1 ExptIntf Namespace

This is namespace ExptIntf.

Topics

Name	Description
Classes (see page 3)	The following table lists classes in this documentation.
Functions (see page 7)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 8)	The following table lists structs, records, enums in this documentation.
Types (see page 9)	The following table lists types in this documentation.
Variables (see page 11)	The following table lists variables in this documentation.
Constants (see page 12)	The following table lists constants in this documentation.

Classes

	Name	Description
	TIExpert (see page 3)	This is class ExptIntf.TIExpert.

Constants

Name	Description
ExpertEntryPoint (see page 12)	This is constant ExptIntf.ExpertEntryPoint.
isExperts (see page 12)	This is constant ExptIntf.isExperts.
ValidExpertVersion (see page 12)	This is constant ExptIntf.ValidExpertVersion.

Functions

	Name	Description
	RegisterLibraryExpert (see page 7)	Registers an expert so that it is installed when a package is installed.

Structs, Records, Enums

	Name	Description
	TExpertStyle (see page 8)	This is record ExptIntf.TExpertStyle.

Types

Name	Description
TExpertInitProc (see page 9)	This is type ExptIntf.TExpertInitProc.
TExpertRegisterProc (see page 9)	This is type ExptIntf.TExpertRegisterProc.
TExpertState (see page 10)	This is type ExptIntf.TExpertState.
TExpertTerminateProc (see page 10)	This is type ExptIntf.TExpertTerminateProc.

Variables

Name	Description
LibraryExpertProc (see page 11)	This is variable ExptIntf.LibraryExpertProc.
ToolServices (see page 11)	This is variable ExptIntf.ToolServices.

1.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TIExpert (see page 3)	This is class ExptIntf.TIExpert.

1.1.1 TIExpert Class

Class Hierarchy

Pascal

```
TIExpert = class(TInterface);
```

C++

```
class TIExpert : public TInterface;
```

File

ExptIntf

Description

This is class ExptIntf.TIExpert.

1.1.1.1 TIExpert Members

The following tables list the members exposed by TIExpert.

Public Methods

	Name	Description
	Execute (see page 4)	This is Execute, a member of class TIExpert.
	GetAuthor (see page 4)	This is GetAuthor, a member of class TIExpert.
	GetComment (see page 4)	This is GetComment, a member of class TIExpert.
	GetGlyph (see page 4)	This is GetGlyph, a member of class TIExpert.
	GetIDString (see page 5)	This is GetIDString, a member of class TIExpert.
	GetMenuText (see page 5)	This is GetMenuText, a member of class TIExpert.
	GetName (see page 5)	This is GetName, a member of class TIExpert.
	GetPage (see page 5)	This is GetPage, a member of class TIExpert.
	GetState (see page 6)	This is GetState, a member of class TIExpert.
	GetStyle (see page 6)	This is GetStyle, a member of class TIExpert.

1.1.1.2 TIExpert Methods

The methods of the TIExpert class are listed here.

Public Methods

	Name	Description
	Execute (see page 4)	This is Execute, a member of class TIExpert.
	GetAuthor (see page 4)	This is GetAuthor, a member of class TIExpert.
	GetComment (see page 4)	This is GetComment, a member of class TIExpert.
	GetGlyph (see page 4)	This is GetGlyph, a member of class TIExpert.
	GetIDString (see page 5)	This is GetIDString, a member of class TIExpert.
	GetMenuText (see page 5)	This is GetMenuText, a member of class TIExpert.
	GetName (see page 5)	This is GetName, a member of class TIExpert.
	GetPage (see page 5)	This is GetPage, a member of class TIExpert.
	GetState (see page 6)	This is GetState, a member of class TIExpert.
	GetStyle (see page 6)	This is GetStyle, a member of class TIExpert.

1.1.1.2.1 TIExpert.Execute Method

Pascal

```
procedure Execute; virtual; abstract; stdcall;
```

C++

```
virtual __fastcall __stdcall Execute() = 0;
```

Description

This is Execute, a member of class TIExpert.

1.1.1.2.2 TIExpert.GetAuthor Method

Pascal

```
function GetAuthor: string; virtual; abstract; stdcall;
```

C++

```
virtual __fastcall __stdcall UnicodeString GetAuthor() = 0;
```

Description

This is GetAuthor, a member of class TIExpert.

1.1.1.2.3 TIExpert.GetComment Method

Pascal

```
function GetComment: string; virtual; abstract; stdcall;
```

C++

```
virtual __fastcall __stdcall UnicodeString GetComment() = 0;
```

Description

This is GetComment, a member of class TIExpert.

1.1.1.2.4 TIExpert.GetGlyph Method

Pascal

```
function GetGlyph: HICON; virtual; abstract; stdcall;
```

C++

```
virtual __fastcall __stdcall HICON GetGlyph() = 0;
```

Description

This is GetGlyph, a member of class TIExpert.

1.1.1.2.5 TIExpert.GetIDString Method

Pascal

```
function GetIDString: string; virtual; abstract; stdcall;
```

C++

```
virtual __fastcall __stdcall UnicodeString GetIDString() = 0;
```

Description

This is GetIDString, a member of class TIExpert.

1.1.1.2.6 TIExpert.GetMenuText Method

Pascal

```
function GetMenuText: string; virtual; abstract; stdcall;
```

C++

```
virtual __fastcall __stdcall UnicodeString GetMenuText() = 0;
```

Description

This is GetMenuText, a member of class TIExpert.

1.1.1.2.7 TIExpert.GetName Method

Pascal

```
function GetName: string; virtual; abstract; stdcall;
```

C++

```
virtual __fastcall __stdcall UnicodeString GetName() = 0;
```

Description

This is GetName, a member of class TIExpert.

1.1.1.2.8 TIExpert.GetPage Method

Pascal

```
function GetPage: string; virtual; abstract; stdcall;
```

C++

```
virtual __fastcall __stdcall UnicodeString GetPage() = 0;
```

Description

This is GetPage, a member of class TIExpert.

1.1.1.2.9 TIExpert.GetState Method

Pascal

```
function GetState: TExpertState; virtual; abstract; stdcall;
```

C++

```
virtual __fastcall __stdcall TExpertState GetState() = 0;
```

Description

This is GetState, a member of class TIExpert.

1.1.1.2.10 TIExpert.GetStyle Method

Pascal

```
function GetStyle: TExpertStyle; virtual; abstract; stdcall;
```

C++

```
virtual __fastcall __stdcall TExpertStyle GetStyle() = 0;
```

Description

This is GetStyle, a member of class TIExpert.

1.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	RegisterLibraryExpert (see page 7)	Registers an expert so that it is installed when a package is installed.

1.2.1 ExptIntf.RegisterLibraryExpert Function

Registers an expert so that it is installed when a package is installed.

Pascal

```
procedure RegisterLibraryExpert(Expert: TIExpert);
```

C++

```
RegisterLibraryExpert(TIExpert Expert);
```

File

ExptIntf

Description

Call RegisterLibrary to register an expert for a package so that it appears in the New Items dialog. If the package already has a registered expert, RegisterLibraryExpert does nothing.

1.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TExpertStyle (see page 8)	This is record ExptIntf.TExpertStyle.

1.3.1 ExptIntf.TExpertStyle Enumeration

Pascal

```
TExpertStyle = (
  esStandard,
  esForm,
  esProject,
  esAddIn
);
```

C++

```
enum TExpertStyle {
  esStandard,
  esForm,
  esProject,
  esAddIn
};
```

File

ExptIntf

Description

This is record ExptIntf.TExpertStyle.

1.4 Types

The following table lists types in this documentation.

Types

Name	Description
TExpertInitProc (see page 9)	This is type ExptIntf.TExpertInitProc.
TExpertRegisterProc (see page 9)	This is type ExptIntf.TExpertRegisterProc.
TExpertState (see page 10)	This is type ExptIntf.TExpertState.
TExpertTerminateProc (see page 10)	This is type ExptIntf.TExpertTerminateProc.

1.4.1 ExptIntf.TExpertInitProc Type

Pascal

```
TExpertInitProc = function (ToolServices: TIToolServices; RegisterProc: TExpertRegisterProc;
var Terminate: TExpertTerminateProc): Boolean stdcall;
```

C++

```
(ToolServices: TIToolServices; RegisterProc: TExpertRegisterProc; var Terminate:
TExpertTerminateProc): Boolean stdcall ( TExpertInitProc)();
```

File

ExptIntf

Description

This is type ExptIntf.TExpertInitProc.

1.4.2 ExptIntf.TExpertRegisterProc Type

Pascal

```
TExpertRegisterProc = function (Expert: TIExpert): Boolean;
```

C++

```
(Expert: TIExpert): Boolean ( TExpertRegisterProc)();
```

File

ExptIntf

Description

This is type ExptIntf.TExpertRegisterProc.

1.4.3 ExptIntf.TExpertState Type

Pascal

```
TExpertState = set of (esEnabled, esChecked);
```

C++

```
(esEnabled, esChecked) TExpertState;
```

File

ExptIntf

Description

This is type ExptIntf.TExpertState.

1.4.4 ExptIntf.TExpertTerminateProc Type

Pascal

```
TExpertTerminateProc = procedure;
```

C++

```
( TExpertTerminateProc)();
```

File

ExptIntf

Description

This is type ExptIntf.TExpertTerminateProc.

1.5 Variables

The following table lists variables in this documentation.

Variables

Name	Description
LibraryExpertProc (see page 11)	This is variable ExptIntf.LibraryExpertProc.
ToolServices (see page 11)	This is variable ExptIntf.ToolServices.

1.5.1 ExptIntf.LibraryExpertProc Variable

Pascal

```
LibraryExpertProc: TExpertRegisterProc = nil;
```

C++

```
TExpertRegisterProc LibraryExpertProc = nil;
```

File

ExptIntf

Description

This is variable ExptIntf.LibraryExpertProc.

1.5.2 ExptIntf.ToolServices Variable

Pascal

```
ToolServices: TIToolServices = nil;
```

C++

```
TIToolServices ToolServices = nil;
```

File

ExptIntf

Description

This is variable ExptIntf.ToolServices.

1.6 Constants

The following table lists constants in this documentation.

Constants

Name	Description
ExpertEntryPoint (see page 12)	This is constant ExptIntf.ExpertEntryPoint.
isExperts (see page 12)	This is constant ExptIntf.isExperts.
ValidExpertVersion (see page 12)	This is constant ExptIntf.ValidExpertVersion.

1.6.1 ExptIntf.ExpertEntryPoint Constant

Pascal

```
ExpertEntryPoint = 'INITEXPERT0017';
```

C++

```
ExpertEntryPoint = 'INITEXPERT0017';
```

File

ExptIntf

Description

This is constant ExptIntf.ExpertEntryPoint.

1.6.2 ExptIntf.isExperts Constant

Pascal

```
isExperts = 'Experts';
```

C++

```
isExperts = 'Experts';
```

File

ExptIntf

Description

This is constant ExptIntf.isExperts.

1.6.3 ExptIntf.ValidExpertVersion Constant

Pascal

```
ValidExpertVersion = 3;
```

C++

```
ValidExpertVersion = 3;
```

File

ExptIntf

Description

This is constant ExptIntf.ValidExpertVersion.

2 ExtActns Namespace

This is namespace ExtActns.

Topics

Name	Description
Classes (see page 17)	The following table lists classes in this documentation.
Structs, Records, Enums (see page 157)	The following table lists structs, records, enums in this documentation.
Types (see page 158)	The following table lists types in this documentation.

Classes

	Name	Description
	TCustomFileRun (see page 17)	TCustomFileRun is the base class for actions that perform a specified operation on a file.
	TFileRun (see page 27)	TFileRun is the standard action for performing a specified operation on a file.
	TListControlAction (see page 37)	TListControlAction is the base class for action objects that operate on the selection of a list control (list box or list view).
	TListControlClearSelection (see page 41)	TListControlClearSelection deselects all selected items in a list control (list view or list box).
	TListControlCopySelection (see page 50)	TListControlCopySelection copies the selected items in a list control (list view or list box) to another (destination) list control.
	TListControlDeleteSelection (see page 60)	TListControlDeleteSelection deletes the selected items in a list control (list view or listbox).
	TListControlMoveSelection (see page 68)	TListControlMoveSelection moves the selected items in a list control (list view or list box) to another (destination) list control.
	TListControlSelectAll (see page 71)	TListControlSelectAll selects all the items in a list control (list view or listbox).
	TNextTab (see page 80)	TNextTab moves a tabbed control to its next page.
	TOpenPicture (see page 92)	TOpenPicture is the standard action for displaying the open picture dialog.
	TPreviousTab (see page 101)	TPreviousTab moves a page control to its previous page.
	TRichEditAction (see page 112)	TRichEditAction is the base class for action objects that apply rich text attributes to a rich edit control.
	TRichEditAlignCenter (see page 115)	TRichEditAlignCenter centers the text horizontally in the current paragraph of a rich edit control.
	TRichEditAlignLeft (see page 117)	TRichEditAlignLeft left-justifies the text in the current paragraph of a rich edit control.
	TRichEditAlignRight (see page 119)	TRichEditAlignRight right-justifies the text in the current paragraph of a rich edit control.
	TRichEditBold (see page 121)	TRichEditBold toggles the bold attribute of the currently selected text in a rich edit control.

	TRichEditBullets (see page 123)	TRichEditBullets toggles whether the current paragraph of a rich edit control is bulleted.
	TRichEditItalic (see page 125)	TRichEditItalic toggles the italic attribute of the currently selected text in a rich edit control.
	TRichEditStrikeOut (see page 127)	TRichEditStrikeOut toggles the strikeout attribute of the currently selected text in a rich edit control.
	TRichEditUnderline (see page 130)	TRichEditUnderline toggles the underline attribute of the currently selected text in a rich edit control.
	TSavePicture (see page 132)	TSavePicture is the standard action for displaying the save picture dialog.
	TSendMail (see page 141)	TSendMail is the standard action for sending an email message.
	TTabAction (see page 150)	TTabAction is the base class for action objects designed to respond to the buttons in a tabbed dialog.

Structs, Records, Enums

	Name	Description
	TShowCmd (see page 157)	This is record ExtActns.TShowCmd.

Types

Name	Description
TValidateTabEvent (see page 158)	This is type ExtActns.TValidateTabEvent.

2.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TCustomFileRun (see page 17)	TCustomFileRun is the base class for actions that perform a specified operation on a file.
	TFileRun (see page 27)	TFileRun is the standard action for performing a specified operation on a file.
	TListControlAction (see page 37)	TListControlAction is the base class for action objects that operate on the selection of a list control (list box or list view).
	TListControlClearSelection (see page 41)	TListControlClearSelection deselects all selected items in a list control (list view or list box).
	TListControlCopySelection (see page 50)	TListControlCopySelection copies the selected items in a list control (list view or list box) to another (destination) list control.
	TListControlDeleteSelection (see page 60)	TListControlDeleteSelection deletes the selected items in a list control (list view or listbox).
	TListControlMoveSelection (see page 68)	TListControlMoveSelection moves the selected items in a list control (list view or list box) to another (destination) list control.
	TListControlSelectAll (see page 71)	TListControlSelectAll selects all the items in a list control (list view or listbox).
	TNextTab (see page 80)	TNextTab moves a tabbed control to its next page.
	TOpenPicture (see page 92)	TOpenPicture is the standard action for displaying the open picture dialog.
	TPreviousTab (see page 101)	TPreviousTab moves a page control to its previous page.
	TRichEditAction (see page 112)	TRichEditAction is the base class for action objects that apply rich text attributes to a rich edit control.
	TRichEditAlignCenter (see page 115)	TRichEditAlignCenter centers the text horizontally in the current paragraph of a rich edit control.
	TRichEditAlignLeft (see page 117)	TRichEditAlignLeft left-justifies the text in the current paragraph of a rich edit control.
	TRichEditAlignRight (see page 119)	TRichEditAlignRight right-justifies the text in the current paragraph of a rich edit control.
	TRichEditBold (see page 121)	TRichEditBold toggles the bold attribute of the currently selected text in a rich edit control.
	TRichEditBullets (see page 123)	TRichEditBullets toggles whether the current paragraph of a rich edit control is bulleted.
	TRichEditItalic (see page 125)	TRichEditItalic toggles the italic attribute of the currently selected text in a rich edit control.
	TRichEditStrikeOut (see page 127)	TRichEditStrikeOut toggles the strikeout attribute of the currently selected text in a rich edit control.
	TRichEditUnderline (see page 130)	TRichEditUnderline toggles the underline attribute of the currently selected text in a rich edit control.
	TSavePicture (see page 132)	TSavePicture is the standard action for displaying the save picture dialog.
	TSendMail (see page 141)	TSendMail is the standard action for sending an email message.
	TTabAction (see page 150)	TTabAction is the base class for action objects designed to respond to the buttons in a tabbed dialog.

2.1.1 TCustomFileRun Class

TCustomFileRun is the base class for actions that perform a specified operation on a file.

Class Hierarchy

Pascal

```
TCustomFileRun = class(TCustomAction);
```

C++

```
class TCustomFileRun : public TCustomAction;
```

File

ExtActns

Description

Use TCustomFileRun as a base class when defining a pre-defined action that uses ShellExecute to perform an operation on a file. TCustomFileRun implements properties for specifying

A target file or the option of letting the user select one using a browse dialog.

The operation to perform on the target file.

Parameters (see page 25) to supply to an external application that performs the desired operation.

The startup directory for the external application.

The state of the window that appears when performing the specified operation.

When the ExecuteTarget (see page 20) method is called, TCustomFileRun uses these properties to call the Windows API ShellExecute, which performs the specified operation if it is listed as applicable to the target file type in the system registry. Depending on the operation, this may involve launching an external application, calling a dynamic-link library (DLL), or displaying a system dialog (such as the file properties dialog).

Do not add TCustomFileRun to an action list or action manager. To add a generic file run action, use TFileRun (see page 27) instead.

See Also

TFileRun (see page 27)

2.1.1.1 TCustomFileRun Members

The following tables list the members exposed by TCustomFileRun.

Protected Methods

	Name	Description
	Notification (see page 21)	Responds when components are created or destroyed.

Public Methods

	Name	Description
	Create (see page 19)	Creates an instance of TCustomFileRun (see page 17).
	ExecuteTarget (see page 20)	Performs the specified operation on a target file.
	HandlesTarget (see page 20)	Indicates whether the action can execute.
	SetupBrowseDialog (see page 21)	Creates an instance of TOpenDialog and assigns it as the value of the BrowseDlg (see page 23) property.
	UpdateTarget (see page 21)	Enables or disables the action, depending on current conditions.

Public Properties

	Name	Description
	Browse (see page 22)	Controls whether an open dialog automatically appears to let users browse for the target file.
	BrowseDlg (see page 23)	Specifies the dialog that allows users to select the target file to run.

	Directory (see page 23)	Specifies the default directory for the externally-launched application.
	FileName (see page 23)	Specifies the target file to run.
R	HInst (see page 24)	Indicates the Windows error code that is returned when TCustomFileRun (see page 17) launches the external application.
	Operation (see page 25)	Indicates what TCustomFileRun (see page 17) should do with the target file.
	Parameters (see page 25)	Specifies parameters to be passed to the application when the target file is an executable.
	ParentControl (see page 26)	This is ParentControl, a member of class TCustomFileRun.
	ShowCmd (see page 26)	Specifies how the launched application window appears.

2.1.1.2 TCustomFileRun.Create Constructor

Creates an instance of TCustomFileRun (see page 17).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomFileRun(TComponent * AOwner);
```

Description

Most applications do not need to call the TCustomFileRun (see page 17) constructor because actions are added at design time to an action list or action manager.

AOwner specifies the Owner for the action. This is the component that is responsible for freeing the TCustomFileRun (see page 17) instance.

Create initializes the action's properties and creates a default TOpenDialog instance to act as the value of the BrowseDlg (see page 23) property.

See Also

Owner

SetupBrowseDialog (see page 21)

BrowseDlg (see page 23)

2.1.1.3 TCustomFileRun Methods

The methods of the TCustomFileRun class are listed here.

Protected Methods

	Name	Description
V	Notification (see page 21)	Responds when components are created or destroyed.

Public Methods

	Name	Description
V	ExecuteTarget (see page 20)	Performs the specified operation on a target file.
V	HandlesTarget (see page 20)	Indicates whether the action can execute.
	SetupBrowseDialog (see page 21)	Creates an instance of TOpenDialog and assigns it as the value of the BrowseDlg (see page 23) property.
V	UpdateTarget (see page 21)	Enables or disables the action, depending on current conditions.

2.1.1.3.1 TCustomFileRun.ExecuteTarget Method

Performs the specified operation on a target file.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

ExecuteTarget ignores the Target parameter and performs the operation specified by the Operation (see page 25) property on the target file specified by the FileName (see page 23) property or chosen by the user if the value of the Browse (see page 22) property is true. The values of Parameters (see page 25), ShowCmd (see page 26), and Directory (see page 23), as well as the window handle for ParentControl (see page 26) are passed to Windows with the request to perform the specified operation.

Note: If the attempt to perform the operation fails, the HInst (see page 24) property contains an error code that indicates what was wrong. If the attempt succeeds, the HInst (see page 24) property is greater than 32.

See Also

FileName (see page 23)

Browse (see page 22)

Operation (see page 25)

Parameters (see page 25)

ShowCmd (see page 26)

Directory (see page 23)

parentcontrol (see page 26)

HInst (see page 24)

2.1.1.3.2 TCustomFileRun.HandlesTarget Method

Indicates whether the action can execute.

Pascal

```
function HandlesTarget(Target: TObject): Boolean; override;
```

C++

```
virtual __fastcall Boolean HandlesTarget(TObject * Target);
```

Description

Do not call the HandlesTarget method. This method is called automatically when the user invokes an object (such as a tool button or menu item) that is linked to this action. The HandlesTarget method lets the action object indicate whether it is appropriate to execute at this time with the object specified by the Target parameter as a "target".

HandlesTarget always returns true, because TCustomFileRun (see page 17) does not use the target object.

2.1.1.3.3 TCustomFileRun.Notification Method

Responds when components are created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation.

TBasicAction overrides the Notification method to check whether the component that is the value of the ActionComponent property is about to be freed. If so, it sets the ActionComponent property to nil (Delphi) or NULL (C++).

See Also

ActionComponent

2.1.1.3.4 TCustomFileRun.SetupBrowseDialog Method

Creates an instance of TOpenDialog and assigns it as the value of the BrowseDlg (see page 23) property.

Pascal

```
procedure SetupBrowseDialog;
```

C++

```
__fastcall SetupBrowseDialog();
```

Description

SetupBrowseDialog generates the default open dialog instance for the dialog that appears when the Browse (see page 22) property is true. It assigns this newly created dialog component as the value of the BrowseDlg (see page 23) property.

Most applications do not need to call SetupBrowseDialog because it is called automatically by the TCustomFileRun (see page 17) constructor.

See Also

BrowseDlg (see page 23)

TOpenDialog

Browse (see page 22)

2.1.1.3.5 TCustomFileRun.UpdateTarget Method

Enables or disables the action, depending on current conditions.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically when application is idle so that the action can update itself to reflect current conditions.

In TCustomFileRun (see page 17), UpdateTarget checks whether it can obtain a target file. If the FileName (see page 23) property specifies a target file, or if the Browse (see page 22) property is true, indicating that users can select a target file, then UpdateTarget sets Enabled to true. If not, UpdateTarget sets Enabled to false.

See Also

Enabled

FileName (see page 23)

Browse (see page 22)

2.1.1.4 TCustomFileRun Properties

The properties of the TCustomFileRun class are listed here.

Public Properties

	Name	Description
	Browse (see page 22)	Controls whether an open dialog automatically appears to let users browse for the target file.
	BrowseDlg (see page 23)	Specifies the dialog that allows users to select the target file to run.
	Directory (see page 23)	Specifies the default directory for the externally-launched application.
	FileName (see page 23)	Specifies the target file to run.
R	HInst (see page 24)	Indicates the Windows error code that is returned when TCustomFileRun (see page 17) launches the external application.
	Operation (see page 25)	Indicates what TCustomFileRun (see page 17) should do with the target file.
	Parameters (see page 25)	Specifies parameters to be passed to the application when the target file is an executable.
	ParentControl (see page 26)	This is ParentControl, a member of class TCustomFileRun.
	ShowCmd (see page 26)	Specifies how the launched application window appears.

2.1.1.4.1 TCustomFileRun.Browse Property

Controls whether an open dialog automatically appears to let users browse for the target file.

Pascal

```
property Browse: Boolean;
```

C++

```
__property Boolean Browse;
```

Description

Browse controls whether TCustomFileRun (see page 17) displays the dialog specified by BrowseDlg (see page 23) when it fires, letting users select the target file to be launched. When Browse is true, firing TCustomFileRun (see page 17) displays the open dialog specified by BrowseDlg (see page 23), and then (if the user does not cancel) performs the operation specified by Operation (see page 25) on the chosen file. When Browse is false, your application must specify the target file by explicitly setting the FileName (see page 23) property.

Note: When Browse is true, TCustomFileRun (see page 17) ignores the FileName (see page 23) property.

See Also

BrowseDlg (see page 23)

FileName (see page 23)

Operation (see page 25)

2.1.1.4.2 TCustomFileRun.BrowseDlg Property

Specifies the dialog that allows users to select the target file to run.

Pascal

```
property BrowseDlg: TOpenDialog;
```

C++

```
__property TOpenDialog BrowseDlg;
```

Description

Use BrowseDlg when the Browse (see page 22) property is true to configure the dialog that users use to select a target file. By expanding BrowseDlg in the Object Inspector at design time, or by setting its properties at runtime, you can customize the way the dialog first appears when the action fires.

By default, BrowseDlg is an internally-generated TOpenDialog object. When using the default dialog, there is no need to explicitly add a dialog component to your application. If you want to use a specialized TOpenDialog descendant (such as TOpenPictureDialog (see page 1560)), however, set BrowseDlg to an open dialog component you place in the same form or data module as the TCustomFileRun (see page 17) action.

See Also

Browse (see page 22)

FileName (see page 23)

TOpenDialog

2.1.1.4.3 TCustomFileRun.Directory Property

Specifies the default directory for the externally-launched application.

Pascal

```
property Directory: TFileName;
```

C++

```
__property TFileName Directory;
```

Description

Set Directory to specify a default (startup) directory for the external application that is launched when the action fires.

See Also

Parameters (see page 25)

FileName (see page 23)

2.1.1.4.4 TCustomFileRun.FileName Property

Specifies the target file to run.

Pascal

```
property FileName: TFileName;
```

C++

```
__property TFileName FileName;
```

Description

Set FileName to specify the file on which TCustomFileRun (see page 17) performs the operation specified by Operation (see page 25) when the action fires. FileName can specify a file that is opened using an external application (such as a .txt file that causes a text editor to launch), or it can specify an executable file for the application itself. When the action fires in response to a user action, TCustomFileRun (see page 17) launches an external application or dll to perform Operation (see page 25) on the file specified by FileName.

Note:

See Also

Browse (see page 22)

BrowseDlg (see page 23)

Parameters (see page 25)

Operation (see page 25)

2.1.1.4.5 TCustomFileRun.HInst Property

Indicates the Windows error code that is returned when TCustomFileRun (see page 17) launches the external application.

Pascal

