

Pascal

```
property DSWriter: IDSWriter;
```

C++

```
__property IDSWriter DSWriter;
```

Description

This is DSWriter, a member of class TCustomPacketWriter.

72.1.4 TCustomProvider Class

TCustomProvider is the base class for data providers.

Class Hierarchy

Pascal

```
TCustomProvider = class(TComponent);
```

C++

```
class TCustomProvider : public TComponent;
```

File

Provider

Description

TCustomProvider defines the fundamental properties, methods, and events required of all provider objects, either through abstract (in C++ terminology, pure virutal) method declarations, or through virtual methods that do nothing but provide a backstop.

Do not create instances of TCustomProvider. To add a provider component to a form or data module, use a descendant of TCustomProvider such as TDataSetProvider (see page 6510) or TXMLTransformProvider.

A provider derived from TCustomProvider is an intermediate link between TClientDataSet or TXMLBroker object and a source dataset or source XML document. The source dataset or XML document can reside in the same application as the client dataset or XML broker, or it can be part of a separate application server. The provider packages data from the source dataset or XML document and passes it in one or more transportable data packets to the client dataset or XML broker. The client dataset reconstructs the data in the data packet to create a local, in-memory copy for user access. When user access is complete, the client dataset repackages any changed data and sends the updates back to the provider. The provider applies the updates to the database or source dataset.

When the provider supplies data to a client dataset, the client dataset reconstructs the data in the data packet to create a local, in-memory copy for user access. When user access is complete, the client dataset repackages any changed data and sends the updates back to the provider. The provider applies the updates to the database, to the source dataset, or to the source XML document.

If the provider can encode data packets in XML, it can supply data to an XML broker, which adds the data packet to an HTML document that is downloaded by a Web client. When the XML broker receives updates from the Web client, it sends the updates to the provider, which applies them to the database, to the source dataset, or to the source XML document.

Client datasets and XML brokers communicate with a provider through the IAppServer (see page 5222) interface. In multi-tiered applications, this is the interface of the remote data module that contains the provider. To enable the remote data module to pass calls to the provider, the provider's Exported (see page 6482) property must be true, and its Owner property must specify the remote data module.

TXMLTransformProvider

72.1.4.1 TCustomProvider Members

The following tables list the members exposed by TCustomProvider.

Protected Events

	Name	Description
	AfterApplyUpdates (see page 6483)	Occurs after the provider applies updates.
	AfterExecute (see page 6484)	Occurs after the provider passes an execute command to its dataset.
	AfterGetParams (see page 6485)	This is AfterGetParams, a member of class TCustomProvider.
	AfterGetRecords (see page 6485)	Occurs after the provider creates a data packet to send to the client dataset.
	AfterRowRequest (see page 6486)	Occurs after the provider fetches new information about the current record.
	BeforeApplyUpdates (see page 6487)	Occurs before the provider applies updates from a client dataset.
	BeforeExecute (see page 6487)	This is BeforeExecute, a member of class TCustomProvider.
	BeforeGetParams (see page 6488)	Occurs before the provider creates an OleVariant that encodes the current parameter values and sends them to a client dataset.
	BeforeGetRecords (see page 6488)	Occurs before the provider creates a data packet and sends it to a client dataset.
	BeforeRowRequest (see page 6490)	Occurs before the provider creates a delta packet with information about the current record.
	OnDataRequest (see page 6490)	Occurs when a provider calls its DataRequest (see page 6468) method.
	OnValidate (see page 6491)	This is OnValidate, a member of class TCustomProvider.

Protected Methods

	Name	Description
	DoAfterApplyUpdates (see page 6469)	Generates an AfterApplyUpdates (see page 6483) event.
	DoAfterExecute (see page 6469)	Generates an AfterExecute (see page 6484) event.
	DoAfterGetParams (see page 6470)	Generates an AfterGetParams (see page 6485) event.
	DoAfterGetRecords (see page 6470)	Generates an AfterGetRecords (see page 6485) event.
	DoAfterRowRequest (see page 6471)	Generates an AfterRowRequest (see page 6486) event.
	DoApplyUpdates (see page 6471)	This is DoApplyUpdates, a member of class TCustomProvider.
	DoBeforeApplyUpdates (see page 6471)	Generates a BeforeApplyUpdates (see page 6487) event.
	DoBeforeExecute (see page 6472)	Generates a BeforeExecute (see page 6487) event.
	DoBeforeGetParams (see page 6472)	Generates a BeforeGetParams (see page 6488) event.
	DoBeforeGetRecords (see page 6473)	Generates a BeforeGetRecords (see page 6488) event.
	DoBeforeRowRequest (see page 6474)	Generates a BeforeRowRequest (see page 6490) event.
	DoGetRecords (see page 6474)	This is DoGetRecords, a member of class TCustomProvider.
	InternalApplyUpdates (see page 6477)	Provides the underlying implementation of the ApplyUpdates (see page 6468) method.
	InternalExecute (see page 6478)	Provides the underlying implementation of the Execute (see page 6474) method.
	InternalGetParams (see page 6478)	Returns the requested parameter values as a Variant array.
	InternalGetRecords (see page 6479)	Provides the underlying implementation of the GetRecords (see page 6476) method.

	InternalRowRequest (see page 6480)	Provides the underlying implementation of the RowRequest (see page 6480) method.
	SetActiveUpdateException (see page 6481)	This is SetActiveUpdateException, a member of class TCustomProvider.

Protected Properties

	Name	Description
	ActiveUpdateException (see page 6482)	This is ActiveUpdateException, a member of class TCustomProvider.
	OwnerData (see page 6483)	This is OwnerData, a member of class TCustomProvider.

Public Methods

	Name	Description
	ApplyUpdates (see page 6468)	This is the overview for the ApplyUpdates method overload.
	Create (see page 6466)	Creates a new TCustomProvider (see page 6464) object.
	DataRequest (see page 6468)	Generates an OnDataRequest (see page 6490) event.
	Destroy (see page 6467)	Frees an instance of a provider object.
	Execute (see page 6474)	Executes a query, stored procedure, or custom SQL statement.
	GetParams (see page 6475)	Returns the current parameter values.
	GetRecords (see page 6476)	This is the overview for the GetRecords method overload.
	RowRequest (see page 6480)	Returns information from a specified record.

Public Properties

	Name	Description
	Data (see page 6482)	Denotes a data packet created by the provider.
	Exported (see page 6482)	Allows client applications to pass calls to the provider when it resides on an application server.

72.1.4.2 TCustomProvider.Create Constructor

Creates a new TCustomProvider (see page 6464) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomProvider(TComponent * AOwner);
```

Description

Call Create to instantiate a provider at runtime. Providers placed in forms or data modules at design time are created automatically.

The constructor assigns the AOwner parameter as the owner of the provider. This owner is responsible for freeing the provider when it is destroyed. If the owner is a remote data module, the constructor registers the provider with that remote data module so that it is available to client applications through the IAppServer (see page 5222) interface.

See Also

IAppServer (see page 5222)

Providers

registerprovider

Owner

72.1.4.3 TCustomProvider.Destroy Destructor

Frees an instance of a provider object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomProvider();
```

Description

Do not call Destroy directly. Instead, call Free, which checks that the provider is not nil before calling its Destroy method. If the provider's Owner is a remote data module, Destroy unregisters the provider from that remote data module.

72.1.4.4 TCustomProvider Methods

The methods of the TCustomProvider class are listed here.

Protected Methods

	Name	Description
	DoAfterApplyUpdates (see page 6469)	Generates an AfterApplyUpdates (see page 6483) event.
	DoAfterExecute (see page 6469)	Generates an AfterExecute (see page 6484) event.
	DoAfterGetParams (see page 6470)	Generates an AfterGetParams (see page 6485) event.
	DoAfterGetRecords (see page 6470)	Generates an AfterGetRecords (see page 6485) event.
	DoAfterRowRequest (see page 6471)	Generates an AfterRowRequest (see page 6486) event.
	DoApplyUpdates (see page 6471)	This is DoApplyUpdates, a member of class TCustomProvider.
	DoBeforeApplyUpdates (see page 6471)	Generates a BeforeApplyUpdates (see page 6487) event.
	DoBeforeExecute (see page 6472)	Generates a BeforeExecute (see page 6487) event.
	DoBeforeGetParams (see page 6472)	Generates a BeforeGetParams (see page 6488) event.
	DoBeforeGetRecords (see page 6473)	Generates a BeforeGetRecords (see page 6488) event.
	DoBeforeRowRequest (see page 6474)	Generates a BeforeRowRequest (see page 6490) event.
	DoGetRecords (see page 6474)	This is DoGetRecords, a member of class TCustomProvider.
	InternalApplyUpdates (see page 6477)	Provides the underlying implementation of the ApplyUpdates (see page 6468) method.
	InternalExecute (see page 6478)	Provides the underlying implementation of the Execute (see page 6474) method.
	InternalGetParams (see page 6478)	Returns the requested parameter values as a Variant array.
	InternalGetRecords (see page 6479)	Provides the underlying implementation of the GetRecords (see page 6476) method.
	InternalRowRequest (see page 6480)	Provides the underlying implementation of the RowRequest (see page 6480) method.
	SetActiveUpdateException (see page 6481)	This is SetActiveUpdateException, a member of class TCustomProvider.

Public Methods

	Name	Description
	ApplyUpdates (see page 6468)	This is the overview for the ApplyUpdates method overload.
	DataRequest (see page 6468)	Generates an OnDataRequest (see page 6490) event.
	Execute (see page 6474)	Executes a query, stored procedure, or custom SQL statement.
	GetParams (see page 6475)	Returns the current parameter values.
	GetRecords (see page 6476)	This is the overview for the GetRecords method overload.
	RowRequest (see page 6480)	Returns information from a specified record.

72.1.4.4.1 ApplyUpdates Method

This is the overview for the ApplyUpdates method overload.

Overload List

	Name	Description
	TCustomProvider.ApplyUpdates (OleVariant, Integer, Integer) (see page 6468)	This is ApplyUpdates, a member of class TCustomProvider.
	TCustomProvider.ApplyUpdates (OleVariant, Integer, Integer, OleVariant) (see page 6468)	This is ApplyUpdates, a member of class TCustomProvider.

72.1.4.4.1.1 TCustomProvider.ApplyUpdates Method (OleVariant, Integer, Integer)

Pascal

```
function ApplyUpdates(const Delta: OleVariant; MaxErrors: Integer; out ErrorCount: Integer):
OleVariant; overload;
```

C++

```
__fastcall OleVariant ApplyUpdates(const OleVariant Delta, int MaxErrors, int ErrorCount);
```

Description

This is ApplyUpdates, a member of class TCustomProvider.

72.1.4.4.1.2 TCustomProvider.ApplyUpdates Method (OleVariant, Integer, Integer, OleVariant)

Pascal

```
function ApplyUpdates(const Delta: OleVariant; MaxErrors: Integer; out ErrorCount: Integer;
var OwnerData: OleVariant): OleVariant; overload;
```

C++

```
__fastcall OleVariant ApplyUpdates(const OleVariant Delta, int MaxErrors, int ErrorCount,
OleVariant OwnerData);
```

Description

This is ApplyUpdates, a member of class TCustomProvider.

72.1.4.4.2 TCustomProvider.DataRequest Method

Generates an OnDataRequest (see page 6490) event.

Pascal

```
function DataRequest(Input: OleVariant): OleVariant; virtual;
```

C++

```
virtual __fastcall OleVariant DataRequest(OleVariant Input);
```

Description

Write an OnDataRequest (see page 6490) event handler and call the DataRequest function to invoke the event handler at runtime. This function and the event it invokes enable an application to perform custom processing in response to a request for data.

Note: Calling the client dataset's DataRequest method causes a call to the provider's DataRequest method.

See Also

OnDataRequest (see page 6490)

AS_DataRequest (see page 5224)

DataRequest

Communicating with the Client Dataset

72.1.4.4.3 TCustomProvider.DoAfterApplyUpdates Method

Generates an AfterApplyUpdates (see page 6483) event.

Pascal

```
procedure DoAfterApplyUpdates(var OwnerData: OleVariant); virtual;
```

C++

```
virtual __fastcall DoAfterApplyUpdates(OleVariant OwnerData);
```

Description

The ApplyUpdates (see page 6468) method calls DoAfterApplyUpdates to generate the AfterApplyUpdates (see page 6483) event after applying updates and resolving any update errors that are handled by the provider.

OwnerData (see page 6483) supplies custom information to the AfterApplyUpdates (see page 6483) event handler. This is the same as the outgoing OwnerData (see page 6483) parameter of the BeforeApplyUpdates (see page 6487) event handler. The AfterApplyUpdates (see page 6483) event handler can change this value. The returned value is then passed to the client if it supplied an OwnerData (see page 6483) parameter when calling ApplyUpdates (see page 6468).

See Also

applyupdates (see page 6468)

AfterApplyUpdates (see page 6483)

BeforeApplyUpdates (see page 6487)

72.1.4.4.4 TCustomProvider.DoAfterExecute Method

Generates an AfterExecute (see page 6484) event.

Pascal

```
procedure DoAfterExecute(var OwnerData: OleVariant); virtual;
```

C++

```
virtual __fastcall DoAfterExecute(OleVariant OwnerData);
```

Description

The Execute (see page 6474) method calls DoAfterExecute to generate the AfterExecute (see page 6484) event after executing CommandText or the associated query or stored procedure but before fetching any output parameters.

OwnerData (see page 6483) supplies custom information to the AfterExecute (see page 6484) event handler. This is the same as the outgoing OwnerData (see page 6483) parameter of the BeforeExecute (see page 6487) event handler. The AfterExecute (see page 6484) event handler can change this value. The returned value is then passed to the client.

See Also

Execute (see page 6474)

AfterExecute (see page 6484)

beforeexecute (see page 6487)

72.1.4.4.5 TCustomProvider.DoAfterGetParams Method

Generates an AfterGetParams (see page 6485) event.

Pascal

```
procedure DoAfterGetParams(var OwnerData: OleVariant); virtual;
```

C++

```
virtual __fastcall DoAfterGetParams(OleVariant OwnerData);
```

Description

The GetParams (see page 6475) method calls DoAfterGetParams to generate the AfterGetParams (see page 6485) event after fetching the current parameter values of the associated dataset.

OwnerData (see page 6483) supplies custom information to the AfterGetParams (see page 6485) event handler. This is the same as the outgoing OwnerData (see page 6483) parameter of the BeforeGetParams (see page 6488) event handler. The AfterGetParams (see page 6485) event handler can change this value. The returned value is then passed to the client.

See Also

GetParams (see page 6475)

aftergetparams (see page 6485)

BeforeGetParams (see page 6488)

72.1.4.4.6 TCustomProvider.DoAfterGetRecords Method

Generates an AfterGetRecords (see page 6485) event.

Pascal

```
procedure DoAfterGetRecords(var OwnerData: OleVariant); virtual;
```

C++

```
virtual __fastcall DoAfterGetRecords(OleVariant OwnerData);
```

Description

The GetRecords (see page 6476) method calls DoAfterGetRecords to generate the AfterGetRecords (see page 6485) event after assembling a data packet but before updating the parameters to reflect any output parameters.

OwnerData (see page 6483) supplies custom information to the AfterGetRecords (see page 6485) event handler. This is the same as the outgoing OwnerData (see page 6483) parameter of the BeforeGetRecords (see page 6488) event handler. The AfterGetRecords (see page 6485) event handler can change this value. The returned value is then passed to the client.

See Also

GetRecords (see page 6476)

AfterGetRecords (see page 6485)

BeforeGetRecords (see page 6488)

72.1.4.4.7 TCustomProvider.DoAfterRowRequest Method

Generates an AfterRowRequest (see page 6486) event.

Pascal

```
procedure DoAfterRowRequest(var OwnerData: OleVariant); virtual;
```

C++

```
virtual __fastcall DoAfterRowRequest(OleVariant OwnerData);
```

Description

The RowRequest (see page 6480) method calls DoAfterRowRequest to generate the AfterRowRequest (see page 6486) event after fetching the requested data.

OwnerData (see page 6483) supplies custom information to the AfterRowRequest (see page 6486) event handler. This is the same as the outgoing OwnerData (see page 6483) parameter of the BeforeRowRequest (see page 6490) event handler. The AfterRowRequest (see page 6486) event handler can change this value. The returned value is then passed to the client.

See Also

RowRequest (see page 6480)

AfterRowRequest (see page 6486)

BeforeRowRequest (see page 6490)

72.1.4.4.8 TCustomProvider.DoApplyUpdates Method

Pascal

```
function DoApplyUpdates(const Delta: OleVariant; MaxErrors: Integer; out ErrorCount: Integer;
var OwnerData: OleVariant): OleVariant; virtual;
```

C++

```
virtual __fastcall OleVariant DoApplyUpdates(const OleVariant Delta, int MaxErrors, int
ErrorCount, OleVariant OwnerData);
```

Description

This is DoApplyUpdates, a member of class TCustomProvider.

72.1.4.4.9 TCustomProvider.DoBeforeApplyUpdates Method

Generates a BeforeApplyUpdates (see page 6487) event.

Pascal

```
procedure DoBeforeApplyUpdates(var OwnerData: OleVariant); virtual;
```

C++

```
virtual __fastcall DoBeforeApplyUpdates(OleVariant OwnerData);
```

Description

The ApplyUpdates (see page 6468) method calls DoBeforeApplyUpdates to generate the BeforeApplyUpdates (see page 6487) event before it applies the updates in Delta.

Delta is the delta packet containing the updates as received from the client.

MaxErrors is the number of errors tolerated before the update operation should aborted.

OwnerData (see page 6483) supplies custom information to the BeforeApplyUpdates (see page 6487) event handler. The BeforeApplyUpdates (see page 6487) event handler can change this value. The returned value is then passed to the AfterApplyUpdates (see page 6483) event handler after applying the updates in Delta.

As implemented in TCustomProvider (see page 6464), Delta and MaxErrors are ignored.

See Also

applyupdates (see page 6468)

AfterApplyUpdates (see page 6483)

BeforeApplyUpdates (see page 6487)

72.1.4.4.10 TCustomProvider.DoBeforeExecute Method

Generates a BeforeExecute (see page 6487) event.

Pascal

```
procedure DoBeforeExecute(const CommandText: WideString; var Params: OleVariant; var
OwnerData: OleVariant); virtual;
```

C++

```
virtual __fastcall DoBeforeExecute(const BSTR CommandText, OleVariant Params, OleVariant
OwnerData);
```

Description

The Execute (see page 6474) method calls DoBeforeExecute to generate the BeforeExecute (see page 6487) event before it executes CommandText or executes an associated query or stored procedure.

CommandText specifies an optional SQL statement that replaces the SQL of an associated query, or the name of a stored procedure that replaces the associated stored procedure. This parameter is ignored if the Options property does not include poAllowCommandText.

Params contains any parameter values that should be applied to CommandText or to the query or stored procedure before execution.

OwnerData (see page 6483) supplies custom information to the BeforeExecute (see page 6487) event handler. The event handler can change this value. The returned value is then passed to an AfterExecute (see page 6484) event handler and then returned to the caller of the Execute (see page 6474) method.

As implemented in TCustomProvider (see page 6464), CommandText and Params are ignored. Descendant classes apply these values before generating the BeforeExecute (see page 6487) event.

See Also

Execute (see page 6474)

beforeexecute (see page 6487)

AfterExecute (see page 6484)

Options (see page 6455)

72.1.4.4.11 TCustomProvider.DoBeforeGetParams Method

Generates a BeforeGetParams (see page 6488) event.

Pascal

```
procedure DoBeforeGetParams(var OwnerData: OleVariant); virtual;
```

C++

```
virtual __fastcall DoBeforeGetParams(OleVariant OwnerData);
```

Description

The GetParams (see page 6475) method calls DoBeforeGetParams to generate the BeforeGetParams (see page 6488) event before fetching the current parameter values of the associated dataset.

OwnerData (see page 6483) supplies custom information to the BeforeGetParams (see page 6488) event handler. The event handler can change this value. The returned value is then passed to an AfterGetParams (see page 6485) event handler and then returned to the caller of the GetParams (see page 6475) method.

See Also

GetParams (see page 6475)

BeforeGetParams (see page 6488)

aftergetparams (see page 6485)

72.1.4.4.12 TCustomProvider.DoBeforeGetRecords Method

Generates a BeforeGetRecords (see page 6488) event.

Pascal

```
procedure DoBeforeGetRecords(Count: Integer; Options: Integer; const CommandText: WideString;
var Params: OleVariant; var OwnerData: OleVariant); virtual;
```

C++

```
virtual __fastcall DoBeforeGetRecords(int Count, int Options, const BSTR CommandText,
OleVariant Params, OleVariant OwnerData);
```

Description

The GetRecords (see page 6476) method calls DoBeforeGetRecords to generate the BeforeGetRecords (see page 6488) event before it fetches data and assembles it into a data packet.

Count is the number of records requested. If Count is –1, all records are requested.

Options indicates whether the data packet should include metadata, whether it should start with the first record, and whether the data packet should be encoded in XML. For details, see the GetRecords (see page 6476) method.

CommandText specifies an optional SQL statement that replaces the SQL of an associated query, or the name of a table or stored procedure that replaces the associated table or stored procedure. This parameter is ignored if the Options property does not include poAllowCommandText or if the provider does not have an Options property.

Params contains any parameter values that should be applied to CommandText or to a query or stored procedure before fetching data into a data packet.

OwnerData (see page 6483) supplies custom information to the BeforeGetRecords (see page 6488) event handler. The event handler can change this value. The returned value is then passed to an AfterGetRecords (see page 6485) event handler and then (optionally) returned to the caller of the GetRecords (see page 6476) method.

As implemented in TCustomProvider (see page 6464), Count, Options, CommandText, and Params are ignored. Descendant classes can apply these values before generating the BeforeExecute (see page 6487) event.

See Also

GetRecords (see page 6476)

BeforeGetRecords (see page 6488)

AfterGetRecords (see page 6485)

Options (see page 6455)

72.1.4.4.13 TCustomProvider.DoBeforeRowRequest Method

Generates a BeforeRowRequest (see page 6490) event.

Pascal

```
procedure DoBeforeRowRequest(var OwnerData: OleVariant); virtual;
```

C++

```
virtual __fastcall DoBeforeRowRequest(OleVariant OwnerData);
```

Description

The RowRequest (see page 6480) method calls DoBeforeRowRequest to generate the BeforeRowRequest (see page 6490) event before fetching the requested data.

OwnerData (see page 6483) supplies custom information to the BeforeRowRequest (see page 6490) event handler. The event handler can change this value. The returned value is then passed to an AfterRowRequest (see page 6486) event handler and then returned to the caller of the RowRequest (see page 6480) method.

See Also

RowRequest (see page 6480)

BeforeRowRequest (see page 6490)

AfterRowRequest (see page 6486)

72.1.4.4.14 TCustomProvider.DoGetRecords Method

Pascal

```
function DoGetRecords(Count: Integer; out RecsOut: Integer; Options: Integer; const
CommandText: WideString; var Params: OleVariant; var OwnerData: OleVariant): OleVariant;
virtual;
```

C++

```
virtual __fastcall OleVariant DoGetRecords(int Count, int RecsOut, int Options, const BSTR
CommandText, OleVariant Params, OleVariant OwnerData);
```

Description

This is DoGetRecords, a member of class TCustomProvider.

72.1.4.4.15 TCustomProvider.Execute Method

Executes a query, stored procedure, or custom SQL statement.

Pascal

```
procedure Execute(const CommandText: WideString; var Params: OleVariant; var OwnerData:
OleVariant); virtual;
```

C++

```
virtual __fastcall Execute(const BSTR CommandText, OleVariant Params, OleVariant OwnerData);
```

Description

Client datasets call Execute through the AS_Execute method of the IAppServer (see page 5222) interface. In response, the

provider executes an SQL command. If the provider represents a query or stored procedure that does not return a cursor, calling Execute causes the provider to execute the query or stored procedure. If the caller supplies a value for CommandText, Execute may execute that statement instead (see below).

Before executing the appropriate command, Execute generates a BeforeExecute (see page 6487) event. After executing the command, it generates an AfterExecute (see page 6484) event. Finally, it returns any output parameters as the value of the Params parameter.

CommandText is an SQL statement that replaces the SQL of an associated query, or the name of a stored procedure that replaces the associated stored procedure. This parameter is ignored if the Options property does not include poAllowCommandText.

On entry, Params supplies parameter values for the query, stored procedure, or CommandText string. On exit, Params returns any output parameters.

OwnerData (see page 6483) contains custom information passed to the provider from the client dataset's BeforeExecute (see page 6487) event handler. This information is passed in to the provider's BeforeExecute (see page 6487) event handler and is returned by the provider's AfterExecute (see page 6484) event handler.

Communicating with the Client Dataset

72.1.4.4.16 TCustomProvider.GetParams Method

Returns the current parameter values.

Pascal

```
function GetParams(var OwnerData: OleVariant): OleVariant; virtual;
```

C++

```
virtual __fastcall OleVariant GetParams(OleVariant OwnerData);
```

Description

GetParams returns a variant array of variant arrays that contains the current parameter values for the provider's data source. The first array dimension is an index into all the parameter values. Its value runs from 0 to one less than the number of parameters. The second array dimension has four values: The parameter name (a Delphi string or a C++ AnsiString), the parameter data type (a TFieldType), the parameter type (a TParamType), and the parameter value (a Variant). The values in this array can be applied to a TParams object using the global UnpackParams procedure.

Before fetching the current parameter values, GetParams generates a BeforeGetParams (see page 6488) event, passing the value supplied as the OwnerData (see page 6483) parameter to the event handler. After creating the OleVariant that contains

the parameter values, GetParams generates an AfterGetParams (see page 6485) event, passing in the current value of OwnerData (see page 6483). Finally, the value of OwnerData (see page 6483) returned by the AfterGetParams (see page 6485) is returned in the OwnerData (see page 6483) parameter.

72.1.4.4.17 GetRecords Method

This is the overview for the GetRecords method overload.

Overload List

	Name	Description
	TCustomProvider.GetRecords (Integer, Integer, Integer) (see page 6476)	Retrieves a data packet that represents the provider's associated data.
	TCustomProvider.GetRecords (Integer, Integer, Integer, WideString, OleVariant, OleVariant) (see page 6476)	Retrieves a data packet that represents the provider's associated data.

72.1.4.4.17.1 TCustomProvider.GetRecords Method (Integer, Integer, Integer)

Retrieves a data packet that represents the provider's associated data.

Pascal

```
function GetRecords(Count: Integer; out RecsOut: Integer; Options: Integer): OleVariant;
overload;
function GetRecords(Count: Integer; out RecsOut: Integer; Options: Integer; const CommandText:
WideString; var Params: OleVariant; var OwnerData: OleVariant): OleVariant; overload;
```

C++

```
__fastcall OleVariant GetRecords(int Count, int RecsOut, int Options);
__fastcall OleVariant GetRecords(int Count, int RecsOut, int Options, const BSTR CommandText,
OleVariant Params, OleVariant OwnerData);
```

Description

Call GetRecords to retrieve a data packet containing a specified number of records. GetRecords generates a BeforeGetRecords (see page 6488) event, assembles a data packet, and then generates an AfterGetRecords (see page 6485) event.

Count indicates the number of records to retrieve. If Count is -1, all records are retrieved. If Count is 0, only metadata is retrieved. If Count is greater than 0, only the specified number of records are retrieved.

RecsOut returns the actual number of records in the data packet.

Options indicates what information should be added to the data packet in addition to data. It is a combination of the GetRecordOption constants. For example, the following value requests metadata along with a data packet encoded in XML:

```
MetaDataOption + XMLOption
MetaDataOption || XMLOption
```

CommandText specifies an optional SQL statement that replaces the SQL of an associated query, or the name of a table or stored procedure that replaces the associated table or stored procedure. This parameter is ignored if the Options property does not include poAllowCommandText or if the provider does not have an Options property.

Params specifies any parameter values that should be applied to CommandText or to an associated query or stored procedure. If the provider is associated with a TTable, Params specifies field values that filter the result set. On exit from GetRecords, Params returns any output parameters.

OwnerData (see page 6483) contains custom information that is supplied by a client dataset's BeforeGetRecords (see page 6488) event handler. This information is passed to the provider's BeforeGetRecords (see page 6488) event handler and is returned by the provider's AfterGetRecords (see page 6485) event handler.

Records are returned as a data packet in a Variant.

Note: GetRecords always generates the BeforeGetRecords (see page 6488) and AfterGetRecords (see page 6485) events, even if you use the syntax that does not include an OwnerData (see page 6483) parameter. In that case, the value of OwnerData (see page 6483) is nil (Delphi) or NULL (C++) on entry to the BeforeGetRecords (see page 6488) event handler and is discarded on exit from the AfterGetRecords (see page 6485) event handler.

Tip: If the provider is part of a stateless application server, there is no guarantee that the provider will be positioned on the desired record before it creates a data packet. Use a BeforeGetRecords (see page 6488) event handler to position the cursor before the call to GetRecords.

Responding to Client Data Requests

72.1.4.4.18 TCustomProvider.InternalApplyUpdates Method

Provides the underlying implementation of the ApplyUpdates (see page 6468) method.

Pascal

```
function InternalApplyUpdates(const Delta: OleVariant; MaxErrors: Integer; out ErrorCount:
```

```
Integer): OleVariant; virtual; abstract;
```

C++

```
virtual __fastcall OleVariant InternalApplyUpdates(const OleVariant Delta, int MaxErrors, int
ErrorCount) = 0;
```

Description

The ApplyUpdates (see page 6468) method calls InternalApplyUpdates to apply the updates contained in a delta packet after generating the BeforeApplyUpdates (see page 6487) event and before generating the AfterApplyUpdates (see page 6483) event. The InternalApplyUpdates method of TCustomProvider (see page 6464) is abstract (Delphi) or pure virtual (C++), meaning that it has no implementation. Descendant classes override this method to apply updates, resolve update errors, and return any updates that could not be applied.

Delta is the delta packet containing insertions, deletions, and modifications to be applied.

MaxErrors indicates the maximum number of errors that can be applied before stopping the update operation. If MaxErrors is –1, the provider tries to apply all updates.

ErrorCount returns the number of errors encountered during the update operation.

InternalApplyUpdates returns a data packet of updates that could not be applied to the database as an OleVariant.

See Also

applyupdates (see page 6468)

72.1.4.4.19 TCustomProvider.InternalExecute Method

Provides the underlying implementation of the Execute (see page 6474) method.

Pascal

```
procedure InternalExecute(const CommandText: WideString; var Params: OleVariant); virtual;
```

C++

```
virtual __fastcall InternalExecute(const BSTR CommandText, OleVariant Params);
```

Description

The Execute (see page 6474) method calls InternalExecute to execute the appropriate SQL statement after calling DoBeforeExecute (see page 6472) to generate a BeforeExecute (see page 6487) event and apply the CommandText and Params. As Implemented in TCustomProvider (see page 6464), InternalExecute does nothing. Descendants override this method to pass the execute command on to an associated dataset.

CommandText is an SQL statement that replaces the SQL of an associated query, or the name of a stored procedure that replaces the associated stored procedure. This parameter is ignored if the Options property does not include poAllowCommandText.

On entry, Params supplies parameter values for the query, stored procedure, or CommandText string. On exit, Params returns any output parameters.

See Also

Execute (see page 6474)

DoBeforeExecute (see page 6472)

72.1.4.4.20 TCustomProvider.InternalGetParams Method

Returns the requested parameter values as a Variant array.

Pascal

```
function InternalGetParams(Types: TParamTypes = AllParamTypes): OleVariant; virtual;
```

C++

```
virtual __fastcall OleVariant InternalGetParams(TParamTypes Types = AllParamTypes);
```

Description

TCustomProvider (see page 6464) uses InternalGetParams internally whenever it needs to assemble the current parameter values into an OleVariant. This provides the underlying implementation of the GetParams (see page 6475) method, as well as assembling parameter values for methods that return output parameters (such as Execute (see page 6474) or GetRecords (see page 6476)).

The Types parameter limits the parameter values that are returned to a subset of all possible parameter types. If this parameter is omitted, all parameter values are returned.

As implemented in TCustomProvider (see page 6464), InternalGetParams always returns NULL. Descendants override this method to return the requested parameter values.

See Also

GetParams (see page 6475)

Execute (see page 6474)

GetRecords (see page 6476)

72.1.4.4.21 TCustomProvider.InternalGetRecords Method

Provides the underlying implementation of the GetRecords (see page 6476) method.

Pascal

```
function InternalGetRecords(Count: Integer; out RecsOut: Integer; Options: TGetRecordOptions;
const CommandText: WideString; var Params: OleVariant): OleVariant; virtual;
```

C++

```
virtual __fastcall OleVariant InternalGetRecords(int Count, int RecsOut, TGetRecordOptions
Options, const BSTR CommandText, OleVariant Params);
```

Description

The GetRecords (see page 6476) method calls InternalGetRecords to assemble a data packet after calling DoBeforeGetRecords (see page 6473) to apply the CommandText and Params and generate a BeforeGetRecords (see page 6488) event. As implemented in TCustomProvider (see page 6464), InternalGetRecords always returns NULL. Descendant classes override this method to fetch the requested records and assemble them into a data packet.

Count indicates the number of records to retrieve. If Count is -1, all records are retrieved. If Count is 0, only metadata is retrieved. If Count is greater than 0, only the specified number of records are retrieved.

RecsOut returns the actual number of records retrieved.

Options indicates what information should be added to the data packet in addition to data. It can include grMetaData (include metadata), grReset (start providing records with the first one in the dataset), and grXML (encode the datapacket in XML rather than as an OleVariant) or grXMLUTF8 (same as grXML except extended characters are encoded using UTF8).

CommandText specifies an optional SQL statement that replaces the SQL of an associated query, or the name of a table or stored procedure that replaces the associated table or stored procedure. This parameter is ignored if the Options property does not include poAllowCommandText or if the provider does not have an Options property.

Params specifies any parameter values that should be applied to CommandText or to an associated query or stored procedure.

If the provider is associated with a TTable object, Params specifies field values that filter the result set. On exit from GetRecords (see page 6476), Params returns any output parameters.

Records are returned as a data packet in a Variant.

See Also

GetRecords (see page 6476)

DoBeforeGetRecords (see page 6473)

72.1.4.4.22 TCustomProvider.InternalRowRequest Method

Provides the underlying implementation of the RowRequest (see page 6480) method.

Pascal

```
function InternalRowRequest(const Row: OleVariant; RequestType: TFetchOptions): OleVariant;
virtual;
```

C++

```
virtual __fastcall OleVariant InternalRowRequest(const OleVariant Row, TFetchOptions
RequestType);
```

Description

The RowRequest (see page 6480) method calls InternalRowRequest to assemble the specified information after generating a BeforeRowRequest (see page 6490) event and before generating an AfterRowRequest (see page 6486) event. As implemented in TCustomProvider (see page 6464), InternalRowRequest does nothing. Descendant classes override this method to assemble the requested information into an OleVariant.

The Row parameter is an OleVariant that describes the current record on the client dataset. It enables the provider to locate the record of interest.

InternalRowRequest returns the requested information in a delta packet.

See Also

RowRequest (see page 6480)

72.1.4.4.23 TCustomProvider.RowRequest Method

Returns information from a specified record.

Pascal

```
function RowRequest(const Row: OleVariant; RequestType: Integer; var OwnerData: OleVariant):
OleVariant; virtual;
```

C++

```
virtual __fastcall OleVariant RowRequest(const OleVariant Row, int RequestType, OleVariant
OwnerData);
```

Description

RowRequest is called automatically in response to the client dataset's FetchBlobs, FetchDetails, or RefreshRecord method. It generates a BeforeRowRequest (see page 6490) event, assembles the requested information, and generates an AfterRowRequest (see page 6486) event.

The Row parameter is an OleVariant that describes the record about which information is requested. It enables the provider to locate the record of interest.

The RequestType parameter indicates the type of information required. It is an integer version of the TFetchOptions type. (Its an

integer because the value must be marshaled over an IAppServer (see page 5222) interface). In Delphi, to convert the TFetchOptions value to the appropriate integer, use the Ord function. In C++, to combine TFetchOption values, use the bitwise "or" operator. For example:

```
Ord(foBlobs) + Ord(foDetails);
foBlobs || foDetails
```

RowRequest returns the requested information in a delta packet.

As implemented in TCustomProvider (see page 6464), RowRequest always returns NULL. Descendant classes override this method to return the requested data.

72.1.4.4.24 TCustomProvider.SetActiveUpdateException Method

Pascal

```
procedure SetActiveUpdateException(E: Exception);
```

C++

```
__fastcall SetActiveUpdateException(Exception E);
```

Description

This is SetActiveUpdateException, a member of class TCustomProvider.

72.1.4.5 TCustomProvider Properties

The properties of the TCustomProvider class are listed here.

Protected Properties

	Name	Description
	ActiveUpdateException (see page 6482)	This is ActiveUpdateException, a member of class TCustomProvider.
	OwnerData (see page 6483)	This is OwnerData, a member of class TCustomProvider.

Public Properties

	Name	Description
	Data (see page 6482)	Denotes a data packet created by the provider.
	Exported (see page 6482)	Allows client applications to pass calls to the provider when it resides on an application server.

72.1.4.5.1 TCustomProvider.ActiveUpdateException Property

Pascal

```
property ActiveUpdateException: Exception;
```

C++

```
__property Exception ActiveUpdateException;
```

Description

This is ActiveUpdateException, a member of class TCustomProvider.

72.1.4.5.2 TCustomProvider.Data Property

Denotes a data packet created by the provider.

Pascal

```
property Data: OleVariant;
```

C++

```
__property OleVariant Data;
```

Description

Data is a read-only property that provides access to a data packet containing all records. Reading Data calls GetRecords (see page 6476) with a parameter of -1.

As implemented in TCustomProvider (see page 6464), GetRecords (see page 6476) returns NULL. Descendants of TCustomProvider (see page 6464) reimplement the GetRecords (see page 6476) method to implement the Data property.

See Also

GetRecords (see page 6476)

72.1.4.5.3 TCustomProvider.Exported Property

Allows client applications to pass calls to the provider when it resides on an application server.

Pascal

```
property Exported: Boolean;
```

C++

```
__property Boolean Exported;
```

Description

Use Exported to indicate whether the provider is made available to clients of a remote data module that owns it. When Exported is true, client applications can specify the provider as a target for calls made using the IAppServer (see page 5222) interface. When Exported is false, IAppServer (see page 5222) calls that specify the provider cause an exception.

Note: In addition to the Exported property, the provider must be registered with the remote data module for clients to access it using the data module's IAppServer (see page 5222) interface. When the provider's Owner is the remote data module, it is automatically registered. If the provider has a different owner, the server application must explicitly register providers using the remote data module's RegisterProvider method.

IAppServer (see page 5222)

Providers

registerprovider

72.1.4.5.4 TCustomProvider.OwnerData Property

Pascal

```
property OwnerData: OleVariant;
```

C++

```
__property OleVariant OwnerData;
```

Description

This is OwnerData, a member of class TCustomProvider.

72.1.4.6 TCustomProvider Events

The events of the TCustomProvider class are listed here.

Protected Events

	Name	Description
	AfterApplyUpdates (see page 6483)	Occurs after the provider applies updates.
	AfterExecute (see page 6484)	Occurs after the provider passes an execute command to its dataset.
	AfterGetParams (see page 6485)	This is AfterGetParams, a member of class TCustomProvider.
	AfterGetRecords (see page 6485)	Occurs after the provider creates a data packet to send to the client dataset.
	AfterRowRequest (see page 6486)	Occurs after the provider fetches new information about the current record.
	BeforeApplyUpdates (see page 6487)	Occurs before the provider applies updates from a client dataset.
	BeforeExecute (see page 6487)	This is BeforeExecute, a member of class TCustomProvider.
	BeforeGetParams (see page 6488)	Occurs before the provider creates an OleVariant that encodes the current parameter values and sends them to a client dataset.
	BeforeGetRecords (see page 6488)	Occurs before the provider creates a data packet and sends it to a client dataset.
	BeforeRowRequest (see page 6490)	Occurs before the provider creates a delta packet with information about the current record.
	OnDataRequest (see page 6490)	Occurs when a provider calls its DataRequest (see page 6468) method.
	OnValidate (see page 6491)	This is OnValidate, a member of class TCustomProvider.

72.1.4.6.1 TCustomProvider.AfterApplyUpdates Event

Occurs after the provider applies updates.

Pascal

```
property AfterApplyUpdates: TRemoteEvent;
```

C++

```
__property TRemoteEvent AfterApplyUpdates;
```

Description

Write an AfterApplyUpdates event handler to return custom information to a client dataset after applying updates. AfterApplyUpdates is part of the mechanism by which a client dataset and a provider communicate information about updates. When the provider is part of a stateless application server, this mechanism allows the provider and the client dataset to communicate persistent state information.

When the client dataset calls the AS_ApplyUpdates method of the IAppServer (see page 5222) interface, the following events occur:

1.The provider receives a BeforeApplyUpdates (see page 6487) event, where it can respond to or change custom information that the client dataset sends.

2.If it is a dataset provider, the provider receives an OnUpdateData event where it can edit the updates before they are applied.

3. The provider applies the updates, and attempts to resolve problems.

4.The provider receives an AfterApplyUpdates event, where it can encode custom information into its OwnerData (see page 6483) parameter or respond to information from the BeforeApplyUpdates (see page 6487) event handler.

5.The client dataset receives an AfterApplyUpdates event, where it can respond to the custom information returned by the provider in its AfterApplyUpdates event handler.

Note: If ApplyUpdates (see page 6468) is called without the OwnerData (see page 6483) parameter, on entry to the event handler the OwnerData (see page 6483) parameter contains the value set in the BeforeApplyUpdates (see page 6487) event handler and it is ignored on exit from the AfterApplyUpdates event handler.

Responding to Client Update Requests

Communicating with the Client Dataset

72.1.4.6.2 TCustomProvider.AfterExecute Event

Occurs after the provider passes an execute command to its dataset.

Pascal

```
property AfterExecute: TRemoteEvent;
```

C++

```
__property TRemoteEvent AfterExecute;
```

Description

Write an AfterExecute event handler to return custom information to a client dataset after executing a query or stored procedure. AfterExecute is part of the mechanism by which a client dataset and a provider communicate information when executing queries or stored procedures that do not return a cursor. When the provider is part of a stateless application server, this mechanism allows the provider and the client dataset to communicate persistent state information.

When the client dataset calls the AS_Execute method of the IAppServer (see page 5222) interface, the following events occur:

1.The provider receives a BeforeExecute (see page 6487) event, where it can respond to or change custom information that the client dataset sends.

2.The provider dispatches its Execute (see page 6474) method to execute a query or stored procedure.

3.The provider receives an AfterExecute event, where it can encode custom information into its OwnerData (see page 6483) parameter or respond to information from the BeforeExecute (see page 6487) event handler.

4.The client dataset receives an AfterExecute event, where it can respond to the custom information returned by the provider in its AfterExecute event handler.

72.1.4.6.3 TCustomProvider.AfterGetParams Event

Pascal

```
property AfterGetParams: TRemoteEvent;
```

C++

```
__property TRemoteEvent AfterGetParams;
```

Description

This is AfterGetParams, a member of class TCustomProvider.

72.1.4.6.4 TCustomProvider.AfterGetRecords Event

Occurs after the provider creates a data packet to send to the client dataset.

Pascal

```
property AfterGetRecords: TRemoteEvent;
```

C++

```
__property TRemoteEvent AfterGetRecords;
```

Description

Write an AfterGetRecords event handler to send custom information to a client dataset when providing a data packet. AfterGetRecords is part of the mechanism by which a provider and a client dataset communicate information about data fetching. When the provider is part of a stateless application server, this mechanism allows the provider and the client dataset to communicate persistent state information.

When the client dataset calls the AS_GetRecords method of the IAppServer (see page 5222) interface, the following events occur:

1.The provider receives a BeforeGetRecords (see page 6488) event, where it can respond to or change custom information that the client dataset sends.

2.If it is a dataset provider, the provider receives an OnGetData event where it can edit the data before creating a data packet, and then generates the data packet.

3.The provider receives an AfterGetRecords event, where it can encode custom information into its OwnerData (see page 6483) parameter or respond to information from the BeforeGetRecords (see page 6488) event handler.

4.The client dataset receives an AfterGetRecords event, where it can respond to the custom information returned by the provider

in its AfterGetRecords event handler.

Responding to Client Data Requests

72.1.4.6.5 TCustomProvider.AfterRowRequest Event

Occurs after the provider fetches new information about the current record.

Pascal

```
property AfterRowRequest: TRemoteEvent;
```

C++

```
__property TRemoteEvent AfterRowRequest;
```

Description

Write an AfterRowRequest event handler to send custom information to a client dataset along with information about the current record. AfterRowRequest is part of the mechanism by which a provider and a client dataset communicate information about data fetching. When the provider is part of a stateless application server, this mechanism allows the provider and the client dataset to communicate persistent state information.

When the client dataset calls the AS_RowRequest method of the IAppServer (see page 5222) interface, the following events occur:

1.The provider receives a BeforeRowRequest (see page 6490) event, where it can respond to or change custom information that the client dataset sends.

2.The provider creates a delta packet that contains the requested information.

3.The provider receives an AfterRowRequest event, where it can encode custom information into its OwnerData (see page 6483) parameter or respond to information from the BeforeRowRequest (see page 6490) event handler.

4.The client dataset receives an AfterRowRequest event, where it can respond to the custom information returned by the provider in its AfterRowRequest event handler.

72.1.4.6.6 TCustomProvider.BeforeApplyUpdates Event

Occurs before the provider applies updates from a client dataset.

Pascal

```
property BeforeApplyUpdates: TRemoteEvent;
```

C++

```
__property TRemoteEvent BeforeApplyUpdates;
```

Description

Write a BeforeApplyUpdates event handler to respond to custom information from a client dataset. BeforeApplyUpdates is part of the mechanism by which a provider and a client dataset communicate information about updates. When the provider is part of a stateless application server, this mechanism allows the provider and the client dataset to communicate persistent state information.

When the client dataset's ApplyUpdates (see page 6468) method is called, the following events occur:

1.The client dataset receives a BeforeApplyUpdates event, where it can encode custom information into an OleVariant.

2.The provider receives a BeforeApplyUpdates event, where the OleVariant from the client dataset appears as the OwnerData (see page 6483) parameter. The provider can respond to or change that information before applying the updates.

3.If it is a dataset provider, the provider applies the updates, and receives an OnUpdateError event for any problem records.

4.The provider receives an AfterApplyUpdates (see page 6483) event, where it can encode custom information into its OwnerData (see page 6483) parameter or respond to information from the BeforeApplyUpdates event handler.

5.The client dataset receives an AfterApplyUpdates (see page 6483) event, where it can respond to the custom information returned by the provider in its AfterApplyUpdates (see page 6483) event handler.

Note: If ApplyUpdates (see page 6468) is called without the OwnerData (see page 6483) parameter, the OwnerData (see page 6483) parameter is nil (Delphi) or NULL (C++) on entry to the event handler and its value (on exit) is only passed to the AfterApplyUpdates (see page 6483) event handler but not returned to the caller.

72.1.4.6.7 TCustomProvider.BeforeExecute Event

Pascal

```
property BeforeExecute: TRemoteEvent;
```

C++

```
__property TRemoteEvent BeforeExecute;
```

Description

This is BeforeExecute, a member of class TCustomProvider.

72.1.4.6.8 TCustomProvider.BeforeGetParams Event

Occurs before the provider creates an OleVariant that encodes the current parameter values and sends them to a client dataset.

Pascal

```
property BeforeGetParams: TRemoteEvent;
```

C++

```
__property TRemoteEvent BeforeGetParams;
```

Description

Write a BeforeGetParams event handler to respond to custom information from a client dataset. BeforeGetParams is part of the mechanism by which a provider and a client dataset communicate information during parameter fetching. When the provider is part of a stateless application server, this mechanism allows the provider and the client dataset to communicate persistent state information.

When the client dataset fetches parameter values from the provider, the following events occur:

1.The client dataset receives a BeforeGetParams event, where it can encode custom information into an OleVariant.

2.The provider receives a BeforeGetParams event, where the OleVariant from the client dataset appears as the OwnerData (see page 6483) parameter. The provider can respond to or change that information before it fetches and encodes the parameter values.

3.The provider generates an OleVariant for the current parameter values of its dataset, if appropriate.

4.The provider receives an AfterGetParams (see page 6485) event, where it can encode custom information into its OwnerData (see page 6483) parameter or respond to information from the BeforeGetParams event handler.

5.The client dataset receives an AfterGetParams (see page 6485) event, where it can respond to the custom information returned by the provider in its AfterGetParams (see page 6485) event handler.

Communicating with the Client Dataset

72.1.4.6.9 TCustomProvider.BeforeGetRecords Event

Occurs before the provider creates a data packet and sends it to a client dataset.

Pascal

```
property BeforeGetRecords: TRemoteEvent;
```

C++

```
__property TRemoteEvent BeforeGetRecords;
```

Description

Write a BeforeGetRecords event handler to respond to custom information from a client dataset. BeforeGetRecords is part of the mechanism by which a provider and a client dataset communicate information about data fetching. When the provider is part of a stateless application server, this mechanism allows the provider and the client dataset to communicate persistent state information.

When the client dataset fetches data from the provider, the following events occur:

1.The client dataset receives a BeforeGetRecords event, where it can encode custom information into an OleVariant.

2.The provider receives a BeforeGetRecords event, where the OleVariant from the client dataset appears as the OwnerData (see page 6483) parameter. The provider can respond to or change that information before it creates a data packet.

3.The provider generates the data packet.

4.The provider receives an AfterGetRecords (see page 6485) event, where it can encode custom information into its OwnerData (see page 6483) parameter or respond to information from the BeforeGetRecords event handler.

5.The client dataset receives an AfterGetRecords (see page 6485) event, where it can respond to the custom information returned by the provider in its AfterGetRecords (see page 6485) event handler.

Delphi Examples:

```
{
This example shows the implementation of a provider BeforeGetRecords
event handler and a RemoteDataModule UpdateRegistry method.  The
complete project using this code example is in
Demos/DelphiWin32/VCLWin32/MIDAS/Pooler.
}
procedure TPooledRDM.DataSetProvider1BeforeGetRecords(Sender: TObject;
  var OwnerData: OleVariant);
begin
  try
    Query1.Close;
    Query1.SQL.Text := OwnerData[0];
    if not VarIsNull(OwnerData[1]) and not VarIsEmpty(OwnerData[1]) then
    begin
      Query1.Open;
      if not Query1.Locate(Query1.Fields[0].FieldName, OwnerData[1], []) then
        raise Exception.Create('Record not found');
      Query1.Next;
    end;
  finally
    OwnerData := NULL;
  end;
end;
```

Communicating with the Client Dataset

Responding to Client Data Requests

72.1.4.6.10 TCustomProvider.BeforeRowRequest Event

Occurs before the provider creates a delta packet with information about the current record.

Pascal

```
property BeforeRowRequest: TRemoteEvent;
```

C++

```
__property TRemoteEvent BeforeRowRequest;
```

Description

Write a BeforeRowRequest event handler to respond to custom information from a client dataset. BeforeRowRequest is part of the mechanism by which a provider and a client dataset communicate information about data fetching. When the provider is part of a stateless application server, this mechanism allows the provider and the client dataset to communicate persistent state information.