```
property HInst: HInst;
```

C++

```
__property HInst HInst;
```

Description

TCustomFileRun (see page 17) sets HInst to the Windows return value when it launches the external application. If this value is less than 32, it represents an error code that indicates why the application failed to launch. This value is only available after the action has executed.

The following table lists the possible error values (defined in shellapi.pas) that can be the value of HInst when it is less than 32.

Value	Meaning
0	The operating system is out of memory or resources.
ERROR_FILE_NOT_FOUND	The specified file was not found.
ERROR_PATH_NOT_FOUND	The specified path was not found.
ERROR_BAD_FORMAT	The .exe file is invalid (does not have the correct internal format).
SE_ERR_ACCESSDENIED	The operating system denied access to the specified file.
SE_ERR_ASSOCINCOMPLETE	The file name association is incomplete or invalid.
SE_ERR_DDEBUSY	A DDE transaction could not be completed because other DDE transactions were being processed.
SE_ERR_DDEFAIL	A DDE transaction failed.
SE_ERR_DDETIMEOUT	A DDE transaction could not be completed because the request timed out.

SE_ERR_DLLNOTFOUND	A specified dynamic-link library was not found.
SE_ERR_FNF	The specified file was not found.
SE_ERR_NOASSOC	There is no application associated with the given file name extension or TCustomFileRun (see page 17) attempted to print an unprintable file.
SE_ERR_OOM	There was not enough memory to complete the operation.
SE_ERR_PNF	The specified path was not found.
SE_ERR_SHARE	A sharing violation occurred.

2.1.1.4.6 TCustomFileRun.Operation Property

Indicates what TCustomFileRun (see page 17) should do with the target file.

Pascal

```
property Operation: String;
```

C++

```
__property UnicodeString Operation;
```

Description

Set Operation to indicate what should be done with the target file when TCustomFileRun (see page 17) fires. The possible values for Operation depend on the particular file or folder specified by FileName (see page 23) or selected by the user when Browse (see page 22) is true. The possible operations for a particular file or folder are listed in the system Registry (see page 6599).

The following strings are usually valid:

Value	Meaning
edit	TCustomFileRun (see page 17) opens an editor. If FileName (see page 23) is not an editable file, the action fails.
explore	TCustomFileRun (see page 17) launches the Windows explorer for the folder specified by FileName (see page 23).
open	TCustomFileRun (see page 17) opens the file specified by FileName (see page 23). FileName (see page 23) can be an executable file, a file associated with an application that can open it, or a folder.
print	TCustomFileRun (see page 17) prints the file specified by FileName (see page 23). If FileName (see page 23) is a binary file (for example, if it is an executable), the action fails.
properties	TCustomFileRun (see page 17) displays the file or folder's properties in a Properties dialog.

Note: If Operation is an empty string, Windows tries to use the "open" operation. If the specified file does not support the "open" operation, Windows tries to use the default operation. If there is no "open" operation and no default operation, and if the application is running on Windows 2000 or later, Windows uses the first verb listed in the Registry (see page 6599).

See Also

FileName (see page 23)

Browse (see page 22)

2.1.1.4.7 TCustomFileRun.Parameters Property

Specifies parameters to be passed to the application when the target file is an executable.

Pascal

```
property Parameters: String;
```

C++

```
__property UnicodeString Parameters;
```

Description

Use Parameters to specify any parameters that should be passed to the external application when it is launched. Only set Parameters if FileName (see page 23) is the name of an Executable file or the user is browsing for an executable file. If the target file holds data associated with the application to launch, Parameters should be an empty string.

See Also

FileName (see page 23)

Operation (see page 25)

2.1.1.4.8 TCustomFileRun.ParentControl Property

Pascal

```
property ParentControl: TWinControl;
```

C++

```
__property TWinControl * ParentControl;
```

Description

This is ParentControl, a member of class TCustomFileRun.

2.1.1.4.9 TCustomFileRun.ShowCmd Property

Specifies how the launched application window appears.

Pascal

```
property ShowCmd: TShowCmd;
```

C++

```
__property TShowCmd ShowCmd;
```

Description

Use ShowCmd to indicate how you want the application window to appear when TCustomFileRun (see page 17) performs the specified operation on its target file. ShowCmd can have any of the following values:

Value	Meaning
scHide	The external application window is hidden. If it was active, another window is activated.
scMaximize	The external application window is maximized (but not necessarily activated)
scMinimize	The external application window is minimized (but not necessarily activated).
scRestore	The external application window is activated. If it was minimized or maximized, Windows restores it to its original size and position.
scShow	The external application window is activated in its current size and position.
scShowDefault	The external application window is shown in the default startup state specified by that external application.
scShowMaximized	The external application window is activated and maximized.

scShowMinimized	The external application window is activated and minimized.
scShowMinNoActive	The external application window is minimized. The active window does not change.
scShowNA	The external application window is displayed (after being hidden) but activation does not change.
scShowNoActivate	The external application window is displayed in its most recent size and position, but activation does not change.
scShowNormal	The external application window is activated and restored to its original size and position if it was maximized or minimized.

See Also

Operation (see page 25)

2.1.2 TFileRun Class

TFileRun is the standard action for performing a specified operation on a file.

Class Hierarchy

Pascal

```
TFileRun = class(TCustomFileRun);
```

C++

```
class TFileRun : public TCustomFileRun;
```

File

ExtActns

Description

Add TFileRun to an action list to let your application launch an external application or dll in response to user actions. Controls linked to this action cause your application to perform the operation specified by the Operation (see page 33) property on the file specified by the FileName (see page 31) property.

Before this action fires, configure its properties to indicate what application to launch and how to launch it:

To indicate the target file to run, set the FileName (see page 31) property to the name of a file on which the external application operates or to the name of the application's executable file. If you want to let the user select the file name instead when the action fires, set the Browse (see page 29) property to true, and an open dialog appears when the action fires.

To indicate what action to perform on the specified file, set the Operation (see page 33) property.

To supply parameters to the external application when it is launched, use the Parameters (see page 33) property.

To specify a default directory for the external application, use the Directory (see page 30) property.

To control how the external application's window appears (minimized, maximized, hidden, and so on), use the ShowCmd (see page 35) property.

If the external application needs a parent window (to parent a dialog such as a properties dialog), or if you want to allow TFileRun to display error messages, use the ParentControl (see page 34) property.

2.1.2.1 TFileRun Members

The following tables list the members exposed by TFileRun.

Protected Methods

	Name	Description
	Notification (see page 21)	Responds when components are created or destroyed.

Public Methods

	Name	Description
	Create (see page 19)	Creates an instance of TCustomFileRun (see page 17).
	ExecuteTarget (see page 20)	Performs the specified operation on a target file.
	HandlesTarget (see page 20)	Indicates whether the action can execute.
	SetupBrowseDialog (see page 21)	Creates an instance of TOpenDialog and assigns it as the value of the BrowseDlg (see page 23) property.
	UpdateTarget (see page 21)	Enables or disables the action, depending on current conditions.

Public Properties

	Name	Description
	HInst (see page 24)	Indicates the Windows error code that is returned when TCustomFileRun (see page 17) launches the external application.

Published Events

	Name	Description
	OnHint (see page 36)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 36)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	Browse (see page 29)	Controls whether an open dialog automatically appears to let users browse for the target file.
	BrowseDlg (see page 29)	Specifies the dialog that allows users to select the target file to run.
	Caption (see page 30)	Represents the caption of client controls and menu items.
	Directory (see page 30)	Specifies the default directory for the externally-launched application.
	Enabled (see page 31)	Indicates whether client controls and menu items are enabled.
	FileName (see page 31)	Specifies the target file to run.
	HelpContext (see page 31)	Indicates the help context ID for client controls and menu items.
	Hint (see page 32)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 32)	Indicates the ImageIndex property for client controls and menu items.
	Operation (see page 33)	Indicates what TCustomFileRun should do with the target file.
	Parameters (see page 33)	Specifies parameters to be passed to the application when the target file is an executable.
	ParentControl (see page 34)	This is ParentControl, a member of class TFileRun.
	SecondaryShortCuts (see page 34)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 34)	Specifies the ShortCut property for client menu items.
	ShowCmd (see page 35)	Specifies how the launched application window appears.
	Visible (see page 35)	Specifies the Visible property for client controls and menu items.

2.1.2.2 TFileRun Properties

The properties of the TFileRun class are listed here.

Published Properties

	Name	Description
	Browse (see page 29)	Controls whether an open dialog automatically appears to let users browse for the target file.
	BrowseDlg (see page 29)	Specifies the dialog that allows users to select the target file to run.
	Caption (see page 30)	Represents the caption of client controls and menu items.
	Directory (see page 30)	Specifies the default directory for the externally-launched application.
	Enabled (see page 31)	Indicates whether client controls and menu items are enabled.
	FileName (see page 31)	Specifies the target file to run.
	HelpContext (see page 31)	Indicates the help context ID for client controls and menu items.
	Hint (see page 32)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 32)	Indicates the ImageIndex property for client controls and menu items.
	Operation (see page 33)	Indicates what TCustomFileRun should do with the target file.
	Parameters (see page 33)	Specifies parameters to be passed to the application when the target file is an executable.
	ParentControl (see page 34)	This is ParentControl, a member of class TFileRun.
	SecondaryShortCuts (see page 34)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 34)	Specifies the ShortCut property for client menu items.
	ShowCmd (see page 35)	Specifies how the launched application window appears.
	Visible (see page 35)	Specifies the Visible property for client controls and menu items.

2.1.2.2.1 TFileRun.Browse Property

Controls whether an open dialog automatically appears to let users browse for the target file.

Pascal

```
property Browse: Boolean;
```

C++

```
__property Boolean Browse;
```

Description

Browse controls whether TCustomFileRun displays the dialog specified by BrowseDlg when it fires, letting users select the target file to be launched. When Browse is true, firing TCustomFileRun displays the open dialog specified by BrowseDlg, and then (if the user does not cancel) performs the operation specified by Operation on the chosen file. When Browse is false, your application must specify the target file by explicitly setting the FileName property.

Note: When Browse is true, TCustomFileRun ignores the FileName property.

See Also

BrowseDlg (see page 23)

FileName (see page 23)

Operation (see page 25)

2.1.2.2.2 TFileRun.BrowseDlg Property

Specifies the dialog that allows users to select the target file to run.

Pascal

```
property BrowseDlg: TOpenDialog;
```

C++

```
__property TOpenDialog BrowseDlg;
```

Description

Use BrowseDlg when the Browse property is true to configure the dialog that users use to select a target file. By expanding BrowseDlg in the Object Inspector at design time, or by setting its properties at runtime, you can customize the way the dialog first appears when the action fires.

By default, BrowseDlg is an internally-generated TOpenDialog object. When using the default dialog, there is no need to explicitly add a dialog component to your application. If you want to use a specialized TOpenDialog descendant (such as TOpenPictureDialog), however, set BrowseDlg to an open dialog component you place in the same form or data module as the TCustomFileRun action.

See Also

Browse (see page 22)

FileName (see page 23)

TOpenDialog

2.1.2.2.3 TFileRun.Caption Property

Represents the caption of client controls and menu items.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Caption holds the string that is the caption for the action when it is set. The value of Caption is propagated to client controls and menu items.

See Also

Caption

Caption (see page 4902)

2.1.2.2.4 TFileRun.Directory Property

Specifies the default directory for the externally-launched application.

Pascal

```
property Directory: TFileName;
```

C++

```
__property TFileName Directory;
```

Description

Set Directory to specify a default (startup) directory for the external application that is launched when the action fires.

See Also

Parameters (see page 25)

FileName (see page 23)

2.1.2.2.5 TFileRun.Enabled Property

Indicates whether client controls and menu items are enabled.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Enabled specifies the enabled state for the action. The value of Enabled is propagated to client controls and menu items.

See Also

Enabled

Enabled (see page 4912)

2.1.2.2.6 TFileRun.FileName Property

Specifies the target file to run.

Pascal

```
property FileName: TFileName;
```

C++

```
__property TFileName FileName;
```

Description

Set FileName to specify the file on which TCustomFileRun performs the operation specified by Operation when the action fires. FileName can specify a file that is opened using an external application (such as a .txt file that causes a text editor to launch), or it can specify an executable file for the application itself. When the action fires in response to a user action, TCustomFileRun launches an external application or dll to perform Operation on the file specified by FileName.

Note:

See Also

Browse (see page 22)

BrowseDlg (see page 23)

Parameters (see page 25)

Operation (see page 25)

2.1.2.2.7 TFileRun.HelpContext Property

Indicates the help context ID for client controls and menu items.

Pascal

```
property HelpContext;
```

C++

```
__property HelpContext;
```

Description

HelpContext specifies the help context for the action when it is set. This value is propagated to client controls and menu items.

When a client control has focus and the user presses the F1 key, the control uses the value of HelpContext for this associated action to invoke the online help targeting a specific topic. The target topic is uniquely identified by a nonzero HelpContext value. Leave the HelpContext property of the client control at its default value of zero. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpContext is only used when the HelpType property of this action or the client control is htInteger.

See Also

HelpType

HelpKeyword

2.1.2.2.8 TFileRun.Hint Property

Indicates the Help hint for client controls and menu items.

Pascal

```
property Hint;
```

C++

```
__property Hint;
```

Description

Hint holds the string that is the hint for that action when it is set. This value is propagated to client controls and menu items.

See Also

Hint

Hint (see page 4916)

2.1.2.2.9 TFileRun.ImageIndex Property

Indicates the ImageIndex property for client controls and menu items.

Pascal

```
property ImageIndex;
```

C++

```
__property ImageIndex;
```

Description

ImageIndex is an index into the Images property of the action list or action manager that contains the action. It identifies an image that is associated with controls and menu items that use this action.

See Also

ImageIndex

ImageIndex (see page 4916)

Images

2.1.2.2.10 TFileRun.Operation Property

Indicates what TCustomFileRun should do with the target file.

Pascal

```
property Operation: String;
```

C++

```
__property UnicodeString Operation;
```

Description

Set Operation to indicate what should be done with the target file when TCustomFileRun fires. The possible values for Operation depend on the particular file or folder specified by FileName or selected by the user when Browse is true. The possible operations for a particular file or folder are listed in the system Registry.

The following strings are usually valid:

Value	Meaning
edit	TCustomFileRun opens an editor. If FileName is not an editable file, the action fails.
explore	TCustomFileRun launches the Windows explorer for the folder specified by FileName.
open	TCustomFileRun opens the file specified by FileName. FileName can be an executable file, a file associated with an application that can open it, or a folder.
print	TCustomFileRun prints the file specified by FileName. If FileName is a binary file (for example, if it is an executable), the action fails.
properties	TCustomFileRun displays the file or folder's properties in a Properties dialog.

Note: If Operation is an empty string, Windows tries to use the "open" operation. If the specified file does not support the "open" operation, Windows tries to use the default operation. If there is no "open" operation and no default operation, and if the application is running on Windows 2000 or later, Windows uses the first verb listed in the Registry.

See Also

FileName (see page 23)

Browse (see page 22)

2.1.2.2.11 TFileRun.Parameters Property

Specifies parameters to be passed to the application when the target file is an executable.

Pascal

```
property Parameters: String;
```

C++

```
__property UnicodeString Parameters;
```

Description

Use Parameters to specify any parameters that should be passed to the external application when it is launched. Only set Parameters if FileName is the name of an Executable file or the user is browsing for an executable file. If the target file holds data associated with the application to launch, Parameters should be an empty string.

See Also

FileName (see page 23)

Operation (see page 25)

2.1.2.2.12 TFileRun.ParentControl Property

Pascal

```
property ParentControl: TWinControl;
```

C++

```
__property TWinControl * ParentControl;
```

Description

This is ParentControl, a member of class TFileRun.

2.1.2.2.13 TFileRun.SecondaryShortCuts Property

Specifies the short cuts (in addition to ShortCut) for triggering clients.

Pascal

```
property SecondaryShortCuts;
```

C++

```
__property SecondaryShortCuts;
```

Description

Actions can execute in response to multiple short cut key combinations. SecondaryShortCuts lists all the short cut key combinations (other than the one specified by the ShortCut property) that can trigger the action. This lets you specify shortcuts for clients that do not have a ShortCut property or provide additional, secondary shortcuts.

When the user types one of the key combinations listed in SecondaryShortCuts, the action's Execute method is called.

See Also

ShortCut

Execute

2.1.2.2.14 TFileRun.ShortCut Property

Specifies the ShortCut property for client menu items.

Pascal

```
property ShortCut;
```

C++

```
__property ShortCut;
```

Description

ShortCut holds the value that is the shortcut for the action when it is set. This value is propagated to client menu items.

See Also

ShortCut (see page 4920)

SecondaryShortCuts

2.1.2.2.15 TFileRun.ShowCmd Property

Specifies how the launched application window appears.

Pascal

```
property ShowCmd: TShowCmd;
```

C++

```
__property TShowCmd ShowCmd;
```

Description

Use ShowCmd to indicate how you want the application window to appear when TCustomFileRun performs the specified operation on its target file. ShowCmd can have any of the following values:

Value	Meaning
scHide	The external application window is hidden. If it was active, another window is activated.
scMaximize	The external application window is maximized (but not necessarily activated)
scMinimize	The external application window is minimized (but not necessarily activated).
scRestore	The external application window is activated. If it was minimized or maximized, Windows restores it to its original size and position.
scShow	The external application window is activated in its current size and position.
scShowDefault	The external application window is shown in the default startup state specified by that external application.
scShowMaximized	The external application window is activated and maximized.
scShowMinimized	The external application window is activated and minimized.
scShowMinNoActive	The external application window is minimized. The active window does not change.
scShowNA	The external application window is displayed (after being hidden) but activation does not change.
scShowNoActivate	The external application window is displayed in its most recent size and position, but activation does not change.
scShowNormal	The external application window is activated and restored to its original size and position if it was maximized or minimized.

See Also

Operation (see page 25)

2.1.2.2.16 TFileRun.Visible Property

Specifies the Visible property for client controls and menu items.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Visible specifies the visible state for the action. This value is propagated to client controls and menu items.

See Also

Visible (see page 4921)

Visible

2.1.2.3 TFileRun Events

The events of the TFileRun class are listed here.

Published Events

	Name	Description
	OnHint (see page 36)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 36)	Occurs when the application is idle or when the action list updates.

2.1.2.3.1 TFileRun.OnHint Event

Occurs when the mouse pauses over a client control or menu item.

Pascal

```
property OnHint;
```

C++

```
__property OnHint;
```

Description

Use OnHint to override the default hint that appears when the user pauses the mouse over a client control or menu item. The OnHint event handler can change the hint that appears (by changing the HintStr parameter), or display the hint in some application-specific way.

2.1.2.3.2 TFileRun.OnUpdate Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnUpdate;
```

C++

```
__property OnUpdate;
```

Description

Write an OnUpdate event handler to execute centralized code while an application is idle. For example, actions may want to update enabling and disabling, or checking and unchecking of client targets.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. Double click
```

```
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
*/
Boolean checked;

void __fastcall TForm1::Action1Update(TObject *Sender)
{
   // Indicate whether ToolBar1 is currently visible.
   TAction* pa = dynamic_cast<TAction*>(Sender);
   if (pa)
   {
     if (checked != ToolBar1->Visible)
     {
       lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
     }
     checked = ToolBar1->Visible;
   }
//   pa->Checked = True;  // set this statically and don't change it!
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Update(Sender: TObject);
begin
  if ((Sender as TAction).Checked <> ToolBar1.Visible) then
    lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
    { Indicate whether ToolBar1 is currently visible }
    (Sender as TAction).Checked := ToolBar1.Visible;
end;
```

See Also

UpdateAction

2.1.3 TListControlAction Class

TListControlAction is the base class for action objects that operate on the selection of a list control (list box or list view).

Class Hierarchy

Pascal

```
TListControlAction = class(TCustomAction);
```

C++

```
class TListControlAction : public TCustomAction;
```

File

ExtActns

Description

TListControlAction implements the common behavior for actions that work with list controls (list boxes and list views). Each descendant class performs a specific operation on the target list control. Do not use TListControlAction directly in an application. Instead, use a TListControlAction descendant such as TListControlSelectAll (see page 71), TListControlClearSelection (see page 41), TListControlDeleteSelection (see page 60), TListControlCopySelection (see page 50), or TListControlMoveSelection (see page 68).

TListControlAction makes the target list control available to descendant classes as the value of the ListControl (see page 40) property. TListControlAction descendants then override the ExecuteTarget method to perform their specific function on the target list control.

See Also

TListControlClearSelection (see page 41)

TListControlCopySelection (see page 50)

TListControlMoveSelection (see page 68)

TListCOntrolDeleteSelection

TListControlSelectAll (see page 71)

TCustomListControl

2.1.3.1 TListControlAction Members

The following tables list the members exposed by TListControlAction.

Protected Methods

	Name	Description
	IsEnabled (see page 40)	This is IsEnabled, a member of class TListControlAction.
V	Notification (see page 40)	Responds when components are created or destroyed.

Public Methods

	Name	Description
V	Create (see page 38)	Creates an instance of TListControlAction (see page 37).
V	HandlesTarget (see page 39)	Indicates whether the action can execute its function.

Public Properties

	Name	Description
	ListControl (see page 40)	Provides access to the target of the action.

2.1.3.2 TListControlAction.Create Constructor

Creates an instance of TListControlAction (see page 37).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TListControlAction(TComponent * AOwner);
```

Description

Most applications do not need to call the TListControlAction (see page 37) constructor because actions are added at design time to an action list or action manager.

AOwner specifies the Owner for the action. This is the component that is responsible for freeing the TListControlAction (see page 37) instance.

See Also

Owner

2.1.3.3 TListControlAction Methods

The methods of the TListControlAction class are listed here.

Protected Methods

	Name	Description
	IsEnabled (see page 40)	This is IsEnabled, a member of class TListControlAction.
V	Notification (see page 40)	Responds when components are created or destroyed.

Public Methods

	Name	Description
V	HandlesTarget (see page 39)	Indicates whether the action can execute its function.

2.1.3.3.1 TListControlAction.HandlesTarget Method

Indicates whether the action can execute its function.

Pascal

```
function HandlesTarget(Target: TObject): Boolean; override;
```

C++

```
virtual __fastcall Boolean HandlesTarget(TObject * Target);
```

Description

Do not call the HandlesTarget method. This method is called automatically when the user invokes an object (such as a tool button or menu item) that is linked to this action. The HandlesTarget method provides the action object with an opportunity to indicate whether it is appropriate to execute at this time with the object specified by the Target parameter as a "target".

Target is the currently active object.

HandlesTarget checks that the target is a TCustomListControl descendant (or that the ListControl (see page 40) property is set if Target is nil (Delphi) or NULL (C++)). HandlesTarget returns true if there is a list control to act as target, false otherwise.

See Also

ExecuteTarget

TCustomListControl

ListControl (see page 40)

2.1.3.3.2 TListControlAction.IsEnabled Method

Pascal

```
function IsEnabled(Target: TObject): Boolean;
```

C++

```
__fastcall Boolean IsEnabled(TObject * Target);
```

Description

This is IsEnabled, a member of class TListControlAction.

2.1.3.3.3 TListControlAction.Notification Method

Responds when components are created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation.

TBasicAction overrides the Notification method to check whether the component that is the value of the ActionComponent property is about to be freed. If so, it sets the ActionComponent property to nil (Delphi) or NULL (C++).

See Also

ActionComponent

2.1.3.4 TListControlAction Properties

The properties of the TListControlAction class are listed here.

Public Properties

	Name	Description
	ListControl (see page 40)	Provides access to the target of the action.

2.1.3.4.1 TListControlAction.ListControl Property

Provides access to the target of the action.

Pascal

```
property ListControl: TCustomListControl;
```

C++

```
__property TCustomListControl ListControl;
```

Description

ListControl is the list control on which the action performs its function. It is a TCustomListControl descendant, such a TListView or TListBox.

Set ListControl to associate the action with a particular control. If ListControl is not explicitly set, it is assumed to be the active listbox or list view when the action fires.

See Also

TListView

TListBox

2.1.4 TListControlClearSelection Class

TListControlClearSelection deselects all selected items in a list control (list view or list box).

Class Hierarchy

Pascal

```
TListControlClearSelection = class(TListControlAction);
```

C++

```
class TListControlClearSelection : public TListControlAction;
```

File

ExtActns

Description

Add TListControlClearSelection to an action list to allow users to deselect any selected items of a list control by using menu items or toolbar buttons. Controls such as menu items and tool buttons linked to this action cause the application to deselect all selected items in the target control.

TListControlClearSelection is designed to work with a list control (TCustomListControl descendant) as a target. TListControlClearSelection automatically disables itself if the target control is not a list control or if that list box or list view has no selected items.

See Also

TListControlCopySelection

TListControlMoveSelection

TListControlDeleteSelection

TListControlSelectAll

TCustomListControl

2.1.4.1 TListControlClearSelection Members

The following tables list the members exposed by TListControlClearSelection.

Protected Methods

	Name	Description
	IsEnabled (see page 40)	This is IsEnabled, a member of class TListControlAction.
	Notification (see page 40)	Responds when components are created or destroyed.

Public Methods

	Name	Description
	Create (see page 38)	Creates an instance of TListControlAction (see page 37).
	ExecuteTarget (see page 42)	Deselects the currently selected items in the target list control.
	HandlesTarget (see page 39)	Indicates whether the action can execute its function.
	UpdateTarget (see page 43)	Enables or disables the action, depending on the state of the target control.

Published Events

	Name	Description
	OnHint (see page 48)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 48)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	Caption (see page 44)	Represents the caption of client controls and menu items.
	Enabled (see page 44)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 44)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 45)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 45)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 46)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 46)	Indicates the ImageIndex property for client controls and menu items.
	ListControl (see page 46)	Provides access to the target of the action.
	SecondaryShortCuts (see page 47)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 47)	Specifies the ShortCut property for client menu items.
	Visible (see page 47)	Specifies the Visible property for client controls and menu items.

2.1.4.2 TListControlClearSelection Methods

The methods of the TListControlClearSelection class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 42)	Deselects the currently selected items in the target list control.
	UpdateTarget (see page 43)	Enables or disables the action, depending on the state of the target control.

2.1.4.2.1 TListControlClearSelection.ExecuteTarget Method

Deselects the currently selected items in the target list control.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires. It should always be a TCustomListControl descendant (because HandlesTarget (see page 39) returns false if it is not).

ExecuteTarget sets the ListControl (see page 46) property to Target it is not already set. It then calls the list control's

ClearSelection method, deselecting any selected items.

See Also

TCustomListControl

ListControl (see page 40)

ClearSelection

2.1.4.2.2 TListControlClearSelection.UpdateTarget Method

Enables or disables the action, depending on the state of the target control.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically when the application is idle so that actions can update themselves according to current conditions.

In TListControlClearSelection (see page 41), UpdateTarget checks whether the current target object (specified by the ListControl (see page 46) property if it is set, otherwise by the Target parameter) is a list control that includes at least one selected item. If so, UpdateTarget sets Enabled (see page 44) to true. If not, UpdateTarget sets Enabled (see page 44) to false.

Enabled

SelCount

ListControl (see page 40)

2.1.4.3 TListControlClearSelection Properties

The properties of the TListControlClearSelection class are listed here.

Published Properties

	Name	Description
	Caption (see page 44)	Represents the caption of client controls and menu items.
	Enabled (see page 44)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 44)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 45)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 45)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 46)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 46)	Indicates the ImageIndex property for client controls and menu items.
	ListControl (see page 46)	Provides access to the target of the action.
	SecondaryShortCuts (see page 47)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 47)	Specifies the ShortCut property for client menu items.
	Visible (see page 47)	Specifies the Visible property for client controls and menu items.

2.1.4.3.1 TListControlClearSelection.Caption Property

Represents the caption of client controls and menu items.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Caption holds the string that is the caption for the action when it is set. The value of Caption is propagated to client controls and menu items.

See Also

Caption

Caption (see page 4902)

2.1.4.3.2 TListControlClearSelection.Enabled Property

Indicates whether client controls and menu items are enabled.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Enabled specifies the enabled state for the action. The value of Enabled is propagated to client controls and menu items.

See Also

Enabled

Enabled (see page 4912)

2.1.4.3.3 TListControlClearSelection.HelpContext Property

Indicates the help context ID for client controls and menu items.

Pascal

```
property HelpContext;
```

C++

```
__property HelpContext;
```

Description

HelpContext specifies the help context for the action when it is set. This value is propagated to client controls and menu items.

When a client control has focus and the user presses the F1 key, the control uses the value of HelpContext for this associated action to invoke the online help targeting a specific topic. The target topic is uniquely identified by a nonzero HelpContext value. Leave the HelpContext property of the client control at its default value of zero. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpContext is only used when the HelpType property of this action or the client control is htInteger.

See Also

HelpType

HelpKeyword

2.1.4.3.4 TListControlClearSelection.HelpKeyword Property

Indicates the help keyword for client controls and menu items.

Pascal

```
property HelpKeyword;
```

C++

```
__property HelpKeyword;
```

Description

HelpKeyword, when set, specifies the keyword that identifies a help topic for this action. This value is propagated to the HelpKeyword property of client controls and menu items. The interpretation of HelpKeyword depends on which help system is used to display the topic. For example, when using HyperHelp (on Linux) or WinHelp (on Windows), HelpKeyword refers to an A link.

When a client control has focus and the user presses the F1 key (or the key specified by the application's HelpKey property), the control uses the value of HelpKeyword for this associated action object to invoke the online help targeting a specific topic. Leave the HelpKeyword property of the client control unassigned. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpKeyword is only used when the HelpType property of this action or the client control is htKeyword.

See Also

HelpKeyword

HelpContext

HelpType

HelpKey

2.1.4.3.5 TListControlClearSelection.HelpType Property

Indicates the mechanism for client controls and menu items to use when invoking help.

Pascal

```
property HelpType;
```

C++

```
__property HelpType;
```

Description

HelpType, when set, indicates whether client controls and menu items should use the HelpContext or the HelpKeyword property for invoking the help system. This value is propagated to the HelpType property of client controls and menu items.

See Also

HelpType

HelpType

HelpContext

HelpKeyword

2.1.4.3.6 TListControlClearSelection.Hint Property

Indicates the Help hint for client controls and menu items.

Pascal

```
property Hint;
```

C++

```
__property Hint;
```

Description

Hint holds the string that is the hint for that action when it is set. This value is propagated to client controls and menu items.

See Also

Hint

Hint (see page 4916)

2.1.4.3.7 TListControlClearSelection.ImageIndex Property

Indicates the ImageIndex property for client controls and menu items.

Pascal

```
property ImageIndex;
```

C++

```
__property ImageIndex;
```

Description

ImageIndex is an index into the Images property of the action list or action manager that contains the action. It identifies an image that is associated with controls and menu items that use this action.

See Also

ImageIndex

ImageIndex (see page 4916)

Images

2.1.4.3.8 TListControlClearSelection.ListControl Property

Provides access to the target of the action.

Pascal

```
property ListControl: TCustomListControl;
```

C++

```
__property TCustomListControl ListControl;
```

Description

ListControl is the list control on which the action performs its function. It is a TCustomListControl descendant, such a TListView

or TListBox.

Set ListControl to associate the action with a particular control. If ListControl is not explicitly set, it is assumed to be the active listbox or list view when the action fires.

See Also

TListView

TListBox

2.1.4.3.9 TListControlClearSelection.SecondaryShortCuts Property

Specifies the short cuts (in addition to ShortCut) for triggering clients.

Pascal

```
property SecondaryShortCuts;
```

C++

```
__property SecondaryShortCuts;
```

Description

Actions can execute in response to multiple short cut key combinations. SecondaryShortCuts lists all the short cut key combinations (other than the one specified by the ShortCut property) that can trigger the action. This lets you specify shortcuts for clients that do not have a ShortCut property or provide additional, secondary shortcuts.

When the user types one of the key combinations listed in SecondaryShortCuts, the action's Execute method is called.

See Also

ShortCut

Execute

2.1.4.3.10 TListControlClearSelection.ShortCut Property

Specifies the ShortCut property for client menu items.

Pascal

```
property ShortCut;
```

C++

```
__property ShortCut;
```

Description

ShortCut holds the value that is the shortcut for the action when it is set. This value is propagated to client menu items.

See Also

ShortCut (see page 4920)

SecondaryShortCuts

2.1.4.3.11 TListControlClearSelection.Visible Property

Specifies the Visible property for client controls and menu items.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Visible specifies the visible state for the action. This value is propagated to client controls and menu items.

See Also

Visible (see page 4921)

Visible

2.1.4.4 TListControlClearSelection Events

The events of the TListControlClearSelection class are listed here.

Published Events

	Name	Description
	OnHint (see page 48)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 48)	Occurs when the application is idle or when the action list updates.

2.1.4.4.1 TListControlClearSelection.OnHint Event

Occurs when the mouse pauses over a client control or menu item.

Pascal

```
property OnHint;
```

C++

```
__property OnHint;
```

Description

Use OnHint to override the default hint that appears when the user pauses the mouse over a client control or menu item. The OnHint event handler can change the hint that appears (by changing the HintStr parameter), or display the hint in some application-specific way.

2.1.4.4.2 TListControlClearSelection.OnUpdate Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnUpdate;
```

C++

```
__property OnUpdate;
```

Description

Write an OnUpdate event handler to execute centralized code while an application is idle. For example, actions may want to update enabling and disabling, or checking and unchecking of client targets.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
*/
Boolean checked;

void __fastcall TForm1::Action1Update(TObject *Sender)
{
   // Indicate whether ToolBar1 is currently visible.
   TAction* pa = dynamic_cast<TAction*>(Sender);
   if (pa)
   {
     if (checked != ToolBar1->Visible)
     {
       lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
     }
     checked = ToolBar1->Visible;
   }
//   pa->Checked = True;  // set this statically and don't change it!
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Update(Sender: TObject);
begin
  if ((Sender as TAction).Checked <> ToolBar1.Visible) then
    lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
    { Indicate whether ToolBar1 is currently visible }
    (Sender as TAction).Checked := ToolBar1.Visible;
end;
```

UpdateAction

2.1.5 TListControlCopySelection Class

TListControlCopySelection copies the selected items in a list control (list view or list box) to another (destination) list control.

Class Hierarchy

Pascal

```
TListControlCopySelection = class(TListControlAction);
```

C++

```
class TListControlCopySelection : public TListControlAction;
```

File

ExtActns

Description

Add TListControlCopySelection to an action list to allow users to copy the selected items of a list control to another list control by using menu items or toolbar buttons. Controls such as menu items and tool buttons linked to this action cause the application to copy all selected items in the target control to another (destination) list control.

Your application must explicitly set the Destination (see page 53) property to indicate the list to which items are copied.

TListControlCopySelection is designed to work with a list control (TCustomListControl descendant) as a target. This target is the source list control, not the destination. TListControlCopySelection automatically disables itself if the target control is not a list control, if that list box or list view has no selected items, or if there is no destination list control assigned.

TCustomListControl

2.1.5.1 TListControlCopySelection Members

The following tables list the members exposed by TListControlCopySelection.

Protected Methods

	Name	Description
	IsEnabled (see page 40)	This is IsEnabled, a member of class TListControlAction.
V	Notification (see page 40)	Responds when components are created or destroyed.

Public Methods

	Name	Description
V	Create (see page 38)	Creates an instance of TListControlAction (see page 37).
V	ExecuteTarget (see page 51)	Copies the selected items in the target list control to the list control specified by Destination (see page 53).
V	HandlesTarget (see page 52)	Indicates whether the action can execute its function.

	UpdateTarget (see page 52)	Enables or disables the action, depending on the state of the target control.

Published Events

	Name	Description
	OnHint (see page 58)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 58)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	Caption (see page 53)	Represents the caption of client controls and menu items.
	Destination (see page 53)	Specifies the list control to which items are copied.
	Enabled (see page 54)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 54)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 55)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 55)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 56)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 56)	Indicates the ImageIndex property for client controls and menu items.
	ListControl (see page 56)	Provides access to the target of the action.
	SecondaryShortCuts (see page 57)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 57)	Specifies the ShortCut property for client menu items.
	Visible (see page 57)	Specifies the Visible property for client controls and menu items.

2.1.5.2 TListControlCopySelection Methods

The methods of the TListControlCopySelection class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 51)	Copies the selected items in the target list control to the list control specified by Destination (see page 53).
	HandlesTarget (see page 52)	Indicates whether the action can execute its function.
	UpdateTarget (see page 52)	Enables or disables the action, depending on the state of the target control.

2.1.5.2.1 TListControlCopySelection.ExecuteTarget Method

Copies the selected items in the target list control to the list control specified by Destination (see page 53).

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires. It should always be a TCustomListControl descendant (because HandlesTarget (see page 52) returns false if it is not).

ExecuteTarget sets the ListControl (see page 56) property to Target it is not already set. It then calls the list control's ClearSelection method, copying any selected items to the list box or list view specified by the Destination (see page 53) property.

See Also

TCustomListControl

ListControl (see page 40)

CopySelection

Destination

2.1.5.2.2 TListControlCopySelection.HandlesTarget Method

Indicates whether the action can execute its function.

Pascal

```
function HandlesTarget(Target: TObject): Boolean; override;
```

C++

```
virtual __fastcall Boolean HandlesTarget(TObject * Target);
```

Description

Do not call the HandlesTarget method. This method is called automatically when the user invokes an object (such as a tool button or menu item) that is linked to this action. The HandlesTarget method provides the action object with an opportunity to indicate whether it is appropriate to execute at this time with the object specified by the Target parameter as a "target".

Target is the currently active object.

HandlesTarget checks that the target is a TCustomListControl descendant (or that the ListControl (see page 56) property is set if Target is nil (Delphi) or NULL (C++)). It also ensures that the Destination (see page 53) property has been asssigned. HandlesTarget returns true if there is a list control to act as target and a destination control, false otherwise.

See Also

ExecuteTarget

TCustomListControl

ListControl (see page 40)

Destination

2.1.5.2.3 TListControlCopySelection.UpdateTarget Method

Enables or disables the action, depending on the state of the target control.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically when the application is idle so that actions can update themselves according to current conditions.

In TListControlCopySelection (see page 50), UpdateTarget checks whether the current target object (specified by the ListControl (see page 56) property if it is set, otherwise by the Target parameter) is a list control that includes at least one selected item. If so, UpdateTarget sets Enabled (see page 54) to true. If not, UpdateTarget sets Enabled (see page 54) to

false.

Enabled

SelCount

ListControl (see page 40)

2.1.5.3 TListControlCopySelection Properties

The properties of the TListControlCopySelection class are listed here.

Published Properties

	Name	Description
	Caption (see page 53)	Represents the caption of client controls and menu items.
	Destination (see page 53)	Specifies the list control to which items are copied.
	Enabled (see page 54)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 54)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 55)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 55)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 56)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 56)	Indicates the ImageIndex property for client controls and menu items.
	ListControl (see page 56)	Provides access to the target of the action.
	SecondaryShortCuts (see page 57)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 57)	Specifies the ShortCut property for client menu items.
	Visible (see page 57)	Specifies the Visible property for client controls and menu items.

2.1.5.3.1 TListControlCopySelection.Caption Property

Represents the caption of client controls and menu items.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Caption holds the string that is the caption for the action when it is set. The value of Caption is propagated to client controls and menu items.

See Also

Caption

Caption (see page 4902)

2.1.5.3.2 TListControlCopySelection.Destination Property

Specifies the list control to which items are copied.

Pascal

```
property Destination: TCustomListControl;
```

C++

```
__property TCustomListControl Destination;
```

Description

Destination is the list control to which the action copies selected items from its target. It is a TCustomListControl descendant, such a TListView or TListBox.

You must explicitly set Destination to indicate the list control that receives the new items. These items are copied from the list control specified by the ListControl (see page 56) property. Destination and ListControl (see page 56) do not need to be the same type of control, as long as they are both TCustomListControl descendants.

See Also

TListView

TListBox

ListControl (see page 40)

2.1.5.3.3 TListControlCopySelection.Enabled Property

Indicates whether client controls and menu items are enabled.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Enabled specifies the enabled state for the action. The value of Enabled is propagated to client controls and menu items.

See Also

Enabled

Enabled (see page 4912)

2.1.5.3.4 TListControlCopySelection.HelpContext Property

Indicates the help context ID for client controls and menu items.

Pascal

```
property HelpContext;
```

C++

```
__property HelpContext;
```

Description

HelpContext specifies the help context for the action when it is set. This value is propagated to client controls and menu items.

When a client control has focus and the user presses the F1 key, the control uses the value of HelpContext for this associated action to invoke the online help targeting a specific topic. The target topic is uniquely identified by a nonzero HelpContext value. Leave the HelpContext property of the client control at its default value of zero. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpContext is only used when the HelpType property of this action or the client control is htInteger.

See Also

HelpType

HelpKeyword

2.1.5.3.5 TListControlCopySelection.HelpKeyword Property

Indicates the help keyword for client controls and menu items.

Pascal

```
property HelpKeyword;
```

C++

```
__property HelpKeyword;
```

Description

HelpKeyword, when set, specifies the keyword that identifies a help topic for this action. This value is propagated to the HelpKeyword property of client controls and menu items. The interpretation of HelpKeyword depends on which help system is used to display the topic. For example, when using HyperHelp (on Linux) or WinHelp (on Windows), HelpKeyword refers to an A link.

When a client control has focus and the user presses the F1 key (or the key specified by the application's HelpKey property), the control uses the value of HelpKeyword for this associated action object to invoke the online help targeting a specific topic. Leave the HelpKeyword property of the client control unassigned. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpKeyword is only used when the HelpType property of this action or the client control is htKeyword.

See Also

HelpKeyword

HelpContext

HelpType

HelpKey

2.1.5.3.6 TListControlCopySelection.HelpType Property

Indicates the mechanism for client controls and menu items to use when invoking help.

Pascal

```
property HelpType;
```

C++

```
__property HelpType;
```

Description

HelpType, when set, indicates whether client controls and menu items should use the HelpContext or the HelpKeyword property for invoking the help system. This value is propagated to the HelpType property of client controls and menu items.

See Also

HelpType

HelpType

HelpContext

HelpKeyword

2.1.5.3.7 TListControlCopySelection.Hint Property

Indicates the Help hint for client controls and menu items.

Pascal

```
property Hint;
```

C++

```
__property Hint;
```

Description

Hint holds the string that is the hint for that action when it is set. This value is propagated to client controls and menu items.

See Also

Hint

Hint (see page 4916)

2.1.5.3.8 TListControlCopySelection.ImageIndex Property

Indicates the ImageIndex property for client controls and menu items.

Pascal

```
property ImageIndex;
```

C++

```
__property ImageIndex;
```

Description

ImageIndex is an index into the Images property of the action list or action manager that contains the action. It identifies an image that is associated with controls and menu items that use this action.

See Also

ImageIndex

ImageIndex (see page 4916)

Images

2.1.5.3.9 TListControlCopySelection.ListControl Property

Provides access to the target of the action.

Pascal

```
property ListControl: TCustomListControl;
```

C++

```
__property TCustomListControl ListControl;
```

Description

ListControl is the list control on which the action performs its function. It is a TCustomListControl descendant, such a TListView

or TListBox.

Set ListControl to associate the action with a particular control. If ListControl is not explicitly set, it is assumed to be the active listbox or list view when the action fires.

See Also

TListView

TListBox

2.1.5.3.10 TListControlCopySelection.SecondaryShortCuts Property

Specifies the short cuts (in addition to ShortCut) for triggering clients.

Pascal

```
property SecondaryShortCuts;
```

C++

```
__property SecondaryShortCuts;
```

Description

Actions can execute in response to multiple short cut key combinations. SecondaryShortCuts lists all the short cut key combinations (other than the one specified by the ShortCut property) that can trigger the action. This lets you specify shortcuts for clients that do not have a ShortCut property or provide additional, secondary shortcuts.

When the user types one of the key combinations listed in SecondaryShortCuts, the action's Execute method is called.

See Also

ShortCut

Execute

2.1.5.3.11 TListControlCopySelection.ShortCut Property

Specifies the ShortCut property for client menu items.

Pascal

```
property ShortCut;
```

C++

```
__property ShortCut;
```

Description

ShortCut holds the value that is the shortcut for the action when it is set. This value is propagated to client menu items.

See Also

ShortCut (see page 4920)

SecondaryShortCuts

2.1.5.3.12 TListControlCopySelection.Visible Property

Specifies the Visible property for client controls and menu items.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Visible specifies the visible state for the action. This value is propagated to client controls and menu items.

See Also

Visible (see page 4921)

Visible

2.1.5.4 TListControlCopySelection Events

The events of the TListControlCopySelection class are listed here.

Published Events

	Name	Description
	OnHint (see page 58)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 58)	Occurs when the application is idle or when the action list updates.

2.1.5.4.1 TListControlCopySelection.OnHint Event

Occurs when the mouse pauses over a client control or menu item.

Pascal

```
property OnHint;
```

C++

```
__property OnHint;
```

Description

Use OnHint to override the default hint that appears when the user pauses the mouse over a client control or menu item. The OnHint event handler can change the hint that appears (by changing the HintStr parameter), or display the hint in some application-specific way.

2.1.5.4.2 TListControlCopySelection.OnUpdate Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnUpdate;
```

C++

```
__property OnUpdate;
```

Description

Write an OnUpdate event handler to execute centralized code while an application is idle. For example, actions may want to update enabling and disabling, or checking and unchecking of client targets.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
*/
Boolean checked;

void __fastcall TForm1::Action1Update(TObject *Sender)
{
   // Indicate whether ToolBar1 is currently visible.
   TAction* pa = dynamic_cast<TAction*>(Sender);
   if (pa)
   {
     if (checked != ToolBar1->Visible)
     {
       lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
     }
     checked = ToolBar1->Visible;
   }
//   pa->Checked = True;  // set this statically and don't change it!
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Update(Sender: TObject);
begin
  if ((Sender as TAction).Checked <> ToolBar1.Visible) then
    lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
    { Indicate whether ToolBar1 is currently visible }
    (Sender as TAction).Checked := ToolBar1.Visible;
end;
```

2.1.6 TListControlDeleteSelection Class

TListControlDeleteSelection deletes the selected items in a list control (list view or listbox).

Class Hierarchy

Pascal

```
TListControlDeleteSelection = class(TListControlAction);
```

C++

```
class TListControlDeleteSelection : public TListControlAction;
```

File

ExtActns

Description

Add TListControlDeleteSelection to an action list to allow users to delete the selected items of a list control by using menu items or toolbar buttons. Controls such as menu items and tool buttons linked to this action cause the application to delete all selected items in the target control (a listbox or list view).

TListControlDeleteSelection is designed to work with a list control (TCustomListControl descendant) as a target. TListControlDeleteSelection automatically disables itself if the target control is not a list control or if that list box or list view has no selected items.

2.1.6.1 TListControlDeleteSelection Members

The following tables list the members exposed by TListControlDeleteSelection.

Protected Methods

	Name	Description
	IsEnabled (see page 40)	This is IsEnabled, a member of class TListControlAction.
	Notification (see page 40)	Responds when components are created or destroyed.

Public Methods

	Name	Description
	Create (see page 38)	Creates an instance of TListControlAction (see page 37).
	ExecuteTarget (see page 61)	Deletes the selected items in the target list control.
	HandlesTarget (see page 39)	Indicates whether the action can execute its function.
	UpdateTarget (see page 62)	Enables or disables the action, depending on the state of the target control.

Published Events

	Name	Description
	OnHint (see page 67)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 67)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	Caption (see page 62)	Represents the caption of client controls and menu items.
	Enabled (see page 63)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 63)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 64)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 64)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 65)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 65)	Indicates the ImageIndex property for client controls and menu items.
	ListControl (see page 65)	Provides access to the target of the action.
	SecondaryShortCuts (see page 66)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 66)	Specifies the ShortCut property for client menu items.
	Visible (see page 66)	Specifies the Visible property for client controls and menu items.

2.1.6.2 TListControlDeleteSelection Methods

The methods of the TListControlDeleteSelection class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 61)	Deletes the selected items in the target list control.
	UpdateTarget (see page 62)	Enables or disables the action, depending on the state of the target control.

2.1.6.2.1 TListControlDeleteSelection.ExecuteTarget Method

Deletes the selected items in the target list control.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires. It should always be a TCustomListControl descendant (because HandlesTarget (see page 39) returns false if it is not).

ExecuteTarget sets the ListControl (see page 65) property to Target it is not already set. It then calls the list control's DeleteSelected method, deleting any selected items.

See Also

TCustomListControl

ListControl (see page 40)

DeleteSelected

2.1.6.2.2 TListControlDeleteSelection.UpdateTarget Method

Enables or disables the action, depending on the state of the target control.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically when the application is idle so that actions can update themselves according to current conditions.

In TListControlDeleteSelection (see page 60), UpdateTarget checks whether the current target object (specified by the ListControl (see page 65) property if it is set, otherwise by the Target parameter) is a list control that includes at least one selected item. If so, UpdateTarget sets Enabled (see page 63) to true. If not, UpdateTarget sets Enabled (see page 63) to false.

See Also

Enabled

SelCount

ListControl (see page 40)

2.1.6.3 TListControlDeleteSelection Properties

The properties of the TListControlDeleteSelection class are listed here.

Published Properties

	Name	Description
	Caption (see page 62)	Represents the caption of client controls and menu items.
	Enabled (see page 63)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 63)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 64)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 64)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 65)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 65)	Indicates the ImageIndex property for client controls and menu items.
	ListControl (see page 65)	Provides access to the target of the action.
	SecondaryShortCuts (see page 66)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 66)	Specifies the ShortCut property for client menu items.
	Visible (see page 66)	Specifies the Visible property for client controls and menu items.

2.1.6.3.1 TListControlDeleteSelection.Caption Property

Represents the caption of client controls and menu items.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Caption holds the string that is the caption for the action when it is set. The value of Caption is propagated to client controls and menu items.

See Also

Caption

Caption (see page 4902)

2.1.6.3.2 TListControlDeleteSelection.Enabled Property

Indicates whether client controls and menu items are enabled.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Enabled specifies the enabled state for the action. The value of Enabled is propagated to client controls and menu items.

See Also

Enabled

Enabled (see page 4912)

2.1.6.3.3 TListControlDeleteSelection.HelpContext Property

Indicates the help context ID for client controls and menu items.

Pascal

```
property HelpContext;
```

C++

```
__property HelpContext;
```

Description

HelpContext specifies the help context for the action when it is set. This value is propagated to client controls and menu items.

When a client control has focus and the user presses the F1 key, the control uses the value of HelpContext for this associated action to invoke the online help targeting a specific topic. The target topic is uniquely identified by a nonzero HelpContext value. Leave the HelpContext property of the client control at its default value of zero. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpContext is only used when the HelpType property of this action or the client control is htInteger.

See Also

HelpType

HelpKeyword

2.1.6.3.4 TListControlDeleteSelection.HelpKeyword Property

Indicates the help keyword for client controls and menu items.

Pascal

```
property HelpKeyword;
```

C++

```
__property HelpKeyword;
```

Description

HelpKeyword, when set, specifies the keyword that identifies a help topic for this action. This value is propagated to the HelpKeyword property of client controls and menu items. The interpretation of HelpKeyword depends on which help system is used to display the topic. For example, when using HyperHelp (on Linux) or WinHelp (on Windows), HelpKeyword refers to an A link.

When a client control has focus and the user presses the F1 key (or the key specified by the application's HelpKey property), the control uses the value of HelpKeyword for this associated action object to invoke the online help targeting a specific topic. Leave the HelpKeyword property of the client control unassigned. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpKeyword is only used when the HelpType property of this action or the client control is htKeyword.

See Also

HelpKeyword

HelpContext

HelpType

HelpKey

2.1.6.3.5 TListControlDeleteSelection.HelpType Property

Indicates the mechanism for client controls and menu items to use when invoking help.

Pascal

```
property HelpType;
```

C++

```
__property HelpType;
```

Description

HelpType, when set, indicates whether client controls and menu items should use the HelpContext or the HelpKeyword property for invoking the help system. This value is propagated to the HelpType property of client controls and menu items.

See Also

HelpType

HelpType

HelpContext

HelpKeyword

2.1.6.3.6 TListControlDeleteSelection.Hint Property

Indicates the Help hint for client controls and menu items.

Pascal

```
property Hint;
```

C++

```
__property Hint;
```

Description

Hint holds the string that is the hint for that action when it is set. This value is propagated to client controls and menu items.

See Also

Hint

Hint (see page 4916)

2.1.6.3.7 TListControlDeleteSelection.ImageIndex Property

Indicates the ImageIndex property for client controls and menu items.

Pascal

```
property ImageIndex;
```

C++

```
__property ImageIndex;
```

Description

ImageIndex is an index into the Images property of the action list or action manager that contains the action. It identifies an image that is associated with controls and menu items that use this action.

See Also

ImageIndex

ImageIndex (see page 4916)

Images

2.1.6.3.8 TListControlDeleteSelection.ListControl Property

Provides access to the target of the action.

Pascal

```
property ListControl: TCustomListControl;
```

C++

```
__property TCustomListControl ListControl;
```

Description

ListControl is the list control on which the action performs its function. It is a TCustomListControl descendant, such a TListView or TListBox.

Set ListControl to associate the action with a particular control. If ListControl is not explicitly set, it is assumed to be the active listbox or list view when the action fires.

See Also

TListView

TListBox

2.1.6.3.9 TListControlDeleteSelection.SecondaryShortCuts Property

Specifies the short cuts (in addition to ShortCut) for triggering clients.

Pascal

```
property SecondaryShortCuts;
```

C++

```
__property SecondaryShortCuts;
```

Description

Actions can execute in response to multiple short cut key combinations. SecondaryShortCuts lists all the short cut key combinations (other than the one specified by the ShortCut property) that can trigger the action. This lets you specify shortcuts for clients that do not have a ShortCut property or provide additional, secondary shortcuts.

When the user types one of the key combinations listed in SecondaryShortCuts, the action's Execute method is called.

See Also

ShortCut

Execute

2.1.6.3.10 TListControlDeleteSelection.ShortCut Property

Specifies the ShortCut property for client menu items.

Pascal

```
property ShortCut;
```

C++

```
__property ShortCut;
```

Description

ShortCut holds the value that is the shortcut for the action when it is set. This value is propagated to client menu items.

See Also

ShortCut (see page 4920)

SecondaryShortCuts

2.1.6.3.11 TListControlDeleteSelection.Visible Property

Specifies the Visible property for client controls and menu items.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Visible specifies the visible state for the action. This value is propagated to client controls and menu items.

See Also

Visible (see page 4921)

Visible

2.1.6.4 TListControlDeleteSelection Events

The events of the TListControlDeleteSelection class are listed here.

Published Events

	Name	Description
	OnHint (see page 67)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 67)	Occurs when the application is idle or when the action list updates.

2.1.6.4.1 TListControlDeleteSelection.OnHint Event

Occurs when the mouse pauses over a client control or menu item.

Pascal

```
property OnHint;
```

C++

```
__property OnHint;
```

Description

Use OnHint to override the default hint that appears when the user pauses the mouse over a client control or menu item. The OnHint event handler can change the hint that appears (by changing the HintStr parameter), or display the hint in some application-specific way.

2.1.6.4.2 TListControlDeleteSelection.OnUpdate Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnUpdate;
```

C++

```
__property OnUpdate;
```

Description

Write an OnUpdate event handler to execute centralized code while an application is idle. For example, actions may want to update enabling and disabling, or checking and unchecking of client targets.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
```

```
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
*/
Boolean checked;

void __fastcall TForm1::Action1Update(TObject *Sender)
{
   // Indicate whether ToolBar1 is currently visible.
   TAction* pa = dynamic_cast<TAction*>(Sender);
   if (pa)
   {
     if (checked != ToolBar1->Visible)
     {
       lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
     }
     checked = ToolBar1->Visible;
   }
//   pa->Checked = True;  // set this statically and don't change it!
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Update(Sender: TObject);
begin
  if ((Sender as TAction).Checked <> ToolBar1.Visible) then
    lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
    { Indicate whether ToolBar1 is currently visible }
    (Sender as TAction).Checked := ToolBar1.Visible;
end;
```

UpdateAction

2.1.7 TListControlMoveSelection Class

TListControlMoveSelection moves the selected items in a list control (list view or list box) to another (destination) list control.