When the client dataset fetches detail information about the current record or refreshes the current record, the following events occur:

1.The client dataset receives a BeforeRowRequest event, where it can encode custom information into an OleVariant.

2.The provider receives a BeforeRowRequest event, where the custom information appears as the OwnerData (see page 6483) parameter. The provider can respond to or change that information before it looks up the requested information.

3.The provider creates a delta packet that contains the requested information.

4.The provider receives an AfterRowRequest (see page 6486) event, where it can encode custom information into its OwnerData (see page 6483) parameter or respond to information from the BeforeRowRequest event handler.

5.The client dataset receives an AfterRowRequest (see page 6486) event, where it can respond to the custom information returned by the provider in its AfterRowRequest (see page 6486) event handler.

Communicating with the Client Dataset

72.1.4.6.11 TCustomProvider.OnDataRequest Event

Occurs when a provider calls its DataRequest (see page 6468) method.

Pascal

```
property OnDataRequest: TDataRequestEvent;
```

C++

```
__property TDataRequestEvent OnDataRequest;
```

Description

Write an OnDataRequest event handler to do custom processing of data. OnDataRequest has no built-in use. Instead, it allows developers to augment the IAppServer (see page 5222) interface so that clients in a multi-tiered application can communicate directly with an individual provider.

If an application does not provide an OnDataRequest event handler, calls to DataRequest (see page 6468) return NULL.

Note: To provide the same sort of custom processing on the client side, use an automation method on the connection component.

DataRequest (see page 6468)

IAppServer (see page 5222)

Communicating with Providers Using Custom Events

Communicating with the Client Dataset

Responding to Client-generated Events

72.1.4.6.12 TCustomProvider.OnValidate Event

Pascal

```
property OnValidate: TOnValidate;
```

C++

```
__property TOnValidate OnValidate;
```

Description

This is OnValidate, a member of class TCustomProvider.

72.1.5 TCustomResolver Class

TCustomResolver is the base class for components that apply updates on behalf of a provider.

Class Hierarchy

Pascal

```
TCustomResolver = class(TComponent);
```

C++

```
class TCustomResolver : public TComponent;
```

File

Provider

Description

TCustomResolver defines the fundamental properties and methods used by resolver components for applying updates from a client dataset or XML broker and resolving errors that occur as part of that update process.

TCustomResolver has two descendants: TDataSetResolver (see page 6540), which applies updates to a dataset, and TSQLResolver (see page 6564), which applies updates directly to a database server.

Do not create resolver instances. Provider (see page 6501) components create their own TCustomResolver descendants for applying updates.

See Also

TDataSetProvider (see page 6510)

TBaseProvider (see page 6445)

TDataSetResolver (see page 6540)

TSQLResolver (see page 6564)

72.1.5.1 TCustomResolver Members

The following tables list the members exposed by TCustomResolver.

Protected Methods

	Name	Description
	BeginUpdate (see page 6494)	Provides the interface for a method that performs any initialization before applying updates.
	DoDelete (see page 6495)	Defines a method that deletes a record.
	DoInsert (see page 6495)	Defines a method that inserts a record.
	DoUpdate (see page 6496)	Defines a method that modifies a record.
	EndUpdate (see page 6496)	Provides the interface for a method that performs any finalization after applying updates.
	HandleUpdateError (see page 6497)	Manages the resolving process when errors occur while applying updates.
	InitializeConflictBuffer (see page 6497)	Introduces a method for adding information about a failed update that is passed to an OnUpdateError event handler.
	LogUpdateError (see page 6499)	This is LogUpdateError, a member of class TCustomResolver.
	LogUpdateRecord (see page 6500)	Adds records to the error log if their data has been changed by another application.

Public Methods

	Name	Description
	ApplyUpdates (see page 6494)	Applies updates received from a provider.
	Create (see page 6493)	Creates and initializes a resolver.
	Destroy (see page 6493)	Frees an instance of a resolver object.
	FreeTreeData (see page 6497)	This is FreeTreeData, a member of class TCustomResolver.
	InitKeyFields (see page 6498)	Sets the provider flag pfInKey on all key fields in a delta data packet.
	InitTreeData (see page 6498)	This is InitTreeData, a member of class TCustomResolver.
	InternalBeforeResolve (see page 6498)	Initializes internal data structures once the delta packet has been wrapped in an update tree but before any updates are applied.
	InternalUpdateRecord (see page 6499)	Manages the updating process once a delta packet is wrapped in a TUpdateTree (see page 6572) object.
	RowRequest (see page 6500)	Returns information from a specified record.

Public Properties

	Name	Description
	Provider (see page 6501)	Indicates the provider that uses this resolver to apply updates.
	UpdateTree (see page 6501)	This is UpdateTree, a member of class TCustomResolver.

72.1.5.2 TCustomResolver.Create Constructor

Creates and initializes a resolver.

Pascal

```
constructor Create(AProvider: TBaseProvider); reintroduce;
```

C++

```
__fastcall TCustomResolver(TBaseProvider AProvider);
```

Description

Provider (see page 6501) components call the TCustomResolver (see page 6491) constructor when they need a resolver component for applying updates. The AProvider parameter specifies the provider that creates and uses the resolver.

Do not create resolver instances directly. Resolvers are designed to be created and used by providers, and can not function independently of a provider.

See Also

Resolver (see page 6456)

72.1.5.3 TCustomResolver.Destroy Destructor

Frees an instance of a resolver object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomResolver();
```

Description

Applications rarely have to destroy resolvers explicitly. Once a resolver has been assigned as the Resolver property of a provider, the provider is responsible for freeing the resolver.

See Also

System::TObject::Free

Resolver (see page 6456)

72.1.5.4 TCustomResolver Methods

The methods of the TCustomResolver class are listed here.

Protected Methods

	Name	Description
	BeginUpdate (see page 6494)	Provides the interface for a method that performs any initialization before applying updates.
	DoDelete (see page 6495)	Defines a method that deletes a record.
	DoInsert (see page 6495)	Defines a method that inserts a record.
	DoUpdate (see page 6496)	Defines a method that modifies a record.
	EndUpdate (see page 6496)	Provides the interface for a method that performs any finalization after applying updates.

	HandleUpdateError (see page 6497)	Manages the resolving process when errors occur while applying updates.
	InitializeConflictBuffer (see page 6497)	Introduces a method for adding information about a failed update that is passed to an OnUpdateError event handler.
	LogUpdateError (see page 6499)	This is LogUpdateError, a member of class TCustomResolver.
	LogUpdateRecord (see page 6500)	Adds records to the error log if their data has been changed by another application.

Public Methods

	Name	Description
	ApplyUpdates (see page 6494)	Applies updates received from a provider.
	FreeTreeData (see page 6497)	This is FreeTreeData, a member of class TCustomResolver.
	InitKeyFields (see page 6498)	Sets the provider flag pfInKey on all key fields in a delta data packet.
	InitTreeData (see page 6498)	This is InitTreeData, a member of class TCustomResolver.
	InternalBeforeResolve (see page 6498)	Initializes internal data structures once the delta packet has been wrapped in an update tree but before any updates are applied.
	InternalUpdateRecord (see page 6499)	Manages the updating process once a delta packet is wrapped in a TUpdateTree (see page 6572) object.
	RowRequest (see page 6500)	Returns information from a specified record.

72.1.5.4.1 TCustomResolver.ApplyUpdates Method

Applies updates received from a provider.

Pascal

```
function ApplyUpdates(const Delta: OleVariant; MaxErrors: Integer; out ErrorCount: Integer):
OleVariant; virtual;
```

C++

```
virtual __fastcall OleVariant ApplyUpdates(const OleVariant Delta, int MaxErrors, int
ErrorCount);
```

Description

Providers call ApplyUpdates to apply updates received from a client dataset or XML broker.

ApplyUpdates generates an OnUpdateData event on the associated provider, and then applies the updates passed in as the Delta parameter, returning an OleVariant that contains any updates that could not be applied.

The Delta parameter specifies a delta packet that contains the insertions, deletions, and modifications to be applied. MaxErrors indicates the maximum number of errors to permit before aborting the update operation. ErrorCount returns the actual number of errors encountered during the update operation. If ErrorCount is greater than MaxErrors, (or an OnUpdateError event returns rrAbort), all updates that have been successfully applied so far are rolled back, and the update process is aborted.

If the associated provider has an OnUpdateError event handler, it is called automatically whenever a record in Delta cannot be updated. In the OnUpdateError handler, applications can correct error conditions and try reapplying an update before returning unsuccessfully updated records back to the client dataset or XML broker.

See Also

OnUpdateData (see page 6459)

OnUpdateError (see page 6460)

applyupdates (see page 6468)

72.1.5.4.2 TCustomResolver.BeginUpdate Method

Provides the interface for a method that performs any initialization before applying updates.

Pascal

```
procedure BeginUpdate; virtual;
```

C++

```
virtual __fastcall BeginUpdate();
```

Description

The ApplyUpdates (see page 6494) method calls BeginUpdate before applying updates in a delta packet.

As implemented in TCustomResolver (see page 6491), BeginUpdate does nothing. Descendants that need take specific action before applying updates override this method.

See Also

EndUpdate (see page 6496)

ApplyUpdates (see page 6494)

72.1.5.4.3 TCustomResolver.DoDelete Method

Defines a method that deletes a record.

Pascal

```
procedure DoDelete(Tree: TUpdateTree); virtual; abstract;
```

C++

```
virtual __fastcall DoDelete(TUpdateTree Tree) = 0;
```

Description

DoDelete is one of several helper methods internal to the ApplyUpdates (see page 6494) method. These helper methods perform the actual updates in the delta packet. ApplyUpdates (see page 6494) wraps the delta packet in a TUpdateTree (see page 6572) object. For each record that must be deleted, the resolver calls DoDelete.

TCustomResolver (see page 6491) does not implement the DoDelete method. Descendants override this method to delete records in their own specialized way.

See Also

ApplyUpdates (see page 6494)

DoInsert (see page 6495)

DoUpdate (see page 6496)

72.1.5.4.4 TCustomResolver.DoInsert Method

Defines a method that inserts a record.

Pascal

```
procedure DoInsert(Tree: TUpdateTree); virtual; abstract;
```

C++

```
virtual __fastcall DoInsert(TUpdateTree Tree) = 0;
```

Description

DoInsert is one of several helper methods internal to the ApplyUpdates (see page 6494) method. These helper methods perform the actual updates in the delta packet. ApplyUpdates (see page 6494) wraps the delta packet in a TUpdateTree (

see page 6572) object. For each record that must be inserted, the resolver calls DoInsert.

TCustomResolver (see page 6491) does not implement the DoInsert method. Descendants override this method to insert records in their own specialized way.

See Also

ApplyUpdates (see page 6494)

DoDelete (see page 6495)

DoUpdate (see page 6496)

72.1.5.4.5 TCustomResolver.DoUpdate Method

Defines a method that modifies a record.

Pascal

```
procedure DoUpdate(Tree: TUpdateTree); virtual; abstract;
```

C++

```
virtual __fastcall DoUpdate(TUpdateTree Tree) = 0;
```

Description

DoUpdate is one of several helper methods internal to the ApplyUpdates (see page 6494) method. These helper methods perform the actual updates passed in the delta packet. ApplyUpdates (see page 6494) wraps the delta packet in a TUpdateTree (see page 6572) object. For each record that must be modified, the resolver calls DoUpdate.

TCustomResolver (see page 6491) does not implement the DoUpdate method. Descendants override this method to insert records in their own specialized way.

See Also

ApplyUpdates (see page 6494)

DoDelete (see page 6495)

DoInsert (see page 6495)

72.1.5.4.6 TCustomResolver.EndUpdate Method

Provides the interface for a method that performs any finalization after applying updates.

Pascal

```
procedure EndUpdate; virtual;
```

C++

```
virtual __fastcall EndUpdate();
```

Description

The ApplyUpdates (see page 6494) method calls EndUpdate after applying updates.

As implemented in TCustomResolver (see page 6491), EndUpdate does nothing. Descendants that need take specific action after applying updates override this method.

See Also

BeginUpdate (see page 6494)

ApplyUpdates (see page 6494)

72.1.5.4.7 TCustomResolver.FreeTreeData Method

Pascal

```
procedure FreeTreeData(Tree: TUpdateTree); virtual;
```

C++

```
virtual __fastcall FreeTreeData(TUpdateTree Tree);
```

Description

This is FreeTreeData, a member of class TCustomResolver.

72.1.5.4.8 TCustomResolver.HandleUpdateError Method

Manages the resolving process when errors occur while applying updates.

Pascal

```
function HandleUpdateError(Tree: TUpdateTree; E: EUpdateError; var MaxErrors: Integer; var
ErrorCount: Integer): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean HandleUpdateError(TUpdateTree Tree, EUpdateError E, int MaxErrors,
int ErrorCount);
```

Description

When a resolver encounters errors in applying updates, it calls HandleUpdateError to determine how to proceed. HandleUpdateError generates an OnUpdateError event on the associated provider so that applications have an opportunity to correct update errors. Depending on the response provided by the OnUpdateError handler (if any), HandleUpdateError logs the unresolved error or signals that the resolver should try to apply the (corrected) record again.

The Tree parameter specifies the TUpdateTree (see page 6572) that wraps all the updates currently being applied. The MaxErrors parameter indicates the maximum number of errors that the resolver will tolerate before the update operation is rolled back. The ErrorCount parameter specifies how many errors have been encountered so far.

HandleUpdateError returns true if the record has been corrected and the resolver should try to reapply the update. It returns false if the record is added to the error log.

See Also

OnUpdateError (see page 6460)

ApplyUpdates (see page 6494)

72.1.5.4.9 TCustomResolver.InitializeConflictBuffer Method

Introduces a method for adding information about a failed update that is passed to an OnUpdateError event handler.

Pascal

```
procedure InitializeConflictBuffer(Tree: TUpdateTree); virtual; abstract;
```

C++

```
virtual __fastcall InitializeConflictBuffer(TUpdateTree Tree) = 0;
```

Description

The HandleUpdateError (see page 6497) method calls InitializeConflictBuffer before generating an OnUpdateError event. This ensures that the client dataset passed to an OnUpdateError event handler represents the update that caused the problem, with

appropriate values for field's CurValue property.

Descendants of TCustomResolver (see page 6491) implement this method to obtain information from the dataset or server to which they are applying updates.

See Also

HandleUpdateError (see page 6497)

OnUpdateError (see page 6460)

72.1.5.4.10 TCustomResolver.InitKeyFields Method

Sets the provider flag pfInKey on all key fields in a delta data packet.

Pascal

```
procedure InitKeyFields(Tree: TUpdateTree; ADelta: TPacketDataSet); virtual;
```

C++

```
virtual __fastcall InitKeyFields(TUpdateTree Tree, TPacketDataSet ADelta);
```

Description

InitKeyFields is used internally to mark fields from a delta packet that can be used to uniquely identify records in the underlying dataset.

The Tree parameter is the internal TUpdateTree (see page 6572) that the resolver uses to store information about the delta packet. The ADelta parameter is the delta packet of changes to apply. For every field in this delta packet that acts as a key value to uniquely identify records, InitKeyFields adds pfInKey to its ProviderFlags property.

See Also

ProviderFlags

72.1.5.4.11 TCustomResolver.InitTreeData Method

Pascal

```
procedure InitTreeData(Tree: TUpdateTree); virtual;
```

C++

```
virtual __fastcall InitTreeData(TUpdateTree Tree);
```

Description

This is InitTreeData, a member of class TCustomResolver.

72.1.5.4.12 TCustomResolver.InternalBeforeResolve Method

Initializes internal data structures once the delta packet has been wrapped in an update tree but before any updates are applied.

Pascal

```
procedure InternalBeforeResolve(Tree: TUpdateTree); virtual;
```

C++

```
virtual __fastcall InternalBeforeResolve(TUpdateTree Tree);
```

Description

The ApplyUpdates (see page 6494) method wraps delta packets in a TUpdateTree (see page 6572) object. Once this is

complete, InternalBeforeResolve performs any other initialization before the updates are applied.

As implemented in TCustomResolver (see page 6491), InternalBeforeResolve does nothing. Descendants override this method to perform class-specific initialization.

See Also

ApplyUpdates (see page 6494)

inittreedata (see page 6498)

72.1.5.4.13 TCustomResolver.InternalUpdateRecord Method

Manages the updating process once a delta packet is wrapped in a TUpdateTree (see page 6572) object.

Pascal

```
function InternalUpdateRecord(Tree: TUpdateTree): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean InternalUpdateRecord(TUpdateTree Tree);
```

Description

InternalUpdateRecord orchestrates the updating process, ensuring that updates are applied in the correct order and that errors are resolved or logged. For each record that must be updated, InternalUpdateRecord

1.Generates a BeforeUpdateRecord event.

2.Applies the update.

3.Generates an AfterUpdateRecord event if the update is successful, or calls HandleUpdateError (see page 6497) to generate an OnUpdateError event.

See Also

ApplyUpdates (see page 6494)

beforeupdaterecord (see page 6458)

AfterUpdateRecord (see page 6458)

OnUpdateError (see page 6460)

HandleUpdateError (see page 6497)

72.1.5.4.14 TCustomResolver.LogUpdateError Method

Pascal

```
procedure LogUpdateError(Tree: TUpdateTree; E: EUpdateError; Response: TResolverResponse);
virtual;
```

C++

```
virtual __fastcall LogUpdateError(TUpdateTree Tree, EUpdateError E, TResolverResponse
Response);
```

Description

This is LogUpdateError, a member of class TCustomResolver.

72.1.5.4.15 TCustomResolver.LogUpdateRecord Method

Adds records to the error log if their data has been changed by another application.

Pascal

```
procedure LogUpdateRecord(Tree: TUpdateTree); virtual;
```

C++

```
virtual __fastcall LogUpdateRecord(TUpdateTree Tree);
```

Description

When the InternalUpdateRecord (see page 6499) method detects that a record includes other changes than those specified by an update in the delta packet, it calls LogUpdateRecord to add the changed and updated record to the error log so that the client dataset or XML broker can refresh the updated record. This error log is eventually returned by the ApplyUpdates (see page 6494) method when the update operation ends.

The Tree parameter represents the set of updates being applied.

See Also

logupdateerror (see page 6499)

InternalUpdateRecord (see page 6499)

72.1.5.4.16 TCustomResolver.RowRequest Method

Returns information from a specified record.

Pascal

```
function RowRequest(Row: OleVariant; Options: TFetchOptions): OleVariant; virtual;
```

C++

```
virtual __fastcall OleVariant RowRequest(OleVariant Row, TFetchOptions Options);
```

Description

RowRequest is called automatically in response to the associated provider's RowRequest method.

The Row parameter is an OleVariant that describes the record about which information is requested. The resolver uses this to locate the desired record.

The requested information is returned as a delta packet.

See Also

RowRequest (see page 6480)

72.1.5.5 TCustomResolver Properties

The properties of the TCustomResolver class are listed here.

Public Properties

	Name	Description
R	Provider (see page 6501)	Indicates the provider that uses this resolver to apply updates.
R	UpdateTree (see page 6501)	This is UpdateTree, a member of class TCustomResolver.

72.1.5.5.1 TCustomResolver.Provider Property

Indicates the provider that uses this resolver to apply updates.

Pascal

```
property Provider: TBaseProvider;
```

C++

```
__property TBaseProvider Provider;
```

Description

Provider is a read-only property that points to the provider that uses this resolver for applying updates. The Provider property is set in the constructor.

Resolvers use the Provider property internally to obtain information supplied in the provider's properties. They also use it to generate events on the provider at appropriate points in the update process.

See Also

Create (see page 6493)

Resolver (see page 6456)

72.1.5.5.2 TCustomResolver.UpdateTree Property

Pascal

```
property UpdateTree: TUpdateTree;
```

C++

```
__property TUpdateTree UpdateTree;
```

Description

This is UpdateTree, a member of class TCustomResolver.

72.1.6 TDataPacketWriter Class

Class Hierarchy

Pascal

```
TDataPacketWriter = class(TCustomPacketWriter);
```

C++

```
class TDataPacketWriter : public TCustomPacketWriter;
```

File

Provider

Description

This is class Provider.TDataPacketWriter.

72.1.6.1 TDataPacketWriter Members

The following tables list the members exposed by TDataPacketWriter.

Protected Fields

	Name	Description
	FBuffer (see page 6462)	This is FBuffer, a member of class TCustomPacketWriter.

Protected Methods

	Name	Description
V	AddAttribute (see page 6463)	This is AddAttribute, a member of class TCustomPacketWriter.
V	AddColumn (see page 6504)	This is AddColumn, a member of class TDataPacketWriter.
V	AddConstraints (see page 6504)	This is AddConstraints, a member of class TDataPacketWriter.
V	AddDataSetAttributes (see page 6504)	This is AddDataSetAttributes, a member of class TDataPacketWriter.
	AddExtraFieldProps (see page 6504)	This is AddExtraFieldProps, a member of class TDataPacketWriter.
V	AddFieldLinks (see page 6505)	This is AddFieldLinks, a member of class TDataPacketWriter.
V	AddIndexDefs (see page 6505)	This is AddIndexDefs, a member of class TDataPacketWriter.
	Check (see page 6463)	This is Check, a member of class TCustomPacketWriter.
	FreeInfoRecords (see page 6505)	This is FreeInfoRecords, a member of class TDataPacketWriter.
	GetFieldIdx (see page 6506)	This is GetFieldIdx, a member of class TDataPacketWriter.
	InitPutProcs (see page 6506)	This is InitPutProcs, a member of class TDataPacketWriter.
	PutADTField (see page 6506)	This is PutADTField, a member of class TDataPacketWriter.
	PutArrayField (see page 6506)	This is PutArrayField, a member of class TDataPacketWriter.
	PutBlobField (see page 6506)	This is PutBlobField, a member of class TDataPacketWriter.
	PutCalcField (see page 6507)	This is PutCalcField, a member of class TDataPacketWriter.
	PutDataSetField (see page 6507)	This is PutDataSetField, a member of class TDataPacketWriter.
	PutField (see page 6507)	This is PutField, a member of class TDataPacketWriter.
	PutStringField (see page 6507)	This is PutStringField, a member of class TDataPacketWriter.
	PutVarBytesField (see page 6508)	This is PutVarBytesField, a member of class TDataPacketWriter.
	PutWideStringField (see page 6508)	This is PutWideStringField, a member of class TDataPacketWriter.
	RefreshPutProcs (see page 6508)	This is RefreshPutProcs, a member of class TDataPacketWriter.
	SetDSWriter (see page 6463)	This is SetDSWriter, a member of class TCustomPacketWriter.
V	WriteDataSet (see page 6508)	This is WriteDataSet, a member of class TDataPacketWriter.
V	WriteMetaData (see page 6509)	This is WriteMetaData, a member of class TDataPacketWriter.

Protected Properties

	Name	Description
R	DSWriter (see page 6464)	This is DSWriter, a member of class TCustomPacketWriter.

Public Events

	Name	Description
	OnGetParams (see page 6510)	This is OnGetParams, a member of class TDataPacketWriter.

Public Methods

	Name	Description
V	Create (see page 6461)	Constructs an object and initializes its data before the object is first used.
V	Destroy (see page 6503)	Disposes of an object instance.
V	GetDataPacket (see page 6505)	This is GetDataPacket, a member of class TDataPacketWriter.
	Reset (see page 6508)	This is Reset, a member of class TDataPacketWriter.

Public Properties

	Name	Description
	Constraints (see page 6509)	This is Constraints, a member of class TDataPacketWriter.

	Options (see page 6509)	This is Options, a member of class TDataPacketWriter.
	PacketOptions (see page 6510)	This is PacketOptions, a member of class TDataPacketWriter.

72.1.6.2 TDataPacketWriter.Destroy Destructor

Disposes of an object instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDataPacketWriter();
```

Description

Do not call System::TObject::Destroy directly. Call System::TObject::Free instead. Free verifies that the object reference is not nil before calling System::TObject::Destroy.

The System::TObject::Destroy method defined by System::TObject::TObject deallocates memory. Descendant objects usually define a destructor that is customized for that particular kind of object.

When declaring a System::TObject::Destroy method in a descendant, always add the override directive to the declaration and call the inherited System::TObject::Destroy as the last statement in the overriding method. Since System::TObject::Destroy is a virtual method, overriding it ensures that the proper inherited behavior occurs.

Note: If an exception escapes from the constructor, the destructor is called to destroy the partially constructed object instance that failed to initialize completely. Therefore, destructors should check that allocated resources, such as handles, were actually allocated before trying to release them, since their value might be zero.

System::TObject::Destroy should be implemented so that it calls System::TObject::Free on all subobjects created within the object's constructor (that is, allocated by the constructor). Unlike System::TObject::Destroy, System::TObject::Free provides a safeguard when destroying objects that are nil.

See Also

System::TObject::Free

72.1.6.3 TDataPacketWriter Methods

The methods of the TDataPacketWriter class are listed here.

Protected Methods

	Name	Description
V	AddColumn (see page 6504)	This is AddColumn, a member of class TDataPacketWriter.
V	AddConstraints (see page 6504)	This is AddConstraints, a member of class TDataPacketWriter.
V	AddDataSetAttributes (see page 6504)	This is AddDataSetAttributes, a member of class TDataPacketWriter.
	AddExtraFieldProps (see page 6504)	This is AddExtraFieldProps, a member of class TDataPacketWriter.
V	AddFieldLinks (see page 6505)	This is AddFieldLinks, a member of class TDataPacketWriter.
V	AddIndexDefs (see page 6505)	This is AddIndexDefs, a member of class TDataPacketWriter.
	FreeInfoRecords (see page 6505)	This is FreeInfoRecords, a member of class TDataPacketWriter.
	GetFieldIdx (see page 6506)	This is GetFieldIdx, a member of class TDataPacketWriter.
	InitPutProcs (see page 6506)	This is InitPutProcs, a member of class TDataPacketWriter.
	PutADTField (see page 6506)	This is PutADTField, a member of class TDataPacketWriter.
	PutArrayField (see page 6506)	This is PutArrayField, a member of class TDataPacketWriter.
	PutBlobField (see page 6506)	This is PutBlobField, a member of class TDataPacketWriter.

	PutCalcField (see page 6507)	This is PutCalcField, a member of class TDataPacketWriter.
	PutDataSetField (see page 6507)	This is PutDataSetField, a member of class TDataPacketWriter.
	PutField (see page 6507)	This is PutField, a member of class TDataPacketWriter.
	PutStringField (see page 6507)	This is PutStringField, a member of class TDataPacketWriter.
	PutVarBytesField (see page 6508)	This is PutVarBytesField, a member of class TDataPacketWriter.
	PutWideStringField (see page 6508)	This is PutWideStringField, a member of class TDataPacketWriter.
	RefreshPutProcs (see page 6508)	This is RefreshPutProcs, a member of class TDataPacketWriter.
	WriteDataSet (see page 6508)	This is WriteDataSet, a member of class TDataPacketWriter.
	WriteMetaData (see page 6509)	This is WriteMetaData, a member of class TDataPacketWriter.

Public Methods

	Name	Description
	GetDataPacket (see page 6505)	This is GetDataPacket, a member of class TDataPacketWriter.
	Reset (see page 6508)	This is Reset, a member of class TDataPacketWriter.

72.1.6.3.1 TDataPacketWriter.AddColumn Method

Pascal

```
procedure AddColumn(const Info: TPutFieldInfo); virtual;
```

C++

```
virtual __fastcall AddColumn(const TPutFieldInfo Info);
```

Description

This is AddColumn, a member of class TDataPacketWriter.

72.1.6.3.2 TDataPacketWriter.AddConstraints Method

Pascal

```
procedure AddConstraints(DataSet: TDataSet); virtual;
```

C++

```
virtual __fastcall AddConstraints(TDataSet DataSet);
```

Description

This is AddConstraints, a member of class TDataPacketWriter.

72.1.6.3.3 TDataPacketWriter.AddDataSetAttributes Method

Pascal

```
procedure AddDataSetAttributes(DataSet: TDataSet); virtual;
```

C++

```
virtual __fastcall AddDataSetAttributes(TDataSet DataSet);
```

Description

This is AddDataSetAttributes, a member of class TDataPacketWriter.

72.1.6.3.4 TDataPacketWriter.AddExtraFieldProps Method

Pascal

```
procedure AddExtraFieldProps(Field: TField);
```

C++

```
__fastcall AddExtraFieldProps(TField Field);
```

Description

This is AddExtraFieldProps, a member of class TDataPacketWriter.

72.1.6.3.5 TDataPacketWriter.AddFieldLinks Method

Pascal

```
procedure AddFieldLinks(const Info: TInfoArray); virtual;
```

C++

```
virtual __fastcall AddFieldLinks(const TInfoArray Info);
```

Description

This is AddFieldLinks, a member of class TDataPacketWriter.

72.1.6.3.6 TDataPacketWriter.AddIndexDefs Method

Pascal

```
procedure AddIndexDefs(DataSet: TDataSet; const Info: TInfoArray); virtual;
```

C++

```
virtual __fastcall AddIndexDefs(TDataSet DataSet, const TInfoArray Info);
```

Description

This is AddIndexDefs, a member of class TDataPacketWriter.

72.1.6.3.7 TDataPacketWriter.FreeInfoRecords Method

Pascal

```
procedure FreeInfoRecords(var Info: TInfoArray);
```

C++

```
__fastcall FreeInfoRecords(TInfoArray Info);
```

Description

This is FreeInfoRecords, a member of class TDataPacketWriter.

72.1.6.3.8 TDataPacketWriter.GetDataPacket Method

Pascal

```
procedure GetDataPacket(DataSet: TDataSet; var RecsOut: Integer; out Data: OleVariant);
virtual;
```

C++

```
virtual __fastcall GetDataPacket(TDataSet DataSet, int RecsOut, OleVariant Data);
```

Description

This is GetDataPacket, a member of class TDataPacketWriter.

72.1.6.3.9 TDataPacketWriter.GetFieldIdx Method

Pascal

```
function GetFieldIdx(const FieldName: WideString; const Info: TInfoArray): Integer;
```

C++

```
__fastcall int GetFieldIdx(const BSTR FieldName, const TInfoArray Info);
```

Description

This is GetFieldIdx, a member of class TDataPacketWriter.

72.1.6.3.10 TDataPacketWriter.InitPutProcs Method

Pascal

```
function InitPutProcs(ADataSet: TDataSet; var GlobalIdx: Integer): TInfoArray;
```

C++

```
__fastcall TInfoArray InitPutProcs(TDataSet ADataSet, int GlobalIdx);
```

Description

This is InitPutProcs, a member of class TDataPacketWriter.

72.1.6.3.11 TDataPacketWriter.PutADTField Method

Pascal

```
procedure PutADTField(Info: PPutFieldInfo);
```

C++

```
__fastcall PutADTField(PPutFieldInfo Info);
```

Description

This is PutADTField, a member of class TDataPacketWriter.

72.1.6.3.12 TDataPacketWriter.PutArrayField Method

Pascal

```
procedure PutArrayField(Info: PPutFieldInfo);
```

C++

```
__fastcall PutArrayField(PPutFieldInfo Info);
```

Description

This is PutArrayField, a member of class TDataPacketWriter.

72.1.6.3.13 TDataPacketWriter.PutBlobField Method

Pascal

```
procedure PutBlobField(Info: PPutFieldInfo);
```

C++

```
__fastcall PutBlobField(PPutFieldInfo Info);
```

Description

This is PutBlobField, a member of class TDataPacketWriter.

72.1.6.3.14 TDataPacketWriter.PutCalcField Method

Pascal

```
procedure PutCalcField(Info: PPutFieldInfo);
```

C++

```
__fastcall PutCalcField(PPutFieldInfo Info);
```

Description

This is PutCalcField, a member of class TDataPacketWriter.

72.1.6.3.15 TDataPacketWriter.PutDataSetField Method

Pascal

```
procedure PutDataSetField(Info: PPutFieldInfo);
```

C++

```
__fastcall PutDataSetField(PPutFieldInfo Info);
```

Description

This is PutDataSetField, a member of class TDataPacketWriter.

72.1.6.3.16 TDataPacketWriter.PutField Method

Pascal

```
procedure PutField(Info: PPutFieldInfo);
```

C++

```
__fastcall PutField(PPutFieldInfo Info);
```

Description

This is PutField, a member of class TDataPacketWriter.

72.1.6.3.17 TDataPacketWriter.PutStringField Method

Pascal

```
procedure PutStringField(Info: PPutFieldInfo);
```

C++

```
__fastcall PutStringField(PPutFieldInfo Info);
```

Description

This is PutStringField, a member of class TDataPacketWriter.

72.1.6.3.18 TDataPacketWriter.PutVarBytesField Method

Pascal

```
procedure PutVarBytesField(Info: PPutFieldInfo);
```

C++

```
__fastcall PutVarBytesField(PPutFieldInfo Info);
```

Description

This is PutVarBytesField, a member of class TDataPacketWriter.

72.1.6.3.19 TDataPacketWriter.PutWideStringField Method

Pascal

```
procedure PutWideStringField(Info: PPutFieldInfo);
```

C++

```
__fastcall PutWideStringField(PPutFieldInfo Info);
```

Description

This is PutWideStringField, a member of class TDataPacketWriter.

72.1.6.3.20 TDataPacketWriter.RefreshPutProcs Method

Pascal

```
procedure RefreshPutProcs(ADataSet: TDataSet; var Info: TInfoArray);
```

C++

```
__fastcall RefreshPutProcs(TDataSet ADataSet, TInfoArray Info);
```

Description

This is RefreshPutProcs, a member of class TDataPacketWriter.

72.1.6.3.21 TDataPacketWriter.Reset Method

Pascal

```
procedure Reset;
```

C++

```
__fastcall Reset();
```

Description

This is Reset, a member of class TDataPacketWriter.

72.1.6.3.22 TDataPacketWriter.WriteDataSet Method

Pascal

```
function WriteDataSet(DataSet: TDataSet; var Info: TInfoArray; RecsOut: Integer): Integer;
virtual;
```

C++

```
virtual __fastcall int WriteDataSet(TDataSet DataSet, TInfoArray Info, int RecsOut);
```

Description

This is WriteDataSet, a member of class TDataPacketWriter.

72.1.6.3.23 TDataPacketWriter.WriteMetaData Method

Pascal

```
procedure WriteMetaData(DataSet: TDataSet; const Info: TInfoArray; IsReference: Boolean =
False); virtual;
```

C++

```
virtual __fastcall WriteMetaData(TDataSet DataSet, const TInfoArray Info, Boolean IsReference
= False);
```

Description

This is WriteMetaData, a member of class TDataPacketWriter.

72.1.6.4 TDataPacketWriter Properties

The properties of the TDataPacketWriter class are listed here.

Public Properties

	Name	Description
	Constraints (see page 6509)	This is Constraints, a member of class TDataPacketWriter.
	Options (see page 6509)	This is Options, a member of class TDataPacketWriter.
	PacketOptions (see page 6510)	This is PacketOptions, a member of class TDataPacketWriter.

72.1.6.4.1 TDataPacketWriter.Constraints Property

Pascal

```
property Constraints: Boolean;
```

C++

```
__property Boolean Constraints;
```

Description

This is Constraints, a member of class TDataPacketWriter.

72.1.6.4.2 TDataPacketWriter.Options Property

Pascal

```
property Options: TProviderOptions;
```

C++

```
__property TProviderOptions Options;
```

Description

This is Options, a member of class TDataPacketWriter.

72.1.6.4.3 TDataPacketWriter.PacketOptions Property

Pascal

```
property PacketOptions: TGetRecordOptions;
```

C++

```
__property TGetRecordOptions PacketOptions;
```

Description

This is PacketOptions, a member of class TDataPacketWriter.

72.1.6.5 TDataPacketWriter Events

The events of the TDataPacketWriter class are listed here.

Public Events

	Name	Description
	OnGetParams (see page 6510)	This is OnGetParams, a member of class TDataPacketWriter.

72.1.6.5.1 TDataPacketWriter.OnGetParams Event

Pascal

```
property OnGetParams: TGetParamsEvent;
```

C++

```
__property TGetParamsEvent OnGetParams;
```

Description

This is OnGetParams, a member of class TDataPacketWriter.

72.1.7 TDataSetProvider Class

TDataSetProvider provides data from a dataset and resolves updates to that dataset or its database server.

Class Hierarchy

Pascal

```
TDataSetProvider = class(TBaseProvider);
```

C++

```
class TDataSetProvider : public TBaseProvider;
```

File

Provider

Description

Use TDataSetProvider to provide data from a dataset to a client dataset or XML broker and to resolve updates from that client dataset or XML broker back to the dataset or to its underlying database server. TDataSetProvider can be a part of the same

application as the client dataset or XML broker, or it can be placed in the application server of a multi-tiered application. It serves as a data broker between a remote database server and a client dataset.

TDataSetProvider packages data from a dataset and passes it in one or more transportable data packets to the client dataset or XML broker. The client dataset reconstructs the data in the data packet to create a local, in-memory copy for user access. When user access is complete, the client dataset repackages any changed data and sends the updates back to the provider. The provider applies the updates to the database or source dataset.

When the provider supplies data to a client dataset, the client dataset reconstructs the data in the data packet to create a local, in-memory copy for user access. When user access is complete, the client dataset repackages any changed data and sends the updates back to the provider. The provider applies the updates to the database or source dataset.

When the provider supplies data to an XML broker, the XML broker adds the data packet, in XML format, to an HTML document that is downloaded by a Web client. When the XML broker receives updates from the Web client, it sends the updates to the provider, which applies them to the database or source dataset.

Client datasets and XML brokers communicate with a provider through the IAppServer (see page 5222) interface. In multi-tiered applications, this is the interface of the remote data module that contains the provider. To enable the remote data module to pass calls to the provider, the provider's Exported (see page 6526) property must be true, and its Owner property must specify the remote data module.

Determining the Source of Data

Using Provider Components

72.1.7.1 TDataSetProvider Members

The following tables list the members exposed by TDataSetProvider.

Protected Methods

	Name	Description
	CheckDataSet (see page 6514)	This is CheckDataSet, a member of class TDataSetProvider.
	CheckResolver (see page 6449)	Instantiates a resolver for the Resolver (see page 6456) property if it does not already exist.
V	CreateDataPacket (see page 6515)	Generates a data packet for the data associated with the provider.
V	CreateResolver (see page 6515)	Creates a resolver component for handling the application of updates.
V	DoAfterApplyUpdates (see page 6469)	Generates an AfterApplyUpdates (see page 6483) event.
V	DoAfterExecute (see page 6469)	Generates an AfterExecute (see page 6484) event.
V	DoAfterGetParams (see page 6470)	Generates an AfterGetParams (see page 6485) event.
V	DoAfterGetRecords (see page 6470)	Generates an AfterGetRecords (see page 6485) event.
V	DoAfterRowRequest (see page 6471)	Generates an AfterRowRequest (see page 6486) event.
V	DoAfterUpdateRecord (see page 6450)	Generates an AfterUpdateRecord (see page 6458) event.
V	DoApplyUpdates (see page 6471)	This is DoApplyUpdates, a member of class TCustomProvider.
V	DoBeforeApplyUpdates (see page 6471)	Generates a BeforeApplyUpdates (see page 6487) event.
V	DoBeforeCommit (see page 6450)	This is DoBeforeCommit, a member of class TBaseProvider.
V	DoBeforeExecute (see page 6516)	Generates a BeforeExecute (see page 6534) event.
V	DoBeforeGetParams (see page 6472)	Generates a BeforeGetParams (see page 6488) event.
V	DoBeforeGetRecords (see page 6516)	Generates a BeforeGetRecords (see page 6535) event.
V	DoBeforeRowRequest (see page 6474)	Generates a BeforeRowRequest (see page 6490) event.
V	DoBeforeUpdateRecord (see page 6451)	This is DoBeforeUpdateRecord, a member of class TBaseProvider.

	DoGetProviderAttributes (see page 6517)	Fills a list with information about the dataset that can be used when providing or resolving.
	DoGetRecords (see page 6474)	This is DoGetRecords, a member of class TCustomProvider.
	DoGetTableName (see page 6518)	Generates an OnGetTableName (see page 6539) event.
	DoOnGetData (see page 6451)	Generates an OnGetData (see page 6459) event.
	DoOnUpdateData (see page 6451)	Generates an OnUpdateData (see page 6459) event.
	FetchDetails (see page 6518)	Fills a delta dataset with all nested dataset field values.
	FindRecord (see page 6518)	This is FindRecord, a member of class TDataSetProvider.
	FreeResolver (see page 6452)	Frees the resolver specified by the Resolver (see page 6456) property.
	GetDataSetFromDelta (see page 6519)	Returns a dataset positioned on the record of the source dataset that is currently being fetched or updated.
	InternalApplyUpdates (see page 6519)	Provides the underlying implementation of the ApplyUpdates (see page 6468) method.
	InternalExecute (see page 6520)	Provides the underlying implementation of the Execute method.
	InternalGetParams (see page 6520)	Returns the requested parameter values as a Variant array.
	InternalGetRecords (see page 6521)	Provides the underlying implementation of the GetRecords (see page 6476) method.
	InternalRowRequest (see page 6522)	Provides the underlying implementation of the RowRequest (see page 6480) method.
	LocateRecord (see page 6522)	Positions a data set on the record that corresponds to the current update in a specified delta packet.
	Notification (see page 6522)	Responds to notifications that objects are being created or destroyed.
	Reset (see page 6523)	This is Reset, a member of class TDataSetProvider.
	SetActiveUpdateException (see page 6481)	This is SetActiveUpdateException, a member of class TCustomProvider.
	SetCommandText (see page 6523)	This is SetCommandText, a member of class TDataSetProvider.
	SetParams (see page 6523)	This is SetParams, a member of class TDataSetProvider.
	UpdateRecord (see page 6523)	Retrieves specified data from a source dataset into a delta packet.

Protected Properties

	Name	Description
	PacketDataSet (see page 6456)	This is PacketDataSet, a member of class TBaseProvider.
	TransactionStarted (see page 6528)	This is TransactionStarted, a member of class TDataSetProvider.

Public Methods

	Name	Description
	ApplyUpdates (see page 6468)	This is the overview for the ApplyUpdates method overload.
	Create (see page 6513)	Creates and initializes a TDataSetProvider (see page 6510) object.
	DataRequest (see page 6468)	Generates an OnDataRequest (see page 6490) event.
	Destroy (see page 6513)	Frees an instance of a data set provider.
	Execute (see page 6474)	Executes a query, stored procedure, or custom SQL statement.
	GetParams (see page 6475)	Returns the current parameter values.
	GetRecords (see page 6476)	This is the overview for the GetRecords method overload.
	RowRequest (see page 6480)	Returns information from a specified record.

Public Properties

	Name	Description
	ActiveUpdateException (see page 6524)	This is ActiveUpdateException, a member of class TDataSetProvider.
R	Data (see page 6482)	Denotes a data packet created by the provider.
	OwnerData (see page 6527)	This is OwnerData, a member of class TDataSetProvider.
R	Params (see page 6527)	Stores the parameter values currently in use.
R	Resolver (see page 6456)	Provides access to the resolver component that applies updates and resolves update errors.

Published Events

	Name	Description
	AfterApplyUpdates (see page 6529)	Occurs after the provider applies updates.
	AfterExecute (see page 6530)	Occurs after the provider passes an execute command to its dataset.

	AfterGetParams (see page 6531)	This is AfterGetParams, a member of class TDataSetProvider.
	AfterGetRecords (see page 6531)	Occurs after the provider creates a data packet to send to the client dataset.
	AfterRowRequest (see page 6532)	Occurs after the provider fetches new information about the current record.
	AfterUpdateRecord (see page 6533)	Occurs when the associated resolver has just updated a record.
	BeforeApplyUpdates (see page 6533)	Occurs before the provider applies updates from a client dataset.
	BeforeExecute (see page 6534)	This is BeforeExecute, a member of class TDataSetProvider.
	BeforeGetParams (see page 6534)	Occurs before the provider creates an OleVariant that encodes the current parameter values and sends them to a client dataset.
	BeforeGetRecords (see page 6535)	Occurs before the provider creates a data packet and sends it to a client dataset.
	BeforeRowRequest (see page 6536)	Occurs before the provider creates a delta packet with information about the current record.
	BeforeUpdateRecord (see page 6537)	This is BeforeUpdateRecord, a member of class TDataSetProvider.
	OnDataRequest (see page 6537)	Occurs when a provider calls its DataRequest method.
	OnGetData (see page 6537)	Occurs after a provider retrieves data but before it is sent to the client.
	OnGetDataSetProperties (see page 6538)	Occurs when the provider adds additional information to a data packet it is creating.
	OnGetTableName (see page 6539)	This is OnGetTableName, a member of class TDataSetProvider.
	OnUpdateData (see page 6539)	Occurs when a provider begins to apply updates.
	OnUpdateError (see page 6539)	Occurs when a provider can't update a record because of an error condition.
	OnValidate (see page 6540)	This is OnValidate, a member of class TDataSetProvider.

Published Properties

	Name	Description
	Constraints (see page 6525)	Controls whether database constraints are passed to the client so that it can check them locally.
	DataSet (see page 6525)	Specifies the dataset from which the provider provides data and to which it applies updates.
	Exported (see page 6526)	Allows client applications to pass calls to the provider when it resides on an application server.
	Options (see page 6526)	Influences what is included in data packets and how the information in data packets is used.
	ResolveToDataSet (see page 6528)	Specifies whether updates should be applied to a dataset or directly to the database server.
	UpdateMode (see page 6528)	Controls how the provider locates records when applying updates.

72.1.7.2 TDataSetProvider.Create Constructor

Creates and initializes a TDataSetProvider (see page 6510) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TDataSetProvider(TComponent * AOwner);
```

Description

Call Create to instantiate a provider at runtime. Providers placed in forms or data modules at design time are created automatically.

See Also

Create (see page 6447)

72.1.7.3 TDataSetProvider.Destroy Destructor

Frees an instance of a data set provider.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TDataSetProvider();
```

Description

Do not call Destroy directly. Instead, call Free, which checks that the reference to the provider is not nil before calling its Destroy method. Destroy frees all helper objects, including the resolver component referenced by the Resolver (see page 6456) property.

See Also

System::TObject::Free

Resolver (see page 6456)

72.1.7.4 TDataSetProvider Methods

The methods of the TDataSetProvider class are listed here.

Protected Methods

	Name	Description
	CheckDataSet (see page 6514)	This is CheckDataSet, a member of class TDataSetProvider.
V	CreateDataPacket (see page 6515)	Generates a data packet for the data associated with the provider.
V	CreateResolver (see page 6515)	Creates a resolver component for handling the application of updates.
V	DoBeforeExecute (see page 6516)	Generates a BeforeExecute (see page 6534) event.
V	DoBeforeGetRecords (see page 6516)	Generates a BeforeGetRecords (see page 6535) event.
V	DoGetProviderAttributes (see page 6517)	Fills a list with information about the dataset that can be used when providing or resolving.
V	DoGetTableName (see page 6518)	Generates an OnGetTableName (see page 6539) event.
V	FetchDetails (see page 6518)	Fills a delta dataset with all nested dataset field values.
V	FindRecord (see page 6518)	This is FindRecord, a member of class TDataSetProvider.
V	GetDataSetFromDelta (see page 6519)	Returns a dataset positioned on the record of the source dataset that is currently being fetched or updated.
V	InternalApplyUpdates (see page 6519)	Provides the underlying implementation of the ApplyUpdates (see page 6468) method.
V	InternalExecute (see page 6520)	Provides the underlying implementation of the Execute method.
V	InternalGetParams (see page 6520)	Returns the requested parameter values as a Variant array.
V	InternalGetRecords (see page 6521)	Provides the underlying implementation of the GetRecords (see page 6476) method.
V	InternalRowRequest (see page 6522)	Provides the underlying implementation of the RowRequest (see page 6480) method.
V	LocateRecord (see page 6522)	Positions a data set on the record that corresponds to the current update in a specified delta packet.
V	Notification (see page 6522)	Responds to notifications that objects are being created or destroyed.
	Reset (see page 6523)	This is Reset, a member of class TDataSetProvider.
V	SetCommandText (see page 6523)	This is SetCommandText, a member of class TDataSetProvider.
V	SetParams (see page 6523)	This is SetParams, a member of class TDataSetProvider.
V	UpdateRecord (see page 6523)	Retrieves specified data from a source dataset into a delta packet.

72.1.7.4.1 TDataSetProvider.CheckDataSet Method

Pascal

```
procedure CheckDataSet;
```

C++

```
__fastcall CheckDataSet();
```

Description

This is CheckDataSet, a member of class TDataSetProvider.

72.1.7.4.2 TDataSetProvider.CreateDataPacket Method

Generates a data packet for the data associated with the provider.

Pascal

```
procedure CreateDataPacket(PacketOpts: TGetRecordOptions; ProvOpts: TProviderOptions; var
RecsOut: Integer; var Data: OleVariant); override;
```

C++

```
virtual __fastcall CreateDataPacket(TGetRecordOptions PacketOpts, TProviderOptions ProvOpts,
int RecsOut, OleVariant Data);
```

Description

CreateDataPacket is used internally to generate the data packets that are returned by GetRecords (see page 6476).

The PacketOpts parameter indicates what information (other than record values) is included in the data packet. It reflects any Options (see page 6526) passed to the GetRecords (see page 6476) method.

The ProvOpts parameter reflects the current value of the Options (see page 6526) property.

The RecsOut parameter specifies the number of records desired in the packet and returns the actual number of records in the generated data packet.

The Data (see page 6482) parameter returns the generated data packet.

See Also

GetRecords (see page 6476)

DataSet (see page 6525)

Options (see page 6455)

72.1.7.4.3 TDataSetProvider.CreateResolver Method

Creates a resolver component for handling the application of updates.

Pascal

```
function CreateResolver: TCustomResolver; override;
```

C++

```
virtual __fastcall TCustomResolver CreateResolver();
```

Description

CreateResolver is called automatically when a resolver is needed to implement one of the provider's methods. CreateResolver returns a newly instantiated resolver object, which is assigned to the Resolver (see page 6456) property. The type of resolver created depends on the ResolveToDataSet (see page 6528) property:

When ResolveToDataSet (see page 6528) is true, CreateResolver returns a TDataSetResolver (see page 6540) component, which applies updates directly to the dataset specified by the DataSet (see page 6525) property.

When ResolveToDataSet (see page 6528) is false, CreateResolver returns a TSQLResolver (see page 6564) component,

which applies updates directly to the database server associated with DataSet (see page 6525).

See Also

Resolver (see page 6456)

ResolveToDataSet (see page 6528)

72.1.7.4.4 TDataSetProvider.DoBeforeExecute Method

Generates a BeforeExecute (see page 6534) event.

Pascal

```
procedure DoBeforeExecute(const CommandText: WideString; var Params: OleVariant; var
OwnerData: OleVariant); override;
```

C++

```
virtual __fastcall DoBeforeExecute(const BSTR CommandText, OleVariant Params, OleVariant
OwnerData);
```

Description

The Execute (see page 6474) method calls DoBeforeExecute to generate the BeforeExecute (see page 6534) event before it executes CommandText or executes an associated query or stored procedure.

CommandText is either an optional SQL statement that replaces the SQL of an associated query, or the name of a stored procedure that replaces the associated stored procedure. If Options (see page 6526) includes poAllowCommandText, DoBeforeExecute sends CommandText to the associated dataset so that it can execute the provided statement instead of its query or stored procedure.