Class Hierarchy

Pascal

```
TListControlMoveSelection = class(TListControlCopySelection);
```

C++

```
class TListControlMoveSelection : public TListControlCopySelection;
```

File

ExtActns

Description

Add TListControlMoveSelection to an action list to allow users to move the selected items of a list control to another list control by using menu items or toolbar buttons. Controls such as menu items and tool buttons linked to this action cause the application to move all selected items in the target control to another (destination) list control.

Your application must explicitly set the Destination (see page 53) property to indicate the list to which items are copied.

TListControlMoveSelection is designed to work with a list control (TCustomListControl descendant) as a target. This target is the source list control, not the destination. TListControlMoveSelection automatically disables itself if the target control is not a list control, if that list box or list view has no selected items, or if there is no destination list control assigned.

2.1.7.1 TListControlMoveSelection Members

The following tables list the members exposed by TListControlMoveSelection.

Protected Methods

	Name	Description
	IsEnabled (see page 40)	This is IsEnabled, a member of class TListControlAction.
	Notification (see page 40)	Responds when components are created or destroyed.

Public Methods

	Name	Description
	Create (see page 38)	Creates an instance of TListControlAction (see page 37).
	ExecuteTarget (see page 70)	Moves the selected items in the target list control to the list control specified by Destination (see page 53).
	HandlesTarget (see page 39)	Indicates whether the action can execute its function.
	HandlesTarget (see page 52)	Indicates whether the action can execute its function.
	UpdateTarget (see page 52)	Enables or disables the action, depending on the state of the target control.

Public Properties

	Name	Description
	ListControl (see page 40)	Provides access to the target of the action.

Published Events

	Name	Description
	OnHint (see page 58)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 58)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	Caption (see page 53)	Represents the caption of client controls and menu items.
	Destination (see page 53)	Specifies the list control to which items are copied.
	Enabled (see page 54)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 54)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 55)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 55)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 56)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 56)	Indicates the ImageIndex property for client controls and menu items.
	ListControl (see page 56)	Provides access to the target of the action.
	SecondaryShortCuts (see page 57)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 57)	Specifies the ShortCut property for client menu items.
	Visible (see page 57)	Specifies the Visible property for client controls and menu items.

2.1.7.2 TListControlMoveSelection Methods

The methods of the TListControlMoveSelection class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 70)	Moves the selected items in the target list control to the list control specified by Destination (see page 53).

2.1.7.2.1 TListControlMoveSelection.ExecuteTarget Method

Moves the selected items in the target list control to the list control specified by Destination (see page 53).

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires. It should always be a TCustomListControl descendant (because HandlesTarget (see page 52) returns false if it is not).

ExecuteTarget sets the ListControl (see page 56) property to Target it is not already set. It then calls the list control's MoveSelection method, copying any selected items to the list box or list view specified by the Destination (see page 53) property and removing them from the target (source list control).

2.1.8 TListControlSelectAll Class

TListControlSelectAll selects all the items in a list control (list view or listbox).

Class Hierarchy

Pascal

```
TListControlSelectAll = class(TListControlAction);
```

C++

```
class TListControlSelectAll : public TListControlAction;
```

File

ExtActns

Description

Add TListControlSelectAll to an action list to allow users to select all the items of a list control by using menu items or toolbar buttons. Controls such as menu items and tool buttons linked to this action cause the application to select all items in the target control (a listbox or list view).

TListControlSelectAll is designed to work with a list control (TCustomListControl descendant) as a target. TListControlSelectAll automatically disables itself if the target control is not a list control, if that target control does not permit multiple selection, or if all of the items in the target control are already selected.

2.1.8.1 TListControlSelectAll Members

The following tables list the members exposed by TListControlSelectAll.

Protected Methods

	Name	Description
	IsEnabled (see page 40)	This is IsEnabled, a member of class TListControlAction.
	Notification (see page 40)	Responds when components are created or destroyed.

Public Methods

	Name	Description
	Create (see page 38)	Creates an instance of TListControlAction (see page 37).
	ExecuteTarget (see page 72)	Selects all the items in the target list control.
	HandlesTarget (see page 39)	Indicates whether the action can execute its function.
	UpdateTarget (see page 73)	Enables or disables the action, depending on the state of the target control.

Published Events

	Name	Description
	OnHint (see page 78)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 78)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	Caption (see page 74)	Represents the caption of client controls and menu items.
	Enabled (see page 74)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 74)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 75)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 75)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 76)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 76)	Indicates the ImageIndex property for client controls and menu items.
	ListControl (see page 76)	Provides access to the target of the action.
	SecondaryShortCuts (see page 77)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 77)	Specifies the ShortCut property for client menu items.
	Visible (see page 77)	Specifies the Visible property for client controls and menu items.

2.1.8.2 TListControlSelectAll Methods

The methods of the TListControlSelectAll class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 72)	Selects all the items in the target list control.
	UpdateTarget (see page 73)	Enables or disables the action, depending on the state of the target control.

2.1.8.2.1 TListControlSelectAll.ExecuteTarget Method

Selects all the items in the target list control.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires. It should always be a TCustomListControl descendant (because HandlesTarget (see page 39) returns false if it is not).

ExecuteTarget sets the ListControl (see page 76) property to Target it is not already set. It then calls the list control's SelectAll

method, selecting all of its items.

See Also

TCustomListControl

ListControl (see page 40)

SelectAll

2.1.8.2.2 TListControlSelectAll.UpdateTarget Method

Enables or disables the action, depending on the state of the target control.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically when the application is idle so that actions can update themselves according to current conditions.

In TListControlSelectAll (see page 71), UpdateTarget checks whether the current target object (specified by the ListControl (see page 76) property if it is set, otherwise by the Target parameter) is a list control that includes allows multiple selections and that includes at least one unselected item. If so, UpdateTarget sets Enabled (see page 74) to true. If not, UpdateTarget sets Enabled (see page 74) to false.

2.1.8.3 TListControlSelectAll Properties

The properties of the TListControlSelectAll class are listed here.

Published Properties

	Name	Description
	Caption (see page 74)	Represents the caption of client controls and menu items.
	Enabled (see page 74)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 74)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 75)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 75)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 76)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 76)	Indicates the ImageIndex property for client controls and menu items.
	ListControl (see page 76)	Provides access to the target of the action.
	SecondaryShortCuts (see page 77)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 77)	Specifies the ShortCut property for client menu items.
	Visible (see page 77)	Specifies the Visible property for client controls and menu items.

2.1.8.3.1 TListControlSelectAll.Caption Property

Represents the caption of client controls and menu items.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Caption holds the string that is the caption for the action when it is set. The value of Caption is propagated to client controls and menu items.

See Also

Caption

Caption (see page 4902)

2.1.8.3.2 TListControlSelectAll.Enabled Property

Indicates whether client controls and menu items are enabled.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Enabled specifies the enabled state for the action. The value of Enabled is propagated to client controls and menu items.

See Also

Enabled

Enabled (see page 4912)

2.1.8.3.3 TListControlSelectAll.HelpContext Property

Indicates the help context ID for client controls and menu items.

Pascal

```
property HelpContext;
```

C++

```
__property HelpContext;
```

Description

HelpContext specifies the help context for the action when it is set. This value is propagated to client controls and menu items.

When a client control has focus and the user presses the F1 key, the control uses the value of HelpContext for this associated action to invoke the online help targeting a specific topic. The target topic is uniquely identified by a nonzero HelpContext value. Leave the HelpContext property of the client control at its default value of zero. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpContext is only used when the HelpType property of this action or the client control is htInteger.

HelpType

HelpKeyword

2.1.8.3.4 TListControlSelectAll.HelpKeyword Property

Indicates the help keyword for client controls and menu items.

Pascal

```
property HelpKeyword;
```

C++

```
__property HelpKeyword;
```

Description

HelpKeyword, when set, specifies the keyword that identifies a help topic for this action. This value is propagated to the HelpKeyword property of client controls and menu items. The interpretation of HelpKeyword depends on which help system is used to display the topic. For example, when using HyperHelp (on Linux) or WinHelp (on Windows), HelpKeyword refers to an A link.

When a client control has focus and the user presses the F1 key (or the key specified by the application's HelpKey property), the control uses the value of HelpKeyword for this associated action object to invoke the online help targeting a specific topic. Leave the HelpKeyword property of the client control unassigned. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpKeyword is only used when the HelpType property of this action or the client control is htKeyword.

2.1.8.3.5 TListControlSelectAll.HelpType Property

Indicates the mechanism for client controls and menu items to use when invoking help.

Pascal

```
property HelpType;
```

C++

```
__property HelpType;
```

Description

HelpType, when set, indicates whether client controls and menu items should use the HelpContext or the HelpKeyword property for invoking the help system. This value is propagated to the HelpType property of client controls and menu items.

See Also

HelpType

HelpType

HelpContext

HelpKeyword

2.1.8.3.6 TListControlSelectAll.Hint Property

Indicates the Help hint for client controls and menu items.

Pascal

```
property Hint;
```

C++

```
__property Hint;
```

Description

Hint holds the string that is the hint for that action when it is set. This value is propagated to client controls and menu items.

See Also

Hint

Hint (see page 4916)

2.1.8.3.7 TListControlSelectAll.ImageIndex Property

Indicates the ImageIndex property for client controls and menu items.

Pascal

```
property ImageIndex;
```

C++

```
__property ImageIndex;
```

Description

ImageIndex is an index into the Images property of the action list or action manager that contains the action. It identifies an image that is associated with controls and menu items that use this action.

See Also

ImageIndex

ImageIndex (see page 4916)

Images

2.1.8.3.8 TListControlSelectAll.ListControl Property

Provides access to the target of the action.

Pascal

```
property ListControl: TCustomListControl;
```

C++

```
__property TCustomListControl ListControl;
```

Description

ListControl is the list control on which the action performs its function. It is a TCustomListControl descendant, such a TListView

or TListBox.

Set ListControl to associate the action with a particular control. If ListControl is not explicitly set, it is assumed to be the active listbox or list view when the action fires.

See Also

TListView

TListBox

2.1.8.3.9 TListControlSelectAll.SecondaryShortCuts Property

Specifies the short cuts (in addition to ShortCut) for triggering clients.

Pascal

```
property SecondaryShortCuts;
```

C++

```
__property SecondaryShortCuts;
```

Description

Actions can execute in response to multiple short cut key combinations. SecondaryShortCuts lists all the short cut key combinations (other than the one specified by the ShortCut property) that can trigger the action. This lets you specify shortcuts for clients that do not have a ShortCut property or provide additional, secondary shortcuts.

When the user types one of the key combinations listed in SecondaryShortCuts, the action's Execute method is called.

See Also

ShortCut

Execute

2.1.8.3.10 TListControlSelectAll.ShortCut Property

Specifies the ShortCut property for client menu items.

Pascal

```
property ShortCut;
```

C++

```
__property ShortCut;
```

Description

ShortCut holds the value that is the shortcut for the action when it is set. This value is propagated to client menu items.

See Also

ShortCut (see page 4920)

SecondaryShortCuts

2.1.8.3.11 TListControlSelectAll.Visible Property

Specifies the Visible property for client controls and menu items.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Visible specifies the visible state for the action. This value is propagated to client controls and menu items.

See Also

Visible (see page 4921)

Visible

2.1.8.4 TListControlSelectAll Events

The events of the TListControlSelectAll class are listed here.

Published Events

	Name	Description
	OnHint (see page 78)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 78)	Occurs when the application is idle or when the action list updates.

2.1.8.4.1 TListControlSelectAll.OnHint Event

Occurs when the mouse pauses over a client control or menu item.

Pascal

```
property OnHint;
```

C++

```
__property OnHint;
```

Description

Use OnHint to override the default hint that appears when the user pauses the mouse over a client control or menu item. The OnHint event handler can change the hint that appears (by changing the HintStr parameter), or display the hint in some application-specific way.

2.1.8.4.2 TListControlSelectAll.OnUpdate Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnUpdate;
```

C++

```
__property OnUpdate;
```

Description

Write an OnUpdate event handler to execute centralized code while an application is idle. For example, actions may want to update enabling and disabling, or checking and unchecking of client targets.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
*/
Boolean checked;

void __fastcall TForm1::Action1Update(TObject *Sender)
{
   // Indicate whether ToolBar1 is currently visible.
   TAction* pa = dynamic_cast<TAction*>(Sender);
   if (pa)
   {
     if (checked != ToolBar1->Visible)
     {
       lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
     }
     checked = ToolBar1->Visible;
   }
//   pa->Checked = True;  // set this statically and don't change it!
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Update(Sender: TObject);
begin
  if ((Sender as TAction).Checked <> ToolBar1.Visible) then
    lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
    { Indicate whether ToolBar1 is currently visible }
    (Sender as TAction).Checked := ToolBar1.Visible;
end;
```

See Also

UpdateAction

2.1.9 TNextTab Class

TNextTab moves a tabbed control to its next page.

Class Hierarchy

Pascal

```
TNextTab = class(TTabAction);
```

C++

```
class TNextTab : public TTabAction;
```

File

ExtActns

Description

Add TNextTab to an action list to provide the response to the "Next" and "Finish" buttons or menu items in a tabbed dialog. Controls such as menu items and tool buttons linked to this action cause a different response, depending on the value of the Wrap (see page 88) property and on whether the target control is on the last page:

If the target page control is not on the last page, or if Wrap (see page 88) is true, client controls cause this action to change the current page to the next page. (When Wrap (see page 88) is true, the next page after the last tab is the first tabbed page).

If Wrap (see page 88) is false and the target page control is on the last page, this action changes the caption of client controls (for example, from "Next" to "Finish") and, when fired, responds by generating an OnFinish (see page 90) event.

Before you can use TNextTab, you must assign a target page control or tab control as the value of the TabControl (see page 87) property. Once the target control is assigned, TNextTab automatically disables itself if the target control is not enabled.

TTabControl

2.1.9.1 TNextTab Members

The following tables list the members exposed by TNextTab.

Protected Methods

	Name	Description
	Notification (see page 152)	Responds when components are created or destroyed.
	SelectNextTab (see page 152)	This is SelectNextTab, a member of class TTabAction.

Public Methods

	Name	Description
	Create (see page 151)	Creates an instance of TTabAction (see page 150).
	ExecuteTarget (see page 81)	Changes the selected tab in the target tab control to the next one, or generates an OnFinish (see page 90) event.
	HandlesTarget (see page 152)	Indicates whether the action can execute its function.

	UpdateTarget (see page 82)	Updates the action to reflect current conditions.

Published Events

	Name	Description
	AfterTabChange (see page 89)	Occurs immediately after the action changes the page of the associated tab control.
	BeforeTabChange (see page 89)	Occurs immediately before the action changes the page of the associated tab control.
	OnFinish (see page 90)	Occurs when the action fires and the target page control is on its last page.
	OnHint (see page 90)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 90)	Occurs when the application is idle or when the action list updates.
	OnValidateTab (see page 92)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	Caption (see page 83)	Represents the caption of client controls and menu items.
	Enabled (see page 83)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 84)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 84)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 85)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 85)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 85)	Indicates the ImageIndex property for client controls and menu items.
	LastTabCaption (see page 86)	Specifies the caption when the target page control is on its last page and Wrap (see page 88) is false.
	ShortCut (see page 86)	Specifies the ShortCut property for client menu items.
	SkipHiddenTabs (see page 87)	Indicates whether the tab action should consider hidden tabbed pages when moving to the next page.
	TabControl (see page 87)	Specifies the target of the action.
	Visible (see page 88)	Specifies the Visible property for client controls and menu items.
	Wrap (see page 88)	Indicates whether the tab action should "wrap" when navigating to the next tab page.

2.1.9.2 TNextTab Methods

The methods of the TNextTab class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 81)	Changes the selected tab in the target tab control to the next one, or generates an OnFinish (see page 90) event.
	UpdateTarget (see page 82)	Updates the action to reflect current conditions.

2.1.9.2.1 TNextTab.ExecuteTarget Method

Changes the selected tab in the target tab control to the next one, or generates an OnFinish (see page 90) event.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

ExecuteTarget causes the action to perform its default response based on the state of the target tab control.

Target is the currently active object when the action fires. TNextTab (see page 80) ignores this parameter and uses the TabControl (see page 87) property to identify the target control.

ExecuteTarget performs differently, depending on whether the target control is on the last page and on the value of the Wrap (see page 88) property:

If Wrap (see page 88) is true or the target control is not on the last page, ExecuteTarget generates a BeforeTabChange (see page 89) event, changes the target control to the next page, and generates an AfterTabChange (see page 89) event. If Wrap (see page 88) is true and the target control is on the last page, this causes the target control to move to the first page. Note that the SkipHiddenTabs (see page 87) property determines whether the next page can include a hidden page.

If Wrap (see page 88) is false and the target control is on the last page, ExecuteTarget generates an OnFinish (see page 90) event.

Wrap (see page 154)

TabIndex

2.1.9.2.2 TNextTab.UpdateTarget Method

Updates the action to reflect current conditions.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically when the application is idle so that actions can update themselves according to current conditions.

In TNextTab (see page 80), UpdateTarget first checks whether the TabControl (see page 87) property specifies an enabled control that can act as a target. If not, UpdateTarget sets the Enabled (see page 83) property to false.

If the target control is enabled, UpdateTarget sets the Enabled (see page 83) property to true and checks whether the target control is on its last page. If so, (and if Wrap (see page 88) is false) it changes the Caption (see page 83) property to the value of LastTabCaption (see page 86). If not, it restores the Caption (see page 83) property to its original value.

Wrap (see page 154)

2.1.9.3 TNextTab Properties

The properties of the TNextTab class are listed here.

Published Properties

	Name	Description
	Caption (see page 83)	Represents the caption of client controls and menu items.
	Enabled (see page 83)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 84)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 84)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 85)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 85)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 85)	Indicates the ImageIndex property for client controls and menu items.
	LastTabCaption (see page 86)	Specifies the caption when the target page control is on its last page and Wrap (see page 88) is false.
	ShortCut (see page 86)	Specifies the ShortCut property for client menu items.
	SkipHiddenTabs (see page 87)	Indicates whether the tab action should consider hidden tabbed pages when moving to the next page.
	TabControl (see page 87)	Specifies the target of the action.
	Visible (see page 88)	Specifies the Visible property for client controls and menu items.
	Wrap (see page 88)	Indicates whether the tab action should "wrap" when navigating to the next tab page.

2.1.9.3.1 TNextTab.Caption Property

Represents the caption of client controls and menu items.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Caption holds the string that is the caption for the action when it is set. The value of Caption is propagated to client controls and menu items.

See Also

Caption

Caption (see page 4902)

2.1.9.3.2 TNextTab.Enabled Property

Indicates whether client controls and menu items are enabled.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Enabled specifies the enabled state for the action. The value of Enabled is propagated to client controls and menu items.

See Also

Enabled

Enabled (see page 4912)

2.1.9.3.3 TNextTab.HelpContext Property

Indicates the help context ID for client controls and menu items.

Pascal

```
property HelpContext;
```

C++

```
__property HelpContext;
```

Description

HelpContext specifies the help context for the action when it is set. This value is propagated to client controls and menu items.

When a client control has focus and the user presses the F1 key, the control uses the value of HelpContext for this associated action to invoke the online help targeting a specific topic. The target topic is uniquely identified by a nonzero HelpContext value. Leave the HelpContext property of the client control at its default value of zero. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpContext is only used when the HelpType property of this action or the client control is htInteger.

See Also

HelpType

HelpKeyword

2.1.9.3.4 TNextTab.HelpKeyword Property

Indicates the help keyword for client controls and menu items.

Pascal

```
property HelpKeyword;
```

C++

```
__property HelpKeyword;
```

Description

HelpKeyword, when set, specifies the keyword that identifies a help topic for this action. This value is propagated to the HelpKeyword property of client controls and menu items. The interpretation of HelpKeyword depends on which help system is used to display the topic. For example, when using HyperHelp (on Linux) or WinHelp (on Windows), HelpKeyword refers to an A link.

When a client control has focus and the user presses the F1 key (or the key specified by the application's HelpKey property), the control uses the value of HelpKeyword for this associated action object to invoke the online help targeting a specific topic. Leave the HelpKeyword property of the client control unassigned. This allows multiple controls (and multiple types of controls) to be

associated with the same help topic through the one action object.

Note: HelpKeyword is only used when the HelpType property of this action or the client control is htKeyword.

See Also

HelpKeyword

HelpContext

HelpType

HelpKey

2.1.9.3.5 TNextTab.HelpType Property

Indicates the mechanism for client controls and menu items to use when invoking help.

Pascal

```
property HelpType;
```

C++

```
__property HelpType;
```

Description

HelpType, when set, indicates whether client controls and menu items should use the HelpContext or the HelpKeyword property for invoking the help system. This value is propagated to the HelpType property of client controls and menu items.

See Also

HelpType

HelpType

HelpContext

HelpKeyword

2.1.9.3.6 TNextTab.Hint Property

Indicates the Help hint for client controls and menu items.

Pascal

```
property Hint;
```

C++

```
__property Hint;
```

Description

Hint holds the string that is the hint for that action when it is set. This value is propagated to client controls and menu items.

See Also

Hint

Hint (see page 4916)

2.1.9.3.7 TNextTab.ImageIndex Property

Indicates the ImageIndex property for client controls and menu items.

Pascal

```
property ImageIndex;
```

C++

```
__property ImageIndex;
```

Description

ImageIndex is an index into the Images property of the action list or action manager that contains the action. It identifies an image that is associated with controls and menu items that use this action.

See Also

ImageIndex

ImageIndex (see page 4916)

Images

2.1.9.3.8 TNextTab.LastTabCaption Property

Specifies the caption when the target page control is on its last page and Wrap (see page 88) is false.

Pascal

```
property LastTabCaption: String;
```

C++

```
__property UnicodeString LastTabCaption;
```

Description

Set LastTabCaption to the caption of target controls when the control specified by the TabControl (see page 87) property is on its last page and the action can't tab beyond the last page. When the target page control is not on the last page, the caption for client controls is given by the Caption (see page 83) property. When the target page control is on the last page (and Wrap (see page 88) is false), TNextTab (see page 80) caches the original value of Caption (see page 83) and changes the Caption (see page 83) property to LastTabCaption. If the target page control returns to a previous page, TNextTab (see page 80) then restores the original value of the Caption (see page 83) property.

LastTabCaption is designed for client controls such as the button in a tabbed dialog that changes from a "Next" button to a "Finish" button when the tabbed dialog reaches the last page.

See Also

Caption

TabControl (see page 154)

Wrap (see page 154)

2.1.9.3.9 TNextTab.ShortCut Property

Specifies the ShortCut property for client menu items.

Pascal

```
property ShortCut;
```

C++

```
__property ShortCut;
```

Description

ShortCut holds the value that is the shortcut for the action when it is set. This value is propagated to client menu items.

See Also

ShortCut (see page 4920)

SecondaryShortCuts

2.1.9.3.10 TNextTab.SkipHiddenTabs Property

Indicates whether the tab action should consider hidden tabbed pages when moving to the next page.

Pascal

```
property SkipHiddenTabs: Boolean;
```

C++

```
__property Boolean SkipHiddenTabs;
```

Description

Set SkipHiddenTabs to true if you do not want the action to move to a tab page if its TabVisible property is false. Set SkipHiddenTabs to false if the tab action can move to and make visible a hidden page.

Note: SkipHiddenTabs only has an effect when the TabControl property identifies a TPageControl object. (TTabControl does not support hidden pages).

See Also

ExecuteTarget (see page 81)

ExecuteTarget (see page 102)

TabVisible

TPageControl

2.1.9.3.11 TNextTab.TabControl Property

Specifies the target of the action.

Pascal

```
property TabControl: TCustomTabControl;
```

C++

```
__property TCustomTabControl TabControl;
```

Description

Set TabControl to the control on which the action operates when its ExecuteTarget method is called. Typically, this is a page control or tab control object that implements the pages of a tabbed dialog.

An application must explicitly assign a value to the TabControl property before the TTabAction descendant is enabled. The action does not infer the target page control when it fires.

See Also

ExecuteTarget (see page 81)

ExecuteTarget (see page 102)

2.1.9.3.12 TNextTab.Visible Property

Specifies the Visible property for client controls and menu items.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Visible specifies the visible state for the action. This value is propagated to client controls and menu items.

See Also

Visible (see page 4921)

Visible

2.1.9.3.13 TNextTab.Wrap Property

Indicates whether the tab action should "wrap" when navigating to the next tab page.

Pascal

```
property Wrap: Boolean;
```

C++

```
__property Boolean Wrap;
```

Description

When Wrap is true, the tab action can move previous to the first tabbed page or after the last tabbed page in the associated control. When Wrap is false, an attempt to move beyond the first or last page does not result in any page change, although it still results in a BeforeTabChange and an AfterTabChange event or in an OnFinish event.

See Also

ExecuteTarget (see page 81)

ExecuteTarget (see page 102)

TabControl (see page 154)

BeforeTabChange (see page 155)

AfterTabChange (see page 155)

OnFinish (see page 90)

2.1.9.4 TNextTab Events

The events of the TNextTab class are listed here.

Published Events

	Name	Description
	AfterTabChange (see page 89)	Occurs immediately after the action changes the page of the associated tab control.

	BeforeTabChange (see page 89)	Occurs immediately before the action changes the page of the associated tab control.
	OnFinish (see page 90)	Occurs when the action fires and the target page control is on its last page.
	OnHint (see page 90)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 90)	Occurs when the application is idle or when the action list updates.
	OnValidateTab (see page 92)	Occurs when the application is idle or when the action list updates.

2.1.9.4.1 TNextTab.AfterTabChange Event

Occurs immediately after the action changes the page of the associated tab control.

Pascal

```
property AfterTabChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent AfterTabChange;
```

Description

Write an AfterTabChange event handler to perform any additional tasks after the tab action changes the current page of the associated tab control. Typically, this event is used to initialize the current page of the tab control.

Note: AfterTabChange only occurs if the action tries to change the page of the tab control (even if it is not successful). If the action attempts some other task (for example, when TNextPage is on the last page of the tab control), AfterTabChange does not occur.

See Also

BeforeTabChange (see page 155)

TabControl (see page 154)

Wrap (see page 154)

2.1.9.4.2 TNextTab.BeforeTabChange Event

Occurs immediately before the action changes the page of the associated tab control.

Pascal

```
property BeforeTabChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent BeforeTabChange;
```

Description

Write a BeforeTabChange event handler to perform any additional tasks before the tab action changes the current page of the associated tab control. Typically, this event is used to save or respond to the changes the user made on the current page before it changes.

Note: BeforeTabChange only occurs if the action tries to change the page of the tab control (even if it is not successful). If the action attempts some other task (for example, when TNextPage is on the last page of the tab control), BeforeTabChange does not occur.

See Also

AfterTabChange (see page 155)

TabControl (see page 154)

Wrap (see page 154)

2.1.9.4.3 TNextTab.OnFinish Event

Occurs when the action fires and the target page control is on its last page.

Pascal

```
property OnFinish: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnFinish;
```

Description

Write an OnFinish event handler to respond when the user indicates that they are finished with the tabbed dialog by clicking a client control when the tabbed dialog is on its last page. OnFinish only occurs when the target control is on its last page and the Wrap (see page 88) property is false. When the target page control is on any other page, or when Wrap (see page 88) is true, TNextTab (see page 80) generates an BeforeTabChange (see page 89) event, changes the current page of the target control, and generates an AfterTabChange (see page 89) event.

Note: Use the OnFinish event rather than the action's OnExecute event. If you supply an event handler to the OnExecute event, it blocks the default response by this action, and the action won't change the current page when the target tabbed dialog is not on its last page.

See Also

AfterTabChange (see page 155)

BeforeTabChange (see page 155)

TabControl (see page 154)

Wrap (see page 154)

2.1.9.4.4 TNextTab.OnHint Event

Occurs when the mouse pauses over a client control or menu item.