Params (see page 6527) contains any parameter values that should be applied to CommandText or to the query or stored procedure before execution. DoBeforeExecute assigns these parameter values to the dataset (if appropriate).

OwnerData (see page 6527) supplies custom information to the BeforeExecute (see page 6534) event handler. The event handler can change this value. The returned value is then passed to an AfterExecute (see page 6530) event handler and then returned to the caller of the Execute (see page 6474) method.

See Also

Execute (see page 6474)

beforeexecute (see page 6487)

AfterExecute (see page 6484)

DataSet (see page 6525)

72.1.7.4.5 TDataSetProvider.DoBeforeGetRecords Method

Generates a BeforeGetRecords (see page 6535) event.

Pascal

```
procedure DoBeforeGetRecords(Count: Integer; Options: Integer; const CommandText: WideString;
var Params: OleVariant; var OwnerData: OleVariant); override;
```

C++

```
virtual __fastcall DoBeforeGetRecords(int Count, int Options, const BSTR CommandText,
OleVariant Params, OleVariant OwnerData);
```

Description

The GetRecords (see page 6476) method calls DoBeforeGetRecords to generate the BeforeGetRecords (see page 6535) event before it fetches data and assembles it into a data packet.

Count is the number of records requested. TDataSetProvider (see page 6510) does not use this parameter.

Options (see page 6526) indicates whether the data packet should include metadata, whether it should start with the first record, and whether the data packet should be encoded in XML. In TDataSetProvider (see page 6510), DoBeforeGetRecords ignores this parameter.

CommandText specifies either an optional SQL statement that replaces the SQL of an associated query, or the name of a table or stored procedure that replaces the associated table or stored procedure. If Options (see page 6526) includes poAllowCommandText, DoBeforeGetRecords sends CommandText to the associated dataset so that it can generate the set of records.

Params (see page 6527) contains any parameter values that should be applied to CommandText or to a query or stored procedure before fetching data into a data packet. DoBeforeGetRecords assigns these values to the associated dataset, if appropriate.

OwnerData (see page 6527) supplies custom information to the BeforeGetRecords (see page 6535) event handler. The event handler can change this value. The returned value is then passed to an AfterGetRecords (see page 6531) event handler and then (optionally) returned to the caller of the GetRecords (see page 6476) method.

GetRecords (see page 6476)

BeforeGetRecords (see page 6488)

AfterGetRecords (see page 6485)

DataSet (see page 6525)

72.1.7.4.6 TDataSetProvider.DoGetProviderAttributes Method

Fills a list with information about the dataset that can be used when providing or resolving.

Pascal

```
procedure DoGetProviderAttributes(DataSet: TDataSet; List: TList); virtual;
```

C++

```
virtual __fastcall DoGetProviderAttributes(TDataSet DataSet, TList List);
```

Description

DoGetProviderAttributes is used internally to fetch information about the dataset. This includes both information provided by the dataset (using the IProviderSupport method PSGetAttributes) and custom information supplied by an OnGetDataSetProperties (see page 6538) event handler.

The DataSet (see page 6525) parameter specifies the dataset that stores the information. The List parameter is the list that is filled by DoGetProviderAttributes. DoGetProviderAttributes adds information to the list in Name/Value pairs.

See Also

PSGetAttributes

OnGetDataSetProperties (see page 6538)

72.1.7.4.7 TDataSetProvider.DoGetTableName Method

Generates an OnGetTableName (see page 6539) event.

Pascal

```
procedure DoGetTableName(DataSet: TDataSet; var TableName: WideString); virtual;
```

C++

```
virtual __fastcall DoGetTableName(TDataSet DataSet, BSTR TableName);
```

Description

The resolver calls DoGetTableName when it initializes the information it needs to apply updates. Override this method to provide an alternate mechanism for determining the name of the dataset that is the target of an update operation.

DataSet (see page 6525) is the dataset that is the target of the update operation.

The name of the target dataset as it should appear in generated SQL statements is returned as the TableName parameter.

See Also

ongettablename (see page 6539)

Resolver (see page 6456)

72.1.7.4.8 TDataSetProvider.FetchDetails Method

Fills a delta dataset with all nested dataset field values.

Pascal

```
procedure FetchDetails(Source: TDataSet; Delta: TDataSet); override;
```

C++

```
virtual __fastcall FetchDetails(TDataSet Source, TDataSet Delta);
```

Description

FetchDetails is used internally to fetch the current values of any nested datasets when the provider is executing its RowRequest (see page 6480) method. Source is a source dataset that has the current values for all fields. Delta is a delta dataset that must be updated so that its nested detail fields match the values in Source.

See Also

RowRequest (see page 6480)

72.1.7.4.9 TDataSetProvider.FindRecord Method

Pascal

```
function FindRecord(Source: TDataSet; Delta: TDataSet; UpdateMode: TUpdateMode): Boolean;
virtual;
```

C++

```
virtual __fastcall Boolean FindRecord(TDataSet Source, TDataSet Delta, TUpdateMode UpdateMode);
```

Description

This is FindRecord, a member of class TDataSetProvider.

72.1.7.4.10 TDataSetProvider.GetDataSetFromDelta Method

Returns a dataset positioned on the record of the source dataset that is currently being fetched or updated.

Pascal

```
function GetDataSetFromDelta(ATree: TUpdateTree; Source: TDataSet; Delta: TDataSet; Mode:
TUpdateMode): TDataSet; virtual;
```

C++

```
virtual __fastcall TDataSet GetDataSetFromDelta(TUpdateTree ATree, TDataSet Source, TDataSet
Delta, TUpdateMode Mode);
```

Description

GetDataSetFromDelta is used internally to fetch a specific record when the source dataset is unidirectional.

ATree is a TUpdateTree (see page 6572) object that represents the update or data fetch operation.

Source is a source dataset. Because it is unidirectional, however, it is not necessarily positioned on the correct record.

Delta is a delta dataset that indicates the desired record.

Mode indicates the criteria to use for locating a record on the server from the dataset that Source uses. The values that follow these criteria come from Delta.

GetDataSetFromDelta returns a unidirectional dataset that corresponds to Source but that contains a single record based on the criteria in Delta and Mode.

See Also

IsUniDirectional

DataSet (see page 6525)

72.1.7.4.11 TDataSetProvider.InternalApplyUpdates Method

Provides the underlying implementation of the ApplyUpdates (see page 6468) method.

Pascal

```
function InternalApplyUpdates(const Delta: OleVariant; MaxErrors: Integer; out ErrorCount:
Integer): OleVariant; override;
```

C++

```
virtual __fastcall OleVariant InternalApplyUpdates(const OleVariant Delta, int MaxErrors, int
ErrorCount);
```

Description

The ApplyUpdates (see page 6468) method calls InternalApplyUpdates to apply the updates contained in a delta packet after generating the BeforeApplyUpdates (see page 6533) event and before generating the AfterApplyUpdates (see page 6529) event.

If the Options (see page 6526) property includes poReadOnly, InternalApplyUpdates raises an exception. Otherwise, it tells the dataset to start a transaction, calls the ApplyUpdates (see page 6468) method of its Resolver (see page 6456) component to handle the actual update and resolving process, and tells the dataset to complete the transaction.

Delta is the delta packet containing insertions, deletions, and modifications to be applied.

MaxErrors indicates the maximum number of errors that can be applied before stopping the update operation. If MaxErrors is –1, the provider tries to apply all updates.

ErrorCount returns the number of errors encountered during the update operation.

InternalApplyUpdates returns a data packet of updates that could not be applied to the database as an OleVariant.

See Also

Resolver (see page 6456)

ApplyUpdates (see page 6494)

CreateResolver (see page 6515)

Options (see page 6455)

applyupdates (see page 6468)

72.1.7.4.12 TDataSetProvider.InternalExecute Method

Provides the underlying implementation of the Execute method.

Pascal

```
procedure InternalExecute(const CommandText: WideString; var Params: OleVariant); override;
```

C++

```
virtual __fastcall InternalExecute(const BSTR CommandText, OleVariant Params);
```

Description

The Execute method calls InternalExecute to execute the appropriate SQL statement after calling DoBeforeExecute to generate a BeforeExecute event and apply the CommandText and Params. As Implemented in TCustomProvider, InternalExecute does nothing. Descendants override this method to pass the execute command on to an associated dataset.

CommandText is an SQL statement that replaces the SQL of an associated query, or the name of a stored procedure that replaces the associated stored procedure. This parameter is ignored if the Options property does not include poAllowCommandText.

On entry, Params supplies parameter values for the query, stored procedure, or CommandText string. On exit, Params returns any output parameters.

See Also

Execute (see page 6474)

DoBeforeExecute (see page 6472)

72.1.7.4.13 TDataSetProvider.InternalGetParams Method

Returns the requested parameter values as a Variant array.

Pascal

```
function InternalGetParams(Types: TParamTypes = AllParamTypes): OleVariant; override;
```

C++

```
virtual __fastcall OleVariant InternalGetParams(TParamTypes Types = AllParamTypes);
```

Description

The provider uses InternalGetParams internally whenever it needs to assemble the current parameter values into an OleVariant. This provides the underlying implementation of the GetParams (see page 6475) method, as well as assembling parameter values for methods that return output parameters (such as Execute (see page 6474) or GetRecords (see page 6476)).

The Types parameter limits the parameter values that are returned to a subset of all possible parameter types. If this parameter is omitted, all parameter values are returned.

See Also

GetParams (see page 6475)

Execute (see page 6474)

GetRecords (see page 6476)

DataSet (see page 6525)

72.1.7.4.14 TDataSetProvider.InternalGetRecords Method

Provides the underlying implementation of the GetRecords (see page 6476) method.

Pascal

```
function InternalGetRecords(Count: Integer; out RecsOut: Integer; Options: TGetRecordOptions;
const CommandText: WideString; var Params: OleVariant): OleVariant; override;
```

C++

```
virtual __fastcall OleVariant InternalGetRecords(int Count, int RecsOut, TGetRecordOptions
Options, const BSTR CommandText, OleVariant Params);
```

Description

The GetRecords (see page 6476) method calls InternalGetRecords to assemble a data packet after calling DoBeforeGetRecords (see page 6516) to apply the CommandText and Params (see page 6527) and generate a BeforeGetRecords (see page 6535) event. InternalGetRecords calls CreateDataPacket (see page 6515) to create a data packet that reflects the current property settings of the provider. It then generates an OnGetData (see page 6537) event.

Count indicates the number of records to retrieve. If Count is -1, all records are retrieved. If Count is 0, only metadata is retrieved. If Count is greater than 0, only the specified number of records are retrieved.

RecsOut returns the actual number of records retrieved.

Options (see page 6526) indicates what information should be added to the data packet in addition to data. It can include grMetaData (include metadata), grReset (start providing records with the first one in the dataset), and grXML (encode the datapacket in XML rather than as an OleVariant) or grXMLUTF8 (same as grXML but use UTF8 to encode extended characters).

CommandText specifies an optional SQL statement that replaces the SQL of an associated query, or the name of a table or stored procedure that replaces the associated table or stored procedure. This parameter is ignored if the Options (see page 6526) property does not include poAllowCommandText.

Params (see page 6527) specifies any parameter values that should be applied to CommandText or to an associated query or stored procedure. If the provider is associated with a TTable, Params (see page 6527) specifies field values that filter the result set. On exit from GetRecords (see page 6476), Params (see page 6527) returns any output parameters.

Records are returned as a data packet in a Variant.

Note: If the DataSet (see page 6525) property is not set, InternalGetRecords raises an exception.

See Also

Data (see page 6482)

CreateDataPacket (see page 6515)

OnGetData (see page 6459)

BeforeGetRecords (see page 6488)

AfterGetRecords (see page 6485)

DoBeforeGetRecords (see page 6516)

72.1.7.4.15 TDataSetProvider.InternalRowRequest Method

Provides the underlying implementation of the RowRequest (see page 6480) method.

Pascal

```
function InternalRowRequest(const Row: OleVariant; Options: TFetchOptions): OleVariant;
override;
```

C++

```
virtual __fastcall OleVariant InternalRowRequest(const OleVariant Row, TFetchOptions Options);
```

Description

The RowRequest (see page 6480) method calls InternalRowRequest to assemble the specified information after generating a BeforeRowRequest (see page 6536) event and before generating an AfterRowRequest (see page 6532) event. InternalRowRequest passes this request on to its associated Resolver (see page 6456).

The Row parameter is an OleVariant that describes the record about which information is requested.

InternalRowRequest returns the requested information in a delta packet.

See Also

RowRequest (see page 6480)

Resolver (see page 6456)

RowRequest (see page 6500)

72.1.7.4.16 TDataSetProvider.LocateRecord Method

Positions a data set on the record that corresponds to the current update in a specified delta packet.

Pascal

```
procedure LocateRecord(Source: TDataSet; Delta: TDataSet); override;
```

C++

```
virtual __fastcall LocateRecord(TDataSet Source, TDataSet Delta);
```

Description

LocateRecord is called indirectly by the RowRequest (see page 6480) method to locate a record before fetching information about it. The Source parameter is the dataset containing current record values. The Delta parameter is a delta packet that identifies the desired type of information and information identifying the desired record.

LocateRecord uses the criteria specified by UpdateMode (see page 6528) to identify the desired record.

See Also

RowRequest (see page 6480)

UpdateMode (see page 6457)

72.1.7.4.17 TDataSetProvider.Notification Method

Responds to notifications that objects are being created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification overrides the inherited method to add a check that the dataset specified by the DataSet (see page 6525) property is not being deleted. If DataSet (see page 6525) is about to be destroyed, Notification sets the DataSet (see page 6525) property to nil (Delphi) or NULL (C++).

See Also

OnUpdateError (see page 6460)

Create

72.1.7.4.18 TDataSetProvider.Reset Method

Pascal

```
procedure Reset;
```

C++

```
__fastcall Reset();
```

Description

This is Reset, a member of class TDataSetProvider.

72.1.7.4.19 TDataSetProvider.SetCommandText Method

Pascal

```
procedure SetCommandText(const CommandText: WideString); virtual;
```

C++

```
virtual __fastcall SetCommandText(const BSTR CommandText);
```

Description

This is SetCommandText, a member of class TDataSetProvider.

72.1.7.4.20 TDataSetProvider.SetParams Method

Pascal

```
procedure SetParams(Values: OleVariant); virtual;
```

C++

```
virtual __fastcall SetParams(OleVariant Values);
```

Description

This is SetParams, a member of class TDataSetProvider.

72.1.7.4.21 TDataSetProvider.UpdateRecord Method

Retrieves specified data from a source dataset into a delta packet.

Pascal

```
procedure UpdateRecord(Source: TDataSet; Delta: TDataSet; BlobsOnly: Boolean; KeyOnly:
Boolean); override;
```

C++

```
virtual __fastcall UpdateRecord(TDataSet Source, TDataSet Delta, Boolean BlobsOnly, Boolean
KeyOnly);
```

Description

UpdateRecord is called indirectly by the RowRequest (see page 6480) method to fetch information about a specified record. The Source parameter is the dataset containing indicated record. The Delta parameter is a delta packet that returns the requested data. BlobsOnly indicates whether all field values should be provided (BlobsOnly == false) or only Blob field values (BlobsOnly == true).

See Also

RowRequest (see page 6480)

72.1.7.5 TDataSetProvider Properties

The properties of the TDataSetProvider class are listed here.

Protected Properties

	Name	Description
	TransactionStarted (see page 6528)	This is TransactionStarted, a member of class TDataSetProvider.

Public Properties

	Name	Description
	ActiveUpdateException (see page 6524)	This is ActiveUpdateException, a member of class TDataSetProvider.
	OwnerData (see page 6527)	This is OwnerData, a member of class TDataSetProvider.
R	Params (see page 6527)	Stores the parameter values currently in use.

Published Properties

	Name	Description
	Constraints (see page 6525)	Controls whether database constraints are passed to the client so that it can check them locally.
	DataSet (see page 6525)	Specifies the dataset from which the provider provides data and to which it applies updates.
	Exported (see page 6526)	Allows client applications to pass calls to the provider when it resides on an application server.
	Options (see page 6526)	Influences what is included in data packets and how the information in data packets is used.
	ResolveToDataSet (see page 6528)	Specifies whether updates should be applied to a dataset or directly to the database server.
	UpdateMode (see page 6528)	Controls how the provider locates records when applying updates.

72.1.7.5.1 TDataSetProvider.ActiveUpdateException Property

Pascal

```
property ActiveUpdateException: Exception;
```

C++

```
__property Exception ActiveUpdateException;
```

Description

This is ActiveUpdateException, a member of class TDataSetProvider.

72.1.7.5.2 TDataSetProvider.Constraints Property

Controls whether database constraints are passed to the client so that it can check them locally.

Pascal

```
property Constraints: Boolean;
```

C++

```
__property Boolean Constraints;
```

Description

Set Constraints to specify whether data constraints defined for the provider's associated dataset are sent along with the metadata for the dataset. Sending constraints allows client datasets to check for constraint violations locally, so that updates are less likely to fail when sent back to the database server.

When Constraints is true, constraints are sent. To prevent the provider from sending constraint information, set Constraints to false.

Note: Before constraints can be sent to client applications, they must be imported to the data dictionary on the application server. Use SQL explorer to import constraints to the data dictionary.

See Also

Constraints

DataSet (see page 6525)

72.1.7.5.3 TDataSetProvider.DataSet Property

Specifies the dataset from which the provider provides data and to which it applies updates.

Pascal

```
property DataSet: TDataSet;
```

C++

```
__property TDataSet DataSet;
```

Description

Set DataSet to link the dataset provider to a dataset that it represents. The dataset provider packages the records from (and other information about) DataSet into data packets that can be used by client datasets and XML brokers. DataSet must be defined if the provider is used to create data packets.

If the ResolveToDataSet (see page 6528) property is true, the provider applies updates from the application server directly to this dataset. Otherwise, the provider applies updates directly to the underlying database server.

Note: The provider communicates with DataSet using the IProviderSupport interface. This interface is available in all datasets, although in TDataSet most of the IProviderSupport methods are simple stubs that either do nothing or generate an exception. The dataset classes that ship with the IDE (dbExpress datasets, BDE-enabled datasets, ADO-enabled datasets, InterBase Express datasets,

and client datasets) override these protected methods to implement the IProviderSupport interface in a more useful fashion. If

you are using custom dataset components, check with the vendor whether they can work with a dataset provider.

See Also

applyupdates (see page 6468)

Data (see page 6482)

IProviderSupport

Connecting a Client Dataset to Another Dataset in the Same Application

Determining the Source of Data

72.1.7.5.4 TDataSetProvider.Exported Property

Allows client applications to pass calls to the provider when it resides on an application server.

Pascal

```
property Exported: Boolean;
```

C++

```
__property Boolean Exported;
```

Description

Use Exported to indicate whether the provider is made available to clients of a remote data module that owns it. When Exported is true, client applications can specify the provider as a target for calls made using the IAppServer interface. When Exported is false, IAppServer calls that specify the provider cause an exception.

Note: In addition to the Exported property, the provider must be registered with the remote data module for clients to access it using the data module's IAppServer interface. When the provider's Owner is the remote data module, it is automatically registered. If the provider has a different owner, the server application must explicitly register providers using the remote data module's RegisterProvider method.

See Also

IAppServer (see page 5222)

Providers

registerprovider

72.1.7.5.5 TDataSetProvider.Options Property

Influences what is included in data packets and how the information in data packets is used.

Pascal

```
property Options: TProviderOptions;
```

C++

```
__property TProviderOptions Options;
```

Description

Set Options to customize how the provider communicates with client datasets. Options is a set that specifies

Whether nested detail sets and BLOB data are included in data packets or fetched separately.

Whether data packets include field component properties such as formats, display names, and maximum & minimum values.

Whether data packets are provided on a read-only basis, and whether specific types of changes (insertions, edits, or deletions)

are disabled.

Whether changes to master table fields should cause corresponding updates to detail tables.

Whether a single update can affect multiple server records.

Whether the client's records are refreshed when it applies updates.

Whether the client can send SQL statements that override the provider's dataset.

Note: Not all options are supported by an InternetExpress client. Specifically, InternetExpress clients don't support poFetchBlobsOnDemand, poFetchDetailsOnDemand, poDisableInserts, poDisableEdits, psDisableDeletes, poPropogateChanges, and poAllowCommandText.

Overriding the Dataset On the Application Server

Setting Options That Influence the Data Packets

72.1.7.5.6 TDataSetProvider.OwnerData Property

Pascal

```
property OwnerData: OleVariant;
```

C++

```
__property OleVariant OwnerData;
```

Description

This is OwnerData, a member of class TDataSetProvider.

72.1.7.5.7 TDataSetProvider.Params Property

Stores the parameter values currently in use.

Pascal

```
property Params: TParams;
```

C++

```
__property TParams Params;
```

Description

This protected property acts as a temporary cache for parameter values from clients. It is set to the parameter values supplied by calls to the Execute (see page 6474) or GetRecords (see page 6476) method.

Note: If the dataset provider is responding to multiple client datasets or XML brokers

, the value of Params can only be used within the context of a single call to SetParams (see page 6523), Execute (see page 6474), or GetRecords (see page 6476). After that, other client calls can change the value of parameters.

See Also

Execute (see page 6474)

GetRecords (see page 6476)

72.1.7.5.8 TDataSetProvider.ResolveToDataSet Property

Specifies whether updates should be applied to a dataset or directly to the database server.

Pascal

```
property ResolveToDataSet: Boolean;
```

C++

```
__property Boolean ResolveToDataSet;
```

Description

Set ResolveToDataSet to specify how updates are applied. When ResolveToDataSet is true, the Resolver (see page 6456) property is set to a TDataSetResolver (see page 6540) component, which applies updates directly to the dataset specified by the DataSet (see page 6525) property. This can be useful if the application uses the events on the dataset component or if the dataset does not represent the data from a database server (for example, a client dataset).

When ResolveToDataSet is false, the Resolver (see page 6456) property is set to a TSQLResolver (see page 6564) component, which applies updates directly to the database server associated with DataSet (see page 6525). This can be more efficient, because it skips the intermediate step of using the dataset. It is the only way to resolve updates if the source dataset is read-only (for example, a unidirectional dataset).

See Also

DataSet (see page 6525)

Resolver (see page 6456)

Choosing How to Apply Updates Using a Datasetm Provider

72.1.7.5.9 TDataSetProvider.TransactionStarted Property

Pascal

```
property TransactionStarted: Boolean;
```

C++

```
__property Boolean TransactionStarted;
```

Description

This is TransactionStarted, a member of class TDataSetProvider.

72.1.7.5.10 TDataSetProvider.UpdateMode Property

Controls how the provider locates records when applying updates.

Pascal

```
property UpdateMode: TUpdateMode;
```

C++

```
__property TUpdateMode UpdateMode;
```

Description

Use UpdateMode to specify the criteria for locating a record in the dataset when applying updates. UpdateMode specifies whether modified records are located based on all columns (fields), on only the key fields, or on the key fields plus the original

values of fields that have been modified.

Note: To control how the provider locates records by specifying individual fields, use the field components' ProviderFlags property.

applyupdates (see page 6468)

ProviderFlags

Influencing How Updates Are Applied

72.1.7.6 TDataSetProvider Events

The events of the TDataSetProvider class are listed here.

Published Events

	Name	Description
	AfterApplyUpdates (see page 6529)	Occurs after the provider applies updates.
	AfterExecute (see page 6530)	Occurs after the provider passes an execute command to its dataset.
	AfterGetParams (see page 6531)	This is AfterGetParams, a member of class TDataSetProvider.
	AfterGetRecords (see page 6531)	Occurs after the provider creates a data packet to send to the client dataset.
	AfterRowRequest (see page 6532)	Occurs after the provider fetches new information about the current record.
	AfterUpdateRecord (see page 6533)	Occurs when the associated resolver has just updated a record.
	BeforeApplyUpdates (see page 6533)	Occurs before the provider applies updates from a client dataset.
	BeforeExecute (see page 6534)	This is BeforeExecute, a member of class TDataSetProvider.
	BeforeGetParams (see page 6534)	Occurs before the provider creates an OleVariant that encodes the current parameter values and sends them to a client dataset.
	BeforeGetRecords (see page 6535)	Occurs before the provider creates a data packet and sends it to a client dataset.
	BeforeRowRequest (see page 6536)	Occurs before the provider creates a delta packet with information about the current record.
	BeforeUpdateRecord (see page 6537)	This is BeforeUpdateRecord, a member of class TDataSetProvider.
	OnDataRequest (see page 6537)	Occurs when a provider calls its DataRequest method.
	OnGetData (see page 6537)	Occurs after a provider retrieves data but before it is sent to the client.
	OnGetDataSetProperties (see page 6538)	Occurs when the provider adds additional information to a data packet it is creating.
	OnGetTableName (see page 6539)	This is OnGetTableName, a member of class TDataSetProvider.
	OnUpdateData (see page 6539)	Occurs when a provider begins to apply updates.
	OnUpdateError (see page 6539)	Occurs when a provider can't update a record because of an error condition.
	OnValidate (see page 6540)	This is OnValidate, a member of class TDataSetProvider.

72.1.7.6.1 TDataSetProvider.AfterApplyUpdates Event

Occurs after the provider applies updates.

Pascal

```
property AfterApplyUpdates: TRemoteEvent;
```

C++

```
__property TRemoteEvent AfterApplyUpdates;
```

Description

Write an AfterApplyUpdates event handler to return custom information to a client dataset after applying updates. AfterApplyUpdates is part of the mechanism by which a client dataset and a provider communicate information about updates. When the provider is part of a stateless application server, this mechanism allows the provider and the client dataset to

communicate persistent state information.

When the client dataset calls the AS_ApplyUpdates method of the IAppServer interface, the following events occur:

1.The provider receives a BeforeApplyUpdates event, where it can respond to or change custom information that the client dataset sends.

2.If it is a dataset provider, the provider receives an OnUpdateData event where it can edit the updates before they are applied.

3. The provider applies the updates, and attempts to resolve problems.

4.The provider receives an AfterApplyUpdates event, where it can encode custom information into its OwnerData parameter or respond to information from the BeforeApplyUpdates event handler.

5.The client dataset receives an AfterApplyUpdates event, where it can respond to the custom information returned by the provider in its AfterApplyUpdates event handler.

Note: If ApplyUpdates is called without the OwnerData parameter, on entry to the event handler the OwnerData parameter contains the value set in the BeforeApplyUpdates event handler and it is ignored on exit from the AfterApplyUpdates event handler.

Responding to Client Update Requests

Communicating with the Client Dataset

72.1.7.6.2 TDataSetProvider.AfterExecute Event

Occurs after the provider passes an execute command to its dataset.

Pascal

```
property AfterExecute: TRemoteEvent;
```

C++

```
__property TRemoteEvent AfterExecute;
```

Description

Write an AfterExecute event handler to return custom information to a client dataset after executing a query or stored procedure. AfterExecute is part of the mechanism by which a client dataset and a provider communicate information when executing queries or stored procedures that do not return a cursor. When the provider is part of a stateless application server, this mechanism allows the provider and the client dataset to communicate persistent state information.

When the client dataset calls the AS_Execute method of the IAppServer interface, the following events occur:

1.The provider receives a BeforeExecute event, where it can respond to or change custom information that the client dataset sends.

2.The provider dispatches its Execute method to execute a query or stored procedure.

3.The provider receives an AfterExecute event, where it can encode custom information into its OwnerData parameter or respond to information from the BeforeExecute event handler.

4.The client dataset receives an AfterExecute event, where it can respond to the custom information returned by the provider in its AfterExecute event handler.

Communicating with the Client Dataset

72.1.7.6.3 TDataSetProvider.AfterGetParams Event

Pascal

```
property AfterGetParams: TRemoteEvent;
```

C++

```
__property TRemoteEvent AfterGetParams;
```

Description

This is AfterGetParams, a member of class TDataSetProvider.

72.1.7.6.4 TDataSetProvider.AfterGetRecords Event

Occurs after the provider creates a data packet to send to the client dataset.

Pascal

```
property AfterGetRecords: TRemoteEvent;
```

C++

```
__property TRemoteEvent AfterGetRecords;
```

Description

Write an AfterGetRecords event handler to send custom information to a client dataset when providing a data packet. AfterGetRecords is part of the mechanism by which a provider and a client dataset communicate information about data fetching. When the provider is part of a stateless application server, this mechanism allows the provider and the client dataset to communicate persistent state information.

When the client dataset calls the AS_GetRecords method of the IAppServer interface, the following events occur:

1.The provider receives a BeforeGetRecords event, where it can respond to or change custom information that the client dataset sends.

2.If it is a dataset provider, the provider receives an OnGetData event where it can edit the data before creating a data packet, and then generates the data packet.

3.The provider receives an AfterGetRecords event, where it can encode custom information into its OwnerData parameter or respond to information from the BeforeGetRecords event handler.

4.The client dataset receives an AfterGetRecords event, where it can respond to the custom information returned by the provider in its AfterGetRecords event handler.

Communicating with the Client Dataset

Responding to Client Data Requests

72.1.7.6.5 TDataSetProvider.AfterRowRequest Event

Occurs after the provider fetches new information about the current record.

Pascal

```
property AfterRowRequest: TRemoteEvent;
```

C++

```
__property TRemoteEvent AfterRowRequest;
```

Description

Write an AfterRowRequest event handler to send custom information to a client dataset along with information about the current record. AfterRowRequest is part of the mechanism by which a provider and a client dataset communicate information about data fetching. When the provider is part of a stateless application server, this mechanism allows the provider and the client dataset to communicate persistent state information.

When the client dataset calls the AS_RowRequest method of the IAppServer interface, the following events occur:

1.The provider receives a BeforeRowRequest event, where it can respond to or change custom information that the client dataset sends.

2.The provider creates a delta packet that contains the requested information.

3.The provider receives an AfterRowRequest event, where it can encode custom information into its OwnerData parameter or respond to information from the BeforeRowRequest event handler.

4.The client dataset receives an AfterRowRequest event, where it can respond to the custom information returned by the provider in its AfterRowRequest event handler.

RefreshRecord

Communicating with the Client Dataset

72.1.7.6.6 TDataSetProvider.AfterUpdateRecord Event

Occurs when the associated resolver has just updated a record.

Pascal

```
property AfterUpdateRecord: TAfterUpdateRecordEvent;
```

C++

```
__property TAfterUpdateRecordEvent AfterUpdateRecord;
```

Description

Write an AfterUpdateRecord event handler to provide special processing immediately after a record has been successfully updated. For example, use AfterUpdateRecord to maintain a log of successful updates.

See Also

beforeupdaterecord (see page 6458)

AfterApplyUpdates (see page 6483)

72.1.7.6.7 TDataSetProvider.BeforeApplyUpdates Event

Occurs before the provider applies updates from a client dataset.

Pascal

```
property BeforeApplyUpdates: TRemoteEvent;
```

C++

```
__property TRemoteEvent BeforeApplyUpdates;
```

Description

Write a BeforeApplyUpdates event handler to respond to custom information from a client dataset. BeforeApplyUpdates is part of the mechanism by which a provider and a client dataset communicate information about updates. When the provider is part of a stateless application server, this mechanism allows the provider and the client dataset to communicate persistent state information.

When the client dataset's ApplyUpdates method is called, the following events occur:

1.The client dataset receives a BeforeApplyUpdates event, where it can encode custom information into an OleVariant.

2.The provider receives a BeforeApplyUpdates event, where the OleVariant from the client dataset appears as the OwnerData parameter. The provider can respond to or change that information before applying the updates.

3.If it is a dataset provider, the provider applies the updates, and receives an OnUpdateError event for any problem records.

4.The provider receives an AfterApplyUpdates event, where it can encode custom information into its OwnerData parameter or respond to information from the BeforeApplyUpdates event handler.

5.The client dataset receives an AfterApplyUpdates event, where it can respond to the custom information returned by the provider in its AfterApplyUpdates event handler.

Note: If ApplyUpdates is called without the OwnerData parameter, the OwnerData parameter is nil (Delphi) or NULL (C++) on entry to the event handler and its value (on exit) is only passed to the AfterApplyUpdates event handler but not returned to the

caller.

72.1.7.6.8 TDataSetProvider.BeforeExecute Event

Pascal

```
property BeforeExecute: TRemoteEvent;
```

C++

```
__property TRemoteEvent BeforeExecute;
```

Description

This is BeforeExecute, a member of class TDataSetProvider.

72.1.7.6.9 TDataSetProvider.BeforeGetParams Event

Occurs before the provider creates an OleVariant that encodes the current parameter values and sends them to a client dataset.

Pascal

```
property BeforeGetParams: TRemoteEvent;
```

C++

```
__property TRemoteEvent BeforeGetParams;
```

Description

Write a BeforeGetParams event handler to respond to custom information from a client dataset. BeforeGetParams is part of the mechanism by which a provider and a client dataset communicate information during parameter fetching. When the provider is part of a stateless application server, this mechanism allows the provider and the client dataset to communicate persistent state information.

When the client dataset fetches parameter values from the provider, the following events occur:

1.The client dataset receives a BeforeGetParams event, where it can encode custom information into an OleVariant.

2.The provider receives a BeforeGetParams event, where the OleVariant from the client dataset appears as the OwnerData parameter. The provider can respond to or change that information before it fetches and encodes the parameter values.

3.The provider generates an OleVariant for the current parameter values of its dataset, if appropriate.

4.The provider receives an AfterGetParams event, where it can encode custom information into its OwnerData parameter or respond to information from the BeforeGetParams event handler.

5.The client dataset receives an AfterGetParams event, where it can respond to the custom information returned by the provider in its AfterGetParams event handler.

Communicating with the Client Dataset

72.1.7.6.10 TDataSetProvider.BeforeGetRecords Event

Occurs before the provider creates a data packet and sends it to a client dataset.

Pascal

```
property BeforeGetRecords: TRemoteEvent;
```

C++

```
__property TRemoteEvent BeforeGetRecords;
```

Description

Write a BeforeGetRecords event handler to respond to custom information from a client dataset. BeforeGetRecords is part of the mechanism by which a provider and a client dataset communicate information about data fetching. When the provider is part of a stateless application server, this mechanism allows the provider and the client dataset to communicate persistent state information.

When the client dataset fetches data from the provider, the following events occur:

1.The client dataset receives a BeforeGetRecords event, where it can encode custom information into an OleVariant.

2.The provider receives a BeforeGetRecords event, where the OleVariant from the client dataset appears as the OwnerData parameter. The provider can respond to or change that information before it creates a data packet.

3.The provider generates the data packet.

4.The provider receives an AfterGetRecords event, where it can encode custom information into its OwnerData parameter or respond to information from the BeforeGetRecords event handler.

5.The client dataset receives an AfterGetRecords event, where it can respond to the custom information returned by the provider in its AfterGetRecords event handler.

Delphi Examples:

```
{
This example shows the implementation of a provider BeforeGetRecords
event handler and a RemoteDataModule UpdateRegistry method.  The
complete project using this code example is in
Demos/DelphiWin32/VCLWin32/MIDAS/Pooler.
}
procedure TPooledRDM.DataSetProvider1BeforeGetRecords(Sender: TObject;
  var OwnerData: OleVariant);
begin
  try
    Query1.Close;
    Query1.SQL.Text := OwnerData[0];
    if not VarIsNull(OwnerData[1]) and not VarIsEmpty(OwnerData[1]) then
    begin
      Query1.Open;
      if not Query1.Locate(Query1.Fields[0].FieldName, OwnerData[1], []) then
        raise Exception.Create('Record not found');
```

```
      Query1.Next;
    end;
  finally
    OwnerData := NULL;
  end;
end;
```

Communicating with the Client Dataset

Responding to Client Data Requests

72.1.7.6.11 TDataSetProvider.BeforeRowRequest Event

Occurs before the provider creates a delta packet with information about the current record.

Pascal

```
property BeforeRowRequest: TRemoteEvent;
```

C++

```
__property TRemoteEvent BeforeRowRequest;
```

Description

Write a BeforeRowRequest event handler to respond to custom information from a client dataset. BeforeRowRequest is part of the mechanism by which a provider and a client dataset communicate information about data fetching. When the provider is part of a stateless application server, this mechanism allows the provider and the client dataset to communicate persistent state information.

When the client dataset fetches detail information about the current record or refreshes the current record, the following events occur:

1.The client dataset receives a BeforeRowRequest event, where it can encode custom information into an OleVariant.

2.The provider receives a BeforeRowRequest event, where the custom information appears as the OwnerData parameter. The provider can respond to or change that information before it looks up the requested information.

3.The provider creates a delta packet that contains the requested information.

4.The provider receives an AfterRowRequest event, where it can encode custom information into its OwnerData parameter or respond to information from the BeforeRowRequest event handler.

5.The client dataset receives an AfterRowRequest event, where it can respond to the custom information returned by the provider in its AfterRowRequest event handler.

Communicating with the Client Dataset

72.1.7.6.12 TDataSetProvider.BeforeUpdateRecord Event

Pascal

```
property BeforeUpdateRecord: TBeforeUpdateRecordEvent;
```

C++

```
__property TBeforeUpdateRecordEvent BeforeUpdateRecord;
```

Description

This is BeforeUpdateRecord, a member of class TDataSetProvider.

72.1.7.6.13 TDataSetProvider.OnDataRequest Event

Occurs when a provider calls its DataRequest method.

Pascal

```
property OnDataRequest: TDataRequestEvent;
```

C++

```
__property TDataRequestEvent OnDataRequest;
```

Description

Write an OnDataRequest event handler to do custom processing of data. OnDataRequest has no built-in use. Instead, it allows developers to augment the IAppServer interface so that clients in a multi-tiered application can communicate directly with an individual provider.

If an application does not provide an OnDataRequest event handler, calls to DataRequest return NULL.

Note: To provide the same sort of custom processing on the client side, use an automation method on the connection component.

See Also

DataRequest (see page 6468)

IAppServer (see page 5222)

Communicating with Providers Using Custom Events

Communicating with the Client Dataset

Responding to Client-generated Events

72.1.7.6.14 TDataSetProvider.OnGetData Event

Occurs after a provider retrieves data but before it is sent to the client.

Pascal

```
property OnGetData: TProviderDataEvent;
```

C++

```
__property TProviderDataEvent OnGetData;
```

Description

Write an OnGetData event handler to perform any custom data processing the provider should handle before returning data to a client. The OnGetData event occurs after a provider fetches data from its dataset but before the data is sent on to the client. Using the methods of the DataSet parameter, data can be edited in the OnGetData event handler before sending it to the client dataset or XML broker.

Note: OnGetData occurs when the Data property is read, as well as when the GetRecords method is called.

See Also

GetRecords (see page 6476)

OnUpdateData (see page 6459)

BeforeGetRecords (see page 6488)

AfterGetRecords (see page 6485)

Responding to Client Data Requests

72.1.7.6.15 TDataSetProvider.OnGetDataSetProperties Event

Occurs when the provider adds additional information to a data packet it is creating.

Pascal

```
property OnGetDataSetProperties: TGetDSProps;
```

C++

```
__property TGetDSProps OnGetDataSetProperties;
```

Description

Write an OnGetDataSetProperties event handler to include application-defined information in the data packets. This information can later be returned using the GetOptionalParam method of the client dataset that represents the data in the packet.

Note: The following names are reserved and can't be used as the name for storing custom information:

UNIQUE_KEY	DEFAULT_ORDER	CHANGE_LOG	SERVER_COL
CONSTRAINTS	DATASET_CONTEXT	DATASET_DELTA	LCID
BDERECORD_X	TABLE_NAME	MD_FIELDLINKS	UPDATEMODE

Adding Custom Information to Data Packets

72.1.7.6.16 TDataSetProvider.OnGetTableName Event

Pascal

```
property OnGetTableName: TGetTableNameEvent;
```

C++

```
__property TGetTableNameEvent OnGetTableName;
```

Description

This is OnGetTableName, a member of class TDataSetProvider.

72.1.7.6.17 TDataSetProvider.OnUpdateData Event

Occurs when a provider begins to apply updates.

Pascal

```
property OnUpdateData: TProviderDataEvent;
```

C++

```
__property TProviderDataEvent OnUpdateData;
```

Description

Write an OnUpdateData event to handle special processing before the provider begins applying updates received from the client dataset or XML broker. Using the methods belonging to the DataSet parameter, an application can

Examine data (for example, for values or data changes that should not permitted), and raise exceptions that cancel applying of updates before they occur.

Change data (for example encrypting or decrypting values) before it is sent on to the source dataset or database server.

Adding Custom Information to Data Packets

Editing Delta Packets Before Updating the Database

Influencing How Updates Are Applied

72.1.7.6.18 TDataSetProvider.OnUpdateError Event

Occurs when a provider can't update a record because of an error condition.

Pascal

```
property OnUpdateError: TResolverErrorEvent;
```

C++

```
__property TResolverErrorEvent OnUpdateError;
```

Description

Write an OnUpdateError event handler to respond to error conditions that arise when the provider applies a client dataset's updates. The OnUpdateError event handler is called for each record that can't be updated.

Warning: The provider can't detect when an update conflicts with another user's changes to a memo field. This situation will not

generate an OnUpdateError event.

72.1.7.6.19 TDataSetProvider.OnValidate Event

Pascal

```
property OnValidate: TOnValidate;
```

C++

```
__property TOnValidate OnValidate;
```

Description

This is OnValidate, a member of class TDataSetProvider.

72.1.8 TDataSetResolver Class

TDataSetResolver applies updates to a dataset on behalf of a provider.

Class Hierarchy

Pascal

```
TDataSetResolver = class(TCustomResolver);
```

C++

```
class TDataSetResolver : public TCustomResolver;
```

File

Provider

Description

TDataSetProvider (see page 6510) components use TDataSetResolver to apply updates to a dataset when their ResolveToDataSet property is true. Otherwise, they use TSQLResolver (see page 6564).

Do not create instances of TDataSetResolver. Provider (see page 6545) components create their own TDataSetResolver objects for applying updates.

See Also

TDataSetProvider (see page 6510)

TBaseProvider (see page 6445)

TSQLResolver (see page 6564)

TDataSetProvider (see page 6510)

72.1.8.1 TDataSetResolver Members

The following tables list the members exposed by TDataSetResolver.

Protected Methods

	Name	Description
	BeginUpdate (see page 6542)	Provides the interface for a method that performs any initialization before applying updates.
	DoDelete (see page 6543)	Defines a method that deletes a record.
	DoInsert (see page 6543)	Defines a method that inserts a record.
	DoUpdate (see page 6543)	Defines a method that modifies a record.
	EndUpdate (see page 6544)	Provides the interface for a method that performs any finalization after applying updates.
	HandleUpdateError (see page 6497)	Manages the resolving process when errors occur while applying updates.
	InitializeConflictBuffer (see page 6544)	Introduces a method for adding information about a failed update that is passed to an OnUpdateError event handler.
	LogUpdateError (see page 6499)	This is LogUpdateError, a member of class TCustomResolver.
	LogUpdateRecord (see page 6500)	Adds records to the error log if their data has been changed by another application.

Protected Properties

	Name	Description
	Provider (see page 6545)	Indicates the provider that uses this resolver to apply updates.

Public Methods

	Name	Description
	ApplyUpdates (see page 6494)	Applies updates received from a provider.
	Create (see page 6541)	Creates and initializes a dataset resolver.
	Destroy (see page 6493)	Frees an instance of a resolver object.
	FreeTreeData (see page 6497)	This is FreeTreeData, a member of class TCustomResolver.
	InitKeyFields (see page 6498)	Sets the provider flag pfInKey on all key fields in a delta data packet.
	InitTreeData (see page 6498)	This is InitTreeData, a member of class TCustomResolver.
	InternalBeforeResolve (see page 6545)	Initializes internal data structures once the delta packet has been wrapped in an update tree but before any updates are applied.
	InternalUpdateRecord (see page 6499)	Manages the updating process once a delta packet is wrapped in a TUpdateTree (see page 6572) object.
	RowRequest (see page 6500)	Returns information from a specified record.

Public Properties

	Name	Description
	UpdateTree (see page 6501)	This is UpdateTree, a member of class TCustomResolver.

72.1.8.2 TDataSetResolver.Create Constructor

Creates and initializes a dataset resolver.

Pascal

```
constructor Create(AProvider: TDataSetProvider); reintroduce;
```

C++

```
__fastcall TDataSetResolver(TDataSetProvider AProvider);
```

Description

Provider (see page 6545) components call Create when they need a resolver component for applying updates to a dataset. The AProvider parameter specifies the provider that creates and uses the resolver.

Do not create resolver instances directly. Resolvers are designed to be created and used by providers, and can not function independently of a provider.

See Also

Resolver (see page 6456)

72.1.8.3 TDataSetResolver Methods

The methods of the TDataSetResolver class are listed here.

Protected Methods

	Name	Description
	BeginUpdate (see page 6542)	Provides the interface for a method that performs any initialization before applying updates.
	DoDelete (see page 6543)	Defines a method that deletes a record.
	DoInsert (see page 6543)	Defines a method that inserts a record.
	DoUpdate (see page 6543)	Defines a method that modifies a record.
	EndUpdate (see page 6544)	Provides the interface for a method that performs any finalization after applying updates.
	InitializeConflictBuffer (see page 6544)	Introduces a method for adding information about a failed update that is passed to an OnUpdateError event handler.

Public Methods

	Name	Description
	InternalBeforeResolve (see page 6545)	Initializes internal data structures once the delta packet has been wrapped in an update tree but before any updates are applied.

72.1.8.3.1 TDataSetResolver.BeginUpdate Method

Provides the interface for a method that performs any initialization before applying updates.

Pascal

```
procedure BeginUpdate; override;
```

C++

```
virtual __fastcall BeginUpdate();
```

Description

The ApplyUpdates method calls BeginUpdate before applying updates in a delta packet.

As implemented in TCustomResolver, BeginUpdate does nothing. Descendants that need take specific action before applying updates override this method.

See Also

EndUpdate (see page 6496)

ApplyUpdates (see page 6494)

72.1.8.3.2 TDataSetResolver.DoDelete Method

Defines a method that deletes a record.

Pascal

```
procedure DoDelete(Tree: TUpdateTree); override;
```

C++

```
virtual __fastcall DoDelete(TUpdateTree Tree);
```

Description

DoDelete is one of several helper methods internal to the ApplyUpdates method. These helper methods perform the actual updates in the delta packet. ApplyUpdates wraps the delta packet in a TUpdateTree object. For each record that must be deleted, the resolver calls DoDelete.

TCustomResolver does not implement the DoDelete method. Descendants override this method to delete records in their own specialized way.

See Also

ApplyUpdates (see page 6494)

DoInsert (see page 6495)

DoUpdate (see page 6496)

72.1.8.3.3 TDataSetResolver.DoInsert Method

Defines a method that inserts a record.

Pascal

```
procedure DoInsert(Tree: TUpdateTree); override;
```

C++

```
virtual __fastcall DoInsert(TUpdateTree Tree);
```

Description

DoInsert is one of several helper methods internal to the ApplyUpdates method. These helper methods perform the actual updates in the delta packet. ApplyUpdates wraps the delta packet in a TUpdateTree object. For each record that must be inserted, the resolver calls DoInsert.

TCustomResolver does not implement the DoInsert method. Descendants override this method to insert records in their own specialized way.

See Also

ApplyUpdates (see page 6494)

DoDelete (see page 6495)

DoUpdate (see page 6496)

72.1.8.3.4 TDataSetResolver.DoUpdate Method

Defines a method that modifies a record.

Pascal

```
procedure DoUpdate(Tree: TUpdateTree); override;
```

C++

```
virtual __fastcall DoUpdate(TUpdateTree Tree);
```

Description

DoUpdate is one of several helper methods internal to the ApplyUpdates method. These helper methods perform the actual updates passed in the delta packet. ApplyUpdates wraps the delta packet in a TUpdateTree object. For each record that must be modified, the resolver calls DoUpdate.

TCustomResolver does not implement the DoUpdate method. Descendants override this method to insert records in their own specialized way.

See Also

ApplyUpdates (see page 6494)

DoDelete (see page 6495)

DoInsert (see page 6495)

72.1.8.3.5 TDataSetResolver.EndUpdate Method

Provides the interface for a method that performs any finalization after applying updates.

Pascal

```
procedure EndUpdate; override;
```

C++

```
virtual __fastcall EndUpdate();
```

Description

The ApplyUpdates method calls EndUpdate after applying updates.

As implemented in TCustomResolver, EndUpdate does nothing. Descendants that need take specific action after applying updates override this method.

See Also

BeginUpdate (see page 6494)

ApplyUpdates (see page 6494)

72.1.8.3.6 TDataSetResolver.InitializeConflictBuffer Method

Introduces a method for adding information about a failed update that is passed to an OnUpdateError event handler.

Pascal

```
procedure InitializeConflictBuffer(Tree: TUpdateTree); override;
```

C++

```
virtual __fastcall InitializeConflictBuffer(TUpdateTree Tree);
```

Description

The HandleUpdateError method calls InitializeConflictBuffer before generating an OnUpdateError event. This ensures that the client dataset passed to an OnUpdateError event handler represents the update that caused the problem, with appropriate

values for field's CurValue property.

Descendants of TCustomResolver implement this method to obtain information from the dataset or server to which they are applying updates.

See Also

HandleUpdateError (see page 6497)

OnUpdateError (see page 6460)

72.1.8.3.7 TDataSetResolver.InternalBeforeResolve Method

Initializes internal data structures once the delta packet has been wrapped in an update tree but before any updates are applied.

Pascal

```
procedure InternalBeforeResolve(Tree: TUpdateTree); override;
```

C++

```
virtual __fastcall InternalBeforeResolve(TUpdateTree Tree);
```

Description

The ApplyUpdates method wraps delta packets in a TUpdateTree object. Once this is complete, InternalBeforeResolve performs any other initialization before the updates are applied.

As implemented in TCustomResolver, InternalBeforeResolve does nothing. Descendants override this method to perform class-specific initialization.

See Also

ApplyUpdates (see page 6494)

inittreedata (see page 6498)

72.1.8.4 TDataSetResolver Properties

The properties of the TDataSetResolver class are listed here.

Protected Properties

	Name	Description
	Provider (see page 6545)	Indicates the provider that uses this resolver to apply updates.

72.1.8.4.1 TDataSetResolver.Provider Property

Indicates the provider that uses this resolver to apply updates.

Pascal

```
property Provider: TDataSetProvider;
```

C++

```
__property TDataSetProvider Provider;
```

Description

Provider is a read-only property that points to the provider that uses this resolver for applying updates. The Provider property is set in the constructor.

Resolvers use the Provider property internally to obtain information supplied in the provider's properties. They also use it to

generate events on the provider at appropriate points in the update process.

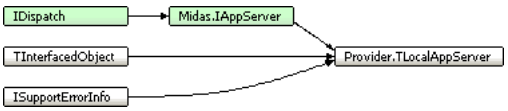
72.1.9 TLocalAppServer Class

Class Hierarchy



Pascal

```
TLocalAppServer = class(TInterfacedObject, IAppServer, ISupportErrorInfo);
```

C++

```
class TLocalAppServer : public TInterfacedObject, public IAppServer, public ISupportErrorInfo;
```

File

Provider

Description

This is class Provider.TLocalAppServer.

72.1.9.1 TLocalAppServer Members

The following tables list the members exposed by TLocalAppServer.

Protected Methods

	Name	Description
	AS_ApplyUpdates (see page 6548)	Applies updates received from a client dataset using a specified provider.
	AS_DataRequest (see page 6549)	Generates an OnAS_DataRequest event on the specified provider component.
	AS_Execute (see page 6549)	AS_Executes the query or stored procedure bound to a specified provider.
	AS_GetParams (see page 6550)	Fetches current parameter values from the dataset bound to a specified provider.
	AS_GetProviderNames (see page 6551)	Returns a list of all the available providers on a remote data module.
	AS_GetRecords (see page 6552)	Returns a data packet that contains the specified data.
	AS_RowRequest (see page 6553)	Returns information from a specified record of the provider's dataset.
	GetIDsOfNames (see page 6554)	This is GetIDsOfNames, a member of class TLocalAppServer.
	GetTypeInfo (see page 6554)	This is GetTypeInfo, a member of class TLocalAppServer.
	GetTypeInfoCount (see page 6554)	This is GetTypeInfoCount, a member of class TLocalAppServer.
	InterfaceSupportsErrorInfo (see page 6554)	This is InterfaceSupportsErrorInfo, a member of class TLocalAppServer.
	Invoke (see page 6555)	This is Invoke, a member of class TLocalAppServer.

Public Methods

	Name	Description
	Create (see page 6547)	This is the overview for the Create constructor overload.
V	Destroy (see page 6547)	Disposes of an object instance.
V	SafeCallException (see page 6555)	Handles exceptions in methods declared using the safecall calling convention.

72.1.9.2 Create Constructor

This is the overview for the Create constructor overload.

Overload List

	Name	Description
	TLocalAppServer.Create (TCustomProvider) (see page 6547)	This is Create, a member of class TLocalAppServer.
	TLocalAppServer.Create (TDataset) (see page 6547)	This is Create, a member of class TLocalAppServer.

72.1.9.2.1 TLocalAppServer.Create Constructor (TCustomProvider)

Pascal

```
constructor Create(AProvider: TCustomProvider); overload;
```

C++

```
__fastcall TLocalAppServer(TCustomProvider AProvider);
```

Description

This is Create, a member of class TLocalAppServer.

72.1.9.2.2 TLocalAppServer.Create Constructor (TDataset)

Pascal

```
constructor Create(ADataset: TDataset); overload;
```

C++

```
__fastcall TLocalAppServer(TDataset ADataset);
```

Description

This is Create, a member of class TLocalAppServer.

72.1.9.3 TLocalAppServer.Destroy Destructor

Disposes of an object instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TLocalAppServer();
```

Description

Do not call System::TObject::Destroy directly. Call System::TObject::Free instead. Free verifies that the object reference is not nil before calling System::TObject::Destroy.

The System::TObject::Destroy method defined by System::TObject::TObject deallocates memory. Descendant objects usually define a destructor that is customized for that particular kind of object.

When declaring a System::TObject::Destroy method in a descendant, always add the override directive to the declaration and call the inherited System::TObject::Destroy as the last statement in the overriding method. Since System::TObject::Destroy is a virtual method, overriding it ensures that the proper inherited behavior occurs.

Note: If an exception escapes from the constructor, the destructor is called to destroy the partially constructed object instance that failed to initialize completely. Therefore, destructors should check that allocated resources, such as handles, were actually allocated before trying to release them, since their value might be zero.

System::TObject::Destroy should be implemented so that it calls System::TObject::Free on all subobjects created within the object's constructor (that is, allocated by the constructor). Unlike System::TObject::Destroy, System::TObject::Free provides a safeguard when destroying objects that are nil.

System::TObject::Free

72.1.9.4 TLocalAppServer Methods

The methods of the TLocalAppServer class are listed here.

Protected Methods

	Name	Description
	AS_ApplyUpdates (see page 6548)	Applies updates received from a client dataset using a specified provider.
	AS_DataRequest (see page 6549)	Generates an OnAS_DataRequest event on the specified provider component.
	AS_Execute (see page 6549)	AS_Executes the query or stored procedure bound to a specified provider.
	AS_GetParams (see page 6550)	Fetches current parameter values from the dataset bound to a specified provider.
	AS_GetProviderNames (see page 6551)	Returns a list of all the available providers on a remote data module.
	AS_GetRecords (see page 6552)	Returns a data packet that contains the specified data.
	AS_RowRequest (see page 6553)	Returns information from a specified record of the provider's dataset.
	GetIDsOfNames (see page 6554)	This is GetIDsOfNames, a member of class TLocalAppServer.
	GetTypeInfo (see page 6554)	This is GetTypeInfo, a member of class TLocalAppServer.
	GetTypeInfoCount (see page 6554)	This is GetTypeInfoCount, a member of class TLocalAppServer.
	InterfaceSupportsErrorInfo (see page 6554)	This is InterfaceSupportsErrorInfo, a member of class TLocalAppServer.
	Invoke (see page 6555)	This is Invoke, a member of class TLocalAppServer.

Public Methods

	Name	Description
	SafeCallException (see page 6555)	Handles exceptions in methods declared using the safecall calling convention.

72.1.9.4.1 TLocalAppServer.AS_ApplyUpdates Method

Applies updates received from a client dataset using a specified provider.

Pascal

```
function AS_ApplyUpdates(const ProviderName: WideString; Delta: OleVariant; MaxErrors:
Integer; out ErrorCount: Integer; var OwnerData: OleVariant): OleVariant; safecall;
```

C++

```
__fastcall OleVariant AS_ApplyUpdates(const BSTR ProviderName, OleVariant Delta, int
MaxErrors, int ErrorCount, OleVariant OwnerData);
```

Description

AS_AS_ApplyUpdates writes client updates to a dataset or database server.

ProviderName specifies the name of the provider component that manages the update operation.

Delta is a Variant containing the updated, inserted, and deleted records to write to the database.

MaxErrors indicates the maximum number of errors to permit before stopping the update operation.

ErrorCount returns the actual number of errors encountered during the update operation.

OwnerData is information supplied by the client application in a BeforeAS_ApplyUpdates event handler and returned to the client application in an AfterAS_ApplyUpdates event handler.

AS_AS_ApplyUpdates (Delphi) or AS_ApplyUpdates_result parameter (C++) returns a Variant that is a data packet containing all records that could not be applied to the database.

BeforeApplyUpdates

AfterApplyUpdates

AS_ApplyUpdates

as_applyupdates

Communicating with the Client Dataset

72.1.9.4.2 TLocalAppServer.AS_DataRequest Method

Generates an OnAS_DataRequest event on the specified provider component.

Pascal

```
function AS_DataRequest(const ProviderName: WideString; Data: OleVariant): OleVariant;
safecall;
```

C++

```
__fastcall OleVariant AS_DataRequest(const BSTR ProviderName, OleVariant Data);
```

Description

Use AS_AS_DataRequest to invoke an OnAS_DataRequest event handler of the provider named by ProviderName. This method is provided to allow application developers to customize the communication between a client application and a provider component. There is no predefined meaning for the Data parameter or the return value (Delphi) or the AS_DataRequest_result parameter (C++), which is returned to the caller.

See Also

OnDataRequest (see page 6490)

DataRequest

Communicating with the Client Dataset

72.1.9.4.3 TLocalAppServer.AS_Execute Method

AS_Executes the query or stored procedure bound to a specified provider.

Pascal

```
procedure AS_Execute(const ProviderName: WideString; const CommandText: WideString; var
Params: OleVariant; var OwnerData: OleVariant); safecall;
```

C++

```
__fastcall AS_Execute(const BSTR ProviderName, const BSTR CommandText, OleVariant Params,
OleVariant OwnerData);
```

Description

Use AS_AS_Execute to pass an execute command to a remote provider, using a specified set of parameters. AS_AS_Execute calls the AS_Execute method of the specified provider after assigning any parameters. Output parameters that result from executing a query or stored procedure are returned in the Params parameter.

The provider's AS_Execute method generates a BeforeAS_Execute event, passes the command on to its associated dataset, and generates an AfterAS_Execute event. The dataset must represent a query or stored procedure that does not return a cursor.

The ProviderName parameter specifies the name of the provider component associated with the query or stored procedure.

CommandText specifies an optional SQL statement that replaces the SQL of the query, or the name of a stored procedure that replaces the dataset's stored procedure. This parameter is ignored if the provider's Options property does not include poAllowCommandText.

The Params parameter encodes any parameters expected by the query or stored procedure and returns any output parameters. To create a properly encoded value for Params from a TParams object, use the PackageParams routine. To decode Params into a TParams object, use the Unpackparams routine.

The OwnerData parameter contains custom information that appears as an argument to the provider's BeforeAS_Execute and AfterAS_Execute event handlers. This information originates in a client dataset's BeforeAS_Execute event handler. The value returned in OwnerData is passed to the client dataset's AfterAS_Execute event handler.

UnpackParams

Communicating with the Client Dataset

72.1.9.4.4 TLocalAppServer.AS_GetParams Method

Fetches current parameter values from the dataset bound to a specified provider.

Pascal

```
function AS_GetParams(const ProviderName: WideString; var OwnerData: OleVariant): OleVariant;
safecall;
```

C++

```
__fastcall OleVariant AS_GetParams(const BSTR ProviderName, OleVariant OwnerData);
```

Description

Use AS_AS_GetParams to retrieve the current parameter values from the dataset associated with a provider.

The ProviderName parameter specifies the name of the provider component whose dataset has the parameters.

The OwnerData represents custom information that originates in a client dataset's BeforeAS_GetParams event handler and returns information that is passed to the client dataset's AfterAS_GetParams event handler.

AS_GetParams_result (C++) or AS_AS_GetParams (Delphi) returns the parameters, encoded as a Variant array, where each element is a 2-element Variant array containing a parameter name and a parameter value. These parameters can be converted to a TParams object using the UnpackParams procedure. If the dataset has no parameters, or if the provider does not support parameter fetching, AS_GetParams_result (C++) or AS_AS_GetParams (Delphi) returns a Null Variant.

Note: AS_AS_GetParams should not be used to retrieve output parameters from stateless application servers, because parameter values may be changed by other applications. When writing a stateless application server, retrieve parameter values using the AS_Execute method instead.

Communicating with the Client Dataset

72.1.9.4.5 TLocalAppServer.AS_GetProviderNames Method

Returns a list of all the available providers on a remote data module.

Pascal

```
function AS_GetProviderNames: OleVariant; safecall;
```

C++

```
__fastcall OleVariant AS_GetProviderNames();
```

Description

Call AS_AS_GetProviderNames for a list of all providers available from a remote data module. These values indicate the possible values for the ProviderName property of a client dataset that uses the IAppServer interface of an application server. When calling any other IAppServer method, pass one of these names to indicate the provider that is the target of the method call.

AS_AS_GetProviderNames returns the names of the providers in a Variant array. Client datasets are associated with a provider

by setting their ProviderName property to one of these names.

ProviderName

Providers

Communicating with the Client Dataset

72.1.9.4.6 TLocalAppServer.AS_GetRecords Method

Returns a data packet that contains the specified data.

Pascal

```
function AS_GetRecords(const ProviderName: WideString; Count: Integer; out RecsOut: Integer;
Options: Integer; const CommandText: WideString; var Params: OleVariant; var OwnerData:
OleVariant): OleVariant; safecall;
```

C++

```
__fastcall OleVariant AS_GetRecords(const BSTR ProviderName, int Count, int RecsOut, int
Options, const BSTR CommandText, OleVariant Params, OleVariant OwnerData);
```

Description

Call AS_AS_GetRecords to retrieve a specified number of records. AS_GetRecords returns the requested records, starting with the current record of the provider's dataset. When working with a stateless remote data module, you may need to reposition the cursor or re-execute a query or stored procedure in the provider's BeforeAS_GetRecords event handler.

ProviderName gives the name of the provider component that provides the records.

Count indicates the number or type of records to retrieve. If Count is -1, all records are retrieved. If Count is 0, only metadata is retrieved. If Count is greater than 0, only Count records are retrieved.

RecsOut returns the actual number of records retrieved.

Options indicates what information should be added to the data packet in addition to data. It is a combination of the GetRecordOption constants. For example, the following value requests metadata along with a data packet encoded in XML:

```
MetaDataOption + XMLOption
MetaDataOption || XMLOption
```

CommandText specifies an optional SQL statement that replaces the SQL of a query, or the name of a table or stored procedure that replaces the provider's table or stored procedure. This parameter is ignored if the Options property does not include poAllowCommandText.

Params is a Variant containing any parameters that should be passed to the provider's dataset before it executes to generate the requested data. It returns any output parameters. You can convert between the Variant format for parameters used by this argument and a TParams object using the global PackageParams and UnpackParams routines.

OwnerData contains custom information that is supplied by a client dataset's BeforeAS_GetRecords event handler. This information is passed to the provider's BeforeAS_GetRecords event handler. OwnerData returns information supplied by the provider's AfterAS_GetRecords event handler.

Records are returned as a data packet in a Variantparameter, AS_GetRecords_result (C++).

Communicating with the Client Dataset

72.1.9.4.7 TLocalAppServer.AS_RowRequest Method

Returns information from a specified record of the provider's dataset.

Pascal

```
function AS_RowRequest(const ProviderName: WideString; Row: OleVariant; RequestType: Integer;
var OwnerData: OleVariant): OleVariant; safecall;
```

C++

```
__fastcall OleVariant AS_RowRequest(const BSTR ProviderName, OleVariant Row, int RequestType,
OleVariant OwnerData);
```

Description

Client datasets call AS_AS_RowRequest automatically to implement their FetchBlobs, FetchDetails , or RefreshRecord method.

The ProviderName parameter indicates the provider associated with the dataset from which information should be fetched.

The Row parameter is an OleVariant that describes the current record on the client dataset.

The RequestType parameter indicates the type of information required. It is an integer version of the TFetchOptions type. (An integer because the value may be marshaled to a remote application server). To create a value for RequestType, take the corresponding TFetchOptions value, cast it to a Byte, and cast the result to an Integer:

```
Integer(Byte([foBlobs, foDetails]));
(int) (Byte) (TFetchOptions() << foBlobs << foDetails);
```

OwnerData contains custom information that is supplied by a client dataset's BeforeAS_RowRequest event handler. This information is passed to the provider's BeforeAS_RowRequest event handler. OwnerData returns custom information supplied by the provider's AfterAS_RowRequest event handler.

The requested data is returned as a delta packet in AS_RowRequest_result (C++).

72.1.9.4.8 TLocalAppServer.GetIDsOfNames Method

Pascal

```
function GetIDsOfNames(const IID: TGUID; Names: Pointer; NameCount: Integer; LocaleID:
Integer; DispIDs: Pointer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetIDsOfNames(const TGUID IID, void * Names, int NameCount, int
LocaleID, void * DispIDs);
```

Description

This is GetIDsOfNames, a member of class TLocalAppServer.

72.1.9.4.9 TLocalAppServer.GetTypeInfo Method

Pascal

```
function GetTypeInfo(Index: Integer; LocaleID: Integer; out TypeInfo): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetTypeInfo(int Index, int LocaleID,  TypeInfo);
```

Description

This is GetTypeInfo, a member of class TLocalAppServer.

72.1.9.4.10 TLocalAppServer.GetTypeInfoCount Method

Pascal

```
function GetTypeInfoCount(out Count: Integer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetTypeInfoCount(int Count);
```

Description

This is GetTypeInfoCount, a member of class TLocalAppServer.

72.1.9.4.11 TLocalAppServer.InterfaceSupportsErrorInfo Method

Pascal

```
function InterfaceSupportsErrorInfo(const iid: TGUID): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT InterfaceSupportsErrorInfo(const TGUID iid);
```

Description

This is InterfaceSupportsErrorInfo, a member of class TLocalAppServer.

72.1.9.4.12 TLocalAppServer.Invoke Method

Pascal

```
function Invoke(DispID: Integer; const IID: TGUID; LocaleID: Integer; Flags: Word; var Params;
VarResult: Pointer; ExcepInfo: Pointer; ArgErr: Pointer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT Invoke(int DispID, const TGUID IID, int LocaleID, Word Flags,
Params, void * VarResult, void * ExcepInfo, void * ArgErr);
```

Description

This is Invoke, a member of class TLocalAppServer.

72.1.9.4.13 TLocalAppServer.SafeCallException Method

Handles exceptions in methods declared using the safecall calling convention.

Pascal

```
function SafeCallException(ExceptObject: TObject; ExceptAddr: Pointer): HResult; override;
```

C++

```
virtual __fastcall HRESULT SafeCallException(TObject * ExceptObject, void * ExceptAddr);
```

Description

System::TObject::SafeCallException handles exceptions in methods that use the safecall calling convention. Some classes that implement interfaces override this method to handle errors that might occur.

As implemented in System::TObject::TObject, System::TObject::SafeCallException simply returns E_UNEXPECTED. This is the appropriate response for classes that do no support interfaces

72.1.10 TPacketDataSet Class

TPacketDataSet represents a data packet or delta packet that is used by a provider.

Class Hierarchy

Pascal

```
TPacketDataSet = class(TCustomClientDataSet);
```

C++

```
class TPacketDataSet : public TCustomClientDataSet;
```

File

Provider

Description

TPacketDataSet represents a data packet that a provider creates to represent its dataset's records and metadata or a delta data packet that a provider receives when it should apply updates. Provider (see page 6441) components create instances of TPacketDataSet to represent data packets before they are sent to clients and to represent delta packets after they are received from clients.

TPacketDataSet provides a convenient way for providers and resolvers to work with data packets. As a descendant of TCustomClientDataSet, TPacketDataSet allows providers and resolvers to use any of the standard dataset properties and methods to manipulate the data packet's records. In addition, TPacketDataSet introduces new properties and methods that describe what information goes into the data packet or how updates should be applied.

Applications do not need to work directly with packet datasets. They are mainly of use to component writers who want to create custom provider components.

TCustomProvider (see page 6464)

72.1.10.1 TPacketDataSet Members

The following tables list the members exposed by TPacketDataSet.

Protected Methods

	Name	Description
	DataEvent (see page 6558)	This is DataEvent, a member of class TPacketDataSet.
	GetStateFieldValue (see page 6559)	This is GetStateFieldValue, a member of class TPacketDataSet.
	InternalClose (see page 6560)	This is InternalClose, a member of class TPacketDataSet.
	InternalInitRecord (see page 6560)	This is InternalInitRecord, a member of class TPacketDataSet.
	InternalOpen (see page 6561)	This is InternalOpen, a member of class TPacketDataSet.
	SetFieldData (see page 6561)	This is SetFieldData, a member of class TPacketDataSet.
	SetStateFieldValue (see page 6561)	This is SetStateFieldValue, a member of class TPacketDataSet.

Protected Properties

	Name	Description
	WritingCurValues (see page 6563)	This is WritingCurValues, a member of class TPacketDataSet.

Public Methods

	Name	Description
	AssignCurValues (see page 6557)	This is the overview for the AssignCurValues method overload.
	Create (see page 6556)	Creates and initializes instance of TPacketDataSet (see page 6555).
	CreateFromDelta (see page 6558)	This is CreateFromDelta, a member of class TPacketDataSet.
	HasCurValues (see page 6559)	Indicates whether the CurValue property is available for fields in the packet dataset.
	HasMergeConflicts (see page 6559)	Indicates whether a current record can be merged with updates in a delta packet.
	InitAltRecBuffers (see page 6560)	Fetches values for the CurValue, OldValue, and NewValue properties of fields.
	UpdateKind (see page 6561)	Indicates the type of update the current record represents.

Public Properties

	Name	Description
	NewValuesModified (see page 6562)	Indicates whether the NewValue property of any field in the current record has changed.
	StreamMetaData (see page 6562)	This is StreamMetaData, a member of class TPacketDataSet.
	UseCurValues (see page 6562)	Indicates that the CurValue property of fields in the dataset should be used instead of the OldValue property.

72.1.10.2 TPacketDataSet.Create Constructor

Creates and initializes instance of TPacketDataSet (see page 6555).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TPacketDataSet(TComponent * AOwner);
```

Description

Most applications do not need to create packet datasets because they are created by the provider components that use them.Create initializes the properties of the packet dataset.

AOwner is the component that is responsible for freeing the TPacketDataSet (see page 6555) instance. If AOwner is nil (Delphi) or NULL (C++), the application must explicitly free the packet data set object.

See Also

Owner

72.1.10.3 TPacketDataSet Methods

The methods of the TPacketDataSet class are listed here.

Protected Methods

	Name	Description
	DataEvent (see page 6558)	This is DataEvent, a member of class TPacketDataSet.
	GetStateFieldValue (see page 6559)	This is GetStateFieldValue, a member of class TPacketDataSet.
	InternalClose (see page 6560)	This is InternalClose, a member of class TPacketDataSet.
	InternalInitRecord (see page 6560)	This is InternalInitRecord, a member of class TPacketDataSet.
	InternalOpen (see page 6561)	This is InternalOpen, a member of class TPacketDataSet.
	SetFieldData (see page 6561)	This is SetFieldData, a member of class TPacketDataSet.
	SetStateFieldValue (see page 6561)	This is SetStateFieldValue, a member of class TPacketDataSet.

Public Methods

	Name	Description
	AssignCurValues (see page 6557)	This is the overview for the AssignCurValues method overload.
	CreateFromDelta (see page 6558)	This is CreateFromDelta, a member of class TPacketDataSet.
	HasCurValues (see page 6559)	Indicates whether the CurValue property is available for fields in the packet dataset.
	HasMergeConflicts (see page 6559)	Indicates whether a current record can be merged with updates in a delta packet.
	InitAltRecBuffers (see page 6560)	Fetches values for the CurValue, OldValue, and NewValue properties of fields.
	UpdateKind (see page 6561)	Indicates the type of update the current record represents.

72.1.10.3.1 AssignCurValues Method

This is the overview for the AssignCurValues method overload.

Overload List

	Name	Description
	TPacketDataSet.AssignCurValues (TDataSet) (see page 6558)	Updates the current field value for each field in the packet dataset.
	TPacketDataSet.AssignCurValues (Variant) (see page 6558)	Updates the current field value for each field in the packet dataset.

72.1.10.3.1.1 TPacketDataSet.AssignCurValues Method (TDataSet)

Updates the current field value for each field in the packet dataset.

Pascal

```
procedure AssignCurValues(Source: TDataSet); overload;
procedure AssignCurValues(const CurValues: Variant); overload;
```

C++

```
__fastcall AssignCurValues(TDataSet Source);
__fastcall AssignCurValues(const Variant CurValues);
```

Description

When a resolver component encounters an update error, it calls AssignCurValues to set the CurValue property of fields before triggering the OnUpdateError event handler.

If AssignCurValues is passed a dataset as the Source parameter, then for each field in the packet dataset, the CurValue property is set to the value of the field with the same name in the source dataset.

If AssignCurValues is passed a Variant array as the CurValues parameter, then each entry in the array is used to assign the CurValue property of a field in the packet dataset. CurValues can have one of two forms: an array of field values, or an array of Variant arrays, where each of those arrays has two elements: a field name and a value. In the first form, field values are assigned by position. In the second form, fields are located based on name and the CurValue property assigned accordingly.

See Also

CurValue

OnUpdateError (see page 6460)

72.1.10.3.2 TPacketDataSet.CreateFromDelta Method

Pascal

```
procedure CreateFromDelta(Source: TPacketDataSet);
```

C++

```
__fastcall CreateFromDelta(TPacketDataSet Source);
```

Description

This is CreateFromDelta, a member of class TPacketDataSet.

72.1.10.3.3 TPacketDataSet.DataEvent Method

Pascal

```
procedure DataEvent(Event: TDataEvent; Info: Longint); override;
```

C++

```
virtual __fastcall DataEvent(TDataEvent Event, Longint Info);
```

Description

This is DataEvent, a member of class TPacketDataSet.

72.1.10.3.4 TPacketDataSet.GetStateFieldValue Method

Pascal

```
function GetStateFieldValue(State: TDataSetState; Field: TField): Variant; override;
```

C++

```
virtual __fastcall Variant GetStateFieldValue(TDataSetState State, TField Field);
```

Description

This is GetStateFieldValue, a member of class TPacketDataSet.

72.1.10.3.5 TPacketDataSet.HasCurValues Method

Indicates whether the CurValue property is available for fields in the packet dataset.

Pascal

```
function HasCurValues: Boolean;
```

C++

```
__fastcall Boolean HasCurValues();
```

Description

When an error occurs while applying an updated record, resolver components attempt to locate the current record in the underlying database (or the dataset to which updates are applied.) This current record can then be used when trying to determine the cause of the update error. If the current record can be located, HasCurValues returns true and the fields in the packet dataset have their CurValue properties set from this record. If the record can't be located (for example, if another user changed a key field value or deleted the record), then HasCurValues returns false and the CurValue property of packet dataset fields can't be used.

See Also

UseCurValues (see page 6562)

CurValue

72.1.10.3.6 TPacketDataSet.HasMergeConflicts Method

Indicates whether a current record can be merged with updates in a delta packet.

Pascal

```
function HasMergeConflicts: Boolean;
```

C++

```
__fastcall Boolean HasMergeConflicts();
```

Description

When resolving update errors in an OnUpdateError event handler, applications can specify that the updated record should be merged automatically with the current field values of the record. (To do this, set the Response parameter to rrMerge.) However, it is not always possible to merge client edits with the current record. If the updated record includes changes to field values that were also changed by other users, the merge will fail and HasMergeConflicts returns true.

See Also

CurValue

NewValue

OnUpdateError (see page 6460)

72.1.10.3.7 TPacketDataSet.InitAltRecBuffers Method

Fetches values for the CurValue, OldValue, and NewValue properties of fields.

Pascal

```
procedure InitAltRecBuffers(CheckModified: Boolean = True);
```

C++

```
__fastcall InitAltRecBuffers(Boolean CheckModified = True);
```

Description

While applying updates, InitAltRecBuffers is called automatically to ensure that fields in the packet dataset have values for the CurValue, OldValue, and NewValue properties. The CheckModified parameter specifies whether InitAltRecBuffers should check if the current record has been modified when it sets values. This check allows the packet dataset to reflect appropriate values when applying updates that are changed by an OnUpdateError event handler.

OldValue

NewValue

CurValue

OnUpdateError (see page 6460)

72.1.10.3.8 TPacketDataSet.InternalClose Method

Pascal

```
procedure InternalClose; override;
```

C++

```
virtual __fastcall InternalClose();
```

Description

This is InternalClose, a member of class TPacketDataSet.

72.1.10.3.9 TPacketDataSet.InternalInitRecord Method

Pascal

```
procedure InternalInitRecord(Buffer: TRecordBuffer); override;
```

C++

```
virtual __fastcall InternalInitRecord(TRecordBuffer Buffer);
```

Description

This is InternalInitRecord, a member of class TPacketDataSet.

72.1.10.3.10 TPacketDataSet.InternalOpen Method

Pascal

```
procedure InternalOpen; override;
```

C++

```
virtual __fastcall InternalOpen();
```

Description

This is InternalOpen, a member of class TPacketDataSet.

72.1.10.3.11 TPacketDataSet.SetFieldData Method

Pascal

```
procedure SetFieldData(Field: TField; Buffer: Pointer); override;
```

C++

```
virtual __fastcall SetFieldData(TField Field, void * Buffer);
```

Description

This is SetFieldData, a member of class TPacketDataSet.

72.1.10.3.12 TPacketDataSet.SetStateFieldValue Method

Pascal

```
procedure SetStateFieldValue(State: TDataSetState; Field: TField; const Value: Variant);
override;
```

C++

```
virtual __fastcall SetStateFieldValue(TDataSetState State, TField Field, const Variant Value);
```

Description

This is SetStateFieldValue, a member of class TPacketDataSet.

72.1.10.3.13 TPacketDataSet.UpdateKind Method

Indicates the type of update the current record represents.

Pascal

```
function UpdateKind: TUpdateKind;
```

C++

```
__fastcall TUpdateKind UpdateKind();
```

Description

Call UpdateKind while applying updates to determine the type of update the current record represents. UpdateKind returns

ukInsert if the current record is a newly inserted record.

ukDelete if the current record represents a record that should be deleted.

ukModify if the current record represents updates to an existing record.

72.1.10.4 TPacketDataSet Properties

The properties of the TPacketDataSet class are listed here.

Protected Properties

	Name	Description
	WritingCurValues (see page 6563)	This is WritingCurValues, a member of class TPacketDataSet.

Public Properties

	Name	Description
R	NewValuesModified (see page 6562)	Indicates whether the NewValue property of any field in the current record has changed.
	StreamMetaData (see page 6562)	This is StreamMetaData, a member of class TPacketDataSet.
	UseCurValues (see page 6562)	Indicates that the CurValue property of fields in the dataset should be used instead of the OldValue property.

72.1.10.4.1 TPacketDataSet.NewValuesModified Property

Indicates whether the NewValue property of any field in the current record has changed.

Pascal

```
property NewValuesModified: Boolean;
```

C++

```
__property Boolean NewValuesModified;
```

Description

Read NewValuesModified to determine whether any fields in the current record were edited during the resolving process.

See Also

NewValue

72.1.10.4.2 TPacketDataSet.StreamMetaData Property

Pascal

```
property StreamMetaData: Boolean;
```

C++

```
__property Boolean StreamMetaData;
```

Description

This is StreamMetaData, a member of class TPacketDataSet.

72.1.10.4.3 TPacketDataSet.UseCurValues Property

Indicates that the CurValue property of fields in the dataset should be used instead of the OldValue property.

Pascal

```
property UseCurValues: Boolean;
```

C++

```
__property Boolean UseCurValues;
```

Description

UseCurValues is set during the resolving process when a record is corrected in an OnUpdateError event handler. This allows the resolver to reapply a corrected record rather than using the originally provided values as the basis of an update.

See Also

HasCurValues (see page 6559)

CurValue

OldValue

OnUpdateError (see page 6460)

72.1.10.4.4 TPacketDataSet.WritingCurValues Property

Pascal

```
property WritingCurValues: Boolean;
```

C++

```
__property Boolean WritingCurValues;
```

Description

This is WritingCurValues, a member of class TPacketDataSet.

72.1.11 TProvider Class

TProvider provides data to and applies updates from a client dataset.

Class Hierarchy

Pascal

```
TProvider = class(TDataSetProvider);
```

C++

```
class TProvider : public TDataSetProvider;
```

File

Provider

Description

TProvider is provided for backward compatibility. It is identical to TDataSetProvider (see page 6510). New applications should use TDataSetProvider (see page 6510) instead.

See Also

TDataSetProvider (see page 6510)

72.1.12 TSQLResolver Class

TSQLResolver applies updates to a database server on behalf of a provider.

Class Hierarchy

Pascal

```
TSQLResolver = class(TCustomResolver);
```

C++

```
class TSQLResolver : public TCustomResolver;
```

File

Provider

Description

Provider (see page 6571) components use TSQLResolver to apply updates from a client application directly to a database server when their ResolveToDataSet property is false. Otherwise, they use TDataSetResolver (see page 6540).

Do not create instances of TSQLResolver. Provider (see page 6571) components create their own TSQLResolver objects for applying updates.

See Also

TBaseProvider (see page 6445)

TDataSetResolver (see page 6540)

TDataSetProvider (see page 6510)

72.1.12.1 TSQLResolver Members

The following tables list the members exposed by TSQLResolver.

Protected Methods

	Name	Description
	BeginUpdate (see page 6494)	Provides the interface for a method that performs any initialization before applying updates.
	DoDelete (see page 6566)	Defines a method that deletes a record.
	DoExecSQL (see page 6567)	This is DoExecSQL, a member of class TSQLResolver.
	DoGetValues (see page 6567)	This is DoGetValues, a member of class TSQLResolver.
	DoInsert (see page 6567)	Defines a method that inserts a record.
	DoUpdate (see page 6568)	Defines a method that modifies a record.
	EndUpdate (see page 6496)	Provides the interface for a method that performs any finalization after applying updates.
	GenDeleteSQL (see page 6568)	This is GenDeleteSQL, a member of class TSQLResolver.
	GenInsertSQL (see page 6569)	This is GenInsertSQL, a member of class TSQLResolver.
	GenSelectSQL (see page 6569)	This is GenSelectSQL, a member of class TSQLResolver.
	GenUpdateSQL (see page 6569)	This is GenUpdateSQL, a member of class TSQLResolver.
	GenWhereSQL (see page 6569)	This is GenWhereSQL, a member of class TSQLResolver.
	GetProvider (see page 6570)	This is GetProvider, a member of class TSQLResolver.
	HandleUpdateError (see page 6497)	Manages the resolving process when errors occur while applying updates.

	InitializeConflictBuffer (see page 6570)	Introduces a method for adding information about a failed update that is passed to an OnUpdateError event handler.
	InternalDoUpdate (see page 6570)	This is InternalDoUpdate, a member of class TSQLResolver.
	LogUpdateError (see page 6499)	This is LogUpdateError, a member of class TCustomResolver.
	LogUpdateRecord (see page 6500)	Adds records to the error log if their data has been changed by another application.
	UseFieldInUpdate (see page 6571)	This is UseFieldInUpdate, a member of class TSQLResolver.
	UseFieldInWhere (see page 6571)	This is UseFieldInWhere, a member of class TSQLResolver.

Protected Properties

	Name	Description
	Provider (see page 6571)	Indicates the provider that uses this resolver to apply updates.

Public Methods

	Name	Description
	ApplyUpdates (see page 6494)	Applies updates received from a provider.
	Create (see page 6565)	Creates and initializes an SQL resolver.
	Destroy (see page 6565)	Destroys an instance of TSQLResolver (see page 6564).
	FreeTreeData (see page 6568)	This is FreeTreeData, a member of class TSQLResolver.
	InitKeyFields (see page 6498)	Sets the provider flag pfInKey on all key fields in a delta data packet.
	InitTreeData (see page 6570)	This is InitTreeData, a member of class TSQLResolver.
	InternalBeforeResolve (see page 6498)	Initializes internal data structures once the delta packet has been wrapped in an update tree but before any updates are applied.
	InternalUpdateRecord (see page 6499)	Manages the updating process once a delta packet is wrapped in a TUpdateTree (see page 6572) object.
	RowRequest (see page 6500)	Returns information from a specified record.

Public Properties

	Name	Description
	UpdateTree (see page 6501)	This is UpdateTree, a member of class TCustomResolver.

72.1.12.2 TSQLResolver.Create Constructor

Creates and initializes an SQL resolver.

Pascal

```
constructor Create(AProvider: TDataSetProvider); reintroduce;
```

C++

```
__fastcall TSQLResolver(TDataSetProvider AProvider);
```

Description

Provider (see page 6571) components call Create when they need a resolver component for applying updates to a database server. Do not create resolver instances directly. Resolvers are designed to be created and used by providers, and can not function independently of a provider.

The AProvider parameter specifies the provider that creates and uses the resolver.

See Also

Resolver (see page 6456)

72.1.12.3 TSQLResolver.Destroy Destructor

Destroys an instance of TSQLResolver (see page 6564).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TSQLResolver();
```

Description

Most applications should not delete instances of TSQLResolver (see page 6564). SQL resolvers are freed automatically by the provider components that use them.

See Also

System::TObject::Free

Resolver (see page 6456)

72.1.12.4 TSQLResolver Methods

The methods of the TSQLResolver class are listed here.

Protected Methods

	Name	Description
	DoDelete (see page 6566)	Defines a method that deletes a record.
	DoExecSQL (see page 6567)	This is DoExecSQL, a member of class TSQLResolver.
	DoGetValues (see page 6567)	This is DoGetValues, a member of class TSQLResolver.
	DoInsert (see page 6567)	Defines a method that inserts a record.
	DoUpdate (see page 6568)	Defines a method that modifies a record.
	GenDeleteSQL (see page 6568)	This is GenDeleteSQL, a member of class TSQLResolver.
	GenInsertSQL (see page 6569)	This is GenInsertSQL, a member of class TSQLResolver.
	GenSelectSQL (see page 6569)	This is GenSelectSQL, a member of class TSQLResolver.
	GenUpdateSQL (see page 6569)	This is GenUpdateSQL, a member of class TSQLResolver.
	GenWhereSQL (see page 6569)	This is GenWhereSQL, a member of class TSQLResolver.
	GetProvider (see page 6570)	This is GetProvider, a member of class TSQLResolver.
	InitializeConflictBuffer (see page 6570)	Introduces a method for adding information about a failed update that is passed to an OnUpdateError event handler.
	InternalDoUpdate (see page 6570)	This is InternalDoUpdate, a member of class TSQLResolver.
	UseFieldInUpdate (see page 6571)	This is UseFieldInUpdate, a member of class TSQLResolver.
	UseFieldInWhere (see page 6571)	This is UseFieldInWhere, a member of class TSQLResolver.

Public Methods

	Name	Description
	FreeTreeData (see page 6568)	This is FreeTreeData, a member of class TSQLResolver.
	InitTreeData (see page 6570)	This is InitTreeData, a member of class TSQLResolver.

72.1.12.4.1 TSQLResolver.DoDelete Method

Defines a method that deletes a record.

Pascal

```
procedure DoDelete(Tree: TUpdateTree); override;
```

C++

```
virtual __fastcall DoDelete(TUpdateTree Tree);
```

Description

DoDelete is one of several helper methods internal to the ApplyUpdates method. These helper methods perform the actual updates in the delta packet. ApplyUpdates wraps the delta packet in a TUpdateTree object. For each record that must be deleted, the resolver calls DoDelete.

TCustomResolver does not implement the DoDelete method. Descendants override this method to delete records in their own specialized way.

See Also

ApplyUpdates (see page 6494)

DoInsert (see page 6495)

DoUpdate (see page 6496)

72.1.12.4.2 TSQLResolver.DoExecSQL Method

Pascal

```
procedure DoExecSQL(SQL: TWideStringList; Params: TParams); virtual;
```

C++

```
virtual __fastcall DoExecSQL(TWideStringList SQL, TParams Params);
```

Description

This is DoExecSQL, a member of class TSQLResolver.

72.1.12.4.3 TSQLResolver.DoGetValues Method

Pascal

```
procedure DoGetValues(SQL: TWideStringList; Params: TParams; DataSet: TDataSet); virtual;
```

C++

```
virtual __fastcall DoGetValues(TWideStringList SQL, TParams Params, TDataSet DataSet);
```

Description

This is DoGetValues, a member of class TSQLResolver.

72.1.12.4.4 TSQLResolver.DoInsert Method

Defines a method that inserts a record.

Pascal

```
procedure DoInsert(Tree: TUpdateTree); override;
```

C++

```
virtual __fastcall DoInsert(TUpdateTree Tree);
```

Description

DoInsert is one of several helper methods internal to the ApplyUpdates method. These helper methods perform the actual updates in the delta packet. ApplyUpdates wraps the delta packet in a TUpdateTree object. For each record that must be inserted, the resolver calls DoInsert.

TCustomResolver does not implement the DoInsert method. Descendants override this method to insert records in their own

specialized way.

See Also

ApplyUpdates (see page 6494)

DoDelete (see page 6495)

DoUpdate (see page 6496)

72.1.12.4.5 TSQLResolver.DoUpdate Method

Defines a method that modifies a record.

Pascal

```
procedure DoUpdate(Tree: TUpdateTree); override;
```

C++

```
virtual __fastcall DoUpdate(TUpdateTree Tree);
```

Description

DoUpdate is one of several helper methods internal to the ApplyUpdates method. These helper methods perform the actual updates passed in the delta packet. ApplyUpdates wraps the delta packet in a TUpdateTree object. For each record that must be modified, the resolver calls DoUpdate.

TCustomResolver does not implement the DoUpdate method. Descendants override this method to insert records in their own specialized way.

See Also

ApplyUpdates (see page 6494)

DoDelete (see page 6495)

DoInsert (see page 6495)

72.1.12.4.6 TSQLResolver.FreeTreeData Method

Pascal

```
procedure FreeTreeData(Tree: TUpdateTree); override;
```

C++

```
virtual __fastcall FreeTreeData(TUpdateTree Tree);
```

Description

This is FreeTreeData, a member of class TSQLResolver.

72.1.12.4.7 TSQLResolver.GenDeleteSQL Method

Pascal

```
procedure GenDeleteSQL(Tree: TUpdateTree; SQL: TWideStrings; Params: TParams; Alias: string);
virtual;
```

C++

```
virtual __fastcall GenDeleteSQL(TUpdateTree Tree, TWideStrings SQL, TParams Params,
UnicodeString Alias);
```

Description

This is GenDeleteSQL, a member of class TSQLResolver.

72.1.12.4.8 TSQLResolver.GenInsertSQL Method

Pascal

```
procedure GenInsertSQL(Tree: TUpdateTree; SQL: TWideStrings; Params: TParams); virtual;
```

C++

```
virtual __fastcall GenInsertSQL(TUpdateTree Tree, TWideStrings SQL, TParams Params);
```

Description

This is GenInsertSQL, a member of class TSQLResolver.

72.1.12.4.9 TSQLResolver.GenSelectSQL Method

Pascal

```
procedure GenSelectSQL(Tree: TUpdateTree; SQL: TWideStrings; Params: TParams; Alias: string;
Mode: TUpdateMode = upWhereKeyOnly); virtual;
```

C++

```
virtual __fastcall GenSelectSQL(TUpdateTree Tree, TWideStrings SQL, TParams Params,
UnicodeString Alias, TUpdateMode Mode = upWhereKeyOnly);
```

Description

This is GenSelectSQL, a member of class TSQLResolver.

72.1.12.4.10 TSQLResolver.GenUpdateSQL Method

Pascal

```
procedure GenUpdateSQL(Tree: TUpdateTree; SQL: TWideStrings; Params: TParams; Alias: string);
virtual;
```

C++

```
virtual __fastcall GenUpdateSQL(TUpdateTree Tree, TWideStrings SQL, TParams Params,
UnicodeString Alias);
```

Description

This is GenUpdateSQL, a member of class TSQLResolver.

72.1.12.4.11 TSQLResolver.GenWhereSQL Method

Pascal

```
procedure GenWhereSQL(Tree: TUpdateTree; SQL: TWideStrings; Params: TParams; GenUpdateMode:
TUpdateMode; Alias: string); virtual;
```

C++

```
virtual __fastcall GenWhereSQL(TUpdateTree Tree, TWideStrings SQL, TParams Params, TUpdateMode
GenUpdateMode, UnicodeString Alias);
```

Description

This is GenWhereSQL, a member of class TSQLResolver.

72.1.12.4.12 TSQLResolver.GetProvider Method

Pascal

```
function GetProvider: TDataSetProvider; virtual;
```

C++

```
virtual __fastcall TDataSetProvider GetProvider();
```

Description

This is GetProvider, a member of class TSQLResolver.

72.1.12.4.13 TSQLResolver.InitializeConflictBuffer Method

Introduces a method for adding information about a failed update that is passed to an OnUpdateError event handler.

Pascal

```
procedure InitializeConflictBuffer(Tree: TUpdateTree); override;
```

C++

```
virtual __fastcall InitializeConflictBuffer(TUpdateTree Tree);
```

Description

The HandleUpdateError method calls InitializeConflictBuffer before generating an OnUpdateError event. This ensures that the client dataset passed to an OnUpdateError event handler represents the update that caused the problem, with appropriate values for field's CurValue property.

Descendants of TCustomResolver implement this method to obtain information from the dataset or server to which they are applying updates.

See Also

HandleUpdateError (see page 6497)

OnUpdateError (see page 6460)

72.1.12.4.14 TSQLResolver.InitTreeData Method

Pascal

```
procedure InitTreeData(Tree: TUpdateTree); override;
```

C++

```
virtual __fastcall InitTreeData(TUpdateTree Tree);
```

Description

This is InitTreeData, a member of class TSQLResolver.

72.1.12.4.15 TSQLResolver.InternalDoUpdate Method

Pascal

```
procedure InternalDoUpdate(Tree: TUpdateTree; UpdateKind: TUpdateKind); virtual;
```

C++

```
virtual __fastcall InternalDoUpdate(TUpdateTree Tree, TUpdateKind UpdateKind);
```

Description

This is InternalDoUpdate, a member of class TSQLResolver.

72.1.12.4.16 TSQLResolver.UseFieldInUpdate Method

Pascal

```
function UseFieldInUpdate(Field: TField): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean UseFieldInUpdate(TField Field);
```

Description

This is UseFieldInUpdate, a member of class TSQLResolver.

72.1.12.4.17 TSQLResolver.UseFieldInWhere Method

Pascal

```
function UseFieldInWhere(Field: TField; Mode: TUpdateMode): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean UseFieldInWhere(TField Field, TUpdateMode Mode);
```

Description

This is UseFieldInWhere, a member of class TSQLResolver.

72.1.12.5 TSQLResolver Properties

The properties of the TSQLResolver class are listed here.

Protected Properties

	Name	Description
	Provider (see page 6571)	Indicates the provider that uses this resolver to apply updates.

72.1.12.5.1 TSQLResolver.Provider Property

Indicates the provider that uses this resolver to apply updates.

Pascal

```
property Provider: TDataSetProvider;
```

C++

```
__property TDataSetProvider Provider;
```

Description

Provider is a read-only property that points to the provider that uses this resolver for applying updates. The Provider property is set in the constructor.

Resolvers use the Provider property internally to obtain information supplied in the provider's properties. They also use it to generate events on the provider at appropriate points in the update process.

See Also

Create (see page 6493)

Resolver (see page 6456)

72.1.13 TUpdateTree Class

TUpdateTree stores information about a delta packet on behalf of a resolver.

Class Hierarchy

Pascal

```
TUpdateTree = class(TObject);
```

C++

```
class TUpdateTree : public TObject;
```

File

Provider

Description

When a client dataset applies its updates to the source dataset or database server, the provider that represents that dataset or server passes the updates to a resolver component. The resolver takes this delta data packet and builds a TUpdateTree to store the updates and information about them in a convenient form. In particular, the TUpdateTree structure allows a resolver to handle master/detail relationships (represented as nested dataset fields in the delta packet) so that updates are applied in the proper order.

Applications can't use TUpdateTree directly. Most of the structured information about the delta packet is represented in protected properties that are only available to the resolver classes in the Provider (see page 6441) unit.

See Also

TCustomResolver (see page 6491)

TCustomClientDataSet

TCustomProvider (see page 6464)

72.1.13.1 TUpdateTree Members

The following tables list the members exposed by TUpdateTree.

Protected Properties

	Name	Description
	DetailList (see page 6577)	This is DetailList, a member of class TUpdateTree.
	Opened (see page 6578)	This is Opened, a member of class TUpdateTree.

Public Methods

	Name	Description
	Clear (see page 6574)	This is Clear, a member of class TUpdateTree.
	Create (see page 6573)	Creates and initializes an instance of TUpdateTree (see page 6572).

	Destroy (see page 6573)	Destroys an instance of TUpdateTree (see page 6572).
	DoUpdates (see page 6574)	This is DoUpdates, a member of class TUpdateTree.
	InitData (see page 6574)	This is InitData, a member of class TUpdateTree.
	InitDelta (see page 6575)	This is the overview for the InitDelta method overload.
	InitErrorPacket (see page 6575)	This is InitErrorPacket, a member of class TUpdateTree.
	RefreshData (see page 6576)	This is RefreshData, a member of class TUpdateTree.

Public Properties

	Name	Description
	Data (see page 6576)	This is Data, a member of class TUpdateTree.
	Delta (see page 6576)	This is Delta, a member of class TUpdateTree.
R	DetailCount (see page 6577)	This is DetailCount, a member of class TUpdateTree.
R	Details (see page 6577)	This is Details, a member of class TUpdateTree.
	ErrorDS (see page 6577)	This is ErrorDS, a member of class TUpdateTree.
R	HasErrors (see page 6578)	This is HasErrors, a member of class TUpdateTree.
R	IsNested (see page 6578)	This is IsNested, a member of class TUpdateTree.
	Name (see page 6578)	This is Name, a member of class TUpdateTree.
R	Parent (see page 6578)	This is Parent, a member of class TUpdateTree.
R	Resolver (see page 6579)	This is Resolver, a member of class TUpdateTree.
	Source (see page 6579)	This is Source, a member of class TUpdateTree.

72.1.13.2 TUpdateTree.Create Constructor

Creates and initializes an instance of TUpdateTree (see page 6572).

Pascal

```
constructor Create(AParent: TUpdateTree; AResolver: TCustomResolver);
```

C++

```
__fastcall TUpdateTree(TUpdateTree AParent, TCustomResolver AResolver);
```

Description

Applications do not need to call the TUpdateTree (see page 6572) constructor. Update trees are created automatically by the resolver components that use them.

The AParent parameter specifies the TUpdateTree (see page 6572) for the updates to a master table if this update tree represents a detail data set. If the TUpdateTree (see page 6572) does not represent the updates to a detail dataset, AParent is nil (Delphi) or NULL (C++).

The AResolver parameter specifies the resolver component that uses this update tree when applying updates. This parameter must be specified because the update tree calls some of this resolver's methods.

72.1.13.3 TUpdateTree.Destroy Destructor

Destroys an instance of TUpdateTree (see page 6572).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TUpdateTree();
```

Description

Applications do not need to free TUpdateTree (see page 6572) instances. Update trees are freed by the resolver components that use them.

See Also

System::TObject::Free

72.1.13.4 TUpdateTree Methods

The methods of the TUpdateTree class are listed here.

Public Methods

	Name	Description
	Clear (see page 6574)	This is Clear, a member of class TUpdateTree.
	DoUpdates (see page 6574)	This is DoUpdates, a member of class TUpdateTree.
	InitData (see page 6574)	This is InitData, a member of class TUpdateTree.
	InitDelta (see page 6575)	This is the overview for the InitDelta method overload.
	InitErrorPacket (see page 6575)	This is InitErrorPacket, a member of class TUpdateTree.
	RefreshData (see page 6576)	This is RefreshData, a member of class TUpdateTree.

72.1.13.4.1 TUpdateTree.Clear Method

Pascal

```
procedure Clear; virtual;
```

C++

```
virtual __fastcall Clear();
```

Description

This is Clear, a member of class TUpdateTree.

72.1.13.4.2 TUpdateTree.DoUpdates Method

Pascal

```
function DoUpdates: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean DoUpdates();
```

Description

This is DoUpdates, a member of class TUpdateTree.

72.1.13.4.3 TUpdateTree.InitData Method

Pascal

```
procedure InitData(ASource: TDataSet); virtual;
```

C++

```
virtual __fastcall InitData(TDataSet ASource);
```

Description

This is InitData, a member of class TUpdateTree.

72.1.13.4.4 InitDelta Method

This is the overview for the InitDelta method overload.

Overload List

	Name	Description
	TUpdateTree.InitDelta (OleVariant) (see page 6575)	This is InitDelta, a member of class TUpdateTree.
	TUpdateTree.InitDelta (TPacketDataSet) (see page 6575)	This is InitDelta, a member of class TUpdateTree.

72.1.13.4.4.1 TUpdateTree.InitDelta Method (OleVariant)

Pascal

```
procedure InitDelta(const ADelta: OleVariant); virtual; overload;
```

C++

```
virtual __fastcall InitDelta(const OleVariant ADelta);
```

Description

This is InitDelta, a member of class TUpdateTree.

72.1.13.4.4.2 TUpdateTree.InitDelta Method (TPacketDataSet)

Pascal

```
procedure InitDelta(ADelta: TPacketDataSet); virtual; overload;
```

C++

```
virtual __fastcall InitDelta(TPacketDataSet ADelta);
```

Description

This is InitDelta, a member of class TUpdateTree.