Pascal

```
property OnHint;
```

C++

```
__property OnHint;
```

Description

Use OnHint to override the default hint that appears when the user pauses the mouse over a client control or menu item. The OnHint event handler can change the hint that appears (by changing the HintStr parameter), or display the hint in some application-specific way.

2.1.9.4.5 TNextTab.OnUpdate Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnUpdate;
```

C++

```
__property OnUpdate;
```

Description

Write an OnUpdate event handler to execute centralized code while an application is idle. For example, actions may want to update enabling and disabling, or checking and unchecking of client targets.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
*/
Boolean checked;

void __fastcall TForm1::Action1Update(TObject *Sender)
{
   // Indicate whether ToolBar1 is currently visible.
   TAction* pa = dynamic_cast<TAction*>(Sender);
   if (pa)
   {
     if (checked != ToolBar1->Visible)
     {
       lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
     }
     checked = ToolBar1->Visible;
   }
//   pa->Checked = True;  // set this statically and don't change it!
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Update(Sender: TObject);
begin
  if ((Sender as TAction).Checked <> ToolBar1.Visible) then
    lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
    { Indicate whether ToolBar1 is currently visible }
    (Sender as TAction).Checked := ToolBar1.Visible;
```

```
end;
```

See Also

UpdateAction

2.1.9.4.6 TNextTab.OnValidateTab Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnValidateTab: TValidateTabEvent;
```

C++

```
__property TValidateTabEvent OnValidateTab;
```

Description

Use the OnValidateTab event rather than the OnUpdate event to update the properties of a tab action when the application is idle. Unlike the OnUpdate event, which prevents the default behavior of the UpdateTarget method, OnValidateTab occurs after UpdateTarget has set the Enabled property to reflect whether the target tab control is enabled.

OnValidateTab can be used to update any of the properties of the tab action, but it is intended primarily for enabling or disabling the action, depending on the contents of the current page of the target tab control.

Sender is the tab action component to update in this event.

TabControl is the target tab control.

Enabled reflects the Enabled property of this action. Set Enabled in the event handler to enable or disable the action depending on current conditions.

Enabled

2.1.10 TOpenPicture Class

TOpenPicture is the standard action for displaying the open picture dialog.

Class Hierarchy

Pascal

```
TOpenPicture = class(TCommonDialogAction);
```

C++

```
class TOpenPicture : public TCommonDialogAction;
```

File

ExtActns

Description

Add TOpenPicture to an action list to add a graphics file selection dialog to your application. Controls such as menu items and tool buttons linked to this action cause the application to display the open picture dialog when invoked. Use the OnAccept (see page 99) event to respond after the user selects a file name in the dialog or the OnCancel (see page 99) event to respond when the user cancels from the dialog. In the event handler, you can read the file name from the dialog specified by the Dialog (see page 94) property.

See Also

TFileOpen

TOpenPictureDialog (see page 1560)

TSavePicture (see page 132)

2.1.10.1 TOpenPicture Members

The following tables list the members exposed by TOpenPicture.

Protected Methods

	Name	Description
	GetDialogClass (see page 94)	This is GetDialogClass, a member of class TOpenPicture.

Published Events

	Name	Description
	OnAccept (see page 99)	This is OnAccept, a member of class TOpenPicture.
	OnCancel (see page 99)	This is OnCancel, a member of class TOpenPicture.
	OnHint (see page 99)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 99)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	Caption (see page 94)	Represents the caption of client controls and menu items.
	Dialog (see page 94)	Provides access the open picture dialog that the action executes.
	Enabled (see page 95)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 95)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 96)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 96)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 97)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 97)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 97)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 98)	Specifies the ShortCut property for client menu items.
	Visible (see page 98)	Specifies the Visible property for client controls and menu items.

2.1.10.2 TOpenPicture Methods

The methods of the TOpenPicture class are listed here.

Protected Methods

	Name	Description
	GetDialogClass (see page 94)	This is GetDialogClass, a member of class TOpenPicture.

2.1.10.2.1 TOpenPicture.GetDialogClass Method

Pascal

```
function GetDialogClass: TCommonDialogClass; override;
```

C++

```
virtual __fastcall TCommonDialogClass GetDialogClass();
```

Description

This is GetDialogClass, a member of class TOpenPicture.

2.1.10.3 TOpenPicture Properties

The properties of the TOpenPicture class are listed here.

Published Properties

	Name	Description
	Caption (see page 94)	Represents the caption of client controls and menu items.
R	Dialog (see page 94)	Provides access the open picture dialog that the action executes.
	Enabled (see page 95)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 95)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 96)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 96)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 97)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 97)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 97)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 98)	Specifies the ShortCut property for client menu items.
	Visible (see page 98)	Specifies the Visible property for client controls and menu items.

2.1.10.3.1 TOpenPicture.Caption Property

Represents the caption of client controls and menu items.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Caption holds the string that is the caption for the action when it is set. The value of Caption is propagated to client controls and menu items.

See Also

Caption

Caption (see page 4902)

2.1.10.3.2 TOpenPicture.Dialog Property

Provides access the open picture dialog that the action executes.

Pascal

```
property Dialog: TOpenPictureDialog;
```

C++

```
__property TOpenPictureDialog Dialog;
```

Description

Use Dialog to configure the graphics file selection dialog before the action fires or to read the selected file name after the action executes the dialog. For example, you can set the dialog's default extension or initially selected file at design time using the Object Inspector or read the dialog's FileName property from an OnAccept (see page 99) event handler to use the file that the user selected.

When using an open picture action, you do not place a TOpenPicture (see page 92) Dialog component on the form or data module at design time. Instead, you add the TOpenPicture (see page 92) object to your action list and then use the Dialog property. The dialog component is created by the TOpenPicture (see page 92) constructor.

See Also

onaccept

oncancel

FileName

2.1.10.3.3 TOpenPicture.Enabled Property

Indicates whether client controls and menu items are enabled.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Enabled specifies the enabled state for the action. The value of Enabled is propagated to client controls and menu items.

See Also

Enabled

Enabled (see page 4912)

2.1.10.3.4 TOpenPicture.HelpContext Property

Indicates the help context ID for client controls and menu items.

Pascal

```
property HelpContext;
```

C++

```
__property HelpContext;
```

Description

HelpContext specifies the help context for the action when it is set. This value is propagated to client controls and menu items.

When a client control has focus and the user presses the F1 key, the control uses the value of HelpContext for this associated

action to invoke the online help targeting a specific topic. The target topic is uniquely identified by a nonzero HelpContext value. Leave the HelpContext property of the client control at its default value of zero. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpContext is only used when the HelpType property of this action or the client control is htInteger.

See Also

HelpType

HelpKeyword

2.1.10.3.5 TOpenPicture.HelpKeyword Property

Indicates the help keyword for client controls and menu items.

Pascal

```
property HelpKeyword;
```

C++

```
__property HelpKeyword;
```

Description

HelpKeyword, when set, specifies the keyword that identifies a help topic for this action. This value is propagated to the HelpKeyword property of client controls and menu items. The interpretation of HelpKeyword depends on which help system is used to display the topic. For example, when using HyperHelp (on Linux) or WinHelp (on Windows), HelpKeyword refers to an A link.

When a client control has focus and the user presses the F1 key (or the key specified by the application's HelpKey property), the control uses the value of HelpKeyword for this associated action object to invoke the online help targeting a specific topic. Leave the HelpKeyword property of the client control unassigned. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpKeyword is only used when the HelpType property of this action or the client control is htKeyword.

See Also

HelpKeyword

HelpContext

HelpType

HelpKey

2.1.10.3.6 TOpenPicture.HelpType Property

Indicates the mechanism for client controls and menu items to use when invoking help.

Pascal

```
property HelpType;
```

C++

```
__property HelpType;
```

Description

HelpType, when set, indicates whether client controls and menu items should use the HelpContext or the HelpKeyword property for invoking the help system. This value is propagated to the HelpType property of client controls and menu items.

See Also

HelpType

HelpType

HelpContext

HelpKeyword

2.1.10.3.7 TOpenPicture.Hint Property

Indicates the Help hint for client controls and menu items.

Pascal

```
property Hint;
```

C++

```
__property Hint;
```

Description

Hint holds the string that is the hint for that action when it is set. This value is propagated to client controls and menu items.

See Also

Hint

Hint (see page 4916)

2.1.10.3.8 TOpenPicture.ImageIndex Property

Indicates the ImageIndex property for client controls and menu items.

Pascal

```
property ImageIndex;
```

C++

```
__property ImageIndex;
```

Description

ImageIndex is an index into the Images property of the action list or action manager that contains the action. It identifies an image that is associated with controls and menu items that use this action.

See Also

ImageIndex

ImageIndex (see page 4916)

Images

2.1.10.3.9 TOpenPicture.SecondaryShortCuts Property

Specifies the short cuts (in addition to ShortCut) for triggering clients.

Pascal

```
property SecondaryShortCuts;
```

C++

```
__property SecondaryShortCuts;
```

Description

Actions can execute in response to multiple short cut key combinations. SecondaryShortCuts lists all the short cut key combinations (other than the one specified by the ShortCut property) that can trigger the action. This lets you specify shortcuts for clients that do not have a ShortCut property or provide additional, secondary shortcuts.

When the user types one of the key combinations listed in SecondaryShortCuts, the action's Execute method is called.

See Also

ShortCut

Execute

2.1.10.3.10 TOpenPicture.ShortCut Property

Specifies the ShortCut property for client menu items.

Pascal

```
property ShortCut;
```

C++

```
__property ShortCut;
```

Description

ShortCut holds the value that is the shortcut for the action when it is set. This value is propagated to client menu items.

See Also

ShortCut (see page 4920)

SecondaryShortCuts

2.1.10.3.11 TOpenPicture.Visible Property

Specifies the Visible property for client controls and menu items.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Visible specifies the visible state for the action. This value is propagated to client controls and menu items.

See Also

Visible (see page 4921)

Visible

2.1.10.4 TOpenPicture Events

The events of the TOpenPicture class are listed here.

Published Events

	Name	Description
	OnAccept (see page 99)	This is OnAccept, a member of class TOpenPicture.
	OnCancel (see page 99)	This is OnCancel, a member of class TOpenPicture.
	OnHint (see page 99)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 99)	Occurs when the application is idle or when the action list updates.

2.1.10.4.1 TOpenPicture.OnAccept Event

Pascal

```
property OnAccept;
```

C++

```
__property OnAccept;
```

Description

This is OnAccept, a member of class TOpenPicture.

2.1.10.4.2 TOpenPicture.OnCancel Event

Pascal

```
property OnCancel;
```

C++

```
__property OnCancel;
```

Description

This is OnCancel, a member of class TOpenPicture.

2.1.10.4.3 TOpenPicture.OnHint Event

Occurs when the mouse pauses over a client control or menu item.

Pascal

```
property OnHint;
```

C++

```
__property OnHint;
```

Description

Use OnHint to override the default hint that appears when the user pauses the mouse over a client control or menu item. The OnHint event handler can change the hint that appears (by changing the HintStr parameter), or display the hint in some application-specific way.

2.1.10.4.4 TOpenPicture.OnUpdate Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnUpdate;
```

C++

```
__property OnUpdate;
```

Description

Write an OnUpdate event handler to execute centralized code while an application is idle. For example, actions may want to update enabling and disabling, or checking and unchecking of client targets.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
*/
Boolean checked;

void __fastcall TForm1::Action1Update(TObject *Sender)
{
   // Indicate whether ToolBar1 is currently visible.
   TAction* pa = dynamic_cast<TAction*>(Sender);
   if (pa)
   {
     if (checked != ToolBar1->Visible)
     {
       lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
     }
     checked = ToolBar1->Visible;
   }
//   pa->Checked = True;  // set this statically and don't change it!
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Update(Sender: TObject);
begin
  if ((Sender as TAction).Checked <> ToolBar1.Visible) then
    lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
    { Indicate whether ToolBar1 is currently visible }
    (Sender as TAction).Checked := ToolBar1.Visible;
```

```
end;
```

UpdateAction

2.1.11 TPreviousTab Class

TPreviousTab moves a page control to its previous page.

Class Hierarchy

Pascal

```
TPreviousTab = class(TTabAction);
```

C++

```
class TPreviousTab : public TTabAction;
```

File

ExtActns

Description

Add TPreviousTab to an action list to allow users to move to the prior page of a page control using menu items or toolbar buttons. Controls such as menu items and tool buttons linked to this action cause the application change the current page of a page control to the previous one. Typically, these client controls are the "Prior" button or menu item in a tabbed dialog.

Before you can use TPreviousTab, you must assign a target tab control as the value of the TabControl (see page 107) property. Once the target tab control is assigned, TPreviousTab automatically disables itself if the target control is not enabled or if it is on the first page and wrapping is not permitted.

TNextTab (see page 80)

TPageControl

TTabControl

2.1.11.1 TPreviousTab Members

The following tables list the members exposed by TPreviousTab.

Protected Methods

	Name	Description
	Notification (see page 152)	Responds when components are created or destroyed.
	SelectNextTab (see page 152)	This is SelectNextTab, a member of class TTabAction.

Public Methods

	Name	Description
	Create (see page 151)	Creates an instance of TTabAction (see page 150).
	ExecuteTarget (see page 102)	Changes the selected page in the target control to the previous one.
	HandlesTarget (see page 152)	Indicates whether the action can execute its function.
	UpdateTarget (see page 103)	Enables or disables the action, depending on the status of the target control.

Published Events

	Name	Description
	AfterTabChange (see page 109)	Occurs immediately after the action changes the page of the associated tab control.
	BeforeTabChange (see page 109)	Occurs immediately before the action changes the page of the associated tab control.
	OnHint (see page 110)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 110)	Occurs when the application is idle or when the action list updates.
	OnValidateTab (see page 111)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	Caption (see page 104)	Represents the caption of client controls and menu items.
	Enabled (see page 104)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 105)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 105)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 106)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 106)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 106)	Indicates the ImageIndex property for client controls and menu items.
	ShortCut (see page 107)	Specifies the ShortCut property for client menu items.
	SkipHiddenTabs (see page 107)	Indicates whether the tab action should consider hidden tabbed pages when moving to the next page.
	TabControl (see page 107)	Specifies the target of the action.
	Visible (see page 108)	Specifies the Visible property for client controls and menu items.
	Wrap (see page 108)	Indicates whether the tab action should "wrap" when navigating to the next tab page.

2.1.11.2 TPreviousTab Methods

The methods of the TPreviousTab class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 102)	Changes the selected page in the target control to the previous one.
	UpdateTarget (see page 103)	Enables or disables the action, depending on the status of the target control.

2.1.11.2.1 TPreviousTab.ExecuteTarget Method

Changes the selected page in the target control to the previous one.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

ExecuteTarget causes the action to perform its default response based on the state of the target tab control.

Target is the currently active object when the action fires. TPreviousTab (see page 101) ignores this parameter and uses the TabControl (see page 107) property to identify the target control.

ExecuteTarget

1. Generates a BeforeTabChange (see page 109) event.
2. Moves the control identified by TabControl (see page 107) to the previous page. If TabControl (see page 107) is on the first page and the Wrap (see page 108) property is true, this moves to the last page. If Wrap (see page 108) is false, ExecuteTarget does not change the page when the tab control is on the first page. Note that the SkipHiddenTabs (see page 107) property controls whether hidden pages are considered when locating the previous page.
3. Generates an AfterTabChange (see page 109) event.

See Also

ExecuteTarget

ActivePageIndex

TabControl (see page 154)

BeforeTabChange (see page 155)

AfterTabChange (see page 155)

Wrap (see page 154)

TabIndex

SkipHiddenTabs (see page 153)

2.1.11.2.2 TPreviousTab.UpdateTarget Method

Enables or disables the action, depending on the status of the target control.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically when the application is idle so that actions can update themselves according to current conditions.

Target is the currently active object.

In TPreviousTab (see page 101), UpdateTarget ignores the Target parameter and checks whether the target control specified by the TabControl (see page 107) property is enabled. If so, it sets Enabled (see page 104) to true if the first page is not currently selected or if Wrap (see page 108) is true. It sets Enabled (see page 104) to false if TabControl (see page 107) is not enabled or if the first page is selected and Wrap (see page 108) is false.

See Also

Enabled

TabControl (see page 154)

2.1.11.3 TPreviousTab Properties

The properties of the TPreviousTab class are listed here.

Published Properties

	Name	Description
	Caption (see page 104)	Represents the caption of client controls and menu items.
	Enabled (see page 104)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 105)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 105)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 106)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 106)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 106)	Indicates the ImageIndex property for client controls and menu items.
	ShortCut (see page 107)	Specifies the ShortCut property for client menu items.
	SkipHiddenTabs (see page 107)	Indicates whether the tab action should consider hidden tabbed pages when moving to the next page.
	TabControl (see page 107)	Specifies the target of the action.
	Visible (see page 108)	Specifies the Visible property for client controls and menu items.
	Wrap (see page 108)	Indicates whether the tab action should "wrap" when navigating to the next tab page.

2.1.11.3.1 TPreviousTab.Caption Property

Represents the caption of client controls and menu items.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Caption holds the string that is the caption for the action when it is set. The value of Caption is propagated to client controls and menu items.

See Also

Caption

Caption (see page 4902)

2.1.11.3.2 TPreviousTab.Enabled Property

Indicates whether client controls and menu items are enabled.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Enabled specifies the enabled state for the action. The value of Enabled is propagated to client controls and menu items.

See Also

Enabled

Enabled (see page 4912)

2.1.11.3.3 TPreviousTab.HelpContext Property

Indicates the help context ID for client controls and menu items.

Pascal

```
property HelpContext;
```

C++

```
__property HelpContext;
```

Description

HelpContext specifies the help context for the action when it is set. This value is propagated to client controls and menu items.

When a client control has focus and the user presses the F1 key, the control uses the value of HelpContext for this associated action to invoke the online help targeting a specific topic. The target topic is uniquely identified by a nonzero HelpContext value. Leave the HelpContext property of the client control at its default value of zero. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpContext is only used when the HelpType property of this action or the client control is htInteger.

See Also

HelpType

HelpKeyword

2.1.11.3.4 TPreviousTab.HelpKeyword Property

Indicates the help keyword for client controls and menu items.

Pascal

```
property HelpKeyword;
```

C++

```
__property HelpKeyword;
```

Description

HelpKeyword, when set, specifies the keyword that identifies a help topic for this action. This value is propagated to the HelpKeyword property of client controls and menu items. The interpretation of HelpKeyword depends on which help system is used to display the topic. For example, when using HyperHelp (on Linux) or WinHelp (on Windows), HelpKeyword refers to an A link.

When a client control has focus and the user presses the F1 key (or the key specified by the application's HelpKey property), the control uses the value of HelpKeyword for this associated action object to invoke the online help targeting a specific topic. Leave the HelpKeyword property of the client control unassigned. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpKeyword is only used when the HelpType property of this action or the client control is htKeyword.

2.1.11.3.5 TPreviousTab.HelpType Property

Indicates the mechanism for client controls and menu items to use when invoking help.

Pascal

```
property HelpType;
```

C++

```
__property HelpType;
```

Description

HelpType, when set, indicates whether client controls and menu items should use the HelpContext or the HelpKeyword property for invoking the help system. This value is propagated to the HelpType property of client controls and menu items.

HelpType

HelpType

HelpContext

HelpKeyword

2.1.11.3.6 TPreviousTab.Hint Property

Indicates the Help hint for client controls and menu items.

Pascal

```
property Hint;
```

C++

```
__property Hint;
```

Description

Hint holds the string that is the hint for that action when it is set. This value is propagated to client controls and menu items.

See Also

Hint

Hint (see page 4916)

2.1.11.3.7 TPreviousTab.ImageIndex Property

Indicates the ImageIndex property for client controls and menu items.

Pascal

```
property ImageIndex;
```

C++

```
__property ImageIndex;
```

Description

ImageIndex is an index into the Images property of the action list or action manager that contains the action. It identifies an image that is associated with controls and menu items that use this action.

See Also

ImageIndex

ImageIndex (see page 4916)

2.1.11.3.8 TPreviousTab.ShortCut Property

Specifies the ShortCut property for client menu items.

Pascal

```
property ShortCut;
```

C++

```
__property ShortCut;
```

Description

ShortCut holds the value that is the shortcut for the action when it is set. This value is propagated to client menu items.

See Also

ShortCut (see page 4920)

SecondaryShortCuts

2.1.11.3.9 TPreviousTab.SkipHiddenTabs Property

Indicates whether the tab action should consider hidden tabbed pages when moving to the next page.

Pascal

```
property SkipHiddenTabs: Boolean;
```

C++

```
__property Boolean SkipHiddenTabs;
```

Description

Set SkipHiddenTabs to true if you do not want the action to move to a tab page if its TabVisible property is false. Set SkipHiddenTabs to false if the tab action can move to and make visible a hidden page.

Note: SkipHiddenTabs only has an effect when the TabControl property identifies a TPageControl object. (TTabControl does not support hidden pages).

See Also

ExecuteTarget (see page 81)

ExecuteTarget (see page 102)

TabVisible

TPageControl

2.1.11.3.10 TPreviousTab.TabControl Property

Specifies the target of the action.

Pascal

```
property TabControl: TCustomTabControl;
```

C++

```
__property TCustomTabControl TabControl;
```

Description

Set TabControl to the control on which the action operates when its ExecuteTarget method is called. Typically, this is a page control or tab control object that implements the pages of a tabbed dialog.

An application must explicitly assign a value to the TabControl property before the TTabAction descendant is enabled. The action does not infer the target page control when it fires.

See Also

ExecuteTarget (see page 81)

ExecuteTarget (see page 102)

2.1.11.3.11 TPreviousTab.Visible Property

Specifies the Visible property for client controls and menu items.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Visible specifies the visible state for the action. This value is propagated to client controls and menu items.

See Also

Visible (see page 4921)

Visible

2.1.11.3.12 TPreviousTab.Wrap Property

Indicates whether the tab action should "wrap" when navigating to the next tab page.

Pascal

```
property Wrap: Boolean;
```

C++

```
__property Boolean Wrap;
```

Description

When Wrap is true, the tab action can move previous to the first tabbed page or after the last tabbed page in the associated control. When Wrap is false, an attempt to move beyond the first or last page does not result in any page change, although it still results in a BeforeTabChange and an AfterTabChange event or in an OnFinish event.

See Also

ExecuteTarget (see page 81)

ExecuteTarget (see page 102)

TabControl (see page 154)

BeforeTabChange (see page 155)

AfterTabChange (see page 155)

OnFinish (see page 90)

2.1.11.4 TPreviousTab Events

The events of the TPreviousTab class are listed here.

Published Events

	Name	Description
	AfterTabChange (see page 109)	Occurs immediately after the action changes the page of the associated tab control.
	BeforeTabChange (see page 109)	Occurs immediately before the action changes the page of the associated tab control.
	OnHint (see page 110)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 110)	Occurs when the application is idle or when the action list updates.
	OnValidateTab (see page 111)	Occurs when the application is idle or when the action list updates.

2.1.11.4.1 TPreviousTab.AfterTabChange Event

Occurs immediately after the action changes the page of the associated tab control.

Pascal

```
property AfterTabChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent AfterTabChange;
```

Description

Write an AfterTabChange event handler to perform any additional tasks after the tab action changes the current page of the associated tab control. Typically, this event is used to initialize the current page of the tab control.

Note: AfterTabChange only occurs if the action tries to change the page of the tab control (even if it is not successful). If the action attempts some other task (for example, when TNextPage is on the last page of the tab control), AfterTabChange does not occur.

See Also

BeforeTabChange (see page 155)

TabControl (see page 154)

Wrap (see page 154)

2.1.11.4.2 TPreviousTab.BeforeTabChange Event

Occurs immediately before the action changes the page of the associated tab control.

Pascal

```
property BeforeTabChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent BeforeTabChange;
```

Description

Write a BeforeTabChange event handler to perform any additional tasks before the tab action changes the current page of the associated tab control. Typically, this event is used to save or respond to the changes the user made on the current page before it changes.

Note: BeforeTabChange only occurs if the action tries to change the page of the tab control (even if it is not successful). If the action attempts some other task (for example, when TNextPage is on the last page of the tab control), BeforeTabChange does not occur.

See Also

AfterTabChange (see page 155)

TabControl (see page 154)

Wrap (see page 154)

2.1.11.4.3 TPreviousTab.OnHint Event

Occurs when the mouse pauses over a client control or menu item.

Pascal

```
property OnHint;
```

C++

```
__property OnHint;
```

Description

Use OnHint to override the default hint that appears when the user pauses the mouse over a client control or menu item. The OnHint event handler can change the hint that appears (by changing the HintStr parameter), or display the hint in some application-specific way.

2.1.11.4.4 TPreviousTab.OnUpdate Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnUpdate;
```

C++

```
__property OnUpdate;
```

Description

Write an OnUpdate event handler to execute centralized code while an application is idle. For example, actions may want to update enabling and disabling, or checking and unchecking of client targets.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
```

```
TToolBar on a form. Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
*/
Boolean checked;

void __fastcall TForm1::Action1Update(TObject *Sender)
{
   // Indicate whether ToolBar1 is currently visible.
   TAction* pa = dynamic_cast<TAction*>(Sender);
   if (pa)
   {
     if (checked != ToolBar1->Visible)
     {
       lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
     }
     checked = ToolBar1->Visible;
   }
//   pa->Checked = True;  // set this statically and don't change it!
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Update(Sender: TObject);
begin
  if ((Sender as TAction).Checked <> ToolBar1.Visible) then
    lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
    { Indicate whether ToolBar1 is currently visible }
    (Sender as TAction).Checked := ToolBar1.Visible;
end;
```

See Also

UpdateAction

2.1.11.4.5 TPreviousTab.OnValidateTab Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnValidateTab: TValidateTabEvent;
```

C++

```
__property TValidateTabEvent OnValidateTab;
```

Description

Use the OnValidateTab event rather than the OnUpdate event to update the properties of a tab action when the application is idle. Unlike the OnUpdate event, which prevents the default behavior of the UpdateTarget method, OnValidateTab occurs after UpdateTarget has set the Enabled property to reflect whether the target tab control is enabled.

OnValidateTab can be used to update any of the properties of the tab action, but it is intended primarily for enabling or disabling the action, depending on the contents of the current page of the target tab control.

Sender is the tab action component to update in this event.

TabControl is the target tab control.

Enabled reflects the Enabled property of this action. Set Enabled in the event handler to enable or disable the action depending on current conditions.

UpdateTarget (see page 153)

TabControl (see page 154)

Enabled

2.1.12 TRichEditAction Class

TRichEditAction is the base class for action objects that apply rich text attributes to a rich edit control.

Class Hierarchy

Pascal

```
TRichEditAction = class(TEditAction);
```

C++

```
class TRichEditAction : public TEditAction;
```

File

ExtActns

Description

TRichEditAction implements the common behavior for actions that assign text attributes to a rich edit control. Each descendant class represents a specific text attribute. Do not use TRichEditAction directly in an application. Instead, use a TRichEditAction descendant such as TRichEditBold (see page 121), TRichEditItalic (see page 125), TRichEditUnderline (see page 130), TRichEditStrikeOut (see page 127), TRichEditAlignCenter (see page 115), TRichEditAlignLeft (see page 117), TRichEditAlignRight (see page 119), or TRichEditBullets (see page 123).

TRichEditAction ensures that the action is only works with a TCustomRichEdit descendant as a target. TRichEditAction descendants toggle their specific text attribute in the target rich edit control: if the attribute is set, it is removed, and if it is not set (or set for only some of the text), the action sets it. If the target rich edit control has a selection, the attribute is toggled for the selected text only. If there is no selection, the attribute is toggled for all of the text.

2.1.12.1 TRichEditAction Members

The following tables list the members exposed by TRichEditAction.

Protected Methods

	Name	Description
	CurrText (see page 114)	This is CurrText, a member of class TRichEditAction.
	SetFontStyle (see page 114)	This is SetFontStyle, a member of class TRichEditAction.