72.1.13.4.5 TUpdateTree.InitErrorPacket Method

Pascal

```
procedure InitErrorPacket(E: EUpdateError; Response: TResolverResponse); virtual;
```

C++

```
virtual __fastcall InitErrorPacket(EUpdateError E, TResolverResponse Response);
```

Description

This is InitErrorPacket, a member of class TUpdateTree.

72.1.13.4.6 TUpdateTree.RefreshData Method

Pascal

```
procedure RefreshData(Options: TFetchOptions); virtual;
```

C++

```
virtual __fastcall RefreshData(TFetchOptions Options);
```

Description

This is RefreshData, a member of class TUpdateTree.

72.1.13.5 TUpdateTree Properties

The properties of the TUpdateTree class are listed here.

Protected Properties

	Name	Description
R	DetailList (see page 6577)	This is DetailList, a member of class TUpdateTree.
	Opened (see page 6578)	This is Opened, a member of class TUpdateTree.

Public Properties

	Name	Description
	Data (see page 6576)	This is Data, a member of class TUpdateTree.
	Delta (see page 6576)	This is Delta, a member of class TUpdateTree.
R	DetailCount (see page 6577)	This is DetailCount, a member of class TUpdateTree.
R	Details (see page 6577)	This is Details, a member of class TUpdateTree.
	ErrorDS (see page 6577)	This is ErrorDS, a member of class TUpdateTree.
R	HasErrors (see page 6578)	This is HasErrors, a member of class TUpdateTree.
R	IsNested (see page 6578)	This is IsNested, a member of class TUpdateTree.
	Name (see page 6578)	This is Name, a member of class TUpdateTree.
R	Parent (see page 6578)	This is Parent, a member of class TUpdateTree.
R	Resolver (see page 6579)	This is Resolver, a member of class TUpdateTree.
	Source (see page 6579)	This is Source, a member of class TUpdateTree.

72.1.13.5.1 TUpdateTree.Data Property

Pascal

```
property Data: Pointer;
```

C++

```
__property void * Data;
```

Description

This is Data, a member of class TUpdateTree.

72.1.13.5.2 TUpdateTree.Delta Property

Pascal

```
property Delta: TPacketDataSet;
```

C++

```
__property TPacketDataSet Delta;
```

Description

This is Delta, a member of class TUpdateTree.

72.1.13.5.3 TUpdateTree.DetailCount Property

Pascal

```
property DetailCount: Integer;
```

C++

```
__property int DetailCount;
```

Description

This is DetailCount, a member of class TUpdateTree.

72.1.13.5.4 TUpdateTree.DetailList Property

Pascal

```
property DetailList: TList;
```

C++

```
__property TList DetailList;
```

Description

This is DetailList, a member of class TUpdateTree.

72.1.13.5.5 TUpdateTree.Details Property

Pascal

```
property Details [Index: Integer]: TUpdateTree;
```

C++

```
__property TUpdateTree Details[int Index];
```

Description

This is Details, a member of class TUpdateTree.

72.1.13.5.6 TUpdateTree.ErrorDS Property

Pascal

```
property ErrorDS: TPacketDataSet;
```

C++

```
__property TPacketDataSet ErrorDS;
```

Description

This is ErrorDS, a member of class TUpdateTree.

72.1.13.5.7 TUpdateTree.HasErrors Property

Pascal

```
property HasErrors: Boolean;
```

C++

```
__property Boolean HasErrors;
```

Description

This is HasErrors, a member of class TUpdateTree.

72.1.13.5.8 TUpdateTree.IsNested Property

Pascal

```
property IsNested: Boolean;
```

C++

```
__property Boolean IsNested;
```

Description

This is IsNested, a member of class TUpdateTree.

72.1.13.5.9 TUpdateTree.Name Property

Pascal

```
property Name: WideString;
```

C++

```
__property BSTR Name;
```

Description

This is Name, a member of class TUpdateTree.

72.1.13.5.10 TUpdateTree.Opened Property

Pascal

```
property Opened: Boolean;
```

C++

```
__property Boolean Opened;
```

Description

This is Opened, a member of class TUpdateTree.

72.1.13.5.11 TUpdateTree.Parent Property

Pascal

```
property Parent: TUpdateTree;
```

C++

```
__property TUpdateTree Parent;
```

Description

This is Parent, a member of class TUpdateTree.

72.1.13.5.12 TUpdateTree.Resolver Property

Pascal

```
property Resolver: TCustomResolver;
```

C++

```
__property TCustomResolver Resolver;
```

Description

This is Resolver, a member of class TUpdateTree.

72.1.13.5.13 TUpdateTree.Source Property

Pascal

```
property Source: TDataSet;
```

C++

```
__property TDataSet Source;
```

Description

This is Source, a member of class TUpdateTree.

72.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IProviderContainer (see page 6580)	This is class Provider.IProviderContainer.

72.2.1 IProviderContainer Interface

Class Hierarchy

Provider.IProviderContainer

Pascal

```
IProviderContainer = interface;
```

C++

```
__interface IProviderContainer;
```

File

Provider

Description

This is class Provider.IProviderContainer.

72.2.1.1 IProviderContainer Members

The following tables list the members exposed by IProviderContainer.

Public Methods

	Name	Description
	RegisterProvider (see page 6581)	This is RegisterProvider, a member of class IProviderContainer.
	UnRegisterProvider (see page 6581)	This is UnRegisterProvider, a member of class IProviderContainer.

72.2.1.2 IProviderContainer Methods

The methods of the IProviderContainer class are listed here.

Public Methods

	Name	Description
	RegisterProvider (see page 6581)	This is RegisterProvider, a member of class IProviderContainer.
	UnRegisterProvider (see page 6581)	This is UnRegisterProvider, a member of class IProviderContainer.

72.2.1.2.1 IProviderContainer.RegisterProvider Method

Pascal

```
procedure RegisterProvider(Prov: TCustomProvider);
```

C++

```
__fastcall RegisterProvider(TCustomProvider Prov);
```

Description

This is RegisterProvider, a member of class IProviderContainer.

72.2.1.2.2 IProviderContainer.UnRegisterProvider Method

Pascal

```
procedure UnRegisterProvider(Prov: TCustomProvider);
```

C++

```
__fastcall UnRegisterProvider(TCustomProvider Prov);
```

Description

This is UnRegisterProvider, a member of class IProviderContainer.

72.3 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	GetObjectProperty (see page 6582)	This is function Provider.GetObjectProperty.
	GetStringProperty (see page 6582)	This is function Provider.GetStringProperty.
	VarArrayFromStrings (see page 6582)	Creates a Variant array that contains the strings in a TStrings object.
	VarArrayFromWideStrings (see page 6583)	This is function Provider.VarArrayFromWideStrings.

72.3.1 Provider.GetObjectProperty Function

Pascal

```
function GetObjectProperty(Instance: TPersistent; const PropName: string): TObject;
```

C++

```
TObject * GetObjectProperty(TPersistent * Instance, const UnicodeString PropName);
```

File

Provider

Description

This is function Provider.GetObjectProperty.

72.3.2 Provider.GetStringProperty Function

Pascal

```
function GetStringProperty(Instance: TPersistent; const PropName: string): WideString;
```

C++

```
BSTR GetStringProperty(TPersistent * Instance, const UnicodeString PropName);
```

File

Provider

Description

This is function Provider.GetStringProperty.

72.3.3 Provider.VarArrayFromStrings Function

Creates a Variant array that contains the strings in a TStrings object.

Pascal

```
function VarArrayFromStrings(Strings: TStrings): Variant;
```

C++

```
Variant VarArrayFromStrings(TStrings Strings);
```

File

Provider

Description

Call VarArrayFromStrings to create a Variant array to represent the strings in a TStrings object. VarArrayFromStrings creates a new Variant array of WideString values, where each WideString corresponds to a string in the specified TStrings object.

Strings is the TStrings object that supplies the strings for the Variant array.

VarArrayFromStrings returns the new Variant array.

See Also

PackageParams

VarArrayCreate

72.3.4 Provider.VarArrayFromWideStrings Function

Pascal

```
function VarArrayFromWideStrings(Strings: TWideStrings): Variant;
```

C++

```
Variant VarArrayFromWideStrings(TWideStrings Strings);
```

File

Provider

Description

This is function Provider.VarArrayFromWideStrings.

72.4 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TGetRecordOption (see page 6584)	TGetRecordOption and TGetRecordOptions (see page 6591) influence what type of information is added to data packets.
	TProviderOption (see page 6585)	TProviderOption and TProviderOptions (see page 6593) influence what type of information is communicated between client datasets and provider components.
	TResolverResponse (see page 6587)	TResolverResponse indicates the action a resolver component should take after an OnUpdateError event handler handles an update error.

Records

	Name	Description
	TPutFieldInfo (see page 6587)	This is record Provider.TPutFieldInfo.

72.4.1 Provider.TGetRecordOption Enumeration

TGetRecordOption and TGetRecordOptions (see page 6591) influence what type of information is added to data packets.

Pascal

```
TGetRecordOption = (
  grMetaData,
  grReset,
  grXML,
  grXMLUTF8
);
```

C++

```
enum TGetRecordOption {
  grMetaData,
  grReset,
  grXML,
  grXMLUTF8
};
```

File

Provider

Description

TGetRecordOptions (see page 6591) is a set of TGetRecordOption values. TGetRecordOption values are listed in the following table:

Value	Meaning
grMetaData	The data packet includes metadata as well as record values.
grReset	The records in the data packet start with the first record, regardless of the contents of any previously sent data packets.
grXML	The data packet is transmitted as a string of XML instead of as an OleVariant. Extended characters are expressed using escape sequences.

grXMLUTF8	The data packet is transmitted as a string of XML instead of as an OleVariant. Extended characters are encoded using UTF-8.

See Also

TCustomProvider (see page 6464)

72.4.2 Provider.TProviderOption Enumeration

TProviderOption and TProviderOptions (see page 6593) influence what type of information is communicated between client datasets and provider components.

Pascal

```
TProviderOption = (
  poFetchBlobsOnDemand,
  poFetchDetailsOnDemand,
  poIncFieldProps,
  poCascadeDeletes,
  poCascadeUpdates,
  poReadOnly,
  poAllowMultiRecordUpdates,
  poDisableInserts,
  poDisableEdits,
  poDisableDeletes,
  poNoReset,
  poAutoRefresh,
  poPropogateChanges,
  poAllowCommandText,
  poRetainServerOrder,
  poUseQuoteChar
);
```

C++

```
enum TProviderOption {
  poFetchBlobsOnDemand,
  poFetchDetailsOnDemand,
  poIncFieldProps,
  poCascadeDeletes,
  poCascadeUpdates,
  poReadOnly,
  poAllowMultiRecordUpdates,
  poDisableInserts,
  poDisableEdits,
  poDisableDeletes,
  poNoReset,
  poAutoRefresh,
  poPropogateChanges,
  poAllowCommandText,
  poRetainServerOrder,
  poUseQuoteChar
};
```

File

Provider

Description

TProviderOptions (see page 6593) is a set of TProviderOption values. TProviderOption values are listed in the following table:

Value	Meaning
poFetchBlobsOnDemand	BLOB fields are not included in data packets. Instead, client applications must request these values on an as-needed basis. If the client dataset's FetchOnDemand property is true, the client requests these values automatically. Otherwise, the client application uses the FetchBlobs method to retrieve BLOB data.
poFetchDetailsOnDemand	When the provider represents the master of a master/detail relationship, nested detail values are not included in the data packet. Instead, client applications request these on an as-needed basis. If the client dataset's FetchOnDemand property is true, the client requests these values automatically. Otherwise the client application uses the FetchDetails method to retrieve nested detail sets.
poIncFieldProps	The data packet includes the following field properties (where applicable): Alignment, DisplayLabel, DisplayWidth, Visible, DisplayFormat, EditFormat, MaxValue, MinValue, Currency, EditMask, DisplayValues
poCascadeDeletes	Tells the server to delete detail records automatically when master table records are deleted. To use this option, the provider must represent the master of a master/detail relationship and the database must support cascaded deletes as part of its referential integrity settings.
poCascadeUpdates	Tells the server to update detail records automatically when master table key values are changed. To use this option, the provider must represent the master of a master/detail relationship and the database must support cascaded updates as part of its referential integrity settings.
poReadOnly	The client dataset can't apply updates to the provider.
poAllowMultiRecordUpdates	Enables individual updates that affect multiple records. When poAllowMultiRecordUpdates is not included, updates that change multiple records are automatically aborted.
poDisableInserts	Clients can't add new records. If the client tries to insert a record an exception is raised. (This does not affect the client's ability to edit or delete records)
poDisableEdits	Clients can't modify existing data values. If the client tries to edit a field an exception is raised. (This does not affect the client's ability to insert or delete records)
poDisableDeletes	Clients can't delete records. If the client tries to delete a record an exception is raised. (This does not affect the client's ability to edit or insert records)
poNoReset	Ignores the reset flag in calls to AS_GetRecords (TGetRecordsOption value of grReset).
poAutoRefresh	Refreshes the client dataset with current record values whenever it applies updates.
poPropogateChanges	Changes made in a BeforeUpdateRecord or AfterUpdateRecord event handler are sent back to the client and merged into the client dataset.
poAllowCommandText	Enables the client to override the provider's dataset by replacing its associated SQL text or the name of its stored procedure or table. These overrides are supplied to the GetRecords or Execute method.
poRetainServerOrder	Signals that the client should not attempt to re-establish the default order by sorting the records in the data packet. This prevents the client from changing the record order because, for example, it is unable to duplicate the locale on the server.
poUseQuoteChar	Specifies that the quote character (“) used by the SQL provider will also be used to quote SQL identifiers in the SQL queries created by the provider. This option is True by default; set it False to eliminate the quotes.

See Also

TBaseProvider (see page 6445)

TGetRecordOption (see page 6584)

72.4.3 Provider.TPutFieldInfo Record

Pascal

```
TPutFieldInfo = record
  FieldNo: Integer;
  Field: TField;
  DataSet: TDataSet;
  Size: Integer;
  IsDetail: Boolean;
  Opened: Boolean;
  PutProc: TPutFieldProc;
  LocalFieldIndex: Integer;
  FieldInfos: Pointer;
end;
```

C++

```
struct TPutFieldInfo {
  int FieldNo;
  TField Field;
  TDataSet DataSet;
  int Size;
  Boolean IsDetail;
  Boolean Opened;
  TPutFieldProc PutProc;
  int LocalFieldIndex;
  void * FieldInfos;
};
```

File

Provider

Description

This is record Provider.TPutFieldInfo.

72.4.4 Provider.TResolverResponse Enumeration

TResolverResponse indicates the action a resolver component should take after an OnUpdateError event handler handles an update error.

Pascal

```
TResolverResponse = (
  rrSkip,
  rrAbort,
  rrMerge,
  rrApply,
  rrIgnore
);
```

C++

```
enum TResolverResponse {
  rrSkip,
  rrAbort,
  rrMerge,
  rrApply,
```

```
  rrIgnore
};
```

File

Provider

Description

The following table lists the possible values for TResolverResponse and what they indicate:

Value	Meaning
rrSkip	Skip updating the record that raised the error condition, and leave the unapplied changes in the cache.
rrAbort	Abort the entire update operation without displaying an error message.
rrMerge	Merge the updates in the delta packet with the new underlying value from the database. This will only succeed if none of the updated fields have been changed by another user.
rrApply	Apply the current record value (as it has been fixed in the OnUpdateError handler) instead of the original update.
rrIgnore	Ignore the error condition: Do not apply the record but do not return the record to the client dataset for resolving either.

See Also

OnUpdateError (see page 6460)

TCustomResolver (see page 6491)

72.5 Types

The following table lists types in this documentation.

Types

Name	Description
PPutFieldInfo (see page 6589)	This is type Provider.PPutFieldInfo.
TAfterUpdateRecordEvent (see page 6589)	This is type Provider.TAfterUpdateRecordEvent.
TBeforeCommitEvent (see page 6590)	This is type Provider.TBeforeCommitEvent.
TBeforeUpdateRecordEvent (see page 6590)	This is type Provider.TBeforeUpdateRecordEvent.
TDataRequestEvent (see page 6590)	This is type Provider.TDataRequestEvent.
TGetDSProps (see page 6591)	This is type Provider.TGetDSProps.
TGetParamsEvent (see page 6591)	This is type Provider.TGetParamsEvent.
TGetRecordOptions (see page 6591)	This is type Provider.TGetRecordOptions.
TGetTableNameEvent (see page 6592)	This is type Provider.TGetTableNameEvent.
TInfoArray (see page 6592)	This is type Provider.TInfoArray.
TOnValidate (see page 6592)	This is type Provider.TOnValidate.
TProviderDataEvent (see page 6593)	This is type Provider.TProviderDataEvent.
TProviderOptions (see page 6593)	This is type Provider.TProviderOptions.
TPutFieldProc (see page 6593)	This is type Provider.TPutFieldProc.
TResolverErrorEvent (see page 6594)	This is type Provider.TResolverErrorEvent.

72.5.1 Provider.PPutFieldInfo Type

Pascal

```
PPutFieldInfo = ^TPutFieldInfo;
```

C++

```
^TPutFieldInfo PPutFieldInfo;
```

File

Provider

Description

This is type Provider.PPutFieldInfo.

72.5.2 Provider.TAfterUpdateRecordEvent Type

Pascal

```
TAfterUpdateRecordEvent = procedure (Sender: TObject; SourceDS: TDataSet; DeltaDS:
TCustomClientDataSet; UpdateKind: TUpdateKind) of object;
```

C++

```
(Sender: TObject; SourceDS: TDataSet; DeltaDS: TCustomClientDataSet; UpdateKind: TUpdateKind)
( TAfterUpdateRecordEvent)();
```

File

Provider

Description

This is type Provider.TAfterUpdateRecordEvent.

72.5.3 Provider.TBeforeCommitEvent Type

Pascal

```
TBeforeCommitEvent = procedure (Sender:TObject; DeltaDS: TCustomClientDataSet; ErrorCount,
MaxErrors: integer; const ResultVar: OleVariant) of object;
```

C++

```
(Sender:TObject; DeltaDS: TCustomClientDataSet; ErrorCount, MaxErrors: integer; const
ResultVar: OleVariant) ( TBeforeCommitEvent)();
```

File

Provider

Description

This is type Provider.TBeforeCommitEvent.

72.5.4 Provider.TBeforeUpdateRecordEvent Type

Pascal

```
TBeforeUpdateRecordEvent = procedure (Sender: TObject; SourceDS: TDataSet; DeltaDS:
TCustomClientDataSet; UpdateKind: TUpdateKind; var Applied: Boolean) of object;
```

C++

```
(Sender: TObject; SourceDS: TDataSet; DeltaDS: TCustomClientDataSet; UpdateKind: TUpdateKind;
var Applied: Boolean) ( TBeforeUpdateRecordEvent)();
```

File

Provider

Description

This is type Provider.TBeforeUpdateRecordEvent.

72.5.5 Provider.TDataRequestEvent Type

Pascal

```
TDataRequestEvent = function (Sender: TObject; Input: OleVariant): OleVariant of object;
```

C++

```
(Sender: TObject; Input: OleVariant): OleVariant ( TDataRequestEvent)();
```

File

Provider

Description

This is type Provider.TDataRequestEvent.

72.5.6 Provider.TGetDSProps Type

Pascal

```
TGetDSProps = procedure (Sender: TObject; DataSet: TDataSet; out Properties: OleVariant) of object;
```

C++

```
(Sender: TObject; DataSet: TDataSet; out Properties: OleVariant) ( TGetDSProps)();
```

File

Provider

Description

This is type Provider.TGetDSProps.

72.5.7 Provider.TGetParamsEvent Type

Pascal

```
TGetParamsEvent = procedure (DataSet: TDataSet; Params: TList) of object;
```

C++

```
(DataSet: TDataSet; Params: TList) ( TGetParamsEvent)();
```

File

Provider

Description

This is type Provider.TGetParamsEvent.

72.5.8 Provider.TGetRecordOptions Type

Pascal

```
TGetRecordOptions = set of TGetRecordOption;
```

C++

```
TGetRecordOption TGetRecordOptions;
```

File

Provider

Description

This is type Provider.TGetRecordOptions.

72.5.9 Provider.TGetTableNameEvent Type

Pascal

```
TGetTableNameEvent = procedure (Sender: TObject; DataSet: TDataSet; var TableName: WideString)
of object;
```

C++

```
(Sender: TObject; DataSet: TDataSet; var TableName: WideString) ( TGetTableNameEvent)();
```

File

Provider

Description

This is type Provider.TGetTableNameEvent.

72.5.10 Provider.TInfoArray Type

Pascal

```
TInfoArray = array of TPutFieldInfo;
```

C++

```
array of TPutFieldInfo TInfoArray;
```

File

Provider

Description

This is type Provider.TInfoArray.

72.5.11 Provider.TOnValidate Type

Pascal

```
TOnValidate = procedure (const Delta: OleVariant) of object;
```

C++

```
(const Delta: OleVariant) ( TOnValidate)();
```

File

Provider

Description

This is type Provider.TOnValidate.

72.5.12 Provider.TProviderDataEvent Type

Pascal

```
TProviderDataEvent = procedure (Sender: TObject; DataSet: TCustomClientDataSet) of object;
```

C++

```
(Sender: TObject; DataSet: TCustomClientDataSet) ( TProviderDataEvent)();
```

File

Provider

Description

This is type Provider.TProviderDataEvent.

72.5.13 Provider.TProviderOptions Type

Pascal

```
TProviderOptions = set of TProviderOption;
```

C++

```
TProviderOption TProviderOptions;
```

File

Provider

Description

This is type Provider.TProviderOptions.

72.5.14 Provider.TPutFieldProc Type

Pascal

```
TPutFieldProc = procedure (Info: PPutFieldInfo) of object;
```

C++

```
(Info: PPutFieldInfo) ( TPutFieldProc)();
```

File

Provider

Description

This is type Provider.TPutFieldProc.

72.5.15 Provider.TResolverErrorEvent Type

Pascal

```
TResolverErrorEvent = procedure (Sender: TObject; DataSet: TCustomClientDataSet; E:
EUpdateError; UpdateKind: TUpdateKind; var Response: TResolverResponse) of object;
```

C++

```
(Sender: TObject; DataSet: TCustomClientDataSet; E: EUpdateError; UpdateKind: TUpdateKind; var
Response: TResolverResponse) ( TResolverErrorEvent)();
```

File

Provider

Description

This is type Provider.TResolverErrorEvent.

72.6 Variables

The following table lists variables in this documentation.

Variables

Name	Description
InformixLob (see page 6595)	This is variable Provider.InformixLob.

72.6.1 Provider.InformixLob Variable

Pascal

```
InformixLob: Boolean;
```

C++

```
Boolean InformixLob;
```

File

Provider

Description

This is variable Provider.InformixLob.

72.7 Constants

The following table lists constants in this documentation.

Constants

Name	Description
MetaDataOption (see page 6596)	Specifies the options available when retrieving metadata from a target database.
ResetOption (see page 6597)	This is constant Provider.ResetOption.
XMLOption (see page 6597)	This is constant Provider.XMLOption.
XMLUTF8Option (see page 6598)	This is constant Provider.XMLUTF8Option.

72.7.1 Provider.MetaDataOption Constant

Specifies the options available when retrieving metadata from a target database.

Pascal

```
MetaDataOption: Integer = 1 shl ord(grMetaData);
```

C++

```
int MetaDataOption = 1 shl ord(grMetaData);
```

File

Provider

Description

Each database provides a number of options for data that can be retrieved from and about the database. When you build your own data provider, it can be helpful to use these options when implementing the ISQLMetaData interface. The following table describes the allowable metadata options.

Element	Description
CatalogName	Specifies a system table name.
DatabaseName	Specifies the name of the database.
DatabaseVersion	Specifies the version number of the database.
MaxColumnInSelect	Limits the number of columns that can be specified in a SELECT statement. The column count starts with the first column. Any columns beyond the limit are not returned.
MaxColumnsInTable	Limits the number of columns that can be returned from a table. The column count starts with the first column. Any columns beyond the limit are not returned.
MaxObjectNameLength	Limits the number of characters returned of a database object name. Names exceeding this limit are truncated. If database object names are similar, truncating them might result in duplicate names or meaningless names.
MaxRowSize	Limits the size of any returned rows. This can be useful if you suspect there might be BLOBs in the rows you are selecting, but you want to protect the performance of your query.
MaxSQLLength	Limits the length, in characters, of a SQL statement.
ObjectQuoteChar	Specifies the quote character to use when delimiting object names containing special characters, such as spaces.

PackageName	Specifies the name of a package.
ProcSupportsCursor	Specifies whether or not a stored procedure supports the use of a cursor. Set to **true** if it supports a cursor, otherwise set to **false**.
ProcSupportsCursors	Specifies whether or not a stored procedure supports the use of multiple cursors. Set to **true** if it supports cursors, otherwise set to **false**.
SQLEscapeChar	Specifies the character to use to delimit escape sequences in SQL statements.
SchemaName	Specifies the name of a database schema if different from the DatabaseName.
SupportsTransaction	Specifies whether or not the database can be named in a transaction-based SQL statement. Set to **true** if it supports a transaction, otherwise set to **false**.
SupportsTransactions	Specifies whether or not the database can be named in multiple transaction-based SQL statements. Set to **true** if it supports transactions, otherwise set to **false**.
TransactionIsoLevel	Specifies the transaction isolation level. Isolation levels supported by BDP.NET include ReadCommitted, RepeatableRead, DirtyRead, and Custom.

72.7.2 Provider.ResetOption Constant

Pascal

```
ResetOption: Integer = 1 shl ord(grReset);
```

C++

```
int ResetOption = 1 shl ord(grReset);
```

File

Provider

Description

This is constant Provider.ResetOption.

72.7.3 Provider.XMLOption Constant

Pascal

```
XMLOption: Integer = 1 shl ord(grXML);
```

C++

```
int XMLOption = 1 shl ord(grXML);
```

File

Provider

Description

This is constant Provider.XMLOption.

72.7.4 Provider.XMLUTF8Option Constant

Pascal

```
XMLUTF8Option: Integer = 1 shl ord(grXMLUTF8);
```

C++

```
int XMLUTF8Option = 1 shl ord(grXMLUTF8);
```

File

Provider

Description

This is constant Provider.XMLUTF8Option.

73 Registry Namespace

This is namespace Registry.

Topics

Name	Description
Classes (see page 6600)	The following table lists classes in this documentation.
Structs, Records, Enums (see page 6691)	The following table lists structs, records, enums in this documentation.

Classes

	Name	Description
	ERegistryException (see page 6600)	ERegistryException is the exception class for registry errors.
	TRegIniFile (see page 6601)	TRegIniFile is a low-level wrapper for the Windows 95/NT system registry.
	TRegistry (see page 6610)	TRegistry is a low-level wrapper for the system registry and functions that operate on the registry.
	TRegistryIniFile (see page 6663)	TRegistryIniFile is a wrapper for the Windows system registry.

Structs, Records, Enums

	Name	Description
	TRegDataInfo (see page 6691)	TRegDataInfo is a type used by the GetDataInfo method of TRegistery.
	TRegDataType (see page 6691)	TRegDataType is a type used by the GetDataInfo method of TRegistery.
	TRegKeyInfo (see page 6692)	TRegKeyInfo is a type used by the GetRegKeyInfo method of TRegistery.

73.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	ERegistryException (see page 6600)	ERegistryException is the exception class for registry errors.
	TRegIniFile (see page 6601)	TRegIniFile is a low-level wrapper for the Windows 95/NT system registry.
	TRegistry (see page 6610)	TRegistry is a low-level wrapper for the system registry and functions that operate on the registry.
	TRegistryIniFile (see page 6663)	TRegistryIniFile is a wrapper for the Windows system registry.

73.1.1 ERegistryException Class

ERegistryException is the exception class for registry errors.

Class Hierarchy

Pascal

```
ERegistryException = class(Exception);
```

C++

```
class ERegistryException : public Exception;
```

File

Registry

Description

ERegistryException is raised when an application cannot

Create a new key in the registry.

Read a data value associated with a key.

Read a binary data value associated with a key into a local buffer.

Write a data value to a key.

Key creation fails when an application attempts to create a subkey under a key for which it does not have KEY_CREATE_SUB_KEY security access.

Reading a data value associated with a key fails when an application does not have KEY_READ security access, or when the application attempts to read the wrong kind of data from a key (for example, attempting to read string data from an integer data value).

Reading a binary data value into a local buffer fails when an application does not allocate a buffer large enough for the data.

Writing a data value to a key fails because an application does not have KEY_WRITE security access for the current key.

TRegistry (see page 6610)

73.1.2 TRegIniFile Class

TRegIniFile is a low-level wrapper for the Windows 95/NT system registry.

Class Hierarchy

Pascal

```
TRegIniFile = class(TRegistry);
```

C++

```
class TRegIniFile : public TRegistry;
```

File

Registry

Description

TRegIniFile presents a simple interface to the system registry, hiding the need to know about the underlying structure of the registry. TRegIniFile acts as a helper object to TRegistryIniFile (see page 6663), which descends from TCustomIniFile (see page 4258) (and is therefore more widely compatible with other INI file classes).

TRegIniFile enables handling the Windows 95/NT system registry as if it were a Windows 3.x INI file. Instead of processing an INI file, however, TRegIniFile reads from and writes to the system registry.

Although TRegIniFile descends from TRegistry (see page 6610), it adds the properties and methods used by a TIniFile (see page 4294) object. The FileName (see page 6610) passed to a TRegIniFile object becomes a subkey under the system registry's root key (HKEY_CURRENT_USER by default). What corresponds to a section in an INI file is treated as a key in the system registry, and what corresponds to data entries under a section in an INI file are treated as data values under a key in the system registry.

Note: TRegIniFile is intended to be used primarily as a helper object to TRegistryIniFile (see page 6663), which unifies the interface to INI files and the system registry. However, applications can use TRegIniFile directly.

See Also

TIniFile (see page 4294)

TMemIniFile (see page 4307)

TCustomIniFile (see page 4258)

TRegistryIniFile (see page 6663)

73.1.2.1 TRegIniFile Members

The following tables list the members exposed by TRegIniFile.

Protected Methods

	Name	Description
	ChangeKey (see page 6619)	This is ChangeKey, a member of class TRegistry.

	GetBaseKey (see page 6626)	This is GetBaseKey, a member of class TRegistry.
	GetData (see page 6626)	This is GetData, a member of class TRegistry.
	GetKey (see page 6628)	This is GetKey, a member of class TRegistry.
	PutData (see page 6637)	This is PutData, a member of class TRegistry.
	SetCurrentKey (see page 6644)	This is SetCurrentKey, a member of class TRegistry.

Public Methods

	Name	Description
	CloseKey (see page 6619)	Writes the current key to the registry and closes the key.
	Create (see page 6603)	This is the overview for the Create constructor overload.
	Create (see page 6615)	This is the overview for the Create constructor overload.
	CreateKey (see page 6622)	Creates a new key in the registry.
	DeleteKey (see page 6604)	Erases a data value that is associated with a key.
	DeleteValue (see page 6625)	Erases a data value that is associated with the current key.
V	Destroy (see page 6617)	Closes the current key and destroys the TRegistry (see page 6610) object.
	EraseSection (see page 6605)	Deletes a key and its data values in the system registry.
	GetDataAsString (see page 6626)	This is GetDataAsString, a member of class TRegistry.
	GetDataInfo (see page 6627)	Returns information about a specified data value associated with the current key.
	GetDataSize (see page 6627)	Returns the size, in bytes, of a specified data value associated with the current key.
	GetDataType (see page 6628)	Returns the enumerated data type of a specified data value associated with the current key.
	GetKeyInfo (see page 6628)	Returns information about the current key.
	GetKeyNames (see page 6629)	Returns a string list containing the names of all subkeys belonging to the current key.
	GetValueNames (see page 6629)	Returns a string list containing the names of all data values associated with the current key.
	HasSubKeys (see page 6630)	Determines if the current key has subkeys.
	KeyExists (see page 6630)	Determines if a specified key exists.
	LoadKey (see page 6632)	Creates a subkey under the root key and loads registry information from a file into the newly created subkey.
	MoveKey (see page 6633)	Moves an existing key, its subkeys, and data values to a new location using a new key name.
	OpenKey (see page 6634)	Opens a specified key.
	OpenKeyReadOnly (see page 6636)	Opens a specified key in a read-only manner.
	ReadBinaryData (see page 6637)	Retrieves a binary value from a specified data value associated with the current key.
	ReadBool (see page 6605)	Retrieves a Boolean value from a specified data value associated with a key.
	ReadCurrency (see page 6638)	Retrieves a currency value from a specified data value associated with the current key.
	ReadDate (see page 6638)	Retrieves a date value from a specified data value associated with the current key.
	ReadDateTime (see page 6639)	Retrieves a date and time value from a specified data value associated with the current key.
	ReadFloat (see page 6639)	Retrieves a float value from a specified data value associated with the current key.
	ReadInteger (see page 6606)	Retrieves an integer value from a specified data value (Ident) associated with a key (Section).
	ReadSection (see page 6606)	Retrieves the names of all data values associated with a key, and stores the names in a TStrings object.
	ReadSections (see page 6607)	Retrieves the names of all subkeys associated with the current key.
	ReadSectionValues (see page 6607)	Retrieves the data-values associated with a specified key, and stores the retrieved values in a string object.
	ReadString (see page 6608)	Retrieves a string value from a specified data value (Ident) associated with a key (Section).
	ReadTime (see page 6641)	Retrieves a time value from a specified data value associated with the current key.
	RegistryConnect (see page 6641)	Establishes a connection to a registry on another computer.
	RenameValue (see page 6642)	Changes the name of a data value associated with the current key.

	ReplaceKey (see page 6642)	Replaces the hive file backing a key and all its subkeys with a hive stored in a different file, so that when the system is next started, the key and subkeys will have the values stored in the new file.
	RestoreKey (see page 6643)	Reopens the specified key, and overwrites any information contained in this key and its subkeys keys with registry data stored in a hive file.
	SaveKey (see page 6643)	Opens the specified key with the security access value KEY_ALL_ACCESS and saves the specified key and all of its subkeys and values to a hive file.
	UnLoadKey (see page 6644)	Removes a hive from the registry.
	ValueExists (see page 6645)	Determines if a specified data value exists for the current key.
	WriteBinaryData (see page 6645)	Stores a specifically named data value associated with the current key.
	WriteBool (see page 6608)	Writes a Boolean value to a specified data value associated with a specified key.
	WriteCurrency (see page 6646)	Stores a currency value in a specifically named data value associated with the current key.
	WriteDate (see page 6646)	Stores a date value in a specifically named data value associated with the current key.
	WriteDateTime (see page 6647)	Stores a datetime value in a specifically named data value associated with the current key.
	WriteExpandString (see page 6650)	Stores a string containing unexpanded references to environment variables in a specifically named data value associated with the current key.
	WriteFloat (see page 6652)	Stores a Double value in a specifically named data value associated with the current key.
	WriteInteger (see page 6609)	Writes a long integer value to a specified data value associated with a specified key.
	WriteString (see page 6609)	Writes a string value to a specified data value associated with a specified key.
	WriteTime (see page 6656)	Stores a time value in a specifically named data value associated with the current key.

Public Properties

	Name	Description
	Access (see page 6657)	Specifies the level of access to use when opening keys.
R	CurrentKey (see page 6660)	Specifies the registry key that is currently open.
R	CurrentPath (see page 6660)	Indicates the registry path associated with the current key.
R	FileName (see page 6610)	Specifies the name of the key opened or created in the system registry.
	LazyWrite (see page 6660)	Specifies how keys are written to the registry when calling the CloseKey (see page 6619) procedure.
	RootKey (see page 6661)	Specifies the root key for the TRegistry (see page 6610) object in an application.

73.1.2.2 Create Constructor

This is the overview for the Create constructor overload.

Overload List

	Name	Description
	TRegIniFile.Create (string) (see page 6603)	Creates a TRegIniFile (see page 6601) object for an application.
	TRegIniFile.Create (string, LongWord) (see page 6603)	Creates a TRegIniFile (see page 6601) object for an application.

73.1.2.2.1 TRegIniFile.Create Constructor (string)

Creates a TRegIniFile (see page 6601) object for an application.

Pascal

```
constructor Create(const FileName: string); overload;
```

```
constructor Create(const FileName: string; AAccess: LongWord); overload;
```

C++

```
__fastcall TRegIniFile(const UnicodeString FileName);
__fastcall TRegIniFile(const UnicodeString FileName, LongWord AAccess);
```

Description

Use Create to construct a TRegIniFile (see page 6601) object for an application.

FileName (see page 6610) initializes the FileName (see page 6610) property.

AAccess initializes the Access (see page 6657) property, which determines the access rights used when opening keys. If no AAccess parameter is supplied, Access (see page 6657) is initialized to KEY_ALL_ACCESS.

See Also

FileName (see page 6610)

Create (see page 6615)

Access (see page 6657)

73.1.2.3 TRegIniFile Methods

The methods of the TRegIniFile class are listed here.

Public Methods

	Name	Description
	DeleteKey (see page 6604)	Erases a data value that is associated with a key.
	EraseSection (see page 6605)	Deletes a key and its data values in the system registry.
	ReadBool (see page 6605)	Retrieves a Boolean value from a specified data value associated with a key.
	ReadInteger (see page 6606)	Retrieves an integer value from a specified data value (Ident) associated with a key (Section).
	ReadSection (see page 6606)	Retrieves the names of all data values associated with a key, and stores the names in a TStrings object.
	ReadSections (see page 6607)	Retrieves the names of all subkeys associated with the current key.
	ReadSectionValues (see page 6607)	Retrieves the data-values associated with a specified key, and stores the retrieved values in a string object.
	ReadString (see page 6608)	Retrieves a string value from a specified data value (Ident) associated with a key (Section).
	WriteBool (see page 6608)	Writes a Boolean value to a specified data value associated with a specified key.
	WriteInteger (see page 6609)	Writes a long integer value to a specified data value associated with a specified key.
	WriteString (see page 6609)	Writes a string value to a specified data value associated with a specified key.

73.1.2.3.1 TRegIniFile.DeleteKey Method

Erases a data value that is associated with a key.

Pascal

```
procedure DeleteKey(const Section: string; const Ident: string);
```

C++

```
__fastcall DeleteKey(const UnicodeString Section, const UnicodeString Ident);
```

Description

Call DeleteKey to erase a data value associated with a key. Section is string containing the name of the system registry key containing the value to delete. Ident is a string containing the name of the data value to delete.

Note: DeleteKey for TRegIniFile (see page 6601) obscures the DeleteKey method of TRegistry (see page 6610), from which TRegIniFile (see page 6601) descends. You can access TRegistry (see page 6610)'s DeleteKey method by casting the call to DeleteKey as type TRegistry (see page 6610), or by using the scope resolution operator.

Note: On Windows 95, DeleteKey will delete the key and all its subkeys. On Windows NT, the subkeys must be explicitly deleted by separate calls to DeleteKey.

See Also

DeleteKey (see page 6623)

EraseSection (see page 6605)

73.1.2.3.2 TRegIniFile.EraseSection Method

Deletes a key and its data values in the system registry.

Pascal

```
procedure EraseSection(const Section: string);
```

C++

```
__fastcall EraseSection(const UnicodeString Section);
```

Description

Call EraseSection to remove a key and its data values from the system registry. Section identifies the key to delete.

See Also

DeleteKey (see page 6604)

73.1.2.3.3 TRegIniFile.ReadBool Method

Retrieves a Boolean value from a specified data value associated with a key.

Pascal

```
function ReadBool(const Section: string; const Ident: string; Default: Boolean): Boolean;
```

C++

```
__fastcall Boolean ReadBool(const UnicodeString Section, const UnicodeString Ident, Boolean
Default);
```

Description

Call ReadBool to retrieve a Boolean value from a specified data value associated with a key.

Section is a string that identifies the key from which to retrieve a data value. Ident is a string that identifies the name of the data value to return. Default is a Boolean value to use if there is no key corresponding to Section or no data value corresponding to Ident.

Note: This function overrides the ReadBool function of TRegistry (see page 6610), from which TRegIniFile (see page 6601) is derived. To call the ReadBool function of TRegistry (see page 6610) instead of this function, cast the call to ReadBool as TRegistry (see page 6610).

See Also

ReadInteger (see page 6606)

ReadString (see page 6608)

ReadBool (see page 6638)

73.1.2.3.4 TRegIniFile.ReadInteger Method

Retrieves an integer value from a specified data value (Ident) associated with a key (Section).

Pascal

```
function ReadInteger(const Section: string; const Ident: string; Default: Longint): Longint;
```

C++

```
__fastcall Longint ReadInteger(const UnicodeString Section, const UnicodeString Ident, Longint
Default);
```

Description

Call ReadInteger to retrieve an integer value from a specified data value associated with a key.

Section is a string that identifies the key from which to retrieve a data value. Ident is a string that identifies the name of the data value to return. Default is an integer value to use if there is no key corresponding to Section or no data value corresponding to Ident.

Note: This function overrides the ReadInteger function of TRegistry (see page 6610), from which TRegIniFile (see page 6601) is derived. To call the ReadInteger function of TRegistry (see page 6610) instead of this function, cast the call to ReadInteger as TRegistry (see page 6610).

See Also

ReadBool (see page 6605)

ReadString (see page 6608)

ReadInteger (see page 6640)

73.1.2.3.5 TRegIniFile.ReadSection Method

Retrieves the names of all data values associated with a key, and stores the names in a TStrings object.

Pascal

```
procedure ReadSection(const Section: string; Strings: TStrings);
```

C++

```
__fastcall ReadSection(const UnicodeString Section, TStrings Strings);
```

Description

Call ReadSection to retrieve the names of all data values associated with a key into a TStrings object.

Section is a string identifying the key for which to retrieve data-value names.

Strings specifies the string object to hold the retrieved names. Strings can point to a TStrings object such as a string list, or to a component property, such as Items for a TListBox component, that is a TStrings object itself.

See Also

ReadSections (see page 6607)

ReadSectionValues (see page 6607)

TListBox

Items

73.1.2.3.6 TRegIniFile.ReadSections Method

Retrieves the names of all subkeys associated with the current key.

Pascal

```
procedure ReadSections(Strings: TStrings);
```

C++

```
__fastcall ReadSections(TStrings Strings);
```

Description

Call ReadSections to retrieve the names of all subkeys associated with the current key.

Strings specifies the string object to hold the retrieved names. Strings can point to a TStrings object, or to a component property, such as Items for a TListBox component, that is a TStrings object itself.

See Also

CurrentKey (see page 6660)

ReadSection (see page 6606)

ReadSectionValues (see page 6607)

TListBox

Items

73.1.2.3.7 TRegIniFile.ReadSectionValues Method

Retrieves the data-values associated with a specified key, and stores the retrieved values in a string object.

Pascal

```
procedure ReadSectionValues(const Section: string; Strings: TStrings);
```

C++

```
__fastcall ReadSectionValues(const UnicodeString Section, TStrings Strings);
```

Description

Call ReadSectionValues to read all data values associated with a specified key into a string object.

Section is the name of the key from which to retrieve data-values.

Strings specifies the string list object to hold the retrieved values. Strings can point to a TStrings object, or to a component property, such as Items for a TListBox component, that is a TStrings object itself. Use the Values property of the string object to access a specific string in the object.

See Also

ReadSection (see page 6606)

ReadSections (see page 6607)

TListBox

Items

Values

73.1.2.3.8 TRegIniFile.ReadString Method

Retrieves a string value from a specified data value (Ident) associated with a key (Section).

Pascal

```
function ReadString(const Section: string; const Ident: string; const Default: string): string;
```

C++

```
__fastcall UnicodeString ReadString(const UnicodeString Section, const UnicodeString Ident,
const UnicodeString Default);
```

Description

Call ReadString to retrieve a string value from a specified data value associated with a key.

Section is a string that identifies the key from which to retrieve a data value. Ident is a string that identifies the name of the data value to return. Default is a string value to use if there is no key corresponding to Section or no data value corresponding to Ident.

Note: This function overrides the ReadString function of TRegistry (see page 6610), from which TRegIniFile (see page 6601) is derived. To call the ReadString function of TRegistry (see page 6610) instead of this function, cast the call to ReadString as TRegistry (see page 6610).

See Also

ReadBool (see page 6605)

ReadInteger (see page 6606)

ReadString (see page 6640)

73.1.2.3.9 TRegIniFile.WriteBool Method

Writes a Boolean value to a specified data value associated with a specified key.

Pascal

```
procedure WriteBool(const Section: string; const Ident: string; Value: Boolean);
```

C++

```
__fastcall WriteBool(const UnicodeString Section, const UnicodeString Ident, Boolean Value);
```

Description

Call WriteBool to store a Boolean value in a data value associated with a specified key.

Section is a string identifying the key into which to store a data value. Ident is a string identifying the name of the data value into which to write. Value is the Boolean value to write into the data value.

Note: This function overrides the WriteBool procedure of TRegistry (see page 6610), from which TRegIniFile (see page 6601) is derived. To call the WriteBool procedure of TRegistry (see page 6610) instead of this procedure, cast the call to WriteBool as TRegistry (see page 6610).

See Also

WriteInteger (see page 6609)

WriteString (see page 6609)

WriteBool (see page 6646)

73.1.2.3.10 TRegIniFile.WriteInteger Method

Writes a long integer value to a specified data value associated with a specified key.

Pascal

```
procedure WriteInteger(const Section: string; const Ident: string; Value: Longint);
```

C++

```
__fastcall WriteInteger(const UnicodeString Section, const UnicodeString Ident, Longint Value);
```

Description

Call WriteInteger to store an integer value in a data value associated with a specified key.

Section is a string identifying the key into which to store a data value. Ident is a string identifying the name of the data value into which to write. Value is the integer value to write into the data value.

Note: This function overrides the WriteInteger procedure of TRegistry (see page 6610), from which TRegIniFile (see page 6601) is derived. To call the WriteInteger procedure of TRegistry (see page 6610) instead of this procedure, cast the call to WriteInteger as TRegistry (see page 6610).

See Also

WriteBool (see page 6608)

WriteString (see page 6609)

WriteInteger (see page 6653)

73.1.2.3.11 TRegIniFile.WriteString Method

Writes a string value to a specified data value associated with a specified key.

Pascal

```
procedure WriteString(const Section: string; const Ident: string; const Value: string);
```

C++

```
__fastcall WriteString(const UnicodeString Section, const UnicodeString Ident, const
UnicodeString Value);
```

Description

Call WriteString to store a string value in a data value associated with a specified key.

Section is a string identifying the key into which to store a data value. Ident is a string identifying the name of the data value into which to write. Value is the string value to write into the data value.

Note: This function overrides the WriteString procedure of TRegistry (see page 6610), from which TRegIniFile (see page 6601) is derived. To call the WriteString procedure of TRegistry (see page 6610) instead of this procedure, cast the call to WriteString as TRegistry (see page 6610).

See Also

WriteBool (see page 6608)

WriteInteger (see page 6609)

WriteString (see page 6653)

73.1.2.4 TRegIniFile Properties

The properties of the TRegIniFile class are listed here.

Public Properties

	Name	Description
	FileName (see page 6610)	Specifies the name of the key opened or created in the system registry.

73.1.2.4.1 TRegIniFile.FileName Property

Specifies the name of the key opened or created in the system registry.

Pascal

```
property FileName: string;
```

C++

```
__property UnicodeString FileName;
```

Description

Query FileName to determine the name of the key in the system registry that is the root key for all TRegIniFile (see page 6601) operations.

See Also

CurrentKey (see page 6660)

RootKey (see page 6661)

73.1.3 TRegistry Class

TRegistry is a low-level wrapper for the system registry and functions that operate on the registry.

Class Hierarchy

Pascal

```
TRegistry = class(TObject);
```

C++

```
class TRegistry : public TObject;
```

File

Registry

Description

Use TRegistry to encapsulate access to the Windows system registry in an application. The registry is a database that an application can use to store and retrieve configuration information. Configuration information is stored in a hierarchical tree. Each node in the tree is called a key. Every key can contain subkeys and data values that represent part of the configuration information for an application.

All keys that an application creates, opens, reads, or writes are subkeys of predefined root keys. By default, a TRegistry object is created with a root key of HKEY_CURRENT_USER.

Only one key is accessible at a time in a TRegistry object. To determine the key that is currently accessible, read the value of the CurrentKey (see page 6660) property. TRegistry methods enable an application to open, close, save, move, copy, and delete keys.

One or more data values containing actual configuration information can be stored in a key. TRegistry methods enable an application to query a key to see if it contains data, to read data in a key, and to write data to a key.

Note: The TRegistry component is not fully compatable with the Windows NT environment. Functions such as RestoreKey (see page 6643) and SaveKey (see page 6643) may not perform properly without a significant number of workarounds.

C++ Examples:

```
/*
This example shows how to use the TRegistry class in order to
find, insert and delete Keys and Items into the Windows Registry.
This example uses two buttons: InsertToRegBtn and DeleteFromRegBtn,
for inserting and deleting the values.
*/
void __fastcall TForm2::InsertToRegBtnClick(TObject *Sender)
{
    TRegistry* reg = new TRegistry(KEY_READ);
    reg->RootKey = HKEY_LOCAL_MACHINE;

    if(!reg->KeyExists("Software\\MyCompanyName\\MyApplication\\"))
    {
        MessageDlg("Key not found! Created now.",
                   mtInformation, TMsgDlgButtons() << mbOK, 0);
    }
    reg->Access = KEY_WRITE;
    bool openResult = reg->OpenKey("Software\\MyCompanyName\\MyApplication\\", true);

    if(!openResult)
    {
        MessageDlg("Unable to create key! Exiting.",
                   mtError, TMsgDlgButtons() << mbOK, 0);
        return;
    }
    //checking if the values exist and inserting when neccesary

    if(!reg->KeyExists("Creation\ Date"))
    {
        TDateTime today = TDateTime::CurrentDateTime();
        reg->WriteDateTime("Creation\ Date", today);
    }

    if(!reg->KeyExists("Licenced\ To"))
    {
        reg->WriteString("Licenced\ To", "MySurname\ MyFirstName");
    }

    if(!reg->KeyExists("App\ Location"))
    {
        reg->WriteExpandString("App\ Location",
                               "%PROGRAMFILES%\\MyCompanyName\\MyApplication\\");
    }

    if(!reg->KeyExists("Projects\ Location"))
    {
        reg->WriteExpandString("Projects\ Location",
                               "%USERPROFILE%\\MyApplication\\Projects\\");
    }

    reg->CloseKey();
```

```
}
//---------------------------------------------------------------------------
void __fastcall TForm2::DelFromRegBtnClick(TObject *Sender)
{
    //deleting the example registry entries
    TRegistry* reg = new TRegistry(KEY_WRITE);
    reg->RootKey = HKEY_LOCAL_MACHINE;

    reg->DeleteKey("Software\\MyCompanyName\\MyApplication");
    reg->DeleteKey("Software\\MyCompanyName");

    reg->CloseKey();
}
//---------------------------------------------------------------------------
```

Delphi Examples:

```
{
This example shows how to use the TRegistry class in order to
find, insert and delete Keys and Items into the Windows Registry.
This example uses two buttons: InsertToRegBtn and DeleteFromRegBtn,
on a form, for inserting and deleting the values.
}
procedure TForm3.InsertToRegBtnClick(Sender: TObject);
var
  reg        : TRegistry;
  openResult : Boolean;
  today      : TDateTime;
begin
  reg := TRegistry.Create(KEY_READ);
  reg.RootKey := HKEY_LOCAL_MACHINE;

  if (not reg.KeyExists('Software\\MyCompanyName\\MyApplication\\')) then
    begin
      MessageDlg('Key not found! Created now.',
                           mtInformation, mbOKCancel, 0);
    end;
  reg.Access := KEY_WRITE;
  openResult := reg.OpenKey('Software\\MyCompanyName\\MyApplication\\',True);

  if not openResult = True then
    begin
      MessageDlg('Unable to create key! Exiting.',
                 mtError, mbOKCancel, 0);
      Exit();
    end;

  {checking if the values exist and inserting when neccesary}

  if not reg.KeyExists('Creation\ Date') then
    begin
      today := Now;
        reg.WriteDateTime('Creation\ Date', today);
    end;

  if not reg.KeyExists('Licenced\ To') then
    begin
        reg.WriteString('Licenced\ To', 'MySurname\ MyFirstName');
    end;

  if not reg.KeyExists('App\ Location') then
    begin
        reg.WriteExpandString('App\ Location',
                              '%PROGRAMFILES%\\MyCompanyName\\MyApplication\\');
    end;

  if not reg.KeyExists('Projects\ Location') then
```

```
    begin
        reg.WriteExpandString('Projects\ Location',
                              '%USERPROFILE%\\MyApplication\\Projects\\');
    end;

  reg.CloseKey();

end;

procedure TForm3.DeleteFromRegBtnClick(Sender: TObject);
var
  reg : TRegistry;
begin
  reg := TRegistry.Create(KEY_WRITE);
  reg.RootKey := HKEY_LOCAL_MACHINE;

  reg.DeleteKey('Software\\MyCompanyName\\MyApplication');
  reg.DeleteKey('Software\\MyCompanyName');

  reg.CloseKey();
end;
```

73.1.3.1 TRegistry Members

The following tables list the members exposed by TRegistry.