Public Methods

	Name	Description
	Create (see page 113)	Creates an instance of TRichEditAction (see page 112).
	HandlesTarget (see page 114)	Indicates whether the action can execute its function.

2.1.12.2 TRichEditAction.Create Constructor

Creates an instance of TRichEditAction (see page 112).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TRichEditAction(TComponent * AOwner);
```

Description

Most applications do not need to call the TRichEditAction (see page 112) constructor because actions are added at design time to an action list or action manager.

AOwner specifies the Owner for the action. This is the component that is responsible for freeing the TRichEditAction (see page 112) instance.

See Also

Owner

2.1.12.3 TRichEditAction Methods

The methods of the TRichEditAction class are listed here.

Protected Methods

	Name	Description
	CurrText (see page 114)	This is CurrText, a member of class TRichEditAction.
	SetFontStyle (see page 114)	This is SetFontStyle, a member of class TRichEditAction.

Public Methods

	Name	Description
	HandlesTarget (see page 114)	Indicates whether the action can execute its function.

2.1.12.3.1 TRichEditAction.CurrText Method

Pascal

```
function CurrText(Edit: TCustomRichEdit): TTextAttributes;
```

C++

```
__fastcall TTextAttributes CurrText(TCustomRichEdit Edit);
```

Description

This is CurrText, a member of class TRichEditAction.

2.1.12.3.2 TRichEditAction.HandlesTarget Method

Indicates whether the action can execute its function.

Pascal

```
function HandlesTarget(Target: TObject): Boolean; override;
```

C++

```
virtual __fastcall Boolean HandlesTarget(TObject * Target);
```

Description

Do not call the HandlesTarget method. This method is called automatically when the user invokes an object (such as a tool button or menu item) that is linked to this action. The HandlesTarget method provides the action object with an opportunity to indicate whether it is appropriate to execute at this time with the object specified by the Target parameter as a "target".

Target is the currently active object.

HandlesTarget returns true if Target is a TCustomRichEdit descendant, false otherwise.

ExecuteTarget

TCustomRichEdit

2.1.12.3.3 TRichEditAction.SetFontStyle Method

Pascal

```
procedure SetFontStyle(Edit: TCustomRichEdit; Style: TFontStyle);
```

C++

```
__fastcall SetFontStyle(TCustomRichEdit Edit, TFontStyle Style);
```

Description

This is SetFontStyle, a member of class TRichEditAction.

2.1.13 TRichEditAlignCenter Class

TRichEditAlignCenter centers the text horizontally in the current paragraph of a rich edit control.

Class Hierarchy

Pascal

```
TRichEditAlignCenter = class(TRichEditAction);
```

C++

```
class TRichEditAlignCenter : public TRichEditAction;
```

File

ExtActns

Description

Add TRichEditAlignCenter to an action list to let users center the text in a rich edit control. Controls such as menu items and tool buttons linked to this action cause the application to center the text in all paragraphs that contain selected text (or the paragraph with the cursor if no text is selected).

TRichEditAlignCenter is designed to work with a rich edit control (TCustomRichEdit descendant) as a target. It automatically disables itself if the active control in a form is not a rich edit control, and adds or removes a check mark to reflect whether the text in the target edit control is centered.

TRichEditAlignLeft (see page 117)

TRichEditBullets (see page 123)

TRichEditBold (see page 121)

2.1.13.1 TRichEditAlignCenter Members

The following tables list the members exposed by TRichEditAlignCenter.

Protected Methods

	Name	Description
	CurrText (see page 114)	This is CurrText, a member of class TRichEditAction.
	SetFontStyle (see page 114)	This is SetFontStyle, a member of class TRichEditAction.

Public Methods

	Name	Description
	Create (see page 113)	Creates an instance of TRichEditAction (see page 112).
	ExecuteTarget (see page 116)	Centers the text in the current paragraph of the target rich edit control.
	HandlesTarget (see page 114)	Indicates whether the action can execute its function.
	UpdateTarget (see page 116)	Configures the action, depending on current conditions.

2.1.13.2 TRichEditAlignCenter Methods

The methods of the TRichEditAlignCenter class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 116)	Centers the text in the current paragraph of the target rich edit control.
	UpdateTarget (see page 116)	Configures the action, depending on current conditions.

2.1.13.2.1 TRichEditAlignCenter.ExecuteTarget Method

Centers the text in the current paragraph of the target rich edit control.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

ExecuteTarget checks that Target is a rich edit control, and if so, sets its Alignment property to taCenter.

Paragraph

Alignment

2.1.13.2.2 TRichEditAlignCenter.UpdateTarget Method

Configures the action, depending on current conditions.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically when the application is idle so that actions can update themselves according to current conditions.

In TRichEditAlignCenter (see page 115), UpdateTarget sets Enabled to true and sets the Checked property to true if the text in

the current paragraph is centered.

Enabled

Checked

2.1.14 TRichEditAlignLeft Class

TRichEditAlignLeft left-justifies the text in the current paragraph of a rich edit control.

Class Hierarchy

Pascal

```
TRichEditAlignLeft = class(TRichEditAction);
```

C++

```
class TRichEditAlignLeft : public TRichEditAction;
```

File

ExtActns

Description

Add TRichEditAlignLeft to an action list to let users left-justify the text in a rich edit control. Controls such as menu items and tool buttons linked to this action cause the application to align the text in all paragraphs that contain selected text (or the paragraph with the cursor if no text is selected) to the left margin.

TRichEditAlignLeft is designed to work with a rich edit control (TCustomRichEdit descendant) as a target. It automatically disables itself if the active control in a form is not a rich edit control, and adds or removes a check mark to indicate whether the text in the target control is left-aligned.

See Also

TCustomRichEdit

TRichEditItalic (see page 125)

TRichEditUnderline (see page 130)

TRichEditStrikeOut (see page 127)

TRichEditAlignCenter (see page 115)

TRichEditBullets (see page 123)

TRichEditBold (see page 121)

2.1.14.1 TRichEditAlignLeft Members

The following tables list the members exposed by TRichEditAlignLeft.

Protected Methods

	Name	Description
	CurrText (see page 114)	This is CurrText, a member of class TRichEditAction.
	SetFontStyle (see page 114)	This is SetFontStyle, a member of class TRichEditAction.

Public Methods

	Name	Description
	Create (see page 113)	Creates an instance of TRichEditAction (see page 112).
	ExecuteTarget (see page 118)	Left-justifies the text in the current paragraph of the target rich edit control.
	HandlesTarget (see page 114)	Indicates whether the action can execute its function.
	UpdateTarget (see page 118)	Configures the action, depending on current conditions.

2.1.14.2 TRichEditAlignLeft Methods

The methods of the TRichEditAlignLeft class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 118)	Left-justifies the text in the current paragraph of the target rich edit control.
	UpdateTarget (see page 118)	Configures the action, depending on current conditions.

2.1.14.2.1 TRichEditAlignLeft.ExecuteTarget Method

Left-justifies the text in the current paragraph of the target rich edit control.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

ExecuteTarget checks that Target is a rich edit control, and if so, sets its Alignment property to taLeftJustify.

Enabled

Checked

2.1.15 TRichEditAlignRight Class

TRichEditAlignRight right-justifies the text in the current paragraph of a rich edit control.

Class Hierarchy

Pascal

```
TRichEditAlignRight = class(TRichEditAction);
```

C++

```
class TRichEditAlignRight : public TRichEditAction;
```

File

ExtActns

Description

Add TRichEditAlignRight to an action list to let users right-justify the text in a rich edit control. Controls such as menu items and tool buttons linked to this action cause the application to align the text in all paragraphs that contain selected text (or the paragraph with the cursor if no text is selected) to the right margin.

TRichEditAlignRight is designed to work with a rich edit control (TCustomRichEdit descendant) as a target. It automatically disables itself if the active control in a form is not a rich edit control, and adds or removes a check mark to indicate whether the current paragraph of the target control is right-aligned.

2.1.15.1 TRichEditAlignRight Members

The following tables list the members exposed by TRichEditAlignRight.

Protected Methods

	Name	Description
	CurrText (see page 114)	This is CurrText, a member of class TRichEditAction.
	SetFontStyle (see page 114)	This is SetFontStyle, a member of class TRichEditAction.

Public Methods

	Name	Description
	Create (see page 113)	Creates an instance of TRichEditAction (see page 112).
	ExecuteTarget (see page 120)	Right-justifies the text in the current paragraph of the target rich edit control.
	HandlesTarget (see page 114)	Indicates whether the action can execute its function.
	UpdateTarget (see page 120)	Configures the action, depending on current conditions.

2.1.15.2 TRichEditAlignRight Methods

The methods of the TRichEditAlignRight class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 120)	Right-justifies the text in the current paragraph of the target rich edit control.
	UpdateTarget (see page 120)	Configures the action, depending on current conditions.

2.1.15.2.1 TRichEditAlignRight.ExecuteTarget Method

Right-justifies the text in the current paragraph of the target rich edit control.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

ExecuteTarget checks that Target is a rich edit control, and if so, sets its Alignment property to taRightJustify.

2.1.16 TRichEditBold Class

TRichEditBold toggles the bold attribute of the currently selected text in a rich edit control.

Class Hierarchy

Pascal

```
TRichEditBold = class(TRichEditAction);
```

C++

```
class TRichEditBold : public TRichEditAction;
```

File

ExtActns

Description

Add TRichEditBold to an action list to let users control whether the selected text in a rich edit control is bold. Controls such as menu items and tool buttons linked to this action cause the application to toggle the bold attribute of selected text (or of all text if there is no text selected).

TRichEditBold is designed to work with a rich edit control (TCustomRichEdit descendant) as a target. It automatically disables itself if the active control in a form is not a rich edit control, and adds or removes a check mark to indicate whether the target control's text is bold.

TRichEditAlignLeft (see page 117)

TRichEditAlignCenter (see page 115)

TRichEditStrikeOut (see page 127)

2.1.16.1 TRichEditBold Members

The following tables list the members exposed by TRichEditBold.

Protected Methods

	Name	Description
	CurrText (see page 114)	This is CurrText, a member of class TRichEditAction.
	SetFontStyle (see page 114)	This is SetFontStyle, a member of class TRichEditAction.

Public Methods

	Name	Description
	Create (see page 113)	Creates an instance of TRichEditAction (see page 112).
	ExecuteTarget (see page 122)	Toggles the fsBold style of the target rich edit control's text attributes.
	HandlesTarget (see page 114)	Indicates whether the action can execute its function.
	UpdateTarget (see page 123)	Sets the Checked property to reflect whether the target control's text is bold.

2.1.16.2 TRichEditBold Methods

The methods of the TRichEditBold class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 122)	Toggles the fsBold style of the target rich edit control's text attributes.
	UpdateTarget (see page 123)	Sets the Checked property to reflect whether the target control's text is bold.

2.1.16.2.1 TRichEditBold.ExecuteTarget Method

Toggles the fsBold style of the target rich edit control's text attributes.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

If the target rich edit control has a selection, ExecuteTarget toggles the fsBold style of the selected text attributes (SelAttributes property), adding the fsBold property if the selected text is not all bold and removing it if the selected text is entirely bold. Note that if the selected text contains both bold and non-bold text, this results in the text becoming entirely bold.

If the target rich edit control has no selection, ExecuteTarget toggles the default fsBold style of the control. This changes the bold attribute of all text that has not had a specific text attribute applied.

Style

SelAttributes

DefAttributes

2.1.16.2.2 TRichEditBold.UpdateTarget Method

Sets the Checked property to reflect whether the target control's text is bold.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically when the application is idle so that actions can update themselves according to current conditions.

Target is the currently active object when the action fires.

UpdateTarget sets the Checked property to true if Target is a rich edit control whose selected text is bold, otherwise it sets Checked to false.

2.1.17 TRichEditBullets Class

TRichEditBullets toggles whether the current paragraph of a rich edit control is bulleted.

Class Hierarchy

Pascal

```
TRichEditBullets = class(TRichEditAction);
```

C++

```
class TRichEditBullets : public TRichEditAction;
```

File

ExtActns

Description

Add TRichEditBullets to an action list to let users control whether the current paragraphs in a rich edit control are bulleted. Controls such as menu items and tool buttons linked to this action cause the application to toggle the bulleted attribute of all paragraphs that contain selected text (or the paragraph with the cursor if no text is selected).

TRichEditBullets is designed to work with a rich edit control (TCustomRichEdit descendant) as a target. It automatically disables itself if the active control in a form is not a rich edit control and adds or removes a check mark to indicate whether that control's paragraphs are bulleted.

2.1.17.1 TRichEditBullets Members

The following tables list the members exposed by TRichEditBullets.

Protected Methods

	Name	Description
	CurrText (see page 114)	This is CurrText, a member of class TRichEditAction.
	SetFontStyle (see page 114)	This is SetFontStyle, a member of class TRichEditAction.

Public Methods

	Name	Description
	Create (see page 113)	Creates an instance of TRichEditAction (see page 112).
	ExecuteTarget (see page 124)	Introduces an interface for invoking an action on a target client component or control.
	HandlesTarget (see page 114)	Indicates whether the action can execute its function.
	UpdateTarget (see page 125)	Configures the action, depending on current conditions.

2.1.17.2 TRichEditBullets Methods

The methods of the TRichEditBullets class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 124)	Introduces an interface for invoking an action on a target client component or control.
	UpdateTarget (see page 125)	Configures the action, depending on current conditions.

2.1.17.2.1 TRichEditBullets.ExecuteTarget Method

Introduces an interface for invoking an action on a target client component or control.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

ExecuteTarget does nothing in TBasicAction. ExecuteTarget was introduced in TBasicAction so that descendants can override it to initiate the action on the target. For example, an edit action that performs copying might copy the contents of an edit control to the clipboard.

See Also

OnExecute

HandlesTarget

2.1.17.2.2 TRichEditBullets.UpdateTarget Method

Configures the action, depending on current conditions.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically when the application is idle so that actions can update themselves according to current conditions.

In UpdateTarget, UpdateTarget sets Enabled to T true and sets the Checked property to T true if the current paragraph is bulleted or to F false if the current paragraph is not bulleted.

Enabled

Checked

2.1.18 TRichEditItalic Class

TRichEditItalic toggles the italic attribute of the currently selected text in a rich edit control.

Class Hierarchy

Pascal

```
TRichEditItalic = class(TRichEditAction);
```

C++

```
class TRichEditItalic : public TRichEditAction;
```

File

ExtActns

Description

Add TRichEditItalic to an action list to let users control whether the selected text in a rich edit control is italic. Controls such as menu items and tool buttons linked to this action cause the application to toggle the italic attribute of selected text (or of all text if there is no text selected).

TRichEditItalic is designed to work with a rich edit control (TCustomRichEdit descendant) as a target. It automatically disables itself if the active control in a form is not a rich edit control, and adds or removes a check mark to reflect whether the target control's text is italic.

2.1.18.1 TRichEditItalic Members

The following tables list the members exposed by TRichEditItalic.

Protected Methods

	Name	Description
	CurrText (see page 114)	This is CurrText, a member of class TRichEditAction.
	SetFontStyle (see page 114)	This is SetFontStyle, a member of class TRichEditAction.

Public Methods

	Name	Description
	Create (see page 113)	Creates an instance of TRichEditAction (see page 112).
	ExecuteTarget (see page 127)	Introduces an interface for invoking an action on a target client component or control.
	HandlesTarget (see page 114)	Indicates whether the action can execute its function.
	UpdateTarget (see page 127)	Enables or disables the action, depending on the currently active control in the form.

2.1.18.2 TRichEditItalic Methods

The methods of the TRichEditItalic class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 127)	Introduces an interface for invoking an action on a target client component or control.
	UpdateTarget (see page 127)	Enables or disables the action, depending on the currently active control in the form.

2.1.18.2.1 TRichEditItalic.ExecuteTarget Method

Introduces an interface for invoking an action on a target client component or control.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

ExecuteTarget does nothing in TBasicAction. ExecuteTarget was introduced in TBasicAction so that descendants can override it to initiate the action on the target. For example, an edit action that performs copying might copy the contents of an edit control to the clipboard.

See Also

OnExecute

HandlesTarget

2.1.18.2.2 TRichEditItalic.UpdateTarget Method

Enables or disables the action, depending on the currently active control in the form.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically when the potential target changes so that actions can update themselves accordingly.

In TEditAction, UpdateTarget checks whether the current target object (specified by the Target parameter) is an edit control and, if the action's function requires it, that some of its text is selected. If so, UpdateTarget sets Enabled to true. If not, UpdateTarget sets Enabled to false.

See Also

Enabled

2.1.19 TRichEditStrikeOut Class

TRichEditStrikeOut toggles the strikeout attribute of the currently selected text in a rich edit control.

Class Hierarchy

Pascal

```
TRichEditStrikeOut = class(TRichEditAction);
```

C++

```
class TRichEditStrikeOut : public TRichEditAction;
```

File

ExtActns

Description

Add TRichEditStrikeOut to an action list to let users control whether the selected text in a rich edit control has a line through it. Controls such as menu items and tool buttons linked to this action cause the application to toggle the strikeout attribute of selected text (or of all text if there is no text selected).

TRichEditStrikeOut is designed to work with a rich edit control (TCustomRichEdit descendant) as a target. It automatically disables itself if the active control in a form is not a rich edit control and adds or removes a check mark to indicate whether the target control's text has the strike out attribute.

TRichEditAlignLeft (see page 117)

TRichEditAlignCenter (see page 115)

2.1.19.1 TRichEditStrikeOut Members

The following tables list the members exposed by TRichEditStrikeOut.

Protected Methods

	Name	Description
	CurrText (see page 114)	This is CurrText, a member of class TRichEditAction.
	SetFontStyle (see page 114)	This is SetFontStyle, a member of class TRichEditAction.

Public Methods

	Name	Description
	Create (see page 113)	Creates an instance of TRichEditAction (see page 112).
	ExecuteTarget (see page 129)	Toggles the fsStrikeOut style of the target rich edit control's text attributes.
	HandlesTarget (see page 114)	Indicates whether the action can execute its function.
	UpdateTarget (see page 129)	Sets the Checked property to reflect whether the target control's text includes a strikeout line.

2.1.19.2 TRichEditStrikeOut Methods

The methods of the TRichEditStrikeOut class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 129)	Toggles the fsStrikeOut style of the target rich edit control's text attributes.

	UpdateTarget (see page 129)	Sets the Checked property to reflect whether the target control's text includes a strikeout line.

2.1.19.2.1 TRichEditStrikeOut.ExecuteTarget Method

Toggles the fsStrikeOut style of the target rich edit control's text attributes.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

If the target rich edit control has a selection, ExecuteTarget toggles the fsStrikeOut style of the selected text attributes (SelAttributes property), adding the fsStrikeOut property if the selected text is not all struck out and removing it if the selected text is entirely struck out. Note that if the selected text contains both strikeout and non-strikeout text, this results in the text becoming entirely struck out.

If the target rich edit control has no selection, ExecuteTarget toggles the default fsStrikeOut style of the control. This changes the strikeout attribute of all text that has not had a specific text attribute applied.

SelAttributes

DefAttributes

2.1.19.2.2 TRichEditStrikeOut.UpdateTarget Method

Sets the Checked property to reflect whether the target control's text includes a strikeout line.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically when the application is idle so that actions can update themselves according to current conditions.

Target is the currently active object when the action fires.

UpdateTarget checks whether Target is a rich edit control with the strikeout font attribute on its selected text. If the selected text is struck out, UpdateTarget sets the Checked property to true, otherwise it sets Checked to false.

2.1.20 TRichEditUnderline Class

TRichEditUnderline toggles the underline attribute of the currently selected text in a rich edit control.

Class Hierarchy

Pascal

```
TRichEditUnderline = class(TRichEditAction);
```

C++

```
class TRichEditUnderline : public TRichEditAction;
```

File

ExtActns

Description

Add TRichEditUnderline to an action list to let users control whether the selected text in a rich edit control is underlined. Controls such as menu items and tool buttons linked to this action cause the application to toggle the underline attribute of selected text (or of all text if there is no text selected).

TRichEditUnderline is designed to work with a rich edit control (TCustomRichEdit descendant) as a target. It automatically disables itself if the active control in a form is not a rich edit control, and adds or removes a check to indicate whether the target control's text is underlined.

2.1.20.1 TRichEditUnderline Members

The following tables list the members exposed by TRichEditUnderline.

Protected Methods

	Name	Description
	CurrText (see page 114)	This is CurrText, a member of class TRichEditAction.
	SetFontStyle (see page 114)	This is SetFontStyle, a member of class TRichEditAction.

Public Methods

	Name	Description
	Create (see page 113)	Creates an instance of TRichEditAction (see page 112).
	ExecuteTarget (see page 131)	Toggles the fsUnderline style of the target rich edit control's text attributes.
	HandlesTarget (see page 114)	Indicates whether the action can execute its function.
	UpdateTarget (see page 131)	Sets the Checked property to reflect whether the target control's text is underlined.

2.1.20.2 TRichEditUnderline Methods

The methods of the TRichEditUnderline class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 131)	Toggles the fsUnderline style of the target rich edit control's text attributes.
	UpdateTarget (see page 131)	Sets the Checked property to reflect whether the target control's text is underlined.

2.1.20.2.1 TRichEditUnderline.ExecuteTarget Method

Toggles the fsUnderline style of the target rich edit control's text attributes.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

If the target rich edit control has a selection, ExecuteTarget toggles the fsUnderline style of the selected text attributes (SelAttributes property), adding the fsUnderline property if the selected text is not all underlined and removing it if the selected text is entirely underlined. Note that if the selected text contains both underlined and non-underlined text, this results in the text becoming entirely underlined.

If the target rich edit control has no selection, ExecuteTarget toggles the default fsUnderline style of the control. This changes the underlined attribute of all text that has not had a specific text attribute applied.

DefAttributes

2.1.20.2.2 TRichEditUnderline.UpdateTarget Method

Sets the Checked property to reflect whether the target control's text is underlined.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically when the application is idle so that actions can update themselves according to current conditions.

Target is the currently active object when the action fires.

UpdateTarget checks the selected text of the target rich edit control (which is specified by the Control property or the Target parameter) is underlined. If the selected text is underlined, UpdateTarget sets the Checked property to true, otherwise it sets Checked to false.

2.1.21 TSavePicture Class

TSavePicture is the standard action for displaying the save picture dialog.

Class Hierarchy

Pascal

```
TSavePicture = class(TCommonDialogAction);
```

C++

```
class TSavePicture : public TCommonDialogAction;
```

File

ExtActns

Description

Add TSavePicture to an action list to add a graphics "save as" dialog to your application. Controls such as menu items and tool buttons linked to this action cause the application to display the save picture dialog when invoked. Use the OnAccept (see page 139) event to respond after the user selects a file name in the dialog or the OnCancel (see page 139) event to respond when the user cancels from the dialog. In the event handler, you can read the file name from the dialog specified by the Dialog (see page 134) property.

See Also

TFileSaveAs

TSavePictureDialog (see page 1577)

TSavePicture

2.1.21.1 TSavePicture Members

The following tables list the members exposed by TSavePicture.

Protected Methods

	Name	Description
	GetDialogClass (see page 133)	This is GetDialogClass, a member of class TSavePicture.

Published Events

	Name	Description
	OnAccept (see page 139)	This is OnAccept, a member of class TSavePicture.
	OnCancel (see page 139)	This is OnCancel, a member of class TSavePicture.
	OnHint (see page 139)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 139)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	Caption (see page 134)	Represents the caption of client controls and menu items.
	Dialog (see page 134)	Provides access the save picture dialog that the action executes.
	Enabled (see page 135)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 135)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 136)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 136)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 137)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 137)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 137)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 138)	Specifies the ShortCut property for client menu items.
	Visible (see page 138)	Specifies the Visible property for client controls and menu items.

2.1.21.2 TSavePicture Methods

The methods of the TSavePicture class are listed here.

Protected Methods

	Name	Description
	GetDialogClass (see page 133)	This is GetDialogClass, a member of class TSavePicture.

2.1.21.2.1 TSavePicture.GetDialogClass Method

Pascal

```
function GetDialogClass: TCommonDialogClass; override;
```

C++

```
virtual __fastcall TCommonDialogClass GetDialogClass();
```

Description

This is GetDialogClass, a member of class TSavePicture.

2.1.21.3 TSavePicture Properties

The properties of the TSavePicture class are listed here.

Published Properties

	Name	Description
	Caption (see page 134)	Represents the caption of client controls and menu items.
R	Dialog (see page 134)	Provides access the save picture dialog that the action executes.
	Enabled (see page 135)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 135)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 136)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 136)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 137)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 137)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 137)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 138)	Specifies the ShortCut property for client menu items.
	Visible (see page 138)	Specifies the Visible property for client controls and menu items.

2.1.21.3.1 TSavePicture.Caption Property

Represents the caption of client controls and menu items.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Caption holds the string that is the caption for the action when it is set. The value of Caption is propagated to client controls and menu items.

See Also

Caption

Caption (see page 4902)

2.1.21.3.2 TSavePicture.Dialog Property

Provides access the save picture dialog that the action executes.

Pascal

```
property Dialog: TSavePictureDialog;
```

C++

```
__property TSavePictureDialog Dialog;
```

Description

Use Dialog to configure the graphics file "save as" dialog before the action fires or to read the specified file name after the action executes the dialog. For example, you can set the dialog's default extension or initial file name at design time using the Object Inspector or read the dialog's FileName property from an OnAccept (see page 139) event handler to use the file name that the user selects.

When using a save picture action, you do not place a TSavePicture (see page 132) Dialog component on the form or data module at design time. Instead, you add the TSavePicture (see page 132) object to your action list and then use the Dialog property. The dialog component is created by the TSavePicture (see page 132) constructor.

See Also

onaccept

oncancel

FileName

2.1.21.3.3 TSavePicture.Enabled Property

Indicates whether client controls and menu items are enabled.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Enabled specifies the enabled state for the action. The value of Enabled is propagated to client controls and menu items.

See Also

Enabled

Enabled (see page 4912)

2.1.21.3.4 TSavePicture.HelpContext Property

Indicates the help context ID for client controls and menu items.

Pascal

```
property HelpContext;
```

C++

```
__property HelpContext;
```

Description

HelpContext specifies the help context for the action when it is set. This value is propagated to client controls and menu items.

When a client control has focus and the user presses the F1 key, the control uses the value of HelpContext for this associated action to invoke the online help targeting a specific topic. The target topic is uniquely identified by a nonzero HelpContext value. Leave the HelpContext property of the client control at its default value of zero. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpContext is only used when the HelpType property of this action or the client control is htInteger.

See Also

HelpType

HelpKeyword

2.1.21.3.5 TSavePicture.HelpKeyword Property

Indicates the help keyword for client controls and menu items.

Pascal

```
property HelpKeyword;
```

C++

```
__property HelpKeyword;
```

Description

HelpKeyword, when set, specifies the keyword that identifies a help topic for this action. This value is propagated to the HelpKeyword property of client controls and menu items. The interpretation of HelpKeyword depends on which help system is used to display the topic. For example, when using HyperHelp (on Linux) or WinHelp (on Windows), HelpKeyword refers to an A link.

When a client control has focus and the user presses the F1 key (or the key specified by the application's HelpKey property), the control uses the value of HelpKeyword for this associated action object to invoke the online help targeting a specific topic. Leave the HelpKeyword property of the client control unassigned. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpKeyword is only used when the HelpType property of this action or the client control is htKeyword.

HelpKeyword

HelpContext

HelpType

HelpKey

2.1.21.3.6 TSavePicture.HelpType Property

Indicates the mechanism for client controls and menu items to use when invoking help.

Pascal

```
property HelpType;
```

C++

```
__property HelpType;
```

Description

HelpType, when set, indicates whether client controls and menu items should use the HelpContext or the HelpKeyword property for invoking the help system. This value is propagated to the HelpType property of client controls and menu items.

See Also

HelpType

HelpType

HelpContext

HelpKeyword

2.1.21.3.7 TSavePicture.Hint Property

Indicates the Help hint for client controls and menu items.

Pascal