Protected Methods

	Name	Description
	ChangeKey (see page 6619)	This is ChangeKey, a member of class TRegistry.
	GetBaseKey (see page 6626)	This is GetBaseKey, a member of class TRegistry.
	GetData (see page 6626)	This is GetData, a member of class TRegistry.
	GetKey (see page 6628)	This is GetKey, a member of class TRegistry.
	PutData (see page 6637)	This is PutData, a member of class TRegistry.
	SetCurrentKey (see page 6644)	This is SetCurrentKey, a member of class TRegistry.

Public Methods

	Name	Description
	CloseKey (see page 6619)	Writes the current key to the registry and closes the key.
	Create (see page 6615)	This is the overview for the Create constructor overload.
	CreateKey (see page 6622)	Creates a new key in the registry.
	DeleteKey (see page 6623)	Removes a specified key and its associated data from the registry.
	DeleteValue (see page 6625)	Erases a data value that is associated with the current key.
	Destroy (see page 6617)	Closes the current key and destroys the TRegistry (see page 6610) object.
	GetDataAsString (see page 6626)	This is GetDataAsString, a member of class TRegistry.
	GetDataInfo (see page 6627)	Returns information about a specified data value associated with the current key.
	GetDataSize (see page 6627)	Returns the size, in bytes, of a specified data value associated with the current key.
	GetDataType (see page 6628)	Returns the enumerated data type of a specified data value associated with the current key.
	GetKeyInfo (see page 6628)	Returns information about the current key.
	GetKeyNames (see page 6629)	Returns a string list containing the names of all subkeys belonging to the current key.
	GetValueNames (see page 6629)	Returns a string list containing the names of all data values associated with the current key.
	HasSubKeys (see page 6630)	Determines if the current key has subkeys.
	KeyExists (see page 6630)	Determines if a specified key exists.
	LoadKey (see page 6632)	Creates a subkey under the root key and loads registry information from a file into the newly created subkey.

	MoveKey (see page 6633)	Moves an existing key, its subkeys, and data values to a new location using a new key name.
	OpenKey (see page 6634)	Opens a specified key.
	OpenKeyReadOnly (see page 6636)	Opens a specified key in a read-only manner.
	ReadBinaryData (see page 6637)	Retrieves a binary value from a specified data value associated with the current key.
	ReadBool (see page 6638)	Retrieves a Boolean value from a specified data value associated with the current key.
	ReadCurrency (see page 6638)	Retrieves a currency value from a specified data value associated with the current key.
	ReadDate (see page 6638)	Retrieves a date value from a specified data value associated with the current key.
	ReadDateTime (see page 6639)	Retrieves a date and time value from a specified data value associated with the current key.
	ReadFloat (see page 6639)	Retrieves a float value from a specified data value associated with the current key.
	ReadInteger (see page 6640)	Retrieves an integer value from a specified data value associated with the current key.
	ReadString (see page 6640)	Retrieves a string value from a specified data value associated with the current key.
	ReadTime (see page 6641)	Retrieves a time value from a specified data value associated with the current key.
	RegistryConnect (see page 6641)	Establishes a connection to a registry on another computer.
	RenameValue (see page 6642)	Changes the name of a data value associated with the current key.
	ReplaceKey (see page 6642)	Replaces the hive file backing a key and all its subkeys with a hive stored in a different file, so that when the system is next started, the key and subkeys will have the values stored in the new file.
	RestoreKey (see page 6643)	Reopens the specified key, and overwrites any information contained in this key and its subkeys keys with registry data stored in a hive file.
	SaveKey (see page 6643)	Opens the specified key with the security access value KEY_ALL_ACCESS and saves the specified key and all of its subkeys and values to a hive file.
	UnLoadKey (see page 6644)	Removes a hive from the registry.
	ValueExists (see page 6645)	Determines if a specified data value exists for the current key.
	WriteBinaryData (see page 6645)	Stores a specifically named data value associated with the current key.
	WriteBool (see page 6646)	Stores a Boolean value in a specifically named data value associated with the current key.
	WriteCurrency (see page 6646)	Stores a currency value in a specifically named data value associated with the current key.
	WriteDate (see page 6646)	Stores a date value in a specifically named data value associated with the current key.
	WriteDateTime (see page 6647)	Stores a datetime value in a specifically named data value associated with the current key.
	WriteExpandString (see page 6650)	Stores a string containing unexpanded references to environment variables in a specifically named data value associated with the current key.
	WriteFloat (see page 6652)	Stores a Double value in a specifically named data value associated with the current key.
	WriteInteger (see page 6653)	Stores an integer value in a specifically named data value associated with the current key.
	WriteString (see page 6653)	Stores a string value in a specifically named data value associated with the current key.
	WriteTime (see page 6656)	Stores a time value in a specifically named data value associated with the current key.

Public Properties

	Name	Description
	Access (see page 6657)	Specifies the level of access to use when opening keys.
R	CurrentKey (see page 6660)	Specifies the registry key that is currently open.
R	CurrentPath (see page 6660)	Indicates the registry path associated with the current key.
	LazyWrite (see page 6660)	Specifies how keys are written to the registry when calling the CloseKey (see page 6619) procedure.
	RootKey (see page 6661)	Specifies the root key for the TRegistry (see page 6610) object in an application.

73.1.3.2 Create Constructor

This is the overview for the Create constructor overload.

Overload List

	Name	Description
	TRegistry.Create () (see page 6615)	Creates a TRegistry (see page 6610) object for an application.
	TRegistry.Create (LongWord) (see page 6615)	Creates a TRegistry (see page 6610) object for an application.

73.1.3.2.1 TRegistry.Create Constructor ()

Creates a TRegistry (see page 6610) object for an application.

Pascal

```
constructor Create; overload;
constructor Create(AAccess: LongWord); overload;
```

C++

```
__fastcall TRegistry();
__fastcall TRegistry(LongWord AAccess);
```

Description

Create instantiates a TRegistry (see page 6610) object and sets the RootKey (see page 6661) property to HKEY_CURRENT_USER and the LazyWrite (see page 6660) property to true. If an AAccess parameter is supplied, this value is used to initialize the Access (see page 6657) property. Otherwise, Access (see page 6657) is initialized to KEY_ALL_ACCESS.

C++ Examples:

```
/*
This example shows how to use the TRegistry class in order to
find, insert and delete Keys and Items into the Windows Registry.
This example uses two buttons: InsertToRegBtn and DeleteFromRegBtn,
for inserting and deleting the values.
*/
void __fastcall TForm2::InsertToRegBtnClick(TObject *Sender)
{
    TRegistry* reg = new TRegistry(KEY_READ);
    reg->RootKey = HKEY_LOCAL_MACHINE;

    if(!reg->KeyExists("Software\\MyCompanyName\\MyApplication\\"))
    {
        MessageDlg("Key not found! Created now.",
                   mtInformation, TMsgDlgButtons() << mbOK, 0);
    }
    reg->Access = KEY_WRITE;
    bool openResult = reg->OpenKey("Software\\MyCompanyName\\MyApplication\\", true);

    if(!openResult)
    {
        MessageDlg("Unable to create key! Exiting.",
                   mtError, TMsgDlgButtons() << mbOK, 0);
        return;
    }
    //checking if the values exist and inserting when neccesary
```

```
    if(!reg->KeyExists("Creation\ Date"))
    {
        TDateTime today = TDateTime::CurrentDateTime();
        reg->WriteDateTime("Creation\ Date", today);
    }

    if(!reg->KeyExists("Licenced\ To"))
    {
        reg->WriteString("Licenced\ To", "MySurname\ MyFirstName");
    }

    if(!reg->KeyExists("App\ Location"))
    {
        reg->WriteExpandString("App\ Location",
                               "%PROGRAMFILES%\\MyCompanyName\\MyApplication\\");
    }

    if(!reg->KeyExists("Projects\ Location"))
    {
        reg->WriteExpandString("Projects\ Location",
                               "%USERPROFILE%\\MyApplication\\Projects\\");
    }

    reg->CloseKey();
}
//---------------------------------------------------------------------------
void __fastcall TForm2::DelFromRegBtnClick(TObject *Sender)
{
    //deleting the example registry entries
    TRegistry* reg = new TRegistry(KEY_WRITE);
    reg->RootKey = HKEY_LOCAL_MACHINE;

    reg->DeleteKey("Software\\MyCompanyName\\MyApplication");
    reg->DeleteKey("Software\\MyCompanyName");

    reg->CloseKey();
}
//---------------------------------------------------------------------------
```

Delphi Examples:

```
{
This example shows how to use the TRegistry class in order to
find, insert and delete Keys and Items into the Windows Registry.
This example uses two buttons: InsertToRegBtn and DeleteFromRegBtn,
on a form, for inserting and deleting the values.
}
procedure TForm3.InsertToRegBtnClick(Sender: TObject);
var
  reg        : TRegistry;
  openResult : Boolean;
  today      : TDateTime;
begin
  reg := TRegistry.Create(KEY_READ);
  reg.RootKey := HKEY_LOCAL_MACHINE;

  if (not reg.KeyExists('Software\\MyCompanyName\\MyApplication\\')) then
    begin
      MessageDlg('Key not found! Created now.',
                          mtInformation, mbOKCancel, 0);
    end;
  reg.Access := KEY_WRITE;
  openResult := reg.OpenKey('Software\\MyCompanyName\\MyApplication\\',True);

  if not openResult = True then
    begin
```

```
        MessageDlg('Unable to create key! Exiting.',
                   mtError, mbOKCancel, 0);
        Exit();
      end;

    {checking if the values exist and inserting when neccesary}

    if not reg.KeyExists('Creation\ Date') then
      begin
        today := Now;
          reg.WriteDateTime('Creation\ Date', today);
      end;

    if not reg.KeyExists('Licenced\ To') then
      begin
          reg.WriteString('Licenced\ To', 'MySurname\ MyFirstName');
      end;

    if not reg.KeyExists('App\ Location') then
      begin
          reg.WriteExpandString('App\ Location',
                                '%PROGRAMFILES%\\MyCompanyName\\MyApplication\\');
      end;

    if not reg.KeyExists('Projects\ Location') then
      begin
          reg.WriteExpandString('Projects\ Location',
                                '%USERPROFILE%\\MyApplication\\Projects\\');
      end;

    reg.CloseKey();

  end;

  procedure TForm3.DeleteFromRegBtnClick(Sender: TObject);
  var
    reg : TRegistry;
  begin
    reg := TRegistry.Create(KEY_WRITE);
    reg.RootKey := HKEY_LOCAL_MACHINE;

    reg.DeleteKey('Software\\MyCompanyName\\MyApplication');
    reg.DeleteKey('Software\\MyCompanyName');

    reg.CloseKey();
  end;
```

73.1.3.3 TRegistry.Destroy Destructor

Closes the current key and destroys the TRegistry (see page 6610) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TRegistry();
```

Description

Destroy closes the current key and frees the resources allocated for a registry object when it is no longer needed.

73.1.3.4 TRegistry Methods

The methods of the TRegistry class are listed here.

Protected Methods

	Name	Description
	ChangeKey (see page 6619)	This is ChangeKey, a member of class TRegistry.
	GetBaseKey (see page 6626)	This is GetBaseKey, a member of class TRegistry.
	GetData (see page 6626)	This is GetData, a member of class TRegistry.
	GetKey (see page 6628)	This is GetKey, a member of class TRegistry.
	PutData (see page 6637)	This is PutData, a member of class TRegistry.
	SetCurrentKey (see page 6644)	This is SetCurrentKey, a member of class TRegistry.

Public Methods

	Name	Description
	CloseKey (see page 6619)	Writes the current key to the registry and closes the key.
	CreateKey (see page 6622)	Creates a new key in the registry.
	DeleteKey (see page 6623)	Removes a specified key and its associated data from the registry.
	DeleteValue (see page 6625)	Erases a data value that is associated with the current key.
	GetDataAsString (see page 6626)	This is GetDataAsString, a member of class TRegistry.
	GetDataInfo (see page 6627)	Returns information about a specified data value associated with the current key.
	GetDataSize (see page 6627)	Returns the size, in bytes, of a specified data value associated with the current key.
	GetDataType (see page 6628)	Returns the enumerated data type of a specified data value associated with the current key.
	GetKeyInfo (see page 6628)	Returns information about the current key.
	GetKeyNames (see page 6629)	Returns a string list containing the names of all subkeys belonging to the current key.
	GetValueNames (see page 6629)	Returns a string list containing the names of all data values associated with the current key.
	HasSubKeys (see page 6630)	Determines if the current key has subkeys.
	KeyExists (see page 6630)	Determines if a specified key exists.
	LoadKey (see page 6632)	Creates a subkey under the root key and loads registry information from a file into the newly created subkey.
	MoveKey (see page 6633)	Moves an existing key, its subkeys, and data values to a new location using a new key name.
	OpenKey (see page 6634)	Opens a specified key.
	OpenKeyReadOnly (see page 6636)	Opens a specified key in a read-only manner.
	ReadBinaryData (see page 6637)	Retrieves a binary value from a specified data value associated with the current key.
	ReadBool (see page 6638)	Retrieves a Boolean value from a specified data value associated with the current key.

	ReadCurrency (see page 6638)	Retrieves a currency value from a specified data value associated with the current key.
	ReadDate (see page 6638)	Retrieves a date value from a specified data value associated with the current key.
	ReadDateTime (see page 6639)	Retrieves a date and time value from a specified data value associated with the current key.
	ReadFloat (see page 6639)	Retrieves a float value from a specified data value associated with the current key.
	ReadInteger (see page 6640)	Retrieves an integer value from a specified data value associated with the current key.
	ReadString (see page 6640)	Retrieves a string value from a specified data value associated with the current key.
	ReadTime (see page 6641)	Retrieves a time value from a specified data value associated with the current key.
	RegistryConnect (see page 6641)	Establishes a connection to a registry on another computer.
	RenameValue (see page 6642)	Changes the name of a data value associated with the current key.
	ReplaceKey (see page 6642)	Replaces the hive file backing a key and all its subkeys with a hive stored in a different file, so that when the system is next started, the key and subkeys will have the values stored in the new file.
	RestoreKey (see page 6643)	Reopens the specified key, and overwrites any information contained in this key and its subkeys keys with registry data stored in a hive file.
	SaveKey (see page 6643)	Opens the specified key with the security access value KEY_ALL_ACCESS and saves the specified key and all of its subkeys and values to a hive file.
	UnLoadKey (see page 6644)	Removes a hive from the registry.
	ValueExists (see page 6645)	Determines if a specified data value exists for the current key.
	WriteBinaryData (see page 6645)	Stores a specifically named data value associated with the current key.
	WriteBool (see page 6646)	Stores a Boolean value in a specifically named data value associated with the current key.
	WriteCurrency (see page 6646)	Stores a currency value in a specifically named data value associated with the current key.
	WriteDate (see page 6646)	Stores a date value in a specifically named data value associated with the current key.
	WriteDateTime (see page 6647)	Stores a datetime value in a specifically named data value associated with the current key.
	WriteExpandString (see page 6650)	Stores a string containing unexpanded references to environment variables in a specifically named data value associated with the current key.
	WriteFloat (see page 6652)	Stores a Double value in a specifically named data value associated with the current key.
	WriteInteger (see page 6653)	Stores an integer value in a specifically named data value associated with the current key.
	WriteString (see page 6653)	Stores a string value in a specifically named data value associated with the current key.
	WriteTime (see page 6656)	Stores a time value in a specifically named data value associated with the current key.

73.1.3.4.1 TRegistry.ChangeKey Method

Pascal

```
procedure ChangeKey(Value: HKey; const Path: string);
```

C++

```
__fastcall ChangeKey(HKey Value, const UnicodeString Path);
```

Description

This is ChangeKey, a member of class TRegistry.

73.1.3.4.2 TRegistry.CloseKey Method

Writes the current key to the registry and closes the key.

Pascal

```
procedure CloseKey;
```

C++

```
__fastcall CloseKey();
```

Description

Call CloseKey to write the current key to the registry and close the key. An application should not keep keys open any longer than necessary. Many TRegistry (see page 6610) methods routinely call CloseKey after reading from or writing to the registry. Calling CloseKey when there is no current key has no effect.

Note: When an application closes a key, the key is written to the registry. The LazyWrite (see page 6660) property determines how the write takes place.

C++ Examples:

```
/*
This example shows how to use the TRegistry class in order to
find, insert and delete Keys and Items into the Windows Registry.
This example uses two buttons: InsertToRegBtn and DeleteFromRegBtn,
for inserting and deleting the values.
*/
void __fastcall TForm2::InsertToRegBtnClick(TObject *Sender)
{
    TRegistry* reg = new TRegistry(KEY_READ);
    reg->RootKey = HKEY_LOCAL_MACHINE;

    if(!reg->KeyExists("Software\\MyCompanyName\\MyApplication\\"))
    {
        MessageDlg("Key not found! Created now.",
                   mtInformation, TMsgDlgButtons() << mbOK, 0);
    }
    reg->Access = KEY_WRITE;
    bool openResult = reg->OpenKey("Software\\MyCompanyName\\MyApplication\\", true);

    if(!openResult)
    {
        MessageDlg("Unable to create key! Exiting.",
                   mtError, TMsgDlgButtons() << mbOK, 0);
        return;
    }
    //checking if the values exist and inserting when neccesary

    if(!reg->KeyExists("Creation\ Date"))
    {
        TDateTime today = TDateTime::CurrentDateTime();
        reg->WriteDateTime("Creation\ Date", today);
    }

    if(!reg->KeyExists("Licenced\ To"))
    {
        reg->WriteString("Licenced\ To", "MySurname\ MyFirstName");
    }

    if(!reg->KeyExists("App\ Location"))
    {
        reg->WriteExpandString("App\ Location",
                               "%PROGRAMFILES%\\MyCompanyName\\MyApplication\\");
    }

    if(!reg->KeyExists("Projects\ Location"))
    {
```

```
        reg->WriteExpandString("Projects\ Location",
                               "%USERPROFILE%\\MyApplication\\Projects\\");
    }

    reg->CloseKey();
}
//---------------------------------------------------------------------------
void __fastcall TForm2::DelFromRegBtnClick(TObject *Sender)
{
    //deleting the example registry entries
    TRegistry* reg = new TRegistry(KEY_WRITE);
    reg->RootKey = HKEY_LOCAL_MACHINE;

    reg->DeleteKey("Software\\MyCompanyName\\MyApplication");
    reg->DeleteKey("Software\\MyCompanyName");

    reg->CloseKey();
}
//---------------------------------------------------------------------------
```

Delphi Examples:

```
{
This example shows how to use the TRegistry class in order to
find, insert and delete Keys and Items into the Windows Registry.
This example uses two buttons: InsertToRegBtn and DeleteFromRegBtn,
on a form, for inserting and deleting the values.
}
procedure TForm3.InsertToRegBtnClick(Sender: TObject);
var
  reg        : TRegistry;
  openResult : Boolean;
  today      : TDateTime;
begin
  reg := TRegistry.Create(KEY_READ);
  reg.RootKey := HKEY_LOCAL_MACHINE;

  if (not reg.KeyExists('Software\\MyCompanyName\\MyApplication\\')) then
    begin
      MessageDlg('Key not found! Created now.',
                           mtInformation, mbOKCancel, 0);
    end;
  reg.Access := KEY_WRITE;
  openResult := reg.OpenKey('Software\\MyCompanyName\\MyApplication\\',True);

  if not openResult = True then
    begin
      MessageDlg('Unable to create key! Exiting.',
                  mtError, mbOKCancel, 0);
      Exit();
    end;

  {checking if the values exist and inserting when neccesary}

  if not reg.KeyExists('Creation\ Date') then
    begin
      today := Now;
        reg.WriteDateTime('Creation\ Date', today);
    end;

  if not reg.KeyExists('Licenced\ To') then
    begin
        reg.WriteString('Licenced\ To', 'MySurname\ MyFirstName');
    end;

  if not reg.KeyExists('App\ Location') then
    begin
```

```
          reg.WriteExpandString('App\ Location',
                                '%PROGRAMFILES%\\MyCompanyName\\MyApplication\\');
      end;

    if not reg.KeyExists('Projects\ Location') then
      begin
          reg.WriteExpandString('Projects\ Location',
                                '%USERPROFILE%\\MyApplication\\Projects\\');
      end;

    reg.CloseKey();

  end;

CurrentKey (see page 6660)

LazyWrite (see page 6660)

73.1.3.4.3 TRegistry.CreateKey Method

Creates a new key in the registry.

Pascal

```
function CreateKey(const Key: string): Boolean;
```

C++

```
__fastcall Boolean CreateKey(const UnicodeString Key);
```

Description

Use CreateKey to add a new key to the registry. Key is the name of the key to create. Key can be an absolute or relative name. An absolute key begins with a backslash (\) and is a subkey of the root key. A relative key is a subkey of the current key.

CreateKey returns true if key creation is successful. On error, an exception is raised. Attempting to create a key that already exists has no effect.

CreateKey creates only non-volatile keys. If you need to create volatile keys on Windows NT, you must call the Windows API directly.

CreateKey creates keys with a security access of KEY_ALL_ACCESS. If you need to create keys with more restricted access, you must call the Windows API directly.

A key created by CreateKey has no values. To set key values, use the WriteCurrency (see page 6646), WriteBinaryData (see page 6645), WriteBool (see page 6646), WriteDate (see page 6646), WriteDateTime (see page 6647), WriteFloat (see page 6652), WriteInteger (see page 6653), WriteString (see page 6653), or WriteTime (see page 6656) procedures.

73.1.3.4.4 TRegistry.DeleteKey Method

Removes a specified key and its associated data from the registry.

Pascal

```
function DeleteKey(const Key: string): Boolean;
```

C++

```
__fastcall Boolean DeleteKey(const UnicodeString Key);
```

Description

Call DeleteKey to remove a specified key and its associated data, if any, from the registry. Under Windows 95, if the key has subkeys, the subkeys and any associated data are also removed. Under Windows NT, subkeys must be explicitly deleted by separate calls to DeleteKey.

DeleteKey returns true if key deletion is successful. On error, DeleteKey returns false.

C++ Examples:

```
/*
This example shows how to use the TRegistry class in order to
find, insert and delete Keys and Items into the Windows Registry.
This example uses two buttons: InsertToRegBtn and DeleteFromRegBtn,
for inserting and deleting the values.
*/
void __fastcall TForm2::InsertToRegBtnClick(TObject *Sender)
{
    TRegistry* reg = new TRegistry(KEY_READ);
    reg->RootKey = HKEY_LOCAL_MACHINE;

    if(!reg->KeyExists("Software\\MyCompanyName\\MyApplication\\"))
    {
        MessageDlg("Key not found! Created now.",
                    mtInformation, TMsgDlgButtons() << mbOK, 0);
    }
    reg->Access = KEY_WRITE;
    bool openResult = reg->OpenKey("Software\\MyCompanyName\\MyApplication\\", true);

    if(!openResult)
    {
        MessageDlg("Unable to create key! Exiting.",
                    mtError, TMsgDlgButtons() << mbOK, 0);
        return;
    }
    //checking if the values exist and inserting when neccesary
```

```
    if(!reg->KeyExists("Creation\ Date"))
    {
        TDateTime today = TDateTime::CurrentDateTime();
        reg->WriteDateTime("Creation\ Date", today);
    }

    if(!reg->KeyExists("Licenced\ To"))
    {
        reg->WriteString("Licenced\ To", "MySurname\ MyFirstName");
    }

    if(!reg->KeyExists("App\ Location"))
    {
        reg->WriteExpandString("App\ Location",
                               "%PROGRAMFILES%\\MyCompanyName\\MyApplication\\");
    }

    if(!reg->KeyExists("Projects\ Location"))
    {
        reg->WriteExpandString("Projects\ Location",
                               "%USERPROFILE%\\MyApplication\\Projects\\");
    }

    reg->CloseKey();
}
//---------------------------------------------------------------------------
void __fastcall TForm2::DelFromRegBtnClick(TObject *Sender)
{
    //deleting the example registry entries
    TRegistry* reg = new TRegistry(KEY_WRITE);
    reg->RootKey = HKEY_LOCAL_MACHINE;

    reg->DeleteKey("Software\\MyCompanyName\\MyApplication");
    reg->DeleteKey("Software\\MyCompanyName");

    reg->CloseKey();
}
//---------------------------------------------------------------------------
```

Delphi Examples:

```
{
This example shows how to use the TRegistry class in order to
find, insert and delete Keys and Items into the Windows Registry.
This example uses two buttons: InsertToRegBtn and DeleteFromRegBtn,
on a form, for inserting and deleting the values.
}
procedure TForm3.InsertToRegBtnClick(Sender: TObject);
var
  reg        : TRegistry;
  openResult : Boolean;
  today      : TDateTime;
begin
  reg := TRegistry.Create(KEY_READ);
  reg.RootKey := HKEY_LOCAL_MACHINE;

  if (not reg.KeyExists('Software\\MyCompanyName\\MyApplication\\')) then
    begin
      MessageDlg('Key not found! Created now.',
                          mtInformation, mbOKCancel, 0);
    end;
  reg.Access := KEY_WRITE;
  openResult := reg.OpenKey('Software\\MyCompanyName\\MyApplication\\',True);

  if not openResult = True then
    begin
      MessageDlg('Unable to create key! Exiting.',
```

```
                    mtError, mbOKCancel, 0);
        Exit();
      end;

    {checking if the values exist and inserting when neccesary}

    if not reg.KeyExists('Creation\ Date') then
      begin
        today := Now;
          reg.WriteDateTime('Creation\ Date', today);
      end;

    if not reg.KeyExists('Licenced\ To') then
      begin
          reg.WriteString('Licenced\ To', 'MySurname\ MyFirstName');
      end;

    if not reg.KeyExists('App\ Location') then
      begin
          reg.WriteExpandString('App\ Location',
                                '%PROGRAMFILES%\\MyCompanyName\\MyApplication\\');
      end;

    if not reg.KeyExists('Projects\ Location') then
      begin
          reg.WriteExpandString('Projects\ Location',
                                '%USERPROFILE%\\MyApplication\\Projects\\');
      end;

    reg.CloseKey();

  end;

  procedure TForm3.DeleteFromRegBtnClick(Sender: TObject);
  var
    reg : TRegistry;
  begin
    reg := TRegistry.Create(KEY_WRITE);
    reg.RootKey := HKEY_LOCAL_MACHINE;

    reg.DeleteKey('Software\\MyCompanyName\\MyApplication');
    reg.DeleteKey('Software\\MyCompanyName');

    reg.CloseKey();
  end;
```

See Also

CreateKey (see page 6622)

DeleteValue (see page 6625)

73.1.3.4.5 TRegistry.DeleteValue Method

Erases a data value that is associated with the current key.

Pascal

```
function DeleteValue(const Name: string): Boolean;
```

C++

```
__fastcall Boolean DeleteValue(const UnicodeString Name);
```

Description

Call DeleteValue to remove a specific data value associated with the current key. Name is string containing the name of the

value to delete. Keys can contain multiple data values, and every value associated with a key has a unique name.

DeleteValue returns true if the deletion is successful, false if the deletion fails.

WriteBinaryData (see page 6645)

WriteBool (see page 6646)

WriteDate (see page 6646)

WriteDateTime (see page 6647)

WriteFloat (see page 6652)

WriteInteger (see page 6653)

WriteString (see page 6653)

WriteTime (see page 6656)

73.1.3.4.6 TRegistry.GetBaseKey Method

Pascal

```
function GetBaseKey(Relative: Boolean): HKey;
```

C++

```
__fastcall HKey GetBaseKey(Boolean Relative);
```

Description

This is GetBaseKey, a member of class TRegistry.

73.1.3.4.7 TRegistry.GetData Method

Pascal

```
function GetData(const Name: string; Buffer: Pointer; BufSize: Integer; var RegData:
TRegDataType): Integer;
```

C++

```
__fastcall int GetData(const UnicodeString Name, void * Buffer, int BufSize, TRegDataType
RegData);
```

Description

This is GetData, a member of class TRegistry.

73.1.3.4.8 TRegistry.GetDataAsString Method

Pascal

```
function GetDataAsString(const ValueName: string; PrefixType: Boolean = false): string;
```

C++

```
__fastcall UnicodeString GetDataAsString(const UnicodeString ValueName, Boolean PrefixType =
false);
```

Description

This is GetDataAsString, a member of class TRegistry.

73.1.3.4.9 TRegistry.GetDataInfo Method

Returns information about a specified data value associated with the current key.

Pascal

```
function GetDataInfo(const ValueName: string; var Value: TRegDataInfo): Boolean;
```

C++

```
__fastcall Boolean GetDataInfo(const UnicodeString ValueName, TRegDataInfo Value);
```

Description

Call GetDataInfo to get information about a data value associated with the current key. ValueName is a string containing the name of the data value to query. Value is a TRegDataInfo (see page 6691) value in which information about the data value is returned. If the data value is of type rdString or rdExpandString, the size of the data value includes an extra byte for the terminating null character.

GetDataInfo returns true if data value information is returned. If GetDataInfo fails, it returns false, and the Value record is filled with zeros.

See Also

CurrentKey (see page 6660)

GetDataSize (see page 6627)

GetDataType (see page 6628)

GetKeyInfo (see page 6628)

73.1.3.4.10 TRegistry.GetDataSize Method

Returns the size, in bytes, of a specified data value associated with the current key.

Pascal

```
function GetDataSize(const ValueName: string): Integer;
```

C++

```
__fastcall int GetDataSize(const UnicodeString ValueName);
```

Description

Call GetDataSize to determine the size, in bytes, of a data value associated with the current key. ValueName is a string containing the name of the data value to query.

On success, GetDataSize returns the size of the data value. On failure, GetDataSize returns -1.

Note: If the data value is a string, GetDataSize returns the size of the data value and one extra byte for the terminating null character.

See Also

CurrentKey (see page 6660)

GetDataInfo (see page 6627)

GetDataType (see page 6628)

GetKeyInfo (see page 6628)

73.1.3.4.11 TRegistry.GetDataType Method

Returns the enumerated data type of a specified data value associated with the current key.

Pascal

```
function GetDataType(const ValueName: string): TRegDataType;
```

C++

```
__fastcall TRegDataType GetDataType(const UnicodeString ValueName);
```

Description

Call GetDataType to determine the data type of a data value associated with the current key. ValueName is a string containing the name of the data value to query.

GetDataType returns a TRegDataType (see page 6691) value that indicates the type of value associated with the current key.

See Also

CurrentKey (see page 6660)

GetDataInfo (see page 6627)

GetDataSize (see page 6627)

GetKeyInfo (see page 6628)

73.1.3.4.12 TRegistry.GetKey Method

Pascal

```
function GetKey(const Key: string): HKEY;
```

C++

```
__fastcall HKEY GetKey(const UnicodeString Key);
```

Description

This is GetKey, a member of class TRegistry.

73.1.3.4.13 TRegistry.GetKeyInfo Method

Returns information about the current key.

Pascal

```
function GetKeyInfo(var Value: TRegKeyInfo): Boolean;
```

C++

```
__fastcall Boolean GetKeyInfo(TRegKeyInfo Value);
```

Description

Call GetKeyInfo to return all information about the current key to an application. Value is a variable declared in an application to store the key information returned by this function.

On success GetKeyInfo returns true. On failure it returns false, and the Value record is set to zeros.

See Also

CurrentKey (see page 6660)

GetKeyNames (see page 6629)

GetValueNames (see page 6629)

HasSubKeys (see page 6630)

73.1.3.4.14 TRegistry.GetKeyNames Method

Returns a string list containing the names of all subkeys belonging to the current key.

Pascal

```
procedure GetKeyNames(Strings: TStrings);
```

C++

```
__fastcall GetKeyNames(TStrings Strings);
```

Description

Call GetKeyNames to determine the names of all subkeys belonging to the current key. Determining the names of subkeys is useful in an application that iterates through a set of keys.

Strings is a variable of type TStrings into which to return the list of subkey names.

See Also

CurrentKey (see page 6660)

GetKeyInfo (see page 6628)

GetValueNames (see page 6629)

73.1.3.4.15 TRegistry.GetValueNames Method

Returns a string list containing the names of all data values associated with the current key.

Pascal

```
procedure GetValueNames(Strings: TStrings);
```

C++

```
__fastcall GetValueNames(TStrings Strings);
```

Description

Call GetValueNames to determine the names of all data values associated with the current key. Determining the names of data values is useful in an application that iterates through a set of data values for a key.

Strings is a variable of type TStrings into which to return the list of data value names.

See Also

CurrentKey (see page 6660)

GetDataInfo (see page 6627)

GetKeyNames (see page 6629)

ValueExists (see page 6645)

73.1.3.4.16 TRegistry.HasSubKeys Method

Determines if the current key has subkeys.

Pascal

```
function HasSubKeys: Boolean;
```

C++

```
__fastcall Boolean HasSubKeys();
```

Description

Call HasSubKeys to determine if the current key has any subkeys. HasSubKeys returns true if the current key has at least one subkey. Otherwise it returns false.

See Also

CurrentKey (see page 6660)

KeyExists (see page 6630)

73.1.3.4.17 TRegistry.KeyExists Method

Determines if a specified key exists.

Pascal

```
function KeyExists(const Key: string): Boolean;
```

C++

```
__fastcall Boolean KeyExists(const UnicodeString Key);
```

Description

Call KeyExists to determine if a key of a specified name exists. Key is the name of the key for which to search.

C++ Examples:

```
/*
This example shows how to use the TRegistry class in order to
find, insert and delete Keys and Items into the Windows Registry.
This example uses two buttons: InsertToRegBtn and DeleteFromRegBtn,
for inserting and deleting the values.
*/
void __fastcall TForm2::InsertToRegBtnClick(TObject *Sender)
{
    TRegistry* reg = new TRegistry(KEY_READ);
    reg->RootKey = HKEY_LOCAL_MACHINE;

    if(!reg->KeyExists("Software\\MyCompanyName\\MyApplication\\"))
    {
        MessageDlg("Key not found! Created now.",
                   mtInformation, TMsgDlgButtons() << mbOK, 0);
    }
    reg->Access = KEY_WRITE;
    bool openResult = reg->OpenKey("Software\\MyCompanyName\\MyApplication\\", true);

    if(!openResult)
    {
        MessageDlg("Unable to create key! Exiting.",
                   mtError, TMsgDlgButtons() << mbOK, 0);
        return;
    }
```

```
    //checking if the values exist and inserting when neccesary

    if(!reg->KeyExists("Creation\ Date"))
    {
        TDateTime today = TDateTime::CurrentDateTime();
        reg->WriteDateTime("Creation\ Date", today);
    }

    if(!reg->KeyExists("Licenced\ To"))
    {
        reg->WriteString("Licenced\ To", "MySurname\ MyFirstName");
    }

    if(!reg->KeyExists("App\ Location"))
    {
        reg->WriteExpandString("App\ Location",
                               "%PROGRAMFILES%\\MyCompanyName\\MyApplication\\");
    }

    if(!reg->KeyExists("Projects\ Location"))
    {
        reg->WriteExpandString("Projects\ Location",
                               "%USERPROFILE%\\MyApplication\\Projects\\");
    }

    reg->CloseKey();
}
//---------------------------------------------------------------------------
void __fastcall TForm2::DelFromRegBtnClick(TObject *Sender)
{
    //deleting the example registry entries
    TRegistry* reg = new TRegistry(KEY_WRITE);
    reg->RootKey = HKEY_LOCAL_MACHINE;

    reg->DeleteKey("Software\\MyCompanyName\\MyApplication");
    reg->DeleteKey("Software\\MyCompanyName");

    reg->CloseKey();
}
//---------------------------------------------------------------------------
```

Delphi Examples:

```
{
This example shows how to use the TRegistry class in order to
find, insert and delete Keys and Items into the Windows Registry.
This example uses two buttons: InsertToRegBtn and DeleteFromRegBtn,
on a form, for inserting and deleting the values.
}
procedure TForm3.InsertToRegBtnClick(Sender: TObject);
var
  reg        : TRegistry;
  openResult : Boolean;
  today      : TDateTime;
begin
  reg := TRegistry.Create(KEY_READ);
  reg.RootKey := HKEY_LOCAL_MACHINE;

  if (not reg.KeyExists('Software\\MyCompanyName\\MyApplication\\')) then
    begin
      MessageDlg('Key not found! Created now.',
                          mtInformation, mbOKCancel, 0);
    end;
  reg.Access := KEY_WRITE;
  openResult := reg.OpenKey('Software\\MyCompanyName\\MyApplication\\',True);

  if not openResult = True then
```

```
      begin
        MessageDlg('Unable to create key! Exiting.',
                   mtError, mbOKCancel, 0);
        Exit();
      end;

    {checking if the values exist and inserting when neccesary}

    if not reg.KeyExists('Creation\ Date') then
      begin
        today := Now;
          reg.WriteDateTime('Creation\ Date', today);
      end;

    if not reg.KeyExists('Licenced\ To') then
      begin
          reg.WriteString('Licenced\ To', 'MySurname\ MyFirstName');
      end;

    if not reg.KeyExists('App\ Location') then
      begin
          reg.WriteExpandString('App\ Location',
                                '%PROGRAMFILES%\\MyCompanyName\\MyApplication\\');
      end;

    if not reg.KeyExists('Projects\ Location') then
      begin
          reg.WriteExpandString('Projects\ Location',
                                '%USERPROFILE%\\MyApplication\\Projects\\');
      end;

    reg.CloseKey();

  end;

  procedure TForm3.DeleteFromRegBtnClick(Sender: TObject);
  var
    reg : TRegistry;
  begin
    reg := TRegistry.Create(KEY_WRITE);
    reg.RootKey := HKEY_LOCAL_MACHINE;

    reg.DeleteKey('Software\\MyCompanyName\\MyApplication');
    reg.DeleteKey('Software\\MyCompanyName');

    reg.CloseKey();
  end;
```

See Also

LoadKey (see page 6632)

ValueExists (see page 6645)

73.1.3.4.18 TRegistry.LoadKey Method

Creates a subkey under the root key and loads registry information from a file into the newly created subkey.

Pascal

```
function LoadKey(const Key: string; const FileName: string): Boolean;
```

C++

```
__fastcall Boolean LoadKey(const UnicodeString Key, const UnicodeString FileName);
```

Description

Call LoadKey to:

1Create (see page 6615) a new subkey under the root key, and

2Load registry information from a file into the subkey. Registry (see page 6599) information can include data values, subkeys, and data values for those subkeys.

LoadKey is intended to simplify creation of a key, its values and subkeys, and the values for those subkeys in a single operation. A key, its subkeys, and all data values of the key and its subkeys is called a hive. Rather than creating each key and value separately, an application can read a hive from a file. This is especially useful for applications that users can reconfigure at run time.

Note: Before an application calls LoadKey, the RootKey (see page 6661) property must be set to HKEY_USERS, HKEY_LOCAL_MACHINE, or to a key returned by a previous call to RegistryConnect (see page 6641).

The Key parameter is the name of the subkey to create. The FileName parameter is the location of the file containing registry information to store in the subkey. The file specified by FileName must be one previously created using the SaveKey (see page 6643) function or the RegSaveKey Windows API function. On systems that use a file allocation table (FAT), FileName cannot include an extension.

See Also

RootKey (see page 6661)

CreateKey (see page 6622)

RegistryConnect (see page 6641)

SaveKey (see page 6643)

UnLoadKey (see page 6644)

73.1.3.4.19 TRegistry.MoveKey Method

Moves an existing key, its subkeys, and data values to a new location using a new key name.

Pascal

```
procedure MoveKey(const OldName: string; const NewName: string; Delete: Boolean);
```

C++

```
__fastcall MoveKey(const UnicodeString OldName, const UnicodeString NewName, Boolean Delete);
```

Description

Call MoveKey to copy or move an existing key, its subkeys, and data values to a different location. Under Windows 95, copying is recursive. If a key contains subkeys and data values, they too, are copied. When the operation is complete, the new key is closed. Under Windows NT, subkeys must be moved explicitly with separate calls to MoveKey.

OldName specifies the key to copy or move. NewName specifies a name for the duplicate key to create. If the key specified by NewName does not exist, MoveKey creates it. Delete specifies whether to delete the old key after the copy operation. If Delete is true, the key specified by OldName is deleted after it is copied. Otherwise the old key is closed.

See Also

CreateKey (see page 6622)

DeleteKey (see page 6623)

OpenKey (see page 6634)

OpenKey (see page 6634)

73.1.3.4.20 TRegistry.OpenKey Method

Opens a specified key.

Pascal

```
function OpenKey(const Key: string; CanCreate: Boolean): Boolean;
```

C++

```
__fastcall Boolean OpenKey(const UnicodeString Key, Boolean CanCreate);
```

Description

Call OpenKey to make a specified key the current key. Key is the name of the key to open. If Key is nil (Delphi) or NULL (C++), the CurrentKey (see page 6660) property is set to the key specified by the RootKey (see page 6661) property.

CanCreate specifies whether to create the specified key if it does not exist. If CanCreate is true, the key is created if necessary.

Key is opened or created with the security access value specified by the Access (see page 6657) property. OpenKey only creates non-volatile keys, A non-volatile key is stored in the registry and is preserved when the system is restarted.

OpenKey returns true if the key is successfully opened or created

C++ Examples:

```
/*
This example shows how to use the TRegistry class in order to
find, insert and delete Keys and Items into the Windows Registry.
This example uses two buttons: InsertToRegBtn and DeleteFromRegBtn,
for inserting and deleting the values.
*/
void __fastcall TForm2::InsertToRegBtnClick(TObject *Sender)
{
    TRegistry* reg = new TRegistry(KEY_READ);
    reg->RootKey = HKEY_LOCAL_MACHINE;

    if(!reg->KeyExists("Software\\MyCompanyName\\MyApplication\\"))
    {
        MessageDlg("Key not found! Created now.",
                   mtInformation, TMsgDlgButtons() << mbOK, 0);
    }
    reg->Access = KEY_WRITE;
    bool openResult = reg->OpenKey("Software\\MyCompanyName\\MyApplication\\", true);

    if(!openResult)
    {
        MessageDlg("Unable to create key! Exiting.",
                   mtError, TMsgDlgButtons() << mbOK, 0);
        return;
    }
    //checking if the values exist and inserting when neccesary

    if(!reg->KeyExists("Creation\ Date"))
    {
        TDateTime today = TDateTime::CurrentDateTime();
        reg->WriteDateTime("Creation\ Date", today);
    }

    if(!reg->KeyExists("Licenced\ To"))
    {
        reg->WriteString("Licenced\ To", "MySurname\ MyFirstName");
    }
```

```
    if(!reg->KeyExists("App\ Location"))
    {
        reg->WriteExpandString("App\ Location",
                               "%PROGRAMFILES%\\MyCompanyName\\MyApplication\\");
    }

    if(!reg->KeyExists("Projects\ Location"))
    {
        reg->WriteExpandString("Projects\ Location",
                               "%USERPROFILE%\\MyApplication\\Projects\\");
    }

    reg->CloseKey();
}
//---------------------------------------------------------------------------
void __fastcall TForm2::DelFromRegBtnClick(TObject *Sender)
{
    //deleting the example registry entries
    TRegistry* reg = new TRegistry(KEY_WRITE);
    reg->RootKey = HKEY_LOCAL_MACHINE;

    reg->DeleteKey("Software\\MyCompanyName\\MyApplication");
    reg->DeleteKey("Software\\MyCompanyName");

    reg->CloseKey();
}
//---------------------------------------------------------------------------
```

Delphi Examples:

```
{
This example shows how to use the TRegistry class in order to
find, insert and delete Keys and Items into the Windows Registry.
This example uses two buttons: InsertToRegBtn and DeleteFromRegBtn,
on a form, for inserting and deleting the values.
}
procedure TForm3.InsertToRegBtnClick(Sender: TObject);
var
  reg        : TRegistry;
  openResult : Boolean;
  today      : TDateTime;
begin
  reg := TRegistry.Create(KEY_READ);
  reg.RootKey := HKEY_LOCAL_MACHINE;

  if (not reg.KeyExists('Software\\MyCompanyName\\MyApplication\\')) then
    begin
      MessageDlg('Key not found! Created now.',
                          mtInformation, mbOKCancel, 0);
    end;
  reg.Access := KEY_WRITE;
  openResult := reg.OpenKey('Software\\MyCompanyName\\MyApplication\\',True);

  if not openResult = True then
    begin
      MessageDlg('Unable to create key! Exiting.',
                 mtError, mbOKCancel, 0);
      Exit();
    end;

  {checking if the values exist and inserting when neccesary}

  if not reg.KeyExists('Creation\ Date') then
    begin
      today := Now;
        reg.WriteDateTime('Creation\ Date', today);
    end;
```

```
    if not reg.KeyExists('Licenced\ To') then
      begin
          reg.WriteString('Licenced\ To', 'MySurname\ MyFirstName');
      end;

    if not reg.KeyExists('App\ Location') then
      begin
          reg.WriteExpandString('App\ Location',
                                '%PROGRAMFILES%\\MyCompanyName\\MyApplication\\');
      end;

    if not reg.KeyExists('Projects\ Location') then
      begin
          reg.WriteExpandString('Projects\ Location',
                                '%USERPROFILE%\\MyApplication\\Projects\\');
      end;

    reg.CloseKey();

  end;

  procedure TForm3.DeleteFromRegBtnClick(Sender: TObject);
  var
    reg : TRegistry;
  begin
    reg := TRegistry.Create(KEY_WRITE);
    reg.RootKey := HKEY_LOCAL_MACHINE;

    reg.DeleteKey('Software\\MyCompanyName\\MyApplication');
    reg.DeleteKey('Software\\MyCompanyName');

    reg.CloseKey();
  end;
```

CreateKey (see page 6622)

OpenKeyReadOnly (see page 6636)

Access (see page 6657)

73.1.3.4.21 TRegistry.OpenKeyReadOnly Method

Opens a specified key in a read-only manner.

Pascal

```
function OpenKeyReadOnly(const Key: String): Boolean;
```

C++

```
__fastcall Boolean OpenKeyReadOnly(const UnicodeString Key);
```

Description

Call OpenKeyReadOnly to make a specified key the current key. Key is the name of the key to open. If Key is nil (Delphi) or NULL (C++), the CurrentKey (see page 6660) property is set to the key specified by the RootKey (see page 6661) property.

Key is opened with the security access value KEY_READ.

OpenKey (see page 6634) returns true if the key is successfully opened and CurrentKey (see page 6660) is set to the key.

Note: After a successful call to OpenKeyReadOnly the Access (see page 6657) property of the registry component is automatically changed to KEY_READ, regardless of what that property was set to prior to the method call.

See Also

CurrentKey (see page 6660)

CreateKey (see page 6622)

OpenKey (see page 6634)

Access (see page 6657)

73.1.3.4.22 TRegistry.PutData Method

Pascal

```
procedure PutData(const Name: string; Buffer: Pointer; BufSize: Integer; RegData:
TRegDataType);
```

C++

```
__fastcall PutData(const UnicodeString Name, void * Buffer, int BufSize, TRegDataType RegData);
```

Description

This is PutData, a member of class TRegistry.

73.1.3.4.23 TRegistry.ReadBinaryData Method

Retrieves a binary value from a specified data value associated with the current key.

Pascal

```
function ReadBinaryData(const Name: string; var Buffer; BufSize: Integer): Integer;
```

C++

```
__fastcall int ReadBinaryData(const UnicodeString Name,  Buffer, int BufSize);
```

Description

Call ReadBinaryData to read a binary value from a specified data value associated with the current key. Name is the name of the data value to read. Buffer is the application variable into which to read the registry data. Buffer must be large enough to hold all of the data returned. BufSize specifies the size of Buffer.

If successful, ReadBinaryData writes the requested data into Buffer and returns the number of bytes written. If the Registry (see page 6599) entry contains a known type (such as a string), ReadBinaryData raises an exception.

Note: Binary data is typically a complex data structure (a record in Delphi or struct in C++). It might also be an icon or a bitmap although Microsoft recommends against storing graphics objects in the registry for performance reasons.

ReadInteger (see page 6640)

ReadString (see page 6640)

ReadTime (see page 6641)

73.1.3.4.24 TRegistry.ReadBool Method

Retrieves a Boolean value from a specified data value associated with the current key.

Pascal

```
function ReadBool(const Name: string): Boolean;
```

C++

```
__fastcall Boolean ReadBool(const UnicodeString Name);
```

Description

Call ReadBool to read a Boolean value from a specified data value associated with the current key. Name is the name of the data value to read.

If successful, ReadBool returns the requested Boolean value. If the Registry (see page 6599) entry does not contain a boolean or integer value, an exception is raised.

See Also

CurrentKey (see page 6660)

WriteBool (see page 6646)

73.1.3.4.25 TRegistry.ReadCurrency Method

Retrieves a currency value from a specified data value associated with the current key.

Pascal

```
function ReadCurrency(const Name: string): Currency;
```

C++

```
__fastcall Currency ReadCurrency(const UnicodeString Name);
```

Description

Call ReadCurrency to read a Currency value from a specified data value associated with the current key. Name is the name of the data value to read.

If successful, ReadCurrency returns a Currency value. If the Registry (see page 6599) entry does not contain a Currency value, an exception is raised.

See Also

CurrentKey (see page 6660)

WriteCurrency (see page 6646)

73.1.3.4.26 TRegistry.ReadDate Method

Retrieves a date value from a specified data value associated with the current key.

Pascal

```
function ReadDate(const Name: string): TDateTime;
```

C++

```
__fastcall TDateTime ReadDate(const UnicodeString Name);
```

Description

Call ReadDate to read a date value from a specified data value associated with the current key. Name is the name of the data value to read.