```
property Hint;
```

C++

```
__property Hint;
```

Description

Hint holds the string that is the hint for that action when it is set. This value is propagated to client controls and menu items.

See Also

Hint

Hint (see page 4916)

2.1.21.3.8 TSavePicture.ImageIndex Property

Indicates the ImageIndex property for client controls and menu items.

Pascal

```
property ImageIndex;
```

C++

```
__property ImageIndex;
```

Description

ImageIndex is an index into the Images property of the action list or action manager that contains the action. It identifies an image that is associated with controls and menu items that use this action.

See Also

ImageIndex

ImageIndex (see page 4916)

Images

2.1.21.3.9 TSavePicture.SecondaryShortCuts Property

Specifies the short cuts (in addition to ShortCut) for triggering clients.

Pascal

```
property SecondaryShortCuts;
```

C++

```
__property SecondaryShortCuts;
```

Description

Actions can execute in response to multiple short cut key combinations. SecondaryShortCuts lists all the short cut key combinations (other than the one specified by the ShortCut property) that can trigger the action. This lets you specify shortcuts for clients that do not have a ShortCut property or provide additional, secondary shortcuts.

When the user types one of the key combinations listed in SecondaryShortCuts, the action's Execute method is called.

See Also

ShortCut

Execute

2.1.21.3.10 TSavePicture.ShortCut Property

Specifies the ShortCut property for client menu items.

Pascal

```
property ShortCut;
```

C++

```
__property ShortCut;
```

Description

ShortCut holds the value that is the shortcut for the action when it is set. This value is propagated to client menu items.

See Also

ShortCut (see page 4920)

SecondaryShortCuts

2.1.21.3.11 TSavePicture.Visible Property

Specifies the Visible property for client controls and menu items.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Visible specifies the visible state for the action. This value is propagated to client controls and menu items.

See Also

Visible (see page 4921)

Visible

2.1.21.4 TSavePicture Events

The events of the TSavePicture class are listed here.

Published Events

	Name	Description
	OnAccept (see page 139)	This is OnAccept, a member of class TSavePicture.
	OnCancel (see page 139)	This is OnCancel, a member of class TSavePicture.
	OnHint (see page 139)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 139)	Occurs when the application is idle or when the action list updates.

2.1.21.4.1 TSavePicture.OnAccept Event

Pascal

```
property OnAccept;
```

C++

```
__property OnAccept;
```

Description

This is OnAccept, a member of class TSavePicture.

2.1.21.4.2 TSavePicture.OnCancel Event

Pascal

```
property OnCancel;
```

C++

```
__property OnCancel;
```

Description

This is OnCancel, a member of class TSavePicture.

2.1.21.4.3 TSavePicture.OnHint Event

Occurs when the mouse pauses over a client control or menu item.

Pascal

```
property OnHint;
```

C++

```
__property OnHint;
```

Description

Use OnHint to override the default hint that appears when the user pauses the mouse over a client control or menu item. The OnHint event handler can change the hint that appears (by changing the HintStr parameter), or display the hint in some application-specific way.

2.1.21.4.4 TSavePicture.OnUpdate Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnUpdate;
```

C++

```
__property OnUpdate;
```

Description

Write an OnUpdate event handler to execute centralized code while an application is idle. For example, actions may want to update enabling and disabling, or checking and unchecking of client targets.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
*/
Boolean checked;

void __fastcall TForm1::Action1Update(TObject *Sender)
{
   // Indicate whether ToolBar1 is currently visible.
   TAction* pa = dynamic_cast<TAction*>(Sender);
   if (pa)
   {
     if (checked != ToolBar1->Visible)
     {
       lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
     }
     checked = ToolBar1->Visible;
   }
//   pa->Checked = True;  // set this statically and don't change it!
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Update(Sender: TObject);
begin
  if ((Sender as TAction).Checked <> ToolBar1.Visible) then
    lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
    { Indicate whether ToolBar1 is currently visible }
    (Sender as TAction).Checked := ToolBar1.Visible;
end;
```

UpdateAction

2.1.22 TSendMail Class

TSendMail is the standard action for sending an email message.

Class Hierarchy

Pascal

```
TSendMail = class(TCustomAction);
```

C++

```
class TSendMail : public TCustomAction;
```

File

ExtActns

Description

Add TSendMail to an action list to let your application send email messages in response to user actions. Controls linked to this action cause the application to send a MAPI mail message containing the message specified in the Text (see page 147) property.

See Also

TFileRun (see page 27)

TSendMail

2.1.22.1 TSendMail Members

The following tables list the members exposed by TSendMail.

Public Methods

	Name	Description
	Destroy (see page 142)	Frees the memory associated with the TSendMail (see page 141) object.
	ExecuteTarget (see page 142)	Displays a dialog where the user can compose an email message and then sends the message.
	HandlesTarget (see page 143)	Indicates whether the action can execute.
	UpdateTarget (see page 143)	Enables the action.

Published Events

	Name	Description
	OnHint (see page 148)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 148)	Occurs when the application is idle or when the action list updates.

Published Properties

	Name	Description
	Caption (see page 144)	Represents the caption of client controls and menu items.
	Enabled (see page 144)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 144)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 145)	Indicates the help keyword for client controls and menu items.
	HelpType (see page 145)	Indicates the mechanism for client controls and menu items to use when invoking help.

	Hint (see page 146)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 146)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 146)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 147)	Specifies the ShortCut property for client menu items.
	Text (see page 147)	Specifies the content of the mail message.
	Visible (see page 148)	Specifies the Visible property for client controls and menu items.

2.1.22.2 TSendMail.Destroy Destructor

Frees the memory associated with the TSendMail (see page 141) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TSendMail();
```

Description

Do not explicitly destroy actions. Action objects are created and destroyed by the action manager or action list that uses them.

See Also

System::TObject::Free

2.1.22.3 TSendMail Methods

The methods of the TSendMail class are listed here.

Public Methods

	Name	Description
	ExecuteTarget (see page 142)	Displays a dialog where the user can compose an email message and then sends the message.
	HandlesTarget (see page 143)	Indicates whether the action can execute.
	UpdateTarget (see page 143)	Enables the action.

2.1.22.3.1 TSendMail.ExecuteTarget Method

Displays a dialog where the user can compose an email message and then sends the message.

Pascal

```
procedure ExecuteTarget(Target: TObject); override;
```

C++

```
virtual __fastcall ExecuteTarget(TObject * Target);
```

Description

Do not call the ExecuteTarget method. This method is called automatically when the action fires in response to a user action (for example, when the user selects a menu item or presses a tool button that is linked to this action).

Target is the currently active object when the action fires.

ExecuteTarget ignores the Target parameter, and displays a dialog where the user can compose an email message. The body of the message is initialized to the value of the Text (see page 147) property. When the user exits the dialog, the message is sent.

ExecuteTarget always spawns a temporary MAPI session for every mail message, which lasts only for the duration of the

message. If necessary, the user is prompted with a login dialog.

See Also

Text (see page 147)

2.1.22.3.2 TSendMail.HandlesTarget Method

Indicates whether the action can execute.

Pascal

```
function HandlesTarget(Target: TObject): Boolean; override;
```

C++

```
virtual __fastcall Boolean HandlesTarget(TObject * Target);
```

Description

Do not call the HandlesTarget method. This method is called automatically when the user invokes an object (such as a tool button or menu item) that is linked to this action. The HandlesTarget method provides the action object with an opportunity to indicate whether it is appropriate to execute at this time with the object specified by the Target parameter as a "target".

HandlesTarget ignores the Target parameter and always returns true, because the ability to send mail is not dependant on the state of the application.

2.1.22.3.3 TSendMail.UpdateTarget Method

Enables the action.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically the application is idle so that actions can update themselves according to current conditions.

In TSendMail (see page 141), UpdateTarget ignores the Target parameter and always sets the Enabled (see page 144) property to true.

See Also

Enabled

2.1.22.4 TSendMail Properties

The properties of the TSendMail class are listed here.

Published Properties

	Name	Description
	Caption (see page 144)	Represents the caption of client controls and menu items.
	Enabled (see page 144)	Indicates whether client controls and menu items are enabled.
	HelpContext (see page 144)	Indicates the help context ID for client controls and menu items.
	HelpKeyword (see page 145)	Indicates the help keyword for client controls and menu items.

	HelpType (see page 145)	Indicates the mechanism for client controls and menu items to use when invoking help.
	Hint (see page 146)	Indicates the Help hint for client controls and menu items.
	ImageIndex (see page 146)	Indicates the ImageIndex property for client controls and menu items.
	SecondaryShortCuts (see page 146)	Specifies the short cuts (in addition to ShortCut) for triggering clients.
	ShortCut (see page 147)	Specifies the ShortCut property for client menu items.
	Text (see page 147)	Specifies the content of the mail message.
	Visible (see page 148)	Specifies the Visible property for client controls and menu items.

2.1.22.4.1 TSendMail.Caption Property

Represents the caption of client controls and menu items.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Caption holds the string that is the caption for the action when it is set. The value of Caption is propagated to client controls and menu items.

See Also

Caption

Caption (see page 4902)

2.1.22.4.2 TSendMail.Enabled Property

Indicates whether client controls and menu items are enabled.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Enabled specifies the enabled state for the action. The value of Enabled is propagated to client controls and menu items.

See Also

Enabled

Enabled (see page 4912)

2.1.22.4.3 TSendMail.HelpContext Property

Indicates the help context ID for client controls and menu items.

Pascal

```
property HelpContext;
```

C++

```
__property HelpContext;
```

Description

HelpContext specifies the help context for the action when it is set. This value is propagated to client controls and menu items.

When a client control has focus and the user presses the F1 key, the control uses the value of HelpContext for this associated action to invoke the online help targeting a specific topic. The target topic is uniquely identified by a nonzero HelpContext value. Leave the HelpContext property of the client control at its default value of zero. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpContext is only used when the HelpType property of this action or the client control is htInteger.

See Also

HelpType

HelpKeyword

2.1.22.4.4 TSendMail.HelpKeyword Property

Indicates the help keyword for client controls and menu items.

Pascal

```
property HelpKeyword;
```

C++

```
__property HelpKeyword;
```

Description

HelpKeyword, when set, specifies the keyword that identifies a help topic for this action. This value is propagated to the HelpKeyword property of client controls and menu items. The interpretation of HelpKeyword depends on which help system is used to display the topic. For example, when using HyperHelp (on Linux) or WinHelp (on Windows), HelpKeyword refers to an A link.

When a client control has focus and the user presses the F1 key (or the key specified by the application's HelpKey property), the control uses the value of HelpKeyword for this associated action object to invoke the online help targeting a specific topic. Leave the HelpKeyword property of the client control unassigned. This allows multiple controls (and multiple types of controls) to be associated with the same help topic through the one action object.

Note: HelpKeyword is only used when the HelpType property of this action or the client control is htKeyword.

See Also

HelpKeyword

HelpContext

HelpType

HelpKey

2.1.22.4.5 TSendMail.HelpType Property

Indicates the mechanism for client controls and menu items to use when invoking help.

Pascal

```
property HelpType;
```

C++

```
__property HelpType;
```

Description

HelpType, when set, indicates whether client controls and menu items should use the HelpContext or the HelpKeyword property for invoking the help system. This value is propagated to the HelpType property of client controls and menu items.

See Also

HelpType

HelpType

HelpContext

HelpKeyword

2.1.22.4.6 TSendMail.Hint Property

Indicates the Help hint for client controls and menu items.

Pascal

```
property Hint;
```

C++

```
__property Hint;
```

Description

Hint holds the string that is the hint for that action when it is set. This value is propagated to client controls and menu items.

See Also

Hint

Hint (see page 4916)

2.1.22.4.7 TSendMail.ImageIndex Property

Indicates the ImageIndex property for client controls and menu items.

Pascal

```
property ImageIndex;
```

C++

```
__property ImageIndex;
```

Description

ImageIndex is an index into the Images property of the action list or action manager that contains the action. It identifies an image that is associated with controls and menu items that use this action.

See Also

ImageIndex

ImageIndex (see page 4916)

Images

2.1.22.4.8 TSendMail.SecondaryShortCuts Property

Specifies the short cuts (in addition to ShortCut) for triggering clients.

Pascal

```
property SecondaryShortCuts;
```

C++

```
__property SecondaryShortCuts;
```

Description

Actions can execute in response to multiple short cut key combinations. SecondaryShortCuts lists all the short cut key combinations (other than the one specified by the ShortCut property) that can trigger the action. This lets you specify shortcuts for clients that do not have a ShortCut property or provide additional, secondary shortcuts.

When the user types one of the key combinations listed in SecondaryShortCuts, the action's Execute method is called.

See Also

ShortCut

Execute

2.1.22.4.9 TSendMail.ShortCut Property

Specifies the ShortCut property for client menu items.

Pascal

```
property ShortCut;
```

C++

```
__property ShortCut;
```

Description

ShortCut holds the value that is the shortcut for the action when it is set. This value is propagated to client menu items.

See Also

ShortCut (see page 4920)

SecondaryShortCuts

2.1.22.4.10 TSendMail.Text Property

Specifies the content of the mail message.

Pascal

```
property Text: TStrings;
```

C++

```
__property TStrings Text;
```

Description

Set Text to the content of the mail message. Because Text is a TStrings object, you can use the string list editor at design time to compose the message. Use the TStrings object's LoadFromFile method to load the value of Text from a file.

When the action executes, TSendMail (see page 141) displays a dialog for the user to compose the mail message. In that dialog, the body of the message is initialized to Text.

See Also

ExecuteTarget (see page 142)

LoadFromFile

2.1.22.4.11 TSendMail.Visible Property

Specifies the Visible property for client controls and menu items.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Visible specifies the visible state for the action. This value is propagated to client controls and menu items.

See Also

Visible (see page 4921)

Visible

2.1.22.5 TSendMail Events

The events of the TSendMail class are listed here.

Published Events

	Name	Description
	OnHint (see page 148)	Occurs when the mouse pauses over a client control or menu item.
	OnUpdate (see page 148)	Occurs when the application is idle or when the action list updates.

2.1.22.5.1 TSendMail.OnHint Event

Occurs when the mouse pauses over a client control or menu item.

Pascal

```
property OnHint;
```

C++

```
__property OnHint;
```

Description

Use OnHint to override the default hint that appears when the user pauses the mouse over a client control or menu item. The OnHint event handler can change the hint that appears (by changing the HintStr parameter), or display the hint in some application-specific way.

2.1.22.5.2 TSendMail.OnUpdate Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnUpdate;
```

C++

```
__property OnUpdate;
```

Description

Write an OnUpdate event handler to execute centralized code while an application is idle. For example, actions may want to update enabling and disabling, or checking and unchecking of client targets.

C++ Examples:

```
/*
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
*/
Boolean checked;

void __fastcall TForm1::Action1Update(TObject *Sender)
{
   // Indicate whether ToolBar1 is currently visible.
   TAction* pa = dynamic_cast<TAction*>(Sender);
   if (pa)
   {
     if (checked != ToolBar1->Visible)
     {
       lbOther->Items->Add("Event Action1Update: toolbar visibility changed");
     }
     checked = ToolBar1->Visible;
   }
//   pa->Checked = True;  // set this statically and don't change it!
}
```

Delphi Examples:

```
{
When the application is idle, the OnUpdate event occurs for
every action that is linked to a visible control or menu
item that is showing. This provides an opportunity for
applications to execute centralized code for enabling and
disabling, checking and unchecking, and so on. For example,
the following code illustrates the OnUpdate event handler
for an action that is "checked" when the toolbar is visible.
This example requires a TActionList (with one TAction) and a
TToolBar on a form. This example requires a TActionList
(with one TAction) and a TToolBar on a form.  Double click
on the TActionList and create an TAction named Action1.  The
TAction has an OnUpdate event handler called Action1Update.
Then set an object's (such as a button or menu item) Action
to Action1.
}
procedure TMainForm.Action1Update(Sender: TObject);
begin
  if ((Sender as TAction).Checked <> ToolBar1.Visible) then
    lbOther.Items.Add('Event Action1Update: toolbar visibility changed');
    { Indicate whether ToolBar1 is currently visible }
    (Sender as TAction).Checked := ToolBar1.Visible;
end;
```

See Also

UpdateAction

2.1.23 TTabAction Class

TTabAction is the base class for action objects designed to respond to the buttons in a tabbed dialog.

Class Hierarchy

Pascal

```
TTabAction = class(TCustomAction);
```

C++

```
class TTabAction : public TCustomAction;
```

File

ExtActns

Description

TTabAction implements the common behavior for actions that operate on tabbed controls (TCustomTabControl descendants). Each descendant class is designed to perform a specific function in a tabbed dialog such as a wizard. Do not use TTabAction directly in an application. Instead, use a TTabAction descendant such as TNextTab (see page 80) or TPreviousTab (see page 101).

TTabAction introduces the TabControl (see page 154) property, which specifies the page control or tab control on which this action operates. It ensures that the action is only enabled when the TabControl (see page 154) property is assigned to an enabled TPageControl or TTabControl object.

See Also

TPreviousTab (see page 101)

TNextTab (see page 80)

TPageControl

TCustomTabControl

TTabControl

2.1.23.1 TTabAction Members

The following tables list the members exposed by TTabAction.

Protected Methods

	Name	Description
	Notification (see page 152)	Responds when components are created or destroyed.
	SelectNextTab (see page 152)	This is SelectNextTab, a member of class TTabAction.

Public Events

	Name	Description
	AfterTabChange (see page 155)	Occurs immediately after the action changes the page of the associated tab control.
	BeforeTabChange (see page 155)	Occurs immediately before the action changes the page of the associated tab control.
	OnValidateTab (see page 156)	Occurs when the application is idle or when the action list updates.

Public Methods

	Name	Description
	Create (see page 151)	Creates an instance of TTabAction (see page 150).
	HandlesTarget (see page 152)	Indicates whether the action can execute its function.
	UpdateTarget (see page 153)	Enables or disables the action, depending on the target tab control.

Public Properties

	Name	Description
	SkipHiddenTabs (see page 153)	Indicates whether the tab action should consider hidden tabbed pages when moving to the next page.
	TabControl (see page 154)	Specifies the target of the action.
	Wrap (see page 154)	Indicates whether the tab action should "wrap" when navigating to the next tab page.

2.1.23.2 TTabAction.Create Constructor

Creates an instance of TTabAction (see page 150).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TTabAction(TComponent * AOwner);
```

Description

Do not call the TTabAction (see page 150) constructor. Actions are added at design time to an action list or action manager.

AOwner specifies the Owner for the action. This is the component that is responsible for freeing the TTabAction (see page 150) instance.

See Also

Owner

2.1.23.3 TTabAction Methods

The methods of the TTabAction class are listed here.

Protected Methods

	Name	Description
	Notification (see page 152)	Responds when components are created or destroyed.
	SelectNextTab (see page 152)	This is SelectNextTab, a member of class TTabAction.

Public Methods

	Name	Description
	HandlesTarget (see page 152)	Indicates whether the action can execute its function.

	UpdateTarget (see page 153)	Enables or disables the action, depending on the target tab control.

2.1.23.3.1 TTabAction.HandlesTarget Method

Indicates whether the action can execute its function.

Pascal

```
function HandlesTarget(Target: TObject): Boolean; override;
```

C++

```
virtual __fastcall Boolean HandlesTarget(TObject * Target);
```

Description

Do not call the HandlesTarget method. This method is called automatically when the user invokes an object (such as a tool button or menu item) that is linked to this action. The HandlesTarget method provides an action object with an opportunity to indicate whether it is appropriate to execute at this time with the object specified by the Target parameter as a "target".

Target is the currently active object.

In TTabAction (see page 150), HandlesTarget ignores the Target parameter, and checks, instead, whether the TabControl (see page 154) property has been set. If a target tab control has been assigned to the TabControl (see page 154) property, HandlesTarget returns true. Otherwise, it returns false.

See Also

ExecuteTarget

TabControl (see page 154)

2.1.23.3.2 TTabAction.Notification Method

Responds when components are created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation.

TBasicAction overrides the Notification method to check whether the component that is the value of the ActionComponent property is about to be freed. If so, it sets the ActionComponent property to nil (Delphi) or NULL (C++).

See Also

ActionComponent

2.1.23.3.3 TTabAction.SelectNextTab Method

Pascal

```
procedure SelectNextTab(GoForward: Boolean = True);
```

C++

```
__fastcall SelectNextTab(Boolean GoForward = True);
```

Description

This is SelectNextTab, a member of class TTabAction.

2.1.23.3.4 TTabAction.UpdateTarget Method

Enables or disables the action, depending on the target tab control.

Pascal

```
procedure UpdateTarget(Target: TObject); override;
```

C++

```
virtual __fastcall UpdateTarget(TObject * Target);
```

Description

Do not call the UpdateTarget method. This method is called automatically when the application is idle so that actions can update themselves according to the current conditions.

Target is the potential target object identified by the application.

In TTabAction (see page 150), UpdateTarget ignores the Target parameter and checks, instead, whether the TabControl (see page 154) property is set. If TabControl (see page 154) identifies an enabled page control or tab control that has more than one page, UpdateTarget sets the Enabled property to true. If not, it sets Enabled to false.

After setting the Enabled property, UpdateTarget generates an OnValidateTab (see page 156) event, where application-specific code can further determine whether the action should be enabled.

See Also

Enabled

TabControl (see page 154)

Enabled

OnValidateTab (see page 156)

2.1.23.4 TTabAction Properties

The properties of the TTabAction class are listed here.

Public Properties

	Name	Description
	SkipHiddenTabs (see page 153)	Indicates whether the tab action should consider hidden tabbed pages when moving to the next page.
	TabControl (see page 154)	Specifies the target of the action.
	Wrap (see page 154)	Indicates whether the tab action should "wrap" when navigating to the next tab page.

2.1.23.4.1 TTabAction.SkipHiddenTabs Property

Indicates whether the tab action should consider hidden tabbed pages when moving to the next page.

Pascal

```
property SkipHiddenTabs: Boolean;
```

C++

```
__property Boolean SkipHiddenTabs;
```

Description

Set SkipHiddenTabs to true if you do not want the action to move to a tab page if its TabVisible property is false. Set SkipHiddenTabs to false if the tab action can move to and make visible a hidden page.

Note: SkipHiddenTabs only has an effect when the TabControl (see page 154) property identifies a TPageControl object. (TTabControl does not support hidden pages).

See Also

ExecuteTarget (see page 81)

ExecuteTarget (see page 102)

TabVisible

TPageControl

2.1.23.4.2 TTabAction.TabControl Property

Specifies the target of the action.

Pascal

```
property TabControl: TCustomTabControl;
```

C++

```
__property TCustomTabControl TabControl;
```

Description

Set TabControl to the control on which the action operates when its ExecuteTarget method is called. Typically, this is a page control or tab control object that implements the pages of a tabbed dialog.

An application must explicitly assign a value to the TabControl property before the TTabAction (see page 150) descendant is enabled. The action does not infer the target page control when it fires.

See Also

ExecuteTarget (see page 81)

ExecuteTarget (see page 102)

2.1.23.4.3 TTabAction.Wrap Property

Indicates whether the tab action should "wrap" when navigating to the next tab page.

Pascal

```
property Wrap: Boolean;
```

C++

```
__property Boolean Wrap;
```

Description

When Wrap is true, the tab action can move previous to the first tabbed page or after the last tabbed page in the associated control. When Wrap is false, an attempt to move beyond the first or last page does not result in any page change, although it still results in a BeforeTabChange (see page 155) and an AfterTabChange (see page 155) event or in an OnFinish event.

See Also

ExecuteTarget (see page 81)

ExecuteTarget (see page 102)

TabControl (see page 154)

BeforeTabChange (see page 155)

AfterTabChange (see page 155)

OnFinish (see page 90)

2.1.23.5 TTabAction Events

The events of the TTabAction class are listed here.

Public Events

	Name	Description
	AfterTabChange (see page 155)	Occurs immediately after the action changes the page of the associated tab control.
	BeforeTabChange (see page 155)	Occurs immediately before the action changes the page of the associated tab control.
	OnValidateTab (see page 156)	Occurs when the application is idle or when the action list updates.

2.1.23.5.1 TTabAction.AfterTabChange Event

Occurs immediately after the action changes the page of the associated tab control.

Pascal

```
property AfterTabChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent AfterTabChange;
```

Description

Write an AfterTabChange event handler to perform any additional tasks after the tab action changes the current page of the associated tab control. Typically, this event is used to initialize the current page of the tab control.

Note: AfterTabChange only occurs if the action tries to change the page of the tab control (even if it is not successful). If the action attempts some other task (for example, when TNextPage is on the last page of the tab control), AfterTabChange does not occur.

See Also

BeforeTabChange (see page 155)

TabControl (see page 154)

Wrap (see page 154)

2.1.23.5.2 TTabAction.BeforeTabChange Event

Occurs immediately before the action changes the page of the associated tab control.

Pascal

```
property BeforeTabChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent BeforeTabChange;
```

Description

Write a BeforeTabChange event handler to perform any additional tasks before the tab action changes the current page of the associated tab control. Typically, this event is used to save or respond to the changes the user made on the current page before it changes.

Note: BeforeTabChange only occurs if the action tries to change the page of the tab control (even if it is not successful). If the action attempts some other task (for example, when TNextPage is on the last page of the tab control), BeforeTabChange does not occur.

See Also

AfterTabChange (see page 155)

TabControl (see page 154)

Wrap (see page 154)

2.1.23.5.3 TTabAction.OnValidateTab Event

Occurs when the application is idle or when the action list updates.

Pascal

```
property OnValidateTab: TValidateTabEvent;
```

C++

```
__property TValidateTabEvent OnValidateTab;
```

Description

Use the OnValidateTab event rather than the OnUpdate event to update the properties of a tab action when the application is idle. Unlike the OnUpdate event, which prevents the default behavior of the UpdateTarget (see page 153) method, OnValidateTab occurs after UpdateTarget (see page 153) has set the Enabled property to reflect whether the target tab control is enabled.

OnValidateTab can be used to update any of the properties of the tab action, but it is intended primarily for enabling or disabling the action, depending on the contents of the current page of the target tab control.

Sender is the tab action component to update in this event.

TabControl (see page 154) is the target tab control.

Enabled reflects the Enabled property of this action. Set Enabled in the event handler to enable or disable the action depending on current conditions.

Enabled

2.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TShowCmd (see page 157)	This is record ExtActns.TShowCmd.

2.2.1 ExtActns.TShowCmd Enumeration

Pascal

```
TShowCmd = (
  scHide,
  scMaximize,
  scMinimize,
  scRestore,
  scShow,
  scShowDefault,
  scShowMaximized,
  scShowMinimized,
  scShowMinNoActive,
  scShowNA,
  scShowNoActivate,
  scShowNormal
);
```

C++

```
enum TShowCmd {
  scHide,
  scMaximize,
  scMinimize,
  scRestore,
  scShow,
  scShowDefault,
  scShowMaximized,
  scShowMinimized,
  scShowMinNoActive,
  scShowNA,
  scShowNoActivate,
  scShowNormal
};
```

File

ExtActns

Description

This is record ExtActns.TShowCmd.

2.3 Types

The following table lists types in this documentation.

Types

Name	Description
TValidateTabEvent (see page 158)	This is type ExtActns.TValidateTabEvent.

2.3.1 ExtActns.TValidateTabEvent Type

Pascal

```
TValidateTabEvent = procedure (Sender: TTabAction; TabControl: TCustomTabControl; var Enabled:
Boolean) of object;
```

C++

```
(Sender: TTabAction; TabControl: TCustomTabControl; var Enabled: Boolean) (
TValidateTabEvent)();
```

File

ExtActns

Description

This is type ExtActns.TValidateTabEvent.

3 ExtCtrls Namespace

This is namespace ExtCtrls.

Topics

Name	Description
Classes (see page 162)	The following table lists classes in this documentation.
Functions (see page 1536)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 1538)	The following table lists structs, records, enums in this documentation.
Types (see page 1547)	The following table lists types in this documentation.
Constants (see page 1556)	The following table lists constants in this documentation.