If successful, ReadDate returns a TDateTime value. The integral part of a TDateTime value is the number of days that have passed since 12/30/1899. The fractional part of a TDateTime value is the time of day.

If the Registry (see page 6599) entry does not contain a date or time value, an exception is raised.

Note: Only use ReadDate to read data values previously stored with the WriteDate (see page 6646) procedure.

See Also

CurrentKey (see page 6660)

WriteDate (see page 6646)

ReadDateTime (see page 6639)

73.1.3.4.27 TRegistry.ReadDateTime Method

Retrieves a date and time value from a specified data value associated with the current key.

Pascal

```
function ReadDateTime(const Name: string): TDateTime;
```

C++

```
__fastcall TDateTime ReadDateTime(const UnicodeString Name);
```

Description

Call ReadDateTime to read a datetime value from a specified data value associated with the current key. Name is the name of the data value to read.

If successful, ReadDateTime returns a TDateTime value. The integral part of a TDateTime value is the number of days that have passed since 12/30/1899. The fractional part of a TDateTime value is the time of day.

If the Registry (see page 6599) entry does not contain a date or time value, an exception is raised.

See Also

CurrentKey (see page 6660)

WriteDateTime (see page 6647)

ReadDate (see page 6638)

ReadTime (see page 6641)

73.1.3.4.28 TRegistry.ReadFloat Method

Retrieves a float value from a specified data value associated with the current key.

Pascal

```
function ReadFloat(const Name: string): Double;
```

C++

```
__fastcall Double ReadFloat(const UnicodeString Name);
```

Description

Call ReadFloat to read a float value from a specified data value associated with the current key. Name is the name of the data value to read.

If the Registry (see page 6599) entry does not contain a floating-point value, an exception is raised.

See Also

CurrentKey (see page 6660)

WriteFloat (see page 6652)

73.1.3.4.29 TRegistry.ReadInteger Method

Retrieves an integer value from a specified data value associated with the current key.

Pascal

```
function ReadInteger(const Name: string): Integer;
```

C++

```
__fastcall int ReadInteger(const UnicodeString Name);
```

Description

Call ReadInteger to read an integer value from a specified data value associated with the current key. Name is the name of the data value to read.

If the Registry (see page 6599) entry does not contain an integer, an exception is raised.

See Also

CurrentKey (see page 6660)

WriteInteger (see page 6653)

73.1.3.4.30 TRegistry.ReadString Method

Retrieves a string value from a specified data value associated with the current key.

Pascal

```
function ReadString(const Name: string): string;
```

C++

```
__fastcall UnicodeString ReadString(const UnicodeString Name);
```

Description

Call ReadString to read a string value from a specified data value associated with the current key. Name is the name of the data value to read.

If there is no Registry (see page 6599) entry with the specified name, ReadString returns an empty string. If the Registry (see page 6599) entry contains something other than a string, an exception is raised.

Note: ReadString retrieves data stored by either the WriteString (see page 6653) or WriteExpandString (see page 6650)

method.

See Also

CurrentKey (see page 6660)

WriteString (see page 6653)

WriteExpandString (see page 6650)

73.1.3.4.31 TRegistry.ReadTime Method

Retrieves a time value from a specified data value associated with the current key.

Pascal

```
function ReadTime(const Name: string): TDateTime;
```

C++

```
__fastcall TDateTime ReadTime(const UnicodeString Name);
```

Description

Call ReadTime to read a time value from a specified data value associated with the current key. Name is the name of the data value to read.

If successful, ReadTime returns a TDateTime value. The integral part of a TDateTime value is the number of days that have passed since 12/30/1899. The fractional part of a TDateTime value is the time of day.

If the specified Registry (see page 6599) entry does not contain a date or time value, an exception is raised.

Note: Only use ReadTime to read data values previously stored with the WriteTime (see page 6656) method.

See Also

CurrentKey (see page 6660)

WriteTime (see page 6656)

ReadDateTime (see page 6639)

73.1.3.4.32 TRegistry.RegistryConnect Method

Establishes a connection to a registry on another computer.

Pascal

```
function RegistryConnect(const UNCName: string): Boolean;
```

C++

```
__fastcall Boolean RegistryConnect(const UnicodeString UNCName);
```

Description

Call RegistryConnect to establish a connection to a registry on another computer running Windows 95 or Windows NT. UNCName is the name of the remote computer, and must take the following form:

```
\\computername
```

where computername is the name of the remote computer. If UNCName is nil (Delphi) or NULL (C++), the local machine name is used.

Note: Before calling RegistryConnect, an application must set the RootKey (see page 6661) property for its registry object to HKEY_USERS or HKEY_LOCAL_MACHINE.

If connection is successful, RegistryConnect sets the RootKey (see page 6661) property to the root key of the remote computer and returns true. If unsuccessful, RegistryConnect returns false, and RootKey (see page 6661) remains unchanged.

See Also

RootKey (see page 6661)

LoadKey (see page 6632)

ReplaceKey (see page 6642)

RestoreKey (see page 6643)

SaveKey (see page 6643)

73.1.3.4.33 TRegistry.RenameValue Method

Changes the name of a data value associated with the current key.

Pascal

```
procedure RenameValue(const OldName: string; const NewName: string);
```

C++

```
__fastcall RenameValue(const UnicodeString OldName, const UnicodeString NewName);
```

Description

Call RenameValue to change the name of a data value associated with the current key. OldName is a string containing the current name of the data value. NewName is a string containing the replacement name for the data value.

If OldName is the name of an existing data value for the current key, and NewName is not the name of an existing data value for the current key, RenameValue changes the data value name as specified. Otherwise the current name remains unchanged.

CurrentKey (see page 6660)

GetValueNames (see page 6629)

ValueExists (see page 6645)

MoveKey (see page 6633)

73.1.3.4.34 TRegistry.ReplaceKey Method

Replaces the hive file backing a key and all its subkeys with a hive stored in a different file, so that when the system is next started, the key and subkeys will have the values stored in the new file.

Pascal

```
function ReplaceKey(const Key: string; const FileName: string; const BackUpFileName: string):
Boolean;
```

C++

```
__fastcall Boolean ReplaceKey(const UnicodeString Key, const UnicodeString FileName, const
UnicodeString BackUpFileName);
```

Description

Call ReplaceKey to replace the hive file backing a key and all its subkeys with a different hive file. A hive is a discrete collection of keys, subkeys, and values that is rooted at the top of the registry hierarchy.

FileName indicates the name of the file containing the new key and subkey information. BackUpFileName is the name of a

backup file used to store the current key and subkey information before it is overwritten.

ReplaceKey returns true if it is successful.

Note: The file specified by FileName parameter must be created with the SaveKey (see page 6643) function, or by directly calling the Windows 95/NT RegSaveKey API function. Under the FAT file system FileName cannot have an extension.

See Also

LoadKey (see page 6632)

RestoreKey (see page 6643)

SaveKey (see page 6643)

73.1.3.4.35 TRegistry.RestoreKey Method

Reopens the specified key, and overwrites any information contained in this key and its subkeys keys with registry data stored in a hive file.

Pascal

```
function RestoreKey(const Key: string; const FileName: string): Boolean;
```

C++

```
__fastcall Boolean RestoreKey(const UnicodeString Key, const UnicodeString FileName);
```

Description

Call RestoreKey to open the specified key with a security access value of KEY_ALL_ACCESS and overwrite any information in the key and its subkeys with registry data stored in a hive file. A hive is a discrete collection of keys, subkeys, and values that is rooted at the top of the registry hierarchy.

Key is the name of the key to open. FileName is the name of the file containing the hive information.

If RestoreKey successfully reads and copies the registry information in FileName to the specified key, the return value of RestoreKey is true and the key is closed.

Note: The file specified by FileName parameter must be created with the SaveKey (see page 6643) function, or by directly calling the Windows 95/NT RegSaveKey API function. Under the FAT file system FileName cannot have an extension.

See Also

LoadKey (see page 6632)

ReplaceKey (see page 6642)

RegistryConnect (see page 6641)

SaveKey (see page 6643)

73.1.3.4.36 TRegistry.SaveKey Method

Opens the specified key with the security access value KEY_ALL_ACCESS and saves the specified key and all of its subkeys and values to a hive file.

Pascal

```
function SaveKey(const Key: string; const FileName: string): Boolean;
```

C++

```
__fastcall Boolean SaveKey(const UnicodeString Key, const UnicodeString FileName);
```

Description

Call SaveKey to open a key with a security access value of KEY_ALL_ACCESS, and save the key and its subkeys and data values to a hive file. A hive is a discrete collection of keys, subkeys, and values that is rooted at the top of the registry hierarchy.

Key is the key to save. FileName is the file into which to save the key information. It must be the name of a new file that does not already exist. On FAT file systems FileName cannot include an extension.

Files created by SaveKey are passed as parameters to the RestoreKey (see page 6643), ReplaceKey (see page 6642) and LoadKey (see page 6632) functions.

If SaveKey is successful it returns true and closes the key.

See Also

LoadKey (see page 6632)

ReplaceKey (see page 6642)

RestoreKey (see page 6643)

73.1.3.4.37 TRegistry.SetCurrentKey Method

Pascal

```
procedure SetCurrentKey(Value: HKEY);
```

C++

```
__fastcall SetCurrentKey(HKEY Value);
```

Description

This is SetCurrentKey, a member of class TRegistry.

73.1.3.4.38 TRegistry.UnLoadKey Method

Removes a hive from the registry.

Pascal

```
function UnLoadKey(const Key: string): Boolean;
```

C++

```
__fastcall Boolean UnLoadKey(const UnicodeString Key);
```

Description

Call UnLoadKey to remove a hive from the registry without modifying its associated hive file, if any. A hive is a discrete collection of keys, subkeys, and values that is rooted at the top of the registry hierarchy.

Key is the name of the key at the root of the hive to remove.

If successful, UnLoadKey returns true.

Note: Before calling this function, set RootKey (see page 6661) to HKEY_USERS, HKEY_LOCAL_MACHINE, or call RegistryConnect (see page 6641).

See Also

RootKey (see page 6661)

LoadKey (see page 6632)

ReplaceKey (see page 6642)

RestoreKey (see page 6643)

SaveKey (see page 6643)

73.1.3.4.39 TRegistry.ValueExists Method

Determines if a specified data value exists for the current key.

Pascal

```
function ValueExists(const Name: string): Boolean;
```

C++

```
__fastcall Boolean ValueExists(const UnicodeString Name);
```

Description

Call ValueExists to determine if a particular data item exists in the registry. Calling ValueExists is especially useful before calling other TRegistry (see page 6610) methods that operate only on existing data items.

Name is the name of the data value for which to check.

ValueExists returns true if a match if found, false otherwise.

See Also

CurrentKey (see page 6660)

KeyExists (see page 6630)

73.1.3.4.40 TRegistry.WriteBinaryData Method

Stores a specifically named data value associated with the current key.

Pascal

```
procedure WriteBinaryData(const Name: string; var Buffer; BufSize: Integer);
```

C++

```
__fastcall WriteBinaryData(const UnicodeString Name,  Buffer, int BufSize);
```

Description

Call WriteBinaryData to store a data value associated with the current key.

Name is a string containing the name of the data value in which to store data. If Name already exists, its current value is overwritten by WriteBinary. If Name does not exist, it is created.

Buffer is a data buffer containing the data to store in the registry. BufSize indicates the size of Buffer.

Note: Data-value lengths are limited by available memory. Long values (more than 2048 bytes) should be stored as separate files, and those file names should be stored in the registry. Application elements such as icons, bitmaps, and executable files should be stored as separate files rather than as values in the registry.

If WriteBinaryData fails, an exception is raised, and the value is not written to the registry.

See Also

CurrentKey (see page 6660)

ReadBinaryData (see page 6637)

73.1.3.4.41 TRegistry.WriteBool Method

Stores a Boolean value in a specifically named data value associated with the current key.

Pascal

```
procedure WriteBool(const Name: string; Value: Boolean);
```

C++

```
__fastcall WriteBool(const UnicodeString Name, Boolean Value);
```

Description

Call WriteBool to store a boolean value in a data value associated with the current key.

Name is a string containing the name of the data value in which to store data. If Name already exists, its current value is overwritten by WriteBool. If Name does not exist, it is created.

If WriteBool fails, an exception is raised, and the value is not written to the registry.

See Also

CurrentKey (see page 6660)

ReadBool (see page 6638)

73.1.3.4.42 TRegistry.WriteCurrency Method

Stores a currency value in a specifically named data value associated with the current key.

Pascal

```
procedure WriteCurrency(const Name: string; Value: Currency);
```

C++

```
__fastcall WriteCurrency(const UnicodeString Name, Currency Value);
```

Description

Call WriteCurrency to store a Currency value in a data value associated with the current key.

Name is a string containing the name of the data value in which to store data. If Name already exists, its current value is overwritten by WriteCurrency. If Name does not exist, it is created.

Value is a Currency value to store in the registry.

If WriteCurrency fails, an exception is raised, and the value is not written to the registry.

See Also

CurrentKey (see page 6660)

ReadCurrency (see page 6638)

73.1.3.4.43 TRegistry.WriteDate Method

Stores a date value in a specifically named data value associated with the current key.

Pascal

```
procedure WriteDate(const Name: string; Value: TDateTime);
```

C++

```
__fastcall WriteDate(const UnicodeString Name, TDateTime Value);
```

Description

Call WriteDate to store a datetime value in a data value associated with the current key.

Name is a string containing the name of the data value in which to store data. If Name already exists, its current value is overwritten by WriteDate. If Name does not exist, it is created.

Value is a datetime value to store in the registry.

If WriteDate fails, an exception is raised, and the value is not written to the registry.

If successful, WriteDate stores a TDateTime value. The integral part of a TDateTime value is the number of days that have passed since 12/30/1899. The fractional part of a TDateTime value is the time of day.

See Also

CurrentKey (see page 6660)

ReadDate (see page 6638)

WriteDateTime (see page 6647)

73.1.3.4.44 TRegistry.WriteDateTime Method

Stores a datetime value in a specifically named data value associated with the current key.

Pascal

```
procedure WriteDateTime(const Name: string; Value: TDateTime);
```

C++

```
__fastcall WriteDateTime(const UnicodeString Name, TDateTime Value);
```

Description

Call WriteDateTime to store a datetime value in a data value associated with the current key.

Name is a string containing the name of the data value in which to store data. If Name already exists, its current value is overwritten by WriteDateTime. If Name does not exist, it is created.

Value is a datetime value to store in the registry.

If WriteDateTime fails, an exception is raised, and the value is not written to the registry.

If successful, WriteDateTime stores a TDateTime value. The integral part of a TDateTime value is the number of days that have passed since 12/30/1899. The fractional part of a TDateTime value is the time of day.

C++ Examples:

```
/*
This example shows how to use the TRegistry class in order to
find, insert and delete Keys and Items into the Windows Registry.
This example uses two buttons: InsertToRegBtn and DeleteFromRegBtn,
for inserting and deleting the values.
*/
void __fastcall TForm2::InsertToRegBtnClick(TObject *Sender)
{
    TRegistry* reg = new TRegistry(KEY_READ);
    reg->RootKey = HKEY_LOCAL_MACHINE;

    if(!reg->KeyExists("Software\\MyCompanyName\\MyApplication\\"))
    {
```

```
        MessageDlg("Key not found! Created now.",
                   mtInformation, TMsgDlgButtons() << mbOK, 0);
    }
    reg->Access = KEY_WRITE;
    bool openResult = reg->OpenKey("Software\\MyCompanyName\\MyApplication\\", true);

    if(!openResult)
    {
        MessageDlg("Unable to create key! Exiting.",
                   mtError, TMsgDlgButtons() << mbOK, 0);
        return;
    }
    //checking if the values exist and inserting when neccesary

    if(!reg->KeyExists("Creation\ Date"))
    {
        TDateTime today = TDateTime::CurrentDateTime();
        reg->WriteDateTime("Creation\ Date", today);
    }

    if(!reg->KeyExists("Licenced\ To"))
    {
        reg->WriteString("Licenced\ To", "MySurname\ MyFirstName");
    }

    if(!reg->KeyExists("App\ Location"))
    {
        reg->WriteExpandString("App\ Location",
                               "%PROGRAMFILES%\\MyCompanyName\\MyApplication\\");
    }

    if(!reg->KeyExists("Projects\ Location"))
    {
        reg->WriteExpandString("Projects\ Location",
                               "%USERPROFILE%\\MyApplication\\Projects\\");
    }

    reg->CloseKey();
}
//---------------------------------------------------------------------------
void __fastcall TForm2::DelFromRegBtnClick(TObject *Sender)
{
    //deleting the example registry entries
    TRegistry* reg = new TRegistry(KEY_WRITE);
    reg->RootKey = HKEY_LOCAL_MACHINE;

    reg->DeleteKey("Software\\MyCompanyName\\MyApplication");
    reg->DeleteKey("Software\\MyCompanyName");

    reg->CloseKey();
}
//---------------------------------------------------------------------------
```

Delphi Examples:

```
{
This example shows how to use the TRegistry class in order to
find, insert and delete Keys and Items into the Windows Registry.
This example uses two buttons: InsertToRegBtn and DeleteFromRegBtn,
on a form, for inserting and deleting the values.
}
procedure TForm3.InsertToRegBtnClick(Sender: TObject);
var
  reg        : TRegistry;
  openResult : Boolean;
  today      : TDateTime;
begin
```

```
    reg := TRegistry.Create(KEY_READ);
    reg.RootKey := HKEY_LOCAL_MACHINE;

    if (not reg.KeyExists('Software\\MyCompanyName\\MyApplication\\')) then
      begin
        MessageDlg('Key not found! Created now.',
                               mtInformation, mbOKCancel, 0);
      end;
    reg.Access := KEY_WRITE;
    openResult := reg.OpenKey('Software\\MyCompanyName\\MyApplication\\',True);

    if not openResult = True then
      begin
        MessageDlg('Unable to create key! Exiting.',
                    mtError, mbOKCancel, 0);
        Exit();
      end;

    {checking if the values exist and inserting when neccesary}

    if not reg.KeyExists('Creation\ Date') then
      begin
        today := Now;
          reg.WriteDateTime('Creation\ Date', today);
      end;

    if not reg.KeyExists('Licenced\ To') then
      begin
          reg.WriteString('Licenced\ To', 'MySurname\ MyFirstName');
      end;

    if not reg.KeyExists('App\ Location') then
      begin
          reg.WriteExpandString('App\ Location',
                                '%PROGRAMFILES%\\MyCompanyName\\MyApplication\\');
      end;

    if not reg.KeyExists('Projects\ Location') then
      begin
          reg.WriteExpandString('Projects\ Location',
                                '%USERPROFILE%\\MyApplication\\Projects\\');
      end;

    reg.CloseKey();

  end;

  procedure TForm3.DeleteFromRegBtnClick(Sender: TObject);
  var
    reg : TRegistry;
  begin
    reg := TRegistry.Create(KEY_WRITE);
    reg.RootKey := HKEY_LOCAL_MACHINE;

    reg.DeleteKey('Software\\MyCompanyName\\MyApplication');
    reg.DeleteKey('Software\\MyCompanyName');

    reg.CloseKey();
  end;
```

73.1.3.4.45 TRegistry.WriteExpandString Method

Stores a string containing unexpanded references to environment variables in a specifically named data value associated with the current key.

Pascal

```
procedure WriteExpandString(const Name: string; const Value: string);
```

C++

```
__fastcall WriteExpandString(const UnicodeString Name, const UnicodeString Value);
```

Description

Call WriteExpandString to store a string that contains unexpanded references to environment variables such as "%PATH%". The string is stored in a data value associated with the current key.

Name is a string containing the name of the data value in which to store data. If Name already exists, its current value is overwritten by WriteExpandString. If Name does not exist, it is created.

Value is a string value to store in the registry.

If WriteExpandString fails, an exception is raised.

Note: To write strings that do not contain unexpanded environment variables, use WriteString (see page 6653) instead.

C++ Examples:

```
/*
This example shows how to use the TRegistry class in order to
find, insert and delete Keys and Items into the Windows Registry.
This example uses two buttons: InsertToRegBtn and DeleteFromRegBtn,
for inserting and deleting the values.
*/
void __fastcall TForm2::InsertToRegBtnClick(TObject *Sender)
{
    TRegistry* reg = new TRegistry(KEY_READ);
    reg->RootKey = HKEY_LOCAL_MACHINE;

    if(!reg->KeyExists("Software\\MyCompanyName\\MyApplication\\"))
    {
        MessageDlg("Key not found! Created now.",
                   mtInformation, TMsgDlgButtons() << mbOK, 0);
    }
    reg->Access = KEY_WRITE;
    bool openResult = reg->OpenKey("Software\\MyCompanyName\\MyApplication\\", true);

    if(!openResult)
    {
        MessageDlg("Unable to create key! Exiting.",
                   mtError, TMsgDlgButtons() << mbOK, 0);
        return;
    }
    //checking if the values exist and inserting when neccesary

    if(!reg->KeyExists("Creation\ Date"))
    {
        TDateTime today = TDateTime::CurrentDateTime();
        reg->WriteDateTime("Creation\ Date", today);
    }
```

```
    if(!reg->KeyExists("Licenced\ To"))
    {
        reg->WriteString("Licenced\ To", "MySurname\ MyFirstName");
    }

    if(!reg->KeyExists("App\ Location"))
    {
        reg->WriteExpandString("App\ Location",
                               "%PROGRAMFILES%\\MyCompanyName\\MyApplication\\");
    }

    if(!reg->KeyExists("Projects\ Location"))
    {
        reg->WriteExpandString("Projects\ Location",
                               "%USERPROFILE%\\MyApplication\\Projects\\");
    }

    reg->CloseKey();
}
//---------------------------------------------------------------------------
void __fastcall TForm2::DelFromRegBtnClick(TObject *Sender)
{
    //deleting the example registry entries
    TRegistry* reg = new TRegistry(KEY_WRITE);
    reg->RootKey = HKEY_LOCAL_MACHINE;

    reg->DeleteKey("Software\\MyCompanyName\\MyApplication");
    reg->DeleteKey("Software\\MyCompanyName");

    reg->CloseKey();
}
//---------------------------------------------------------------------------
```

Delphi Examples:

```
{
This example shows how to use the TRegistry class in order to
find, insert and delete Keys and Items into the Windows Registry.
This example uses two buttons: InsertToRegBtn and DeleteFromRegBtn,
on a form, for inserting and deleting the values.
}
procedure TForm3.InsertToRegBtnClick(Sender: TObject);
var
  reg        : TRegistry;
  openResult : Boolean;
  today      : TDateTime;
begin
  reg := TRegistry.Create(KEY_READ);
  reg.RootKey := HKEY_LOCAL_MACHINE;

  if (not reg.KeyExists('Software\\MyCompanyName\\MyApplication\\')) then
    begin
      MessageDlg('Key not found! Created now.',
                          mtInformation, mbOKCancel, 0);
    end;
  reg.Access := KEY_WRITE;
  openResult := reg.OpenKey('Software\\MyCompanyName\\MyApplication\\',True);

  if not openResult = True then
    begin
      MessageDlg('Unable to create key! Exiting.',
                  mtError, mbOKCancel, 0);
      Exit();
    end;

  {checking if the values exist and inserting when neccesary}
```

```
    if not reg.KeyExists('Creation\ Date') then
      begin
        today := Now;
          reg.WriteDateTime('Creation\ Date', today);
      end;

    if not reg.KeyExists('Licenced\ To') then
      begin
          reg.WriteString('Licenced\ To', 'MySurname\ MyFirstName');
      end;

    if not reg.KeyExists('App\ Location') then
      begin
          reg.WriteExpandString('App\ Location',
                                '%PROGRAMFILES%\\MyCompanyName\\MyApplication\\');
      end;

    if not reg.KeyExists('Projects\ Location') then
      begin
          reg.WriteExpandString('Projects\ Location',
                                '%USERPROFILE%\\MyApplication\\Projects\\');
      end;

    reg.CloseKey();

  end;

  procedure TForm3.DeleteFromRegBtnClick(Sender: TObject);
  var
    reg : TRegistry;
  begin
    reg := TRegistry.Create(KEY_WRITE);
    reg.RootKey := HKEY_LOCAL_MACHINE;

    reg.DeleteKey('Software\\MyCompanyName\\MyApplication');
    reg.DeleteKey('Software\\MyCompanyName');

    reg.CloseKey();
  end;
```

73.1.3.4.46 TRegistry.WriteFloat Method

Stores a Double value in a specifically named data value associated with the current key.

Pascal

```
procedure WriteFloat(const Name: string; Value: Double);
```

C++

```
__fastcall WriteFloat(const UnicodeString Name, Double Value);
```

Description

Call WriteFloat to store a float value in a data value associated with the current key.

Name is a string containing the name of the data value in which to store data. If Name already exists, its current value is overwritten by WriteFloat. If Name does not exist, it is created.

Value is a float value to store in the registry.

If WriteFloat fails, an exception is raised, and the value is not written to the registry.

CurrentKey (see page 6660)

ReadFloat (see page 6639)

73.1.3.4.47 TRegistry.WriteInteger Method

Stores an integer value in a specifically named data value associated with the current key.

Pascal

```
procedure WriteInteger(const Name: string; Value: Integer);
```

C++

```
__fastcall WriteInteger(const UnicodeString Name, int Value);
```

Description

Call WriteInteger to store an integer value in a data value associated with the current key.

Name is a string containing the name of the data value in which to store data. If Name already exists, its current value is overwritten by WriteInteger. If Name does not exist, it is created.

Value is a integer value to store in the registry.

If WriteInteger fails, an exception is raised, and the value is not written to the registry.

73.1.3.4.48 TRegistry.WriteString Method

Stores a string value in a specifically named data value associated with the current key.

Pascal

```
procedure WriteString(const Name: string; const Value: string);
```

C++

```
__fastcall WriteString(const UnicodeString Name, const UnicodeString Value);
```

Description

Call WriteString to store a string value in a data value associated with the current key.

Name is a string containing the name of the data value in which to store data. If Name already exists, its current value is overwritten by WriteString. If Name does not exist, it is created.

Value is a string value to store in the registry.

If WriteString fails, an exception is raised, and the value is not written to the registry.

C++ Examples:

```
/*

WriteExpandString (see page 6650)

73.1.3.4.49 TRegistry.WriteTime Method

Stores a time value in a specifically named data value associated with the current key.

Pascal

```
procedure WriteTime(const Name: string; Value: TDateTime);
```

C++

```
__fastcall WriteTime(const UnicodeString Name, TDateTime Value);
```

Description

Call WriteTime to store a datetime value in a data value associated with the current key.

Name is a string containing the name of the data value in which to store data. If Name already exists, its current value is overwritten by WriteTime. If Name does not exist, it is created.

Value is a datetime value to store in the registry.

If WriteTime fails, an exception is raised, and the value is not written to the registry.

If successful, WriteTime stores a TDateTime value. The integral part of a TDateTime value is the number of days that have passed since 12/30/1899. The fractional part of a TDateTime value is the time of day.

CurrentKey (see page 6660)

ReadTime (see page 6641)

WriteDateTime (see page 6647)

73.1.3.5 TRegistry Properties

The properties of the TRegistry class are listed here.

Public Properties

	Name	Description
	Access (see page 6657)	Specifies the level of access to use when opening keys.
R	CurrentKey (see page 6660)	Specifies the registry key that is currently open.
R	CurrentPath (see page 6660)	Indicates the registry path associated with the current key.
	LazyWrite (see page 6660)	Specifies how keys are written to the registry when calling the CloseKey (see page 6619) procedure.
	RootKey (see page 6661)	Specifies the root key for the TRegistry (see page 6610) object in an application.

73.1.3.5.1 TRegistry.Access Property

Specifies the level of access to use when opening keys.

Pascal

```
property Access: LongWord;
```

C++

```
__property LongWord Access;
```

Description

Use Access to specify the level of security access to use when opening keys. The OpenKey (see page 6634) method uses the value of Access when opening a registry key. Access is initialized by the TRegistry (see page 6610) constructor, but can be altered before calling OpenKey (see page 6634).

The value of Access is a set of flags or'd together, where each flag indicates a type of permission. Choose a value that grants sufficient permission to allow the desired actions while not exceeding the access level of the system running the application. The following table lists the flags that can be included:

Flag	Meaning
KEY_ALL_ACCESS	combination of KEY_READ, KEY_WRITE, and KEY_CREATE_LINK.
KEY_READ	combination of KEY_QUERY_VALUE, KEY_ENUMERATE_SUB_KEYS, and KEY_NOTIFY.
KEY_WRITE	combination of KEY_SET_VALUE and KEY_CREATE_SUB_KEY.
KEY_QUERY_VALUE	grants permission to query subkey data.
KEY_ENUMERATE_SUB_KEYS	grants permission to enumerate subkeys.
KEY_NOTIFY	grants ability to receive change notifications.
KEY_SET_VALUE	grants permission to set subkey data.
KEY_CREATE_SUB_KEY	grants permission to create subkeys.
KEY_CREATE_LINK	grants permission to create symbolic links.
KEY_EXECUTE	restricts permission to read-only access.

Note: Access is ignored by the CreateKey (see page 6622) method, which always uses KEY_ALL_ACCESS.

C++ Examples:

```
/*
This example shows how to use the TRegistry class in order to
find, insert and delete Keys and Items into the Windows Registry.
This example uses two buttons: InsertToRegBtn and DeleteFromRegBtn,
for inserting and deleting the values.
*/
void __fastcall TForm2::InsertToRegBtnClick(TObject *Sender)
{
    TRegistry* reg = new TRegistry(KEY_READ);
    reg->RootKey = HKEY_LOCAL_MACHINE;

    if(!reg->KeyExists("Software\\MyCompanyName\\MyApplication\\"))
    {
        MessageDlg("Key not found! Created now.",
                   mtInformation, TMsgDlgButtons() << mbOK, 0);
    }
```

```
    reg->Access = KEY_WRITE;
    bool openResult = reg->OpenKey("Software\\MyCompanyName\\MyApplication\\", true);

    if(!openResult)
    {
        MessageDlg("Unable to create key! Exiting.",
                   mtError, TMsgDlgButtons() << mbOK, 0);
        return;
    }
    //checking if the values exist and inserting when neccesary

    if(!reg->KeyExists("Creation\ Date"))
    {
        TDateTime today = TDateTime::CurrentDateTime();
        reg->WriteDateTime("Creation\ Date", today);
    }

    if(!reg->KeyExists("Licenced\ To"))
    {
        reg->WriteString("Licenced\ To", "MySurname\ MyFirstName");
    }

    if(!reg->KeyExists("App\ Location"))
    {
        reg->WriteExpandString("App\ Location",
                               "%PROGRAMFILES%\\MyCompanyName\\MyApplication\\");
    }

    if(!reg->KeyExists("Projects\ Location"))
    {
        reg->WriteExpandString("Projects\ Location",
                               "%USERPROFILE%\\MyApplication\\Projects\\");
    }

    reg->CloseKey();
}
//---------------------------------------------------------------------------
void __fastcall TForm2::DelFromRegBtnClick(TObject *Sender)
{
    //deleting the example registry entries
    TRegistry* reg = new TRegistry(KEY_WRITE);
    reg->RootKey = HKEY_LOCAL_MACHINE;

    reg->DeleteKey("Software\\MyCompanyName\\MyApplication");
    reg->DeleteKey("Software\\MyCompanyName");

    reg->CloseKey();
}
//---------------------------------------------------------------------------
```

Delphi Examples:

```
{
This example shows how to use the TRegistry class in order to
find, insert and delete Keys and Items into the Windows Registry.
This example uses two buttons: InsertToRegBtn and DeleteFromRegBtn,
on a form, for inserting and deleting the values.
}
procedure TForm3.InsertToRegBtnClick(Sender: TObject);
var
  reg        : TRegistry;
  openResult : Boolean;
  today      : TDateTime;
begin
  reg := TRegistry.Create(KEY_READ);
  reg.RootKey := HKEY_LOCAL_MACHINE;
```

```
    if (not reg.KeyExists('Software\\MyCompanyName\\MyApplication\\')) then
      begin
        MessageDlg('Key not found! Created now.',
                               mtInformation, mbOKCancel, 0);
      end;
    reg.Access := KEY_WRITE;
    openResult := reg.OpenKey('Software\\MyCompanyName\\MyApplication\\',True);

    if not openResult = True then
      begin
        MessageDlg('Unable to create key! Exiting.',
                     mtError, mbOKCancel, 0);
        Exit();
      end;

    {checking if the values exist and inserting when neccesary}

    if not reg.KeyExists('Creation\ Date') then
      begin
        today := Now;
          reg.WriteDateTime('Creation\ Date', today);
      end;

    if not reg.KeyExists('Licenced\ To') then
      begin
          reg.WriteString('Licenced\ To', 'MySurname\ MyFirstName');
      end;

    if not reg.KeyExists('App\ Location') then
      begin
          reg.WriteExpandString('App\ Location',
                               '%PROGRAMFILES%\\MyCompanyName\\MyApplication\\');
      end;

    if not reg.KeyExists('Projects\ Location') then
      begin
          reg.WriteExpandString('Projects\ Location',
                               '%USERPROFILE%\\MyApplication\\Projects\\');
      end;

    reg.CloseKey();

  end;

  procedure TForm3.DeleteFromRegBtnClick(Sender: TObject);
  var
    reg : TRegistry;
  begin
    reg := TRegistry.Create(KEY_WRITE);
    reg.RootKey := HKEY_LOCAL_MACHINE;

    reg.DeleteKey('Software\\MyCompanyName\\MyApplication');
    reg.DeleteKey('Software\\MyCompanyName');

    reg.CloseKey();
  end;
```

OpenKey (see page 6634)

Create (see page 6615)

OpenKeyReadOnly (see page 6636)

73.1.3.5.2 TRegistry.CurrentKey Property

Specifies the registry key that is currently open.

Pascal

```
property CurrentKey: HKEY;
```

C++

```
__property HKEY CurrentKey;
```

Description

Use CurrentKey to determine the registry key that is currently open. All operations performed by TRegistry (see page 6610) affect only the current key. To access another key, call the OpenKey (see page 6634) or OpenKeyReadOnly (see page 6636) method.

See Also

CurrentPath (see page 6660)

RootKey (see page 6661)

OpenKey (see page 6634)

OpenKeyReadOnly (see page 6636)

73.1.3.5.3 TRegistry.CurrentPath Property

Indicates the registry path associated with the current key.

Pascal

```
property CurrentPath: string;
```

C++

```
__property UnicodeString CurrentPath;
```

Description

Use CurrentPath to determine the registry path of the current key. The system registry is hierarchical, and CurrentPath returns a string that spells out the hierarchy of keys from the root key to the current key, inclusive.

CurrentPath is automatically reset each time a different key becomes the current key.

See Also

CurrentKey (see page 6660)

RootKey (see page 6661)

73.1.3.5.4 TRegistry.LazyWrite Property

Specifies how keys are written to the registry when calling the CloseKey (see page 6619) procedure.

Pascal

```
property LazyWrite: Boolean;
```

C++

```
__property Boolean LazyWrite;
```

Description

Use LazyWrite to specify how keys are written to the registry. LazyWrite is initialized to true when a registry object is first created. When LazyWrite is true, keys are written to the registry when they are closed, but the CloseKey (see page 6619) procedure may return before the write operation takes place.

When LazyWrite is false, keys are written to the registry before CloseKey (see page 6619) returns. Set LazyWrite to false only when absolutely necessary. Setting LazyWrite to false guarantees that the changes an application makes to keys are written to the registry before further application processing takes place, but it uses more system resources when keys are closed. If LazyWrite is false, and an application is displaying or changing many registry entries, there will be a degradation in application performance.

See Also

CloseKey (see page 6619)

73.1.3.5.5 TRegistry.RootKey Property

Specifies the root key for the TRegistry (see page 6610) object in an application.

Pascal

```
property RootKey: HKEY;
```

C++

```
__property HKEY RootKey;
```

Description

Use RootKey to determine the hierarchy of subkeys an application can access, or to specify the root key for the application.

By default, RootKey is set to HKEY_CURRENT_USER when the registry object is created. To change the root key, specify a valid integer value for the RootKey property.

Note: For some operations, such as LoadKey (see page 6632) or RegistryConnect (see page 6641), an application may need to change the default value of RootKey.

C++ Examples:

```
/*
This example shows how to use the TRegistry class in order to
find, insert and delete Keys and Items into the Windows Registry.
This example uses two buttons: InsertToRegBtn and DeleteFromRegBtn,
for inserting and deleting the values.
*/
void __fastcall TForm2::InsertToRegBtnClick(TObject *Sender)
{
    TRegistry* reg = new TRegistry(KEY_READ);
    reg->RootKey = HKEY_LOCAL_MACHINE;

    if(!reg->KeyExists("Software\\MyCompanyName\\MyApplication\\"))
    {
        MessageDlg("Key not found! Created now.",
                    mtInformation, TMsgDlgButtons() << mbOK, 0);
    }
    reg->Access = KEY_WRITE;
    bool openResult = reg->OpenKey("Software\\MyCompanyName\\MyApplication\\", true);

    if(!openResult)
    {
        MessageDlg("Unable to create key! Exiting.",
```

```
                    mtError, TMsgDlgButtons() << mbOK, 0);
        return;
    }
    //checking if the values exist and inserting when neccesary

    if(!reg->KeyExists("Creation\ Date"))
    {
        TDateTime today = TDateTime::CurrentDateTime();
        reg->WriteDateTime("Creation\ Date", today);
    }

    if(!reg->KeyExists("Licenced\ To"))
    {
        reg->WriteString("Licenced\ To", "MySurname\ MyFirstName");
    }

    if(!reg->KeyExists("App\ Location"))
    {
        reg->WriteExpandString("App\ Location",
                               "%PROGRAMFILES%\\MyCompanyName\\MyApplication\\");
    }

    if(!reg->KeyExists("Projects\ Location"))
    {
        reg->WriteExpandString("Projects\ Location",
                               "%USERPROFILE%\\MyApplication\\Projects\\");
    }

    reg->CloseKey();
}
//---------------------------------------------------------------------------
void __fastcall TForm2::DelFromRegBtnClick(TObject *Sender)
{
    //deleting the example registry entries
    TRegistry* reg = new TRegistry(KEY_WRITE);
    reg->RootKey = HKEY_LOCAL_MACHINE;

    reg->DeleteKey("Software\\MyCompanyName\\MyApplication");
    reg->DeleteKey("Software\\MyCompanyName");

    reg->CloseKey();
}
//---------------------------------------------------------------------------
```

Delphi Examples:

```
{
This example shows how to use the TRegistry class in order to
find, insert and delete Keys and Items into the Windows Registry.
This example uses two buttons: InsertToRegBtn and DeleteFromRegBtn,
on a form, for inserting and deleting the values.
}
procedure TForm3.InsertToRegBtnClick(Sender: TObject);
var
  reg        : TRegistry;
  openResult : Boolean;
  today      : TDateTime;
begin
  reg := TRegistry.Create(KEY_READ);
  reg.RootKey := HKEY_LOCAL_MACHINE;

  if (not reg.KeyExists('Software\\MyCompanyName\\MyApplication\\')) then
    begin
      MessageDlg('Key not found! Created now.',
                          mtInformation, mbOKCancel, 0);
    end;
  reg.Access := KEY_WRITE;
```

```
    openResult := reg.OpenKey('Software\\MyCompanyName\\MyApplication\\',True);

    if not openResult = True then
      begin
        MessageDlg('Unable to create key! Exiting.',
                   mtError, mbOKCancel, 0);
        Exit();
      end;

    {checking if the values exist and inserting when neccesary}

    if not reg.KeyExists('Creation\ Date') then
      begin
        today := Now;
          reg.WriteDateTime('Creation\ Date', today);
      end;

    if not reg.KeyExists('Licenced\ To') then
      begin
          reg.WriteString('Licenced\ To', 'MySurname\ MyFirstName');
      end;

    if not reg.KeyExists('App\ Location') then
      begin
          reg.WriteExpandString('App\ Location',
                                '%PROGRAMFILES%\\MyCompanyName\\MyApplication\\');
      end;

    if not reg.KeyExists('Projects\ Location') then
      begin
          reg.WriteExpandString('Projects\ Location',
                                '%USERPROFILE%\\MyApplication\\Projects\\');
      end;

    reg.CloseKey();

  end;

  procedure TForm3.DeleteFromRegBtnClick(Sender: TObject);
  var
    reg : TRegistry;
  begin
    reg := TRegistry.Create(KEY_WRITE);
    reg.RootKey := HKEY_LOCAL_MACHINE;

    reg.DeleteKey('Software\\MyCompanyName\\MyApplication');
    reg.DeleteKey('Software\\MyCompanyName');

    reg.CloseKey();
  end;
```

73.1.4 TRegistryIniFile Class

TRegistryIniFile is a wrapper for the Windows system registry.

Class Hierarchy

Pascal

```
TRegistryIniFile = class(TCustomIniFile);
```

C++

```
class TRegistryIniFile : public TCustomIniFile;
```

File

Registry

Description

TRegistryIniFile presents a simple interface to the system registry and hides the need to know about the underlying structure of the registry. TRegistryIniFile enables handling the Windows system registry as if it were a Windows 3.x INI file. Instead of processing an INI file, however, TRegistryIniFile reads from and writes to the system registry. Because TRegistryIniFile, like TIniFile (see page 4294), descends from TCustomIniFile (see page 4258), you can use it in common code that writes to both INI files and the registry.

In addition, application developers that are switching from the use of INI files to the system registry can use this object to migrate their application with a minimum of coding changes. By finding all references to TIniFile (see page 4294) in an application, replacing them with TRegistryIniFile, and recompiling the application, a developer can update an application to use the system registry instead of INI files without having to code any new logic into the application.

Note: Information contained in existing users' INI files is not migrated into the system registry using the method described above. A one-time operation to explicitly copy the INI file data, through TRegistryIniFile, must be used to do this.

TRegistryIniFile adapts the methods inherited from TCustomIniFile (see page 4258) to operate on Registry (see page 6599) entries rather than INI file keys. It reinterprets the FileName property as a subkey under the system registry's root key (HKEY_CURRENT_USER by default). What corresponds to a section in an INI file is treated as a key in the system registry, and what corresponds to data entries under a section in an INI file are treated as data values under a key in the system registry.

C++ Examples:

```
/*
This example demonstrates the usage of Ini files in order to store
and load form configuration between sessions. Example assumes
a RadioGroup and two buttons are present on the main form.
*/
void __fastcall TForm2::btStoreClick(TObject *Sender)
{
    /* Open an instance */
    TCustomIniFile* SettingsFile = OpenIniFileInstance();

    // Store current form properties to be used in later sessions.
    try
    {
        SettingsFile->WriteInteger (Name, "Top", Top);
        SettingsFile->WriteInteger (Name, "Left", Left);
        SettingsFile->WriteInteger (Name, "Width", Width);
        SettingsFile->WriteInteger (Name, "Height", Height);
        SettingsFile->WriteString  (Name, "Caption", Caption);
        SettingsFile->WriteBool    (Name, "InitMax", WindowState == wsMaximized );
    }
    catch(Exception* e)
    {
    }

    delete SettingsFile;
}
```

```
void __fastcall TForm2::btLoadClick(TObject *Sender)
{
    /* Open an instance */
    TCustomIniFile* SettingsFile = OpenIniFileInstance();

    try
    {
        /*
        Read all saved values from the last session. The section name
        is the name of the form. Also use form's properties as defaults
        */
        Top     = SettingsFile->ReadInteger(Name, "Top", Top );
        Left    = SettingsFile->ReadInteger(Name, "Left", Left );
        Width   = SettingsFile->ReadInteger(Name, "Width", Width );
        Height  = SettingsFile->ReadInteger(Name, "Height", Height );
        Caption = SettingsFile->ReadString (Name, "Caption", Caption);

        // Load last window state
        if (SettingsFile->ReadBool(Name, "InitMax", WindowState == wsMaximized))
            WindowState = wsMaximized;
        else
            WindowState = wsNormal;
    }
    catch(Exception* e)
    {
    }

    delete SettingsFile;
}

TCustomIniFile* __fastcall TForm2::OpenIniFileInstance()
{
    /*
    Open/create a new INI file that has the same name as our executable
    only with the INI extension.
    */

    switch (RadioGroup1->ItemIndex)
    {
        case 0:
            /* Registry mode selected: in HKEY_CURRENT_USER\Software\... */
            return new TRegistryIniFile(String("Software\\") + Application->Title);
        case 1:
            /* Ini file mode selected */
            return new TIniFile(ChangeFileExt(Application->ExeName, ".INI"));
        case 2:
            /* Memory based Ini file mode selected */
            return new TMemIniFile(ChangeFileExt(Application->ExeName, ".INI"));
      }
}
```

Delphi Examples:

```
{
This example demonstrates the use of Ini files in order to store
and load form configurations between sessions. This example requires
a RadioGroup and two buttons.
}
procedure TForm2.btLoadClick(Sender: TObject);
var
  SettingsFile : TCustomIniFile;
begin
  { Open an instance }
  SettingsFile := OpenIniFileInstance();

  try
```

```
      {
      Read all saved values from the last session. The section name
      is the name of the form. Also use form's properties as defaults
      }
      Top     := SettingsFile.ReadInteger(Name, 'Top', Top );
      Left    := SettingsFile.ReadInteger(Name, 'Left', Left );
      Width   := SettingsFile.ReadInteger(Name, 'Width', Width );
      Height  := SettingsFile.ReadInteger(Name, 'Height', Height );
      Caption := SettingsFile.ReadString (Name, 'Caption', Caption);

      { Load last window state }
      case SettingsFile.ReadBool(Name, 'InitMax', WindowState = wsMaximized) of
        true : WindowState := wsMaximized;
        false: WindowState := wsNormal;
      end;

    finally
      SettingsFile.Free;
    end;
  end;

  procedure TForm2.btStoreClick(Sender: TObject);
  var
    SettingsFile: TCustomIniFile;
  begin
    { Open an instance }
    SettingsFile := OpenIniFileInstance();

    {
    Store current form properties to be used in later sessions.
    }
    try
      SettingsFile.WriteInteger (Name, 'Top', Top);
      SettingsFile.WriteInteger (Name, 'Left', Left);
      SettingsFile.WriteInteger (Name, 'Width', Width);
      SettingsFile.WriteInteger (Name, 'Height', Height);
      SettingsFile.WriteString  (Name, 'Caption', Caption);
      SettingsFile.WriteBool    (Name, 'InitMax', WindowState = wsMaximized );
      SettingsFile.WriteDateTime(Name, 'LastRun', Now);
    finally
      SettingsFile.Free;
    end;

  end;

  function TForm2.OpenIniFileInstance: TCustomIniFile;
  begin
    {
    Open/create a new INI file that has the same name as our executable
    only with the INI extension.
    }

    case RadioGroup1.ItemIndex of
      0:
        begin
          { Registry mode selected: in HKEY_CURRENT_USER\Software\... }
          Result := TRegistryIniFile.Create('Software\' + Application.Title);
        end;
      1:
        begin
          { Ini file mode selected }
          Result := TIniFile.Create(ChangeFileExt(Application.ExeName, '.INI'));
        end;
      2:
        begin
          { Memory based Ini file mode selected }
```

```
        Result := TMemIniFile.Create(ChangeFileExt(Application.ExeName, '.INI'));
      end;
  end;
end;
```

73.1.4.1 TRegistryIniFile Members

The following tables list the members exposed by TRegistryIniFile.

Public Methods

	Name	Description
	Create (see page 6668)	This is the overview for the Create constructor overload.
	DeleteKey (see page 6669)	Erases the data value associated with an INI file entry.
	Destroy (see page 6668)	Disposes of an object instance.
	EraseSection (see page 6670)	Erases an entire section of an INI file.
	ReadBinaryStream (see page 6670)	Retrieves a binary value from the registry.
	ReadBool (see page 4265)	Retrieves a Boolean value from an ini file.
	ReadDate (see page 6671)	Retrieves a date value from an INI file.
	ReadDateTime (see page 6671)	Retrieves a date-time value from an INI file.
	ReadFloat (see page 6672)	Retrieves a float value from an INI file.
	ReadInteger (see page 6672)	Retrieves an integer value from an INI file.
	ReadSection (see page 6676)	Reads all the key names from a specified section of an INI file into a string list.
	ReadSections (see page 4273)	This is the overview for the ReadSections method overload.
	ReadSections (see page 6676)	This is the overview for the ReadSections method overload.
	ReadSectionValues (see page 6677)	Retrieves the data-values associated with a specified key, and stores the retrieved values in a string object.
	ReadString (see page 6677)	Retrieves a string value from an INI file.
	ReadTime (see page 6680)	Retrieves a time value from an INI file.
	SectionExists (see page 4278)	Indicates whether a section exists in the ini file.
	UpdateFile (see page 6681)	Flushes buffered INI file data to disk.
	ValueExists (see page 4278)	Indicates whether a key exists in the ini file.
	WriteBinaryStream (see page 6681)	Writes a binary value to the registry.
	WriteBool (see page 4279)	Writes a Boolean value to an ini file.
	WriteDate (see page 6682)	Writes a date value to an INI file.
	WriteDateTime (see page 6682)	Writes a date-time value to an INI file.
	WriteFloat (see page 6683)	Writes a float value to an INI file.
	WriteInteger (see page 6683)	Writes an integer value to an INI file.
	WriteString (see page 6686)	Writes a string value to an INI file.
	WriteTime (see page 6689)	Writes a time value to an INI file.

Public Properties

	Name	Description
	FileName (see page 4291)	Contains the name of the ini file from which to read and to which to write information.
	RegIniFile (see page 6690)	Contains and internal instance of a TRegIniFile (see page 6601) object.

73.1.4.2 Create Constructor

This is the overview for the Create constructor overload.

Overload List

	Name	Description
	TRegistryIniFile.Create (string) (see page 6668)	Creates a TRegistryIniFile (see page 6663) object for an application.
	TRegistryIniFile.Create (string, LongWord) (see page 6668)	Creates a TRegistryIniFile (see page 6663) object for an application.

73.1.4.2.1 TRegistryIniFile.Create Constructor (string)

Creates a TRegistryIniFile (see page 6663) object for an application.

Pascal

```
constructor Create(const FileName: string); overload;
constructor Create(const FileName: string; AAccess: LongWord); overload;
```

C++

```
__fastcall TRegistryIniFile(const UnicodeString FileName);
__fastcall TRegistryIniFile(const UnicodeString FileName, LongWord AAccess);
```

Description

Create constructs a TRegistryIniFile (see page 6663) and creates an internal TRegIniFile (see page 6601) object used to access the system registry. TRegistryIniFile (see page 6663) uses this TRegIniFile (see page 6601) object as a helper object to provide much of its functionality.

FileName is used as the FileName property for the internal TRegIniFile (see page 6601) object in the RegIniFile (see page 6690) property.

AAccess initializes the Access property of the internal TRegIniFile (see page 6601) object.

RegIniFile (see page 6690)

System::TObject::Create

Access (see page 6657)

73.1.4.3 TRegistryIniFile.Destroy Destructor

Disposes of an object instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TRegistryIniFile();
```

Description

Do not call System::TObject::Destroy directly. Call System::TObject::Free instead. Free verifies that the object reference is not nil before calling System::TObject::Destroy.

The System::TObject::Destroy method defined by System::TObject::TObject deallocates memory. Descendant objects usually define a destructor that is customized for that particular kind of object.

When declaring a System::TObject::Destroy method in a descendant, always add the override directive to the declaration and call the inherited System::TObject::Destroy as the last statement in the overriding method. Since System::TObject::Destroy is a virtual method, overriding it ensures that the proper inherited behavior occurs.

Note: If an exception escapes from the constructor, the destructor is called to destroy the partially constructed object instance that failed to initialize completely. Therefore, destructors should check that allocated resources, such as handles, were actually allocated before trying to release them, since their value might be zero.

System::TObject::Destroy should be implemented so that it calls System::TObject::Free on all subobjects created within the object's constructor (that is, allocated by the constructor). Unlike System::TObject::Destroy, System::TObject::Free provides a safeguard when destroying objects that are nil.

System::TObject::Free

73.1.4.4 TRegistryIniFile Methods

The methods of the TRegistryIniFile class are listed here.

Public Methods

	Name	Description
	DeleteKey (see page 6669)	Erases the data value associated with an INI file entry.
	EraseSection (see page 6670)	Erases an entire section of an INI file.
	ReadBinaryStream (see page 6670)	Retrieves a binary value from the registry.
	ReadDate (see page 6671)	Retrieves a date value from an INI file.
	ReadDateTime (see page 6671)	Retrieves a date-time value from an INI file.
	ReadFloat (see page 6672)	Retrieves a float value from an INI file.
	ReadInteger (see page 6672)	Retrieves an integer value from an INI file.
	ReadSection (see page 6676)	Reads all the key names from a specified section of an INI file into a string list.
	ReadSections (see page 6676)	This is the overview for the ReadSections method overload.
	ReadSectionValues (see page 6677)	Retrieves the data-values associated with a specified key, and stores the retrieved values in a string object.
	ReadString (see page 6677)	Retrieves a string value from an INI file.
	ReadTime (see page 6680)	Retrieves a time value from an INI file.
	UpdateFile (see page 6681)	Flushes buffered INI file data to disk.
	WriteBinaryStream (see page 6681)	Writes a binary value to the registry.
	WriteDate (see page 6682)	Writes a date value to an INI file.
	WriteDateTime (see page 6682)	Writes a date-time value to an INI file.
	WriteFloat (see page 6683)	Writes a float value to an INI file.
	WriteInteger (see page 6683)	Writes an integer value to an INI file.
	WriteString (see page 6686)	Writes a string value to an INI file.
	WriteTime (see page 6689)	Writes a time value to an INI file.

73.1.4.4.1 TRegistryIniFile.DeleteKey Method

Erases the data value associated with an INI file entry.

Pascal

```
procedure DeleteKey(const Section: string; const Ident: string); override;
```

C++

```
virtual __fastcall DeleteKey(const UnicodeString Section, const UnicodeString Ident);
```

Description

Call DeleteKey to erase a data value associated with an INI file entry. Section is string containing the name of an INI file section, and Ident is a string containing the name of the key from for which to set a nil (Delphi) or NULL (C++) value.

Note: Attempting to erase a data value in a nonexistent section or attempting to erase data from a nonexistent key are not errors. In these cases, DeleteKey creates the section and key and sets its initial value to an empty value.

See Also

EraseSection (see page 6670)

ValueExists (see page 4278)

73.1.4.4.2 TRegistryIniFile.EraseSection Method

Erases an entire section of an INI file.

Pascal

```
procedure EraseSection(const Section: string); override;
```

C++

```
virtual __fastcall EraseSection(const UnicodeString Section);
```

Description

Call EraseSection to remove a section, all its keys, and their data values from an INI file. Section identifies the INI file section to remove. If a section cannot be removed, an exception is raised.

See Also

SectionExists (see page 4278)

DeleteKey (see page 6669)

73.1.4.4.3 TRegistryIniFile.ReadBinaryStream Method

Retrieves a binary value from the registry.

Pascal

```
function ReadBinaryStream(const Section: string; const Name: string; Value: TStream): Integer;
override;
```

C++

```
virtual __fastcall int ReadBinaryStream(const UnicodeString Section, const UnicodeString Name,
TStream Value);
```

Description

Call ReadBinaryStream to read a binary value into a specified stream. After reading the binary value from the INI file into the current position of the stream, ReadBinaryStream returns the number of bytes written to the stream. The stream is left positioned immediately after the new binary value.

Section is the key for the section that contains the binary data.

Name is the subkey under which the binary data is stored.

Value is a stream to which the binary value is written.

See Also

ReadString (see page 6677)

WriteBinaryStream (see page 6681)

73.1.4.4.4 TRegistryIniFile.ReadDate Method

Retrieves a date value from an INI file.

Pascal

```
function ReadDate(const Section: string; const Name: string; Default: TDateTime): TDateTime;
override;
```

C++

```
virtual __fastcall TDateTime ReadDate(const UnicodeString Section, const UnicodeString Name,
TDateTime Default);
```

Description

Call ReadDate to read a date value from an INI file. Section identifies the section in the file that contains the desired key. Ident is the name of the key from which to retrieve the date value. Default is the date value to return if the:

Section does not exist.

Key does not exist.

Data value for the key is not assigned.

See Also

ReadBool (see page 4265)

ReadDateTime (see page 6671)

ReadFloat (see page 6672)

ReadInteger (see page 6672)

ReadString (see page 6677)

ReadTime (see page 6680)

73.1.4.4.5 TRegistryIniFile.ReadDateTime Method

Retrieves a date-time value from an INI file.

Pascal

```
function ReadDateTime(const Section: string; const Name: string; Default: TDateTime):
TDateTime; override;
```

C++

```
virtual __fastcall TDateTime ReadDateTime(const UnicodeString Section, const UnicodeString
Name, TDateTime Default);
```

Description

Call ReadDateTime to read a date-time value from an INI file. Section identifies the section in the file that contains the desired key. Ident is the name of the key from which to retrieve the date-time value. Default is the date-time value to return if the:

Section does not exist.

Key does not exist.

Data value for the key is not assigned.

See Also

ReadBool (see page 4265)

ReadDate (see page 6671)

ReadDateTime

ReadFloat (see page 6672)

ReadInteger (see page 6672)

ReadString (see page 6677)

ReadTime (see page 6680)

73.1.4.4.6 TRegistryIniFile.ReadFloat Method

Retrieves a float value from an INI file.

Pascal

```
function ReadFloat(const Section: string; const Name: string; Default: Double): Double;
override;
```

C++

```
virtual __fastcall Double ReadFloat(const UnicodeString Section, const UnicodeString Name,
Double Default);
```

Description

Call ReadFloat to read a float value from an INI file. Section identifies the section in the file that contains the desired key. Ident is the name of the key from which to retrieve the float value. Default is the float value to return if the:

Section does not exist.

Key does not exist.

Data value for the key is not assigned.

ReadTime (see page 6680)

73.1.4.4.7 TRegistryIniFile.ReadInteger Method

Retrieves an integer value from an INI file.

Pascal

```
function ReadInteger(const Section: string; const Ident: string; Default: Longint): Longint;
override;
```

C++

```
virtual __fastcall Longint ReadInteger(const UnicodeString Section, const UnicodeString Ident,
Longint Default);
```

Description

Call ReadInteger to read an integer value from an INI file. Section identifies the section in the file that contains the desired key. Ident is the name of the key from which to retrieve the value. Default is the integer value to return if the:

Section does not exist.

Key does not exist.

Data value for the key is not assigned.

C++ Examples:

```
/*
This example demonstrates the usage of Ini files in order to store
and load form configuration between sessions. Example assumes
a RadioGroup and two buttons are present on the main form.
*/
void __fastcall TForm2::btStoreClick(TObject *Sender)
{
    /* Open an instance */
    TCustomIniFile* SettingsFile = OpenIniFileInstance();

    // Store current form properties to be used in later sessions.
    try
    {
        SettingsFile->WriteInteger (Name, "Top", Top);
        SettingsFile->WriteInteger (Name, "Left", Left);
        SettingsFile->WriteInteger (Name, "Width", Width);
        SettingsFile->WriteInteger (Name, "Height", Height);
        SettingsFile->WriteString  (Name, "Caption", Caption);
        SettingsFile->WriteBool    (Name, "InitMax", WindowState == wsMaximized );
    }
    catch(Exception* e)
    {
    }

    delete SettingsFile;
}

void __fastcall TForm2::btLoadClick(TObject *Sender)
{
    /* Open an instance */
    TCustomIniFile* SettingsFile = OpenIniFileInstance();

    try
    {
        /*
        Read all saved values from the last session. The section name
        is the name of the form. Also use form's properties as defaults
        */
        Top     = SettingsFile->ReadInteger(Name, "Top", Top );
        Left    = SettingsFile->ReadInteger(Name, "Left", Left );
        Width   = SettingsFile->ReadInteger(Name, "Width", Width );
        Height  = SettingsFile->ReadInteger(Name, "Height", Height );
        Caption = SettingsFile->ReadString (Name, "Caption", Caption);
```

```
        // Load last window state
        if (SettingsFile->ReadBool(Name, "InitMax", WindowState == wsMaximized))
            WindowState = wsMaximized;
        else
            WindowState = wsNormal;
    }
    catch(Exception* e)
    {
    }

    delete SettingsFile;
}

TCustomIniFile* __fastcall TForm2::OpenIniFileInstance()
{
    /*
    Open/create a new INI file that has the same name as our executable
    only with the INI extension.
    */

    switch (RadioGroup1->ItemIndex)
    {
        case 0:
            /* Registry mode selected: in HKEY_CURRENT_USER\Software\... */
            return new TRegistryIniFile(String("Software\\") + Application->Title);
        case 1:
            /* Ini file mode selected */
            return new TIniFile(ChangeFileExt(Application->ExeName, ".INI"));
        case 2:
            /* Memory based Ini file mode selected */
            return new TMemIniFile(ChangeFileExt(Application->ExeName, ".INI"));
      }
}
```

Delphi Examples:

```
{
This example demonstrates the use of Ini files in order to store
and load form configurations between sessions. This example requires
a RadioGroup and two buttons.
}
procedure TForm2.btLoadClick(Sender: TObject);
var
  SettingsFile : TCustomIniFile;
begin
  { Open an instance }
  SettingsFile := OpenIniFileInstance();

  try
    {
    Read all saved values from the last session. The section name
    is the name of the form. Also use form's properties as defaults
    }
    Top     := SettingsFile.ReadInteger(Name, 'Top', Top );
    Left    := SettingsFile.ReadInteger(Name, 'Left', Left );
    Width   := SettingsFile.ReadInteger(Name, 'Width', Width );
    Height  := SettingsFile.ReadInteger(Name, 'Height', Height );
    Caption := SettingsFile.ReadString (Name, 'Caption', Caption);

    { Load last window state }
    case SettingsFile.ReadBool(Name, 'InitMax', WindowState = wsMaximized) of
      true : WindowState := wsMaximized;
      false: WindowState := wsNormal;
    end;

  finally
    SettingsFile.Free;
```

```
  end;
end;

procedure TForm2.btStoreClick(Sender: TObject);
var
  SettingsFile: TCustomIniFile;
begin
  { Open an instance }
  SettingsFile := OpenIniFileInstance();

  {
  Store current form properties to be used in later sessions.
  }
  try
    SettingsFile.WriteInteger (Name, 'Top', Top);
    SettingsFile.WriteInteger (Name, 'Left', Left);
    SettingsFile.WriteInteger (Name, 'Width', Width);
    SettingsFile.WriteInteger (Name, 'Height', Height);
    SettingsFile.WriteString  (Name, 'Caption', Caption);
    SettingsFile.WriteBool    (Name, 'InitMax', WindowState = wsMaximized );
    SettingsFile.WriteDateTime(Name, 'LastRun', Now);
  finally
    SettingsFile.Free;
  end;

end;

function TForm2.OpenIniFileInstance: TCustomIniFile;
begin
  {
  Open/create a new INI file that has the same name as our executable
  only with the INI extension.
  }

  case RadioGroup1.ItemIndex of
    0:
      begin
        { Registry mode selected: in HKEY_CURRENT_USER\Software\... }
        Result := TRegistryIniFile.Create('Software\' + Application.Title);
      end;
    1:
      begin
        { Ini file mode selected }
        Result := TIniFile.Create(ChangeFileExt(Application.ExeName, '.INI'));
      end;
    2:
      begin
        { Memory based Ini file mode selected }
        Result := TMemIniFile.Create(ChangeFileExt(Application.ExeName, '.INI'));
      end;
  end;
end;
```

73.1.4.4.8 TRegistryIniFile.ReadSection Method

Reads all the key names from a specified section of an INI file into a string list.

Pascal

```
procedure ReadSection(const Section: string; Strings: TStrings); override;
```

C++

```
virtual __fastcall ReadSection(const UnicodeString Section, TStrings Strings);
```

Description

Call ReadSection to retrieve the names of all keys within a specified section of an INI file into a string list object.

Section identifies the section from which to retrieve a list of key names. Strings specifies the string object to hold the retrieved names. Strings can point to a TStrings object such as a string list, or to a component property, such as Items for a TListBox component, that is a TStrings object itself.

SectionExists (see page 4278)

73.1.4.4.9 ReadSections Method

This is the overview for the ReadSections method overload.

Overload List

	Name	Description
	TRegistryIniFile.ReadSections (string, TStrings) (see page 6676)	Reads the names of all sections in an INI file into a string list.
	TRegistryIniFile.ReadSections (TStrings) (see page 6676)	Reads the names of all sections in an INI file into a string list.

73.1.4.4.9.1 TRegistryIniFile.ReadSections Method (TStrings)

Reads the names of all sections in an INI file into a string list.

Pascal

```
procedure ReadSections(Strings: TStrings); override; overload;
procedure ReadSections(const Section: string; Strings: TStrings); override; overload;
```

C++

```
virtual __fastcall ReadSections(TStrings Strings);
virtual __fastcall ReadSections(const UnicodeString Section, TStrings Strings);
```

Description

Call ReadSections to retrieve the names of all sections in an INI file into a string list object.

Strings specifies the string object to hold the retrieved names. Strings can point to a TStrings object, or to a component property, such as Items for a TListBox component, that is a TStrings object itself.

See Also

ReadSection (see page 6676)

ReadSectionValues (see page 6677)

73.1.4.4.10 TRegistryIniFile.ReadSectionValues Method

Retrieves the data-values associated with a specified key, and stores the retrieved values in a string object.

Pascal

```
procedure ReadSectionValues(const Section: string; Strings: TStrings); override;
```

C++

```
virtual __fastcall ReadSectionValues(const UnicodeString Section, TStrings Strings);
```

Description

Call ReadSectionValues to read all data values associated with a specified key into a string object.

Section is the name of the key from which to retrieve data-values.

Strings specifies the string list object to hold the retrieved values. Strings can point to a TStrings object, or to a component property, such as Items for a TListBox component, that is a TStrings object itself. Use the Values property of the string object to access a specific string in the object.

ReadSections (see page 6676)

SectionExists (see page 4278)

73.1.4.4.11 TRegistryIniFile.ReadString Method

Retrieves a string value from an INI file.

Pascal

```
function ReadString(const Section: string; const Ident: string; const Default: string):
string; override;
```

C++

```
virtual __fastcall UnicodeString ReadString(const UnicodeString Section, const UnicodeString
Ident, const UnicodeString Default);
```

Description

Call ReadString to read a string value from an INI file. Section identifies the section in the file that contains the desired key. Ident is the name of the key from which to retrieve the value. Default is the string value to return if the:

Section does not exist.

Key does not exist.

Data value for the key is not assigned.

C++ Examples:

```
/*
This example demonstrates the usage of Ini files in order to store
and load form configuration between sessions. Example assumes
```

```
a RadioGroup and two buttons are present on the main form.
*/
void __fastcall TForm2::btStoreClick(TObject *Sender)
{
    /* Open an instance */
    TCustomIniFile* SettingsFile = OpenIniFileInstance();

    // Store current form properties to be used in later sessions.
    try
    {
        SettingsFile->WriteInteger (Name, "Top", Top);
        SettingsFile->WriteInteger (Name, "Left", Left);
        SettingsFile->WriteInteger (Name, "Width", Width);
        SettingsFile->WriteInteger (Name, "Height", Height);
        SettingsFile->WriteString  (Name, "Caption", Caption);
        SettingsFile->WriteBool    (Name, "InitMax", WindowState == wsMaximized );
    }
    catch(Exception* e)
    {
    }

    delete SettingsFile;
}

void __fastcall TForm2::btLoadClick(TObject *Sender)
{
    /* Open an instance */
    TCustomIniFile* SettingsFile = OpenIniFileInstance();

    try
    {
        /*
        Read all saved values from the last session. The section name
        is the name of the form. Also use form's properties as defaults
        */
        Top     = SettingsFile->ReadInteger(Name, "Top", Top );
        Left    = SettingsFile->ReadInteger(Name, "Left", Left );
        Width   = SettingsFile->ReadInteger(Name, "Width", Width );
        Height  = SettingsFile->ReadInteger(Name, "Height", Height );
        Caption = SettingsFile->ReadString (Name, "Caption", Caption);

        // Load last window state
        if (SettingsFile->ReadBool(Name, "InitMax", WindowState == wsMaximized))
            WindowState = wsMaximized;
        else
            WindowState = wsNormal;
    }
    catch(Exception* e)
    {
    }

    delete SettingsFile;
}

TCustomIniFile* __fastcall TForm2::OpenIniFileInstance()
{
    /*
    Open/create a new INI file that has the same name as our executable
    only with the INI extension.
    */

    switch (RadioGroup1->ItemIndex)
    {
        case 0:
            /* Registry mode selected: in HKEY_CURRENT_USER\Software\... */
            return new TRegistryIniFile(String("Software\\") + Application->Title);
```

```
        case 1:
            /* Ini file mode selected */
            return new TIniFile(ChangeFileExt(Application->ExeName, ".INI"));
        case 2:
            /* Memory based Ini file mode selected */
            return new TMemIniFile(ChangeFileExt(Application->ExeName, ".INI"));
      }
}
```

Delphi Examples:

```
{
This example demonstrates the use of Ini files in order to store
and load form configurations between sessions. This example requires
a RadioGroup and two buttons.
}
procedure TForm2.btLoadClick(Sender: TObject);
var
  SettingsFile : TCustomIniFile;
begin
  { Open an instance }
  SettingsFile := OpenIniFileInstance();

  try
    {
    Read all saved values from the last session. The section name
    is the name of the form. Also use form's properties as defaults
    }
    Top     := SettingsFile.ReadInteger(Name, 'Top', Top );
    Left    := SettingsFile.ReadInteger(Name, 'Left', Left );
    Width   := SettingsFile.ReadInteger(Name, 'Width', Width );
    Height  := SettingsFile.ReadInteger(Name, 'Height', Height );
    Caption := SettingsFile.ReadString (Name, 'Caption', Caption);

    { Load last window state }
    case SettingsFile.ReadBool(Name, 'InitMax', WindowState = wsMaximized) of
      true : WindowState := wsMaximized;
      false: WindowState := wsNormal;
    end;

  finally
    SettingsFile.Free;
  end;
end;

procedure TForm2.btStoreClick(Sender: TObject);
var
  SettingsFile: TCustomIniFile;
begin
  { Open an instance }
  SettingsFile := OpenIniFileInstance();

  {
  Store current form properties to be used in later sessions.
  }
  try
    SettingsFile.WriteInteger (Name, 'Top', Top);
    SettingsFile.WriteInteger (Name, 'Left', Left);
    SettingsFile.WriteInteger (Name, 'Width', Width);
    SettingsFile.WriteInteger (Name, 'Height', Height);
    SettingsFile.WriteString  (Name, 'Caption', Caption);
    SettingsFile.WriteBool    (Name, 'InitMax', WindowState = wsMaximized );
    SettingsFile.WriteDateTime(Name, 'LastRun', Now);
  finally
    SettingsFile.Free;
  end;
```

```
end;

function TForm2.OpenIniFileInstance: TCustomIniFile;
begin
  {
  Open/create a new INI file that has the same name as our executable
  only with the INI extension.
  }

  case RadioGroup1.ItemIndex of
    0:
      begin
        { Registry mode selected: in HKEY_CURRENT_USER\Software\... }
        Result := TRegistryIniFile.Create('Software\' + Application.Title);
      end;
    1:
      begin
        { Ini file mode selected }
        Result := TIniFile.Create(ChangeFileExt(Application.ExeName, '.INI'));
      end;
    2:
      begin
        { Memory based Ini file mode selected }
        Result := TMemIniFile.Create(ChangeFileExt(Application.ExeName, '.INI'));
      end;
  end;
end;
```

ReadInteger (see page 6672)

ReadTime (see page 6680)

73.1.4.4.12 TRegistryIniFile.ReadTime Method

Retrieves a time value from an INI file.

Pascal

```
function ReadTime(const Section: string; const Name: string; Default: TDateTime): TDateTime;
override;
```

C++

```
virtual __fastcall TDateTime ReadTime(const UnicodeString Section, const UnicodeString Name,
TDateTime Default);
```

Description

Call ReadTime to read a time value from an INI file. Section identifies the section in the file that contains the desired key. Ident is the name of the key from which to retrieve the time value. Default is the time value to return if the:

Section does not exist.

Key does not exist.

Data value for the key is not assigned.

ReadBool (see page 4265)

ReadDate (see page 6671)

ReadDateTime (see page 6671)

ReadFloat (see page 6672)

ReadInteger (see page 6672)

ReadString (see page 6677)

73.1.4.4.13 TRegistryIniFile.UpdateFile Method

Flushes buffered INI file data to disk.

Pascal

```
procedure UpdateFile; override;
```

C++

```
virtual __fastcall UpdateFile();
```

Description

Call UpdateFile to flush buffered reads from and writes to the INI file to disk. UpdateFile is useful under Windows95, but has no effect under Windows NT as NT does not buffer INI file reads and writes.

See Also

FileName (see page 4291)

73.1.4.4.14 TRegistryIniFile.WriteBinaryStream Method

Writes a binary value to the registry.

Pascal

```
procedure WriteBinaryStream(const Section: string; const Name: string; Value: TStream);
override;
```

C++

```
virtual __fastcall WriteBinaryStream(const UnicodeString Section, const UnicodeString Name,
TStream Value);
```

Description

Call WriteBinaryStream to write a binary value from a specified stream to a specified key in the registry. WriteBinaryStream writes from the current position in the stream to the end.

Section is the key for the section that contains the subkey where the binary data should be written.

Name is the subkey under which the binary data is stored.

Value is a stream from which the binary value can be read.

Note: Attempting to write a value to a nonexistent section or attempting to write data to a nonexistent key are not errors. In these cases, WriteBinaryStream creates the section and key and sets its initial value to the stream's data.

See Also

WriteString (see page 6686)

ReadBinaryStream (see page 6670)

73.1.4.4.15 TRegistryIniFile.WriteDate Method

Writes a date value to an INI file.

Pascal

```
procedure WriteDate(const Section: string; const Name: string; Value: TDateTime); override;
```

C++

```
virtual __fastcall WriteDate(const UnicodeString Section, const UnicodeString Name, TDateTime
Value);
```

Description

Call WriteDate to write a date value to an INI file. Section identifies the section in the file that contain the key to which to write. Ident is the name of the key for which to set a value. Value is the date value to write.

Note: Attempting to write a data value to a nonexistent section or attempting to write data to a nonexistent key are not errors. In these cases, WriteDate creates the section and key and sets its initial value to Value.

See Also

WriteBool (see page 4279)

WriteDateTime (see page 6682)

WriteFloat (see page 6683)

WriteInteger (see page 6683)

WriteString (see page 6686)

WriteTime (see page 6689)

73.1.4.4.16 TRegistryIniFile.WriteDateTime Method

Writes a date-time value to an INI file.

Pascal

```
procedure WriteDateTime(const Section: string; const Name: string; Value: TDateTime); override;
```

C++

```
virtual __fastcall WriteDateTime(const UnicodeString Section, const UnicodeString Name,
TDateTime Value);
```

Description

Call WriteDateTime to write a date-time value to an INI file. Section identifies the section in the file that contain the key to which to write. Ident is the name of the key for which to set a value. Value is the date-time value to write.

Note: Attempting to write a data value to a nonexistent section or attempting to write data to a nonexistent key are not errors. In these cases, WriteDateTime creates the section and key and sets its initial value to Value.

See Also

WriteBool (see page 4279)

WriteDate (see page 6682)

WriteFloat (see page 6683)

WriteInteger (see page 6683)

WriteString (see page 6686)

WriteTime (see page 6689)

73.1.4.4.17 TRegistryIniFile.WriteFloat Method

Writes a float value to an INI file.

Pascal

```
procedure WriteFloat(const Section: string; const Name: string; Value: Double); override;
```

C++

```
virtual __fastcall WriteFloat(const UnicodeString Section, const UnicodeString Name, Double
Value);
```

Description

Call WriteFloat to write a float value to an INI file. Section identifies the section in the file that contain the key to which to write. Ident is the name of the key for which to set a value. Value is the float value to write.

Note: Attempting to write a data value to a nonexistent section or attempting to write data to a nonexistent key are not errors. In these cases, WriteFloat creates the section and key and sets its initial value to Value.

WriteTime (see page 6689)

73.1.4.4.18 TRegistryIniFile.WriteInteger Method

Writes an integer value to an INI file.

Pascal

```
procedure WriteInteger(const Section: string; const Ident: string; Value: Longint); override;
```

C++

```
virtual __fastcall WriteInteger(const UnicodeString Section, const UnicodeString Ident,
Longint Value);
```

Description

Call WriteInteger to write an integer value to an INI file. Section identifies the section in the file that contain the key to which to write. Ident is the name of the key for which to set a value. Value is the integer value to write.

Note: Attempting to write a data value to a nonexistent section or attempting to write data to a nonexistent key are not errors. In these cases, WriteInteger creates the section and key and sets its initial value to Value.

C++ Examples:

```
/*
This example demonstrates the usage of Ini files in order to store
and load form configuration between sessions. Example assumes
a RadioGroup and two buttons are present on the main form.
*/
void __fastcall TForm2::btStoreClick(TObject *Sender)
{
    /* Open an instance */
    TCustomIniFile* SettingsFile = OpenIniFileInstance();

    // Store current form properties to be used in later sessions.
    try
    {
        SettingsFile->WriteInteger (Name, "Top", Top);
        SettingsFile->WriteInteger (Name, "Left", Left);
        SettingsFile->WriteInteger (Name, "Width", Width);
        SettingsFile->WriteInteger (Name, "Height", Height);
        SettingsFile->WriteString  (Name, "Caption", Caption);
        SettingsFile->WriteBool    (Name, "InitMax", WindowState == wsMaximized );
    }
    catch(Exception* e)
    {
    }

    delete SettingsFile;
}

void __fastcall TForm2::btLoadClick(TObject *Sender)
{
    /* Open an instance */
    TCustomIniFile* SettingsFile = OpenIniFileInstance();

    try
    {
        /*
        Read all saved values from the last session. The section name
        is the name of the form. Also use form's properties as defaults
        */
        Top     = SettingsFile->ReadInteger(Name, "Top", Top );
        Left    = SettingsFile->ReadInteger(Name, "Left", Left );
        Width   = SettingsFile->ReadInteger(Name, "Width", Width );
        Height  = SettingsFile->ReadInteger(Name, "Height", Height );
        Caption = SettingsFile->ReadString (Name, "Caption", Caption);

        // Load last window state
        if (SettingsFile->ReadBool(Name, "InitMax", WindowState == wsMaximized))
            WindowState = wsMaximized;
        else
            WindowState = wsNormal;
    }
    catch(Exception* e)
    {
    }

    delete SettingsFile;
}

TCustomIniFile* __fastcall TForm2::OpenIniFileInstance()
{
    /*
    Open/create a new INI file that has the same name as our executable
    only with the INI extension.
    */

    switch (RadioGroup1->ItemIndex)
    {
```

```
        case 0:
            /* Registry mode selected: in HKEY_CURRENT_USER\Software\... */
            return new TRegistryIniFile(String("Software\\") + Application->Title);
        case 1:
            /* Ini file mode selected */
            return new TIniFile(ChangeFileExt(Application->ExeName, ".INI"));
        case 2:
            /* Memory based Ini file mode selected */
            return new TMemIniFile(ChangeFileExt(Application->ExeName, ".INI"));
      }
}
```

Delphi Examples:

```
{
This example demonstrates the use of Ini files in order to store
and load form configurations between sessions. This example requires
a RadioGroup and two buttons.
}
procedure TForm2.btLoadClick(Sender: TObject);
var
  SettingsFile : TCustomIniFile;
begin
  { Open an instance }
  SettingsFile := OpenIniFileInstance();

  try
    {
    Read all saved values from the last session. The section name
    is the name of the form. Also use form's properties as defaults
    }
    Top     := SettingsFile.ReadInteger(Name, 'Top', Top );
    Left    := SettingsFile.ReadInteger(Name, 'Left', Left );
    Width   := SettingsFile.ReadInteger(Name, 'Width', Width );
    Height  := SettingsFile.ReadInteger(Name, 'Height', Height );
    Caption := SettingsFile.ReadString (Name, 'Caption', Caption);

    { Load last window state }
    case SettingsFile.ReadBool(Name, 'InitMax', WindowState = wsMaximized) of
      true : WindowState := wsMaximized;
      false: WindowState := wsNormal;
    end;

  finally
    SettingsFile.Free;
  end;
end;

procedure TForm2.btStoreClick(Sender: TObject);

73.1.4.4.19 TRegistryIniFile.WriteString Method

Writes a string value to an INI file.

Pascal

```
procedure WriteString(const Section: string; const Ident: string; const Value: string);
override;
```

C++

```
virtual __fastcall WriteString(const UnicodeString Section, const UnicodeString Ident, const
UnicodeString Value);
```

Description

Call WriteString to write a string value to an INI file. Section identifies the section in the file that contain the key to which to write. Ident is the name of the key for which to set a value. Value is the string value to write.

Note: Attempting to write a data value to a nonexistent section or attempting to write data to a nonexistent key are not errors. In these cases, WriteString creates the section and key and sets its initial value to Value.

C++ Examples:

```
/*
This example demonstrates the usage of Ini files in order to store
and load form configuration between sessions. Example assumes
a RadioGroup and two buttons are present on the main form.
*/
void __fastcall TForm2::btStoreClick(TObject *Sender)
{
    /* Open an instance */
    TCustomIniFile* SettingsFile = OpenIniFileInstance();

    // Store current form properties to be used in later sessions.
    try
    {
        SettingsFile->WriteInteger (Name, "Top", Top);
        SettingsFile->WriteInteger (Name, "Left", Left);
        SettingsFile->WriteInteger (Name, "Width", Width);
        SettingsFile->WriteInteger (Name, "Height", Height);
        SettingsFile->WriteString  (Name, "Caption", Caption);
        SettingsFile->WriteBool    (Name, "InitMax", WindowState == wsMaximized );
    }
    catch(Exception* e)
    {
    }

    delete SettingsFile;
}

void __fastcall TForm2::btLoadClick(TObject *Sender)
{
    /* Open an instance */
    TCustomIniFile* SettingsFile = OpenIniFileInstance();

    try
    {
        /*
        Read all saved values from the last session. The section name
        is the name of the form. Also use form's properties as defaults
        */
        Top     = SettingsFile->ReadInteger(Name, "Top", Top );
        Left    = SettingsFile->ReadInteger(Name, "Left", Left );
        Width   = SettingsFile->ReadInteger(Name, "Width", Width );
        Height  = SettingsFile->ReadInteger(Name, "Height", Height );
        Caption = SettingsFile->ReadString (Name, "Caption", Caption);

        // Load last window state
        if (SettingsFile->ReadBool(Name, "InitMax", WindowState == wsMaximized))
            WindowState = wsMaximized;
        else
            WindowState = wsNormal;
    }
    catch(Exception* e)
    {
    }

    delete SettingsFile;
}

TCustomIniFile* __fastcall TForm2::OpenIniFileInstance()
{
    /*
    Open/create a new INI file that has the same name as our executable
    only with the INI extension.
```

```
    */

    switch (RadioGroup1->ItemIndex)
    {
        case 0:
            /* Registry mode selected: in HKEY_CURRENT_USER\Software\... */
            return new TRegistryIniFile(String("Software\\") + Application->Title);
        case 1:
            /* Ini file mode selected */
            return new TIniFile(ChangeFileExt(Application->ExeName, ".INI"));
        case 2:
            /* Memory based Ini file mode selected */
            return new TMemIniFile(ChangeFileExt(Application->ExeName, ".INI"));
      }
}
```

Delphi Examples:

```
{
This example demonstrates the use of Ini files in order to store
and load form configurations between sessions. This example requires
a RadioGroup and two buttons.
}
procedure TForm2.btLoadClick(Sender: TObject);
var
  SettingsFile : TCustomIniFile;
begin
  { Open an instance }
  SettingsFile := OpenIniFileInstance();

  try
    {
    Read all saved values from the last session. The section name
    is the name of the form. Also use form's properties as defaults
    }
    Top     := SettingsFile.ReadInteger(Name, 'Top', Top );
    Left    := SettingsFile.ReadInteger(Name, 'Left', Left );
    Width   := SettingsFile.ReadInteger(Name, 'Width', Width );
    Height  := SettingsFile.ReadInteger(Name, 'Height', Height );
    Caption := SettingsFile.ReadString (Name, 'Caption', Caption);

    { Load last window state }
    case SettingsFile.ReadBool(Name, 'InitMax', WindowState = wsMaximized) of
      true : WindowState := wsMaximized;
      false: WindowState := wsNormal;
    end;

  finally
    SettingsFile.Free;
  end;
end;

procedure TForm2.btStoreClick(Sender: TObject);
var
  SettingsFile: TCustomIniFile;
begin
  { Open an instance }
  SettingsFile := OpenIniFileInstance();

  {
  Store current form properties to be used in later sessions.
  }
  try
    SettingsFile.WriteInteger (Name, 'Top', Top);
    SettingsFile.WriteInteger (Name, 'Left', Left);
    SettingsFile.WriteInteger (Name, 'Width', Width);
    SettingsFile.WriteInteger (Name, 'Height', Height);
```

```
      SettingsFile.WriteString  (Name, 'Caption', Caption);
      SettingsFile.WriteBool    (Name, 'InitMax', WindowState = wsMaximized );
      SettingsFile.WriteDateTime(Name, 'LastRun', Now);
    finally
      SettingsFile.Free;
    end;

  end;

  function TForm2.OpenIniFileInstance: TCustomIniFile;
  begin
    {
    Open/create a new INI file that has the same name as our executable
    only with the INI extension.
    }

    case RadioGroup1.ItemIndex of
      0:
        begin
          { Registry mode selected: in HKEY_CURRENT_USER\Software\... }
          Result := TRegistryIniFile.Create('Software\' + Application.Title);
        end;
      1:
        begin
          { Ini file mode selected }
          Result := TIniFile.Create(ChangeFileExt(Application.ExeName, '.INI'));
        end;
      2:
        begin
          { Memory based Ini file mode selected }
          Result := TMemIniFile.Create(ChangeFileExt(Application.ExeName, '.INI'));
        end;
    end;
  end;
```

WriteInteger (see page 6683)

WriteTime (see page 6689)

73.1.4.4.20 TRegistryIniFile.WriteTime Method

Writes a time value to an INI file.

Pascal

```
procedure WriteTime(const Section: string; const Name: string; Value: TDateTime); override;
```

C++

```
virtual __fastcall WriteTime(const UnicodeString Section, const UnicodeString Name, TDateTime
Value);
```

Description

Call WriteTime to write a time value to an INI file. Section identifies the section in the file that contain the key to which to write. Ident is the name of the key for which to set a value. Value is the time value to write.

Note: Attempting to write a data value to a nonexistent section or attempting to write data to a nonexistent key are not errors. In these cases, WriteTime creates the section and key and sets its initial value to Value.

73.1.4.5 TRegistryIniFile Properties

The properties of the TRegistryIniFile class are listed here.

Public Properties

	Name	Description
	RegIniFile (see page 6690)	Contains and internal instance of a TRegIniFile (see page 6601) object.

73.1.4.5.1 TRegistryIniFile.RegIniFile Property

Contains and internal instance of a TRegIniFile (see page 6601) object.

Pascal

```
property RegIniFile: TRegIniFile;
```

C++

```
__property TRegIniFile RegIniFile;
```

Description

RegIniFile is used internally by the TRegistryIniFile (see page 6663) object as the gateway connection between TRegistryIniFile (see page 6663) methods and the system registry.

See Also

Create (see page 6668)

73.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TRegDataType (see page 6691)	TRegDataType is a type used by the GetDataInfo method of TRegistery.

Records

	Name	Description
	TRegDataInfo (see page 6691)	TRegDataInfo is a type used by the GetDataInfo method of TRegistery.
	TRegKeyInfo (see page 6692)	TRegKeyInfo is a type used by the GetRegKeyInfo method of TRegistery.

73.2.1 Registry.TRegDataInfo Record

TRegDataInfo is a type used by the GetDataInfo method of TRegistery.

Pascal

```
TRegDataInfo = record
  RegData: TRegDataType;
  DataSize: Integer;
end;
```

C++

```
struct TRegDataInfo {
  TRegDataType RegData;
  int DataSize;
};
```

File

Registry

Description

TRegDataInfo is a type used by the GetDataInfo method of TRegistery. Records of type TRegDataInfo contain two fields: a field called RegData, of type TRegDataType (see page 6691), that specifies the data type of the data value; and a field called DataSize that specifies the size, in bytes, of the data value.

73.2.2 Registry.TRegDataType Enumeration

TRegDataType is a type used by the GetDataInfo method of TRegistery.

Pascal

```
TRegDataType = (
  rdUnknown,
  rdString,
  rdExpandString,
  rdInteger,
```

```
    rdBinary
  );
```

C++

```
  enum TRegDataType {
    rdUnknown,
    rdString,
    rdExpandString,
    rdInteger,
    rdBinary
  };
```

File

Registry

Description

TRegDataType is a type used by the GetDataInfo method of TRegistery.It can have the following values:

Value	Meaning
rdUnknown	Data value type is of no defined value type.
rdString	Data value type is a null-terminated string. It is a Unicode or ANSI string depending on whether the application calls the Unicode or ANSI string functions.
rdExpandString	Data value type is a null-terminated string that contains unexpanded references to environment variables (for example, "%PATH%"). It is a Unicode or ANSI string depending on whether the application calls the Unicode or ANSI string functions.
rdInteger	Data value type is a32-bit number.
rdBinary	Data value type is binary data, in any form.

73.2.3 Registry.TRegKeyInfo Record

TRegKeyInfo is a type used by the GetRegKeyInfo method of TRegistery.

Pascal

```
  TRegKeyInfo = record
    NumSubKeys: Integer;
    MaxSubKeyLen: Integer;
    NumValues: Integer;
    MaxValueLen: Integer;
    MaxDataLen: Integer;
    FileTime: TFileTime;
  end;
```

C++

```
  struct TRegKeyInfo {
    int NumSubKeys;
    int MaxSubKeyLen;
    int NumValues;
    int MaxValueLen;
    int MaxDataLen;
    TFileTime FileTime;
  };
```

File

Registry

Description

TRegKeyInfo is a type used by the GetRegKeyInfo method of TRegistery to return information about the current key:

Note: Number of subkeys

Note: Longest subkey name length, in characters

Note: Number of data values

Note: Longest data-value name length

Note: Longest data-value length

Note: Time of last write to the key

74 ReqFiles Namespace

This is namespace ReqFiles.

Topics

Name	Description
Classes (see page 6696)	The following table lists classes in this documentation.

Classes

	Name	Description
	TWebRequestFile (see page 6696)	TWebRequestFile describes the content of a file extracted from an HTTP request.
	TWebRequestFiles (see page 6700)	TWebRequestFiles stores a collection of TWebAbstractRequestFile objects.
	TWebRequestFileStream (see page 6703)	This is class ReqFiles.TWebRequestFileStream.

74.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TWebRequestFile (see page 6696)	TWebRequestFile describes the content of a file extracted from an HTTP request.
	TWebRequestFiles (see page 6700)	TWebRequestFiles stores a collection of TWebAbstractRequestFile objects.
	TWebRequestFileStream (see page 6703)	This is class ReqFiles.TWebRequestFileStream.

74.1.1 TWebRequestFile Class

TWebRequestFile describes the content of a file extracted from an HTTP request.

Class Hierarchy

Pascal

```
TWebRequestFile = class(TAbstractWebRequestFile);
```

C++

```
class TWebRequestFile : public TAbstractWebRequestFile;
```

File

ReqFiles

Description

TWebRequestFile describes and provides access to an uploaded file from an HTTP request. The following properties support this access:

FileName, which gives the name of the uploaded file.

FieldName, which gives the name of the adapter field whose value is the uploaded file.

ContentType, which describes how the file data is encoded.

Stream, which is a stream object from which you can read the file content.

Each TWebRequestFile object describes a single uploaded file. A collection of all the uploaded files from the current request is available as the Files property of TWebRequest (see page 3358). In addition, adapter fields that work with uploaded files surface those files using a TUpdateFileList object or IActionFieldValues interface.

See Also

TWebRequestFiles (see page 6700)

IActionFieldValues

TUpdateFileList

TAdapterFileField

74.1.1.1 TWebRequestFile Members

The following tables list the members exposed by TWebRequestFile.

Protected Methods

	Name	Description
	GetContentType (see page 6698)	Returns the value of the ContentType property.
	GetFieldName (see page 6699)	Returns the value of the FieldName property.
	GetFileName (see page 6699)	Returns the value of the FileName property.
	GetStream (see page 6699)	Returns the value of the Stream property.

Public Methods

	Name	Description
	Create (see page 6697)	Creates an initializes an instance of TWebRequestFile (see page 6696).
	Destroy (see page 6698)	Frees an instance of TWebRequestFile (see page 6696).

Public Properties

	Name	Description
	ContentType (see page 3291)	Describes how the file data is encoded.
	FieldName (see page 3291)	Indicates the name of the adapter field whose value is the contents of the file.
	FileName (see page 3291)	Indicates the name of the uploaded file.
	Stream (see page 3292)	Provides access to the contents of the uploaded file.

74.1.1.2 TWebRequestFile.Create Constructor

Creates an initializes an instance of TWebRequestFile (see page 6696).

Pascal

```
constructor Create(const AFieldName: AnsiString; const AFileName: AnsiString; const
AContentType: AnsiString; AContent: Pointer; AContentLength: Integer);
```

C++

```
__fastcall TWebRequestFile(const AnsiString AFieldName, const AnsiString AFileName, const
AnsiString AContentType, void * AContent, int AContentLength);
```

Description

Typically, applications do not call the TWebRequestFile (see page 6696) constructor. Instead, new Web request file objects are created by calling the Add method of a TWebRequestFiles (see page 6700) collection as the file uploads are extracted from the current Web request.

AFieldName is the name of the adapter field whose value this file represents. It becomes the value of the FieldName property.

AFileName is the name of the file this object represents. It becomes the value of the FileName property.

AContentType describes how the file content is encoded. It becomes the value of the ContentType property.

AContent is an array of bytes that is the content of the file. It is used to initialize the Stream property.

AContentLength is the number of bytes in AContent.

FieldName

FileName

ContentType

Stream

Add (see page 6702)

74.1.1.3 TWebRequestFile.Destroy Destructor

Frees an instance of TWebRequestFile (see page 6696).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TWebRequestFile();
```

Description

Do not free instances of TWebRequestFile (see page 6696). TWebRequestFile (see page 6696) objects are created and destroyed by the TWebRequestFiles (see page 6700) object that lists the uploaded files from the current request.

See Also

TWebRequestFiles (see page 6700)

74.1.1.4 TWebRequestFile Methods

The methods of the TWebRequestFile class are listed here.

Protected Methods

	Name	Description
	GetContentType (see page 6698)	Returns the value of the ContentType property.
	GetFieldName (see page 6699)	Returns the value of the FieldName property.
	GetFileName (see page 6699)	Returns the value of the FileName property.
	GetStream (see page 6699)	Returns the value of the Stream property.

74.1.1.4.1 TWebRequestFile.GetContentType Method

Returns the value of the ContentType property.

Pascal

```
function GetContentType: AnsiString; override;
```

C++

```
virtual __fastcall AnsiString GetContentType();
```

Description

GetContentType is the protected read implementation for the ContentType property.

In TAbstractWebRequestFile, GetContentType is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes must override this method to provide an implementation for the ContentType property.

See Also

ContentType (see page 3291)

74.1.1.4.2 TWebRequestFile.GetFieldName Method

Returns the value of the FieldName property.

Pascal

```
function GetFieldName: AnsiString; override;
```

C++

```
virtual __fastcall AnsiString GetFieldName();
```

Description

GetFieldName is the protected read implementation for the FieldName property.

In TAbstractWebRequestFile, GetFieldName is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes must override this method to provide an implementation for the FieldName property.

See Also

FieldName (see page 3291)

74.1.1.4.3 TWebRequestFile.GetFileName Method

Returns the value of the FileName property.

Pascal

```
function GetFileName: AnsiString; override;
```

C++

```
virtual __fastcall AnsiString GetFileName();
```

Description

GetFileName is the protected read implementation for the FileName property.

In TAbstractWebRequestFile, GetFileName is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes must override this method to provide an implementation for the FileName property.

See Also

FileName (see page 3291)

74.1.1.4.4 TWebRequestFile.GetStream Method

Returns the value of the Stream property.

Pascal

```
function GetStream: TStream; override;
```

C++

```
virtual __fastcall TStream GetStream();
```

Description

GetStream is the protected read implementation for the Stream property.

In TAbstractWebRequestFile, GetStream is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes must override this method to provide an implementation for the Stream property.

See Also

Stream (see page 3292)

74.1.2 TWebRequestFiles Class

TWebRequestFiles stores a collection of TWebAbstractRequestFile objects.

Class Hierarchy

Pascal

```
TWebRequestFiles = class(TAbstractWebRequestFiles);
```

C++

```
class TWebRequestFiles : public TAbstractWebRequestFiles;
```

File

ReqFiles

Description

TWebRequestFiles manages a set of Web request files objects (TWebRequestFile (see page 6696) objects). Each Web request file object in the collection describes an uploaded file that was extracted from the current HTTP request object.

See Also

TWebRequestFile (see page 6696)

TWebRequest (see page 3358)

74.1.2.1 TWebRequestFiles Members

The following tables list the members exposed by TWebRequestFiles.

Protected Methods

	Name	Description
	GetCount (see page 6703)	Returns the value of the Count property.
	GetItem (see page 6703)	Returns the value of the Items property.

Public Methods

	Name	Description
	Add (see page 6701)	This is the overview for the Add method overload.
	Create (see page 6701)	Creates and initializes an instance of TWebRequestFiles (see page 6700).
	Destroy (see page 6701)	Frees an instance of TWebRequestFiles (see page 6700).

Public Properties

	Name	Description
	Count (see page 3294)	Indicates the number of uploaded files in the collection.
	Items (see page 3295)	Lists the uploaded files in the collection.

74.1.2.2 TWebRequestFiles.Create Constructor

Creates and initializes an instance of TWebRequestFiles (see page 6700).

Pascal

```
constructor Create;
```

C++

```
__fastcall TWebRequestFiles();
```

Description

Call Create to instantiate TWebRequestFiles (see page 6700) at runtime. TWebRequestFiles (see page 6700) instances are created automatically by the Web request object to implement its Files property.

See Also

Files (see page 3379)

74.1.2.3 TWebRequestFiles.Destroy Destructor

Frees an instance of TWebRequestFiles (see page 6700).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TWebRequestFiles();
```

Description

Use the Free method to delete an instance of TWebRequestFiles (see page 6700). Free checks for a nil reference before calling Destroy.

See Also

System::TObject::Free

74.1.2.4 TWebRequestFiles Methods

The methods of the TWebRequestFiles class are listed here.

Protected Methods

	Name	Description
	GetCount (see page 6703)	Returns the value of the Count property.
	GetItem (see page 6703)	Returns the value of the Items property.

Public Methods

	Name	Description
	Add (see page 6701)	This is the overview for the Add method overload.

74.1.2.4.1 Add Method

This is the overview for the Add method overload.

Overload List

	Name	Description
	TWebRequestFiles.Add (AnsiString, AnsiString, AnsiString, Pointer, Integer) (see page 6702)	Adds a new Web request file object to the collection.
	TWebRequestFiles.Add (TWebRequestFile) (see page 6702)	Adds a new Web request file object to the collection.

74.1.2.4.1.1 TWebRequestFiles.Add Method (AnsiString, AnsiString, AnsiString, Pointer, Integer)

Adds a new Web request file object to the collection.

Pascal

```
procedure Add(const AName: AnsiString; const AFileName: AnsiString; const AContentType:
AnsiString; AContent: Pointer; AContentLength: Integer); overload;
procedure Add(AFile: TWebRequestFile); overload;
```

C++

```
__fastcall Add(const AnsiString AName, const AnsiString AFileName, const AnsiString
AContentType, void * AContent, int AContentLength);
__fastcall Add(TWebRequestFile AFile);
```

Description

Call Add to add a TWebRequestFile (see page 6696) object to the collection. Add inserts the new Web request file object at the end of the Items property array and increments the value of the Count property.

Use the first syntax to cause TWebRequestFiles (see page 6700) to create the Web request file object you are adding. Use the second syntax to add an existing TWebRequestFile (see page 6696) object. Using either syntax, TWebRequestFiles (see page 6700) assumes ownership of the new Web request file object and is responsible for freeing it.

AName is the name of the adapter field whose value the new file represents. It becomes the value of the FieldName property of the new TWebRequestFile (see page 6696) object.

AFileName is the name of the file to add. It becomes the value of the FileName property of the new TWebRequestFile (see page 6696) object.

AContentType describes how the file content is encoded. It becomes the value of the ContentType property of the new TWebRequestFile (see page 6696) object.

AContent is an array of bytes that is the content of the file. It is used to initialize the Stream property of the new TWebRequestFile (see page 6696) object.

AContentLength is the number of bytes in AContent.

AFile is an existing TWebRequestFile (see page 6696) object that describes the file you are adding.

74.1.2.4.2 TWebRequestFiles.GetCount Method

Returns the value of the Count property.

Pascal

```
function GetCount: Integer; override;
```

C++

```
virtual __fastcall int GetCount();
```

Description

GetCount is the protected read implementation of the Count property.

In TAbstractWebRequestFile, GetCount is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes must override this method to provide an implementation for the Count property.

See Also

Count (see page 3294)

74.1.2.4.3 TWebRequestFiles.GetItem Method

Returns the value of the Items property.

Pascal

```
function GetItem(I: Integer): TAbstractWebRequestFile; override;
```

C++

```
virtual __fastcall TAbstractWebRequestFile GetItem(int I);
```

Description

GetItem is the protected read implementation of the Items property.

I is the index of the Web request file object to return.

In TAbstractWebRequestFile, GetCount is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes must override this method to provide an implementation for the Count property.

74.1.3 TWebRequestFileStream Class

Class Hierarchy

Pascal

```
TWebRequestFileStream = class(TCustomMemoryStream);
```

C++

```
class TWebRequestFileStream : public TCustomMemoryStream;
```

File

ReqFiles

Description

This is class ReqFiles.TWebRequestFileStream.

74.1.3.1 TWebRequestFileStream Members

The following tables list the members exposed by TWebRequestFileStream.

Public Methods

	Name	Description
	Create (see page 6704)	This is Create, a member of class TWebRequestFileStream.