Classes

	Name	Description
	EGridPanelException (see page 163)	The base class for runtime exceptions that occur in grid panels.
	TBevel (see page 163)	TBevel represents a beveled outline.
	TBoundLabel (see page 174)	TBoundLabel is the type of a labeled edit control's label.
	TButtonedEdit (see page 220)	TButtonedEdit is an edit control that has two embedded buttons.
	TCategoryPanel (see page 309)	TCategoryPanel is used to hold the set of display control legends for a particular display category.
	TCategoryPanelGroup (see page 379)	TCategoryPanelGroup is a container for collapsible panels that are TCategoryPanel (see page 309) objects.
	TCategoryPanelSurface (see page 456)	This is class ExtCtrls.TCategoryPanelSurface.
	TCellCollection (see page 458)	A collection of TCellItem (see page 462) objects.
	TCellItem (see page 462)	Represents an item in a TCellCollection (see page 458).
	TColorBox (see page 466)	TColorBox represents a combo box that lets users select a color.
	TColorListBox (see page 525)	TColorListBox represents a list box that lets users select a color.
	TColumnCollection (see page 587)	Controls the **Collection Editor** for columns within a grid panel.
	TColumnItem (see page 590)	This is class ExtCtrls.TColumnItem.
	TControlBar (see page 590)	TControlBar manages the layout of toolbar components.
	TControlCollection (see page 663)	This is class ExtCtrls.TControlCollection.
	TControlItem (see page 668)	This is class ExtCtrls.TControlItem.
	TCustomButtonedEdit (see page 673)	TCustomButtonedEditis the base class for edit controls that contain embedded buttons.
	TCustomCategoryPanel (see page 698)	TCustomCategoryPanel is a base class for the TCategoryPanel (see page 309) class.
	TCustomCategoryPanelGroup (see page 718)	This is class ExtCtrls.TCustomCategoryPanelGroup.
	TCustomColorBox (see page 735)	TCustomColorBox represents a combo box that lets users select a color.

	TCustomColorListBox (see page 745)	This is class ExtCtrls.TCustomColorListBox.
	TCustomControlBar (see page 754)	TCustomControlBar is the base class for control bar components.
	TCustomFlowPanel (see page 774)	The base class for all flow panel components.
	TCustomGridPanel (see page 781)	The base class for all grid panel components.
	TCustomLabeledEdit (see page 790)	TCustomLabeledEdit is the base class for edit controls that have an integrated label.
	TCustomLinkLabel (see page 797)	Base class for label containing HTML link.
	TCustomPanel (see page 802)	TCustomPanel is the base class for all panel components.
	TCustomRadioGroup (see page 815)	TCustomRadioGroup is the base class for radio-group components.
	TCustomTrayIcon (see page 822)	The base class for TTrayIcon (see page 1528).
	TEditButton (see page 835)	Button in a TButtonedEdit (see page 220).
	TFlowPanel (see page 857)	TFlowPanel implements a flow panel control in which components are placed in pre-defined locations.
	TGridPanel (see page 941)	TGridPanel implements a grid panel control in which each component is placed within a cell on a grid.
	THeader (see page 1021)	THeader is a sectioned visual control that displays text and allows each section to be resized with the mouse.
	TImage (see page 1048)	TImage displays a graphical image.
	TLabeledEdit (see page 1100)	TLabeledEdit is an edit control that has an associated label.
	TLinkLabel (see page 1167)	Label containing an HTML link.
	TNotebook (see page 1211)	TNotebook displays multiple pages, each with its own set of controls.
	TPage (see page 1267)	This is class ExtCtrls.TPage.
	TPaintBox (see page 1279)	TPaintBox provides a canvas that applications can use for rendering an image.
	TPanel (see page 1326)	TPanel implements a generic panel control.
	TRadioGroup (see page 1406)	TRadioGroup represents a group of radio buttons that function together.
	TRowCollection (see page 1455)	Controls the **Collection Editor** for rows within a grid panel.
	TRowItem (see page 1457)	This is class ExtCtrls.TRowItem.
	TShape (see page 1458)	TShape represents a geometric shape that can be drawn on a form.
	TSplitter (see page 1492)	TSplitter divides the client area of a form into resizable panes.
	TTimer (see page 1520)	TTimer encapsulates the Windows API timer functions.
	TTrayIcon (see page 1528)	Creates an icon in the system tray next to the clock.

Constants

Name	Description
DefaultCategoryPanelHeight (see page 1556)	This is constant ExtCtrls.DefaultCategoryPanelHeight.
NoColorSelected (see page 1556)	This is constant ExtCtrls.NoColorSelected.
WM_SYSTEM_TRAY_MESSAGE (see page 1556)	This is constant ExtCtrls.WM_SYSTEM_TRAY_MESSAGE.

Functions

	Name	Description
	Frame3D (see page 1536)	Draws a three dimensional frame on a canvas.
	NotebookHandlesNeeded (see page 1537)	This is function ExtCtrls.NotebookHandlesNeeded.

Structs, Records, Enums

	Name	Description
	TBalloonFlags (see page 1538)	A type specified when showing a balloon hint that puts one of the default icons on the balloon message.
	TBandDrawingStyle (see page 1539)	This is record ExtCtrls.TBandDrawingStyle.
	TBandPaintOption (see page 1539)	TBandPaintOption and TBandPaintOptions (see page 1549) specify which parts of a band are painted.
	TBevelShape (see page 1540)	TBevelShape determines the overall shape of a bevel control.
	TBevelStyle (see page 1541)	TBevelStyle indicates whether a bevel appears raised or lowered.
	TColorBoxStyles (see page 1541)	This is record ExtCtrls.TColorBoxStyles.
	TCornerEdge (see page 1542)	The size of the cornering for the edge of the bands in a TControlBar (see page 590).
	TExpandStyle (see page 1542)	Specifies how a grid panel expands.
	TFlowStyle (see page 1543)	This is record ExtCtrls.TFlowStyle.

	TLabelPosition (see page 1543)	TLabelPosition specifies the position of the label in a labeled edit control.
	TResizeStyle (see page 1544)	This is record ExtCtrls.TResizeStyle.
	TShapeType (see page 1544)	TShapeType determines the shape of a TShape (see page 1458) control.
	TSizeStyle (see page 1545)	This is record ExtCtrls.TSizeStyle.
	TSysLinkType (see page 1546)	TSysLinkType describes an HTML link type.

Types

Name	Description
NaturalNumber (see page 1547)	This is type ExtCtrls.NaturalNumber.
TBandDragEvent (see page 1548)	This is type ExtCtrls.TBandDragEvent.
TBandInfoEvent (see page 1548)	This is type ExtCtrls.TBandInfoEvent.
TBandMoveEvent (see page 1548)	This is type ExtCtrls.TBandMoveEvent.
TBandPaintEvent (see page 1549)	This is type ExtCtrls.TBandPaintEvent.
TBandPaintOptions (see page 1549)	This is type ExtCtrls.TBandPaintOptions.
TBeginBandMoveEvent (see page 1549)	This is type ExtCtrls.TBeginBandMoveEvent.
TCanResizeEvent (see page 1550)	This is type ExtCtrls.TCanResizeEvent.
TCategoryPanelClass (see page 1550)	This is type ExtCtrls.TCategoryPanelClass.
TCategoryPanelSurfaceClass (see page 1550)	This is type ExtCtrls.TCategoryPanelSurfaceClass.
TCellSpan (see page 1551)	This is type ExtCtrls.TCellSpan.
TColorBoxStyle (see page 1551)	TColorBoxStyle and TColorBoxStyles (see page 1541) specify how a color box control displays its selections.
TEditButtonClass (see page 1552)	This is type ExtCtrls.TEditButtonClass.
TEndBandMoveEvent (see page 1552)	This is type ExtCtrls.TEndBandMoveEvent.
TGetColorsEvent (see page 1552)	This is type ExtCtrls.TGetColorsEvent.
TLBGetColorsEvent (see page 1553)	This is type ExtCtrls.TLBGetColorsEvent.
TPanelBevel (see page 1553)	TPanelBevel specifies a bevel's cut.
TRowSize (see page 1554)	This is type ExtCtrls.TRowSize.
TSectionEvent (see page 1554)	TSectionEvent is the type of event handlers that respond when a section of a THeader (see page 1021) control is resized.
TSplitterCanResizeEvent (see page 1554)	This is type ExtCtrls.TSplitterCanResizeEvent.
TSysLinkEvent (see page 1555)	Event routine for click on TCustomLinkLabel (see page 797) HTML link.

3.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EGridPanelException (see page 163)	The base class for runtime exceptions that occur in grid panels.
	TBevel (see page 163)	TBevel represents a beveled outline.
	TBoundLabel (see page 174)	TBoundLabel is the type of a labeled edit control's label.
	TButtonedEdit (see page 220)	TButtonedEdit is an edit control that has two embedded buttons.
	TCategoryPanel (see page 309)	TCategoryPanel is used to hold the set of display control legends for a particular display category.
	TCategoryPanelGroup (see page 379)	TCategoryPanelGroup is a container for collapsible panels that are TCategoryPanel (see page 309) objects.
	TCategoryPanelSurface (see page 456)	This is class ExtCtrls.TCategoryPanelSurface.
	TCellCollection (see page 458)	A collection of TCellItem (see page 462) objects.
	TCellItem (see page 462)	Represents an item in a TCellCollection (see page 458).
	TColorBox (see page 466)	TColorBox represents a combo box that lets users select a color.
	TColorListBox (see page 525)	TColorListBox represents a list box that lets users select a color.
	TColumnCollection (see page 587)	Controls the **Collection Editor** for columns within a grid panel.
	TColumnItem (see page 590)	This is class ExtCtrls.TColumnItem.
	TControlBar (see page 590)	TControlBar manages the layout of toolbar components.
	TControlCollection (see page 663)	This is class ExtCtrls.TControlCollection.
	TControlItem (see page 668)	This is class ExtCtrls.TControlItem.
	TCustomButtonedEdit (see page 673)	TCustomButtonedEditis the base class for edit controls that contain embedded buttons.
	TCustomCategoryPanel (see page 698)	TCustomCategoryPanel is a base class for the TCategoryPanel (see page 309) class.
	TCustomCategoryPanelGroup (see page 718)	This is class ExtCtrls.TCustomCategoryPanelGroup.
	TCustomColorBox (see page 735)	TCustomColorBox represents a combo box that lets users select a color.
	TCustomColorListBox (see page 745)	This is class ExtCtrls.TCustomColorListBox.
	TCustomControlBar (see page 754)	TCustomControlBar is the base class for control bar components.
	TCustomFlowPanel (see page 774)	The base class for all flow panel components.
	TCustomGridPanel (see page 781)	The base class for all grid panel components.
	TCustomLabeledEdit (see page 790)	TCustomLabeledEdit is the base class for edit controls that have an integrated label.
	TCustomLinkLabel (see page 797)	Base class for label containing HTML link.
	TCustomPanel (see page 802)	TCustomPanel is the base class for all panel components.
	TCustomRadioGroup (see page 815)	TCustomRadioGroup is the base class for radio-group components.
	TCustomTrayIcon (see page 822)	The base class for TTrayIcon (see page 1528).
	TEditButton (see page 835)	Button in a TButtonedEdit (see page 220).
	TFlowPanel (see page 857)	TFlowPanel implements a flow panel control in which components are placed in pre-defined locations.
	TGridPanel (see page 941)	TGridPanel implements a grid panel control in which each component is placed within a cell on a grid.
	THeader (see page 1021)	THeader is a sectioned visual control that displays text and allows each section to be resized with the mouse.
	TImage (see page 1048)	TImage displays a graphical image.
	TLabeledEdit (see page 1100)	TLabeledEdit is an edit control that has an associated label.
	TLinkLabel (see page 1167)	Label containing an HTML link.
	TNotebook (see page 1211)	TNotebook displays multiple pages, each with its own set of controls.
	TPage (see page 1267)	This is class ExtCtrls.TPage.
	TPaintBox (see page 1279)	TPaintBox provides a canvas that applications can use for rendering an image.

	TPanel (see page 1326)	TPanel implements a generic panel control.
	TRadioGroup (see page 1406)	TRadioGroup represents a group of radio buttons that function together.
	TRowCollection (see page 1455)	Controls the **Collection Editor** for rows within a grid panel.
	TRowItem (see page 1457)	This is class ExtCtrls.TRowItem.
	TShape (see page 1458)	TShape represents a geometric shape that can be drawn on a form.
	TSplitter (see page 1492)	TSplitter divides the client area of a form into resizable panes.
	TTimer (see page 1520)	TTimer encapsulates the Windows API timer functions.
	TTrayIcon (see page 1528)	Creates an icon in the system tray next to the clock.

3.1.1 EGridPanelException Class

The base class for runtime exceptions that occur in grid panels.

Class Hierarchy

Pascal

```
EGridPanelException = class(Exception);
```

C++

```
class EGridPanelException : public Exception;
```

File

ExtCtrls

Description

Use EGridPanelException as the base class for creating custom exceptions that occur in grid panels.

3.1.2 TBevel Class

TBevel represents a beveled outline.

Class Hierarchy

Pascal

```
TBevel = class(TGraphicControl);
```

C++

```
class TBevel : public TGraphicControl;
```

File

ExtCtrls

Description

Use TBevel to create beveled boxes, frames, or lines. The bevel can appear raised or lowered.

See Also

TShape (see page 1458)

Frame3D (see page 1536)

Bevels

Graphic Controls

3.1.2.1 TBevel Members

The following tables list the members exposed by TBevel.

Protected Methods

	Name	Description
	Paint (see page 165)	Render control surface.

Public Methods

	Name	Description
	Create (see page 164)	Creates and initializes an instance of TBevel (see page 163).

Published Properties

	Name	Description
	Align (see page 165)	Determines how the control aligns within its container (parent control).
	Anchors (see page 169)	Specifies how the control is anchored to its parent.
	Constraints (see page 169)	Specifies the size constraints for the control.
	ParentShowHint (see page 170)	Determines where a control looks to find out if its Help Hint should be shown.
	Shape (see page 170)	Determines the shape of the bevel.
	ShowHint (see page 171)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Style (see page 172)	Determines whether the bevel appears raised or lowered.
	Visible (see page 173)	Determines whether the component appears onscreen.

3.1.2.2 TBevel.Create Constructor

Creates and initializes an instance of TBevel (see page 163).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TBevel(TComponent * AOwner);
```

Description

Call Create to instantiate a bevel at runtime. Bevels placed on forms at design time are created automatically.

See Also

Shape (see page 170)

Style (see page 172)

3.1.2.3 TBevel Methods

The methods of the TBevel class are listed here.

Protected Methods

	Name	Description
	Paint (see page 165)	Render control surface.

3.1.2.3.1 TBevel.Paint Method

Render control surface.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

The Paint method is called automatically when a lightweight control needs update its display area. Code in the Paint method uses the Canvas property to render the control surface.

As implemented in TGraphicControl, Paint does nothing. Specific rendering logic is provided by Paint methods in descendant control classes.

See Also

Canvas

3.1.2.4 TBevel Properties

The properties of the TBevel class are listed here.

Published Properties

	Name	Description
	Align (see page 165)	Determines how the control aligns within its container (parent control).
	Anchors (see page 169)	Specifies how the control is anchored to its parent.
	Constraints (see page 169)	Specifies the size constraints for the control.
	ParentShowHint (see page 170)	Determines where a control looks to find out if its Help Hint should be shown.
	Shape (see page 170)	Determines the shape of the bevel.
	ShowHint (see page 171)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Style (see page 172)	Determines whether the bevel appears raised or lowered.
	Visible (see page 173)	Determines whether the component appears onscreen.

3.1.2.4.1 TBevel.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it

continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
```

```
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
```

```
    Split.Left := Dirs.Left + Dirs.Width + 1;
    Split.Align := Dirs.Align; { give it the same alignment as the directory }
    { each pane must be at least one quarter of the form's width }
    Split.MinSize := Form1.ClientWidth div 4;
    { Finally, create the last pane – a file list box }
    Files := TFileListBox.Create(Form1);
    Files.Parent := Form1;
    Files.Align := alClient;
    Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
}

var
  I: Integer;

Parent

Anchors

3.1.2.4.2 TBevel.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

3.1.2.4.3 TBevel.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

OnCanResize

3.1.2.4.4 TBevel.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

ShowHint

3.1.2.4.5 TBevel.Shape Property

Determines the shape of the bevel.

Pascal

```
property Shape: TBevelShape;
```

C++

```
__property TBevelShape Shape;
```

Description

Set Shape to specify whether the bevel appears as a line, box, frame, or space. For shapes that can appear either raised or lowered, the Style (see page 172) property indicates which effect is used.

The default value for Shape is bsBox.

See Also

ClientRect

Style (see page 172)

3.1.2.4.6 TBevel.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
```

```
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}
```

3.1.2.4.7 TBevel.Style Property

Determines whether the bevel appears raised or lowered.

Pascal

```
property Style: TBevelStyle;
```

C++

```
__property TBevelStyle Style;
```

Description

Set Style to indicate whether the bevel should create a raised or a lowered effect. When the Shape (see page 170) property is

bsBox, the entire client area appears raised or lowered. For all other values of Shape (see page 170), the bevel displays a raised or lowered line along the edge or edges of the client area. The default value of Style is bsLowered.

See Also

Shape (see page 170)

3.1.2.4.8 TBevel.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
```

```
  (not the tab area) of the Tab Control to become invisible.
  }
  procedure TForm1.CheckBox1Click(Sender: TObject);
  begin
    PageControl1.ActivePage.Visible := CheckBox1.Checked;
  end;

  procedure TForm1.PageControl1Change(Sender: TObject);
  begin
    CheckBox1.Checked := PageControl1.ActivePage.Visible;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  var
    i: Integer;
  begin
    for i := 0 to 9 do
      with TTabSheet.Create(Self) do
      begin
        PageControl := PageControl1;
        Caption := 'TabSheet' + IntToStr(i);
        with TEdit.Create(Self) do
        begin
          Parent := PageControl1.Pages[i];
          Left := Random(PageControl1.ActivePage.ClientWidth - Width);
          Top := Random(PageControl1.ActivePage.ClientHeight - Height);
        end;
      end;
      PageControl1Change(Sender);
  end;
```

3.1.3 TBoundLabel Class

TBoundLabel is the type of a labeled edit control's label.

Class Hierarchy

Pascal

```
  TBoundLabel = class(TCustomLabel);
```

C++

```
  class TBoundLabel : public TCustomLabel;
```

File

ExtCtrls

Description

TBoundLabel implements the label of a labeled edit control. Unlike other label controls such as TLabel, TBoundLabel "belongs" to the labeled edit control (it is a subcomponent of the edit control). This means that the bound label's Owner is the edit control

rather than the form, and the edit control is responsible for loading and saving the bound label.

Use the properties of TBoundLabel to specify how you want the labeled edit control's label to appear. For example, you can use the Caption (see page 178) property to specify the text that appears in the label. You can use the Alignment and Layout (see page 186) properties to specify the placement of that caption within the label.

TLabeledEdit (see page 1100)

TLabel

TComponent

3.1.3.1 TBoundLabel Members

The following tables list the members exposed by TBoundLabel.

Protected Methods

	Name	Description
	AdjustBounds (see page 176)	Resizes the label when the text changes.

Public Methods

	Name	Description
	Create (see page 176)	Creates a new TBoundLabel (see page 174) object.

Published Events

	Name	Description
	OnClick (see page 201)	Occurs when the user clicks the control.
	OnContextPopup (see page 203)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 203)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 204)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 207)	Occurs when the user drags an object over a control.
	OnEndDock (see page 210)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 210)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnMouseActivate (see page 211)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 212)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseMove (see page 214)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 217)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 219)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 220)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	BiDiMode (see page 178)	Specifies the bi-directional mode for the control.
	Caption (see page 178)	Specifies a text string that identifies the control to the user.
	Color (see page 181)	Specifies the background color of the control.
	DragCursor (see page 181)	Indicates the image used to represent the mouse pointer when the control is being dragged.

	DragKind (see page 182)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 182)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 184)	Controls the attributes of text written on or in the control.
	Height (see page 185)	Specifies the vertical size of the control in pixels.
	Layout (see page 186)	Specifies the vertical placement of the text within the label.
R	Left (see page 186)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	ParentBiDiMode (see page 187)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 188)	Determines where a control looks for its color information.
	ParentFont (see page 188)	Determines where a control looks for its font information.
	ParentShowHint (see page 189)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 189)	Identifies the pop-up menu associated with the control.
	ShowAccelChar (see page 194)	Determines how an ampersand in the label text is displayed.
	ShowHint (see page 195)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
R	Top (see page 197)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Transparent (see page 198)	Specifies whether controls that sit below the label on a form can be seen through the label.
	Width (see page 198)	Specifies the horizontal size of the control or form in pixels.
	WordWrap (see page 200)	Specifies whether the label text wraps when it is too long for the width of the label.

3.1.3.2 TBoundLabel.Create Constructor

Creates a new TBoundLabel (see page 174) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TBoundLabel(TComponent * AOwner);
```

Description

Do not create instances of TBoundLabel (see page 174). Bound labels are instantiated by the labeled edit controls to which they belong.

AOwner specifies the labeled edit control that acts as the bound label's Owner.

See Also

TLabeledEdit (see page 1100)

Owner

3.1.3.3 TBoundLabel Methods

The methods of the TBoundLabel class are listed here.

Protected Methods

	Name	Description
V	AdjustBounds (see page 176)	Resizes the label when the text changes.

3.1.3.3.1 TBoundLabel.AdjustBounds Method

Resizes the label when the text changes.

Pascal

```
procedure AdjustBounds; override;
```

C++

```
virtual __fastcall AdjustBounds();
```

Description

When the text in the label or the font changes, AdjustBounds is implicitly called. It redraws the text in the client area, and then resizes the label if the AutoSize property is true.

When WordWrap is true, the width of the label is fixed. If AutoSize is also true, changes to the text cause the label to change in height. When AutoSize is true and WordWrap is false, the height of the label is determined by the font, and changes to the text cause the label to change in width.

Override AdjustBounds to make additional adjustments when the text changes.

DoDrawText

AutoSize

3.1.3.4 TBoundLabel Properties

The properties of the TBoundLabel class are listed here.

Published Properties

	Name	Description
	BiDiMode (see page 178)	Specifies the bi-directional mode for the control.
	Caption (see page 178)	Specifies a text string that identifies the control to the user.
	Color (see page 181)	Specifies the background color of the control.
	DragCursor (see page 181)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 182)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 182)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 184)	Controls the attributes of text written on or in the control.
	Height (see page 185)	Specifies the vertical size of the control in pixels.
	Layout (see page 186)	Specifies the vertical placement of the text within the label.
R	Left (see page 186)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	ParentBiDiMode (see page 187)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 188)	Determines where a control looks for its color information.
	ParentFont (see page 188)	Determines where a control looks for its font information.
	ParentShowHint (see page 189)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 189)	Identifies the pop-up menu associated with the control.
	ShowAccelChar (see page 194)	Determines how an ampersand in the label text is displayed.
	ShowHint (see page 195)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
R	Top (see page 197)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Transparent (see page 198)	Specifies whether controls that sit below the label on a form can be seen through the label.
	Width (see page 198)	Specifies the horizontal size of the control or form in pixels.
	WordWrap (see page 200)	Specifies whether the label text wraps when it is too long for the width of the label.

3.1.3.4.1 TBoundLabel.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

UseRightToLeftAlignment

UseRightToLeftReading

UseRightToLeftScrollBar

Including Bi-directional Functionality in Applications

3.1.3.4.2 TBoundLabel.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
```

```
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>
#include <memory>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);  // The owner (toolBar) will clean this up.
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this); // The owner (this) will clean this up.
  myToolBar->Parent = this;
//  TStringList *captions = new TStringList();
  std::auto_ptr<TStringList> captions(new TStringList());

  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions.get());
//  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
```

```
  constant, even though the length of the label's caption
  changes. As a result, the caption of the label is probably
  too long to display in the label when the user clicks the
  button:
  }
  procedure TForm1.Button1Click(Sender: TObject);
  begin
    Label1.AutoSize := False;
    Label1.Caption :=
      'This string is too long to be the caption of this label';
  end;
  {
  This example requires a TPageControl populated by several
  TabSheets, a TEdit and a TButton. When the button is
  clicked, the caption of the active tab changes to that of
  the TEdit.  These lines of code could also be written:
  PageControl1.ActivePage.Caption := Edit1.Text;
  This would obviate the need for a TTabSheet variable since
  PageControl1.->ActivePage is already of type TTabSheet.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    sheet: TTabSheet;
  begin
    sheet := PageControl1.ActivePage;
    sheet.Caption := Edit1.Text;
  end;
  {
  This example creates a ToolBar and adds ToolButtons to it.
  Include ComCtlrs in the uses clause.
  }
  procedure AddButtons(ToolBar: TToolBar;
    Const ButtonCaptions: array of String);
  var
    I: Integer;
  begin
    for I := 0 to High(ButtonCaptions) do
      begin
        with TToolButton.Create(ToolBar) do
        begin
          Parent := ToolBar;
          Caption := ButtonCaptions[I];
          if (ButtonCaptions[I] = '|') then
            Style := tbsSeparator
          else
            Style := tbsButton;
        end;
      end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    ToolBar1 := TToolBar.Create(Self);
    ToolBar1.Parent := Self;
    AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
    ToolBar1.ShowCaptions := True;
    ToolBar1.Height := 40;
  end;

  procedure TForm1.FormDestroy(Sender: TObject);
  var
    I: Integer;
  begin
    for I := ToolBar1.ButtonCount - 1 downto 0 do
      ToolBar1.Buttons[I].Free;
    ToolBar1.Free;
```

```
end;
```

3.1.3.4.3 TBoundLabel.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

ParentColor

3.1.3.4.4 TBoundLabel.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

3.1.3.4.5 TBoundLabel.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

3.1.3.4.6 TBoundLabel.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
```

```
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

3.1.3.4.7 TBoundLabel.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
```

```
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;

3.1.3.4.8 TBoundLabel.Height Property

Specifies the vertical size of the control in pixels.

Pascal

```
property Height: Integer;
```

C++

```
__property int Height;
```

Description

Use the Height property to read or change the height of the control.

C++ Examples:

```
/*
This example needs only a blank form.  Three Rich Edit
controls are placed vertically on the form, each contain a
line of text, and the second form has HideSelection set to
false.  Try tabbing between the three Rich Edit controls and
observe the effect on the selected text.
*/
#include <ComCtrls.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int I = 0; I <= 2; I++)
  {
    TRichEdit *pRich = new TRichEdit(this);
    pRich->Parent = this;
    pRich->Top = pRich->Height * I;
    pRich->Text = "This text will take the focus.";
    pRich->SelStart = 0;
    pRich->SelLength = pRich->Text.Length();
    if (I == 1)
      pRich->HideSelection = false;
  }
}
```

Delphi Examples:

```
{
This example needs only a blank form. Three Rich Edit
controls are placed vertically on the form, each contain a
line of text, and the second form has HideSelection set to
false.  Try tabbing between the three Rich Edit controls and
observe the effect on the selected text.
}
uses ComCtrls;
```

```
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  for I := 0 to 2 do
    with TRichEdit.Create(Self) do
    begin
      Parent := Self;
      Top := Height * I;
      Text := 'This text will take the focus.';
      SelStart := 0;
      SelLength := Length(Text);
      if (I = 1) then
        HideSelection := False;
    end;
end;

3.1.3.4.9 TBoundLabel.Layout Property

Specifies the vertical placement of the text within the label.

Pascal

```
property Layout;
```

C++

```
__property Layout;
```

Description

Set Layout to specify how the text of the label is placed within the ClientRect of the label control. Layout is the vertical analog to the Alignment property.

See Also

Alignment

ClientRect

3.1.3.4.10 TBoundLabel.Left Property

Specifies the horizontal coordinate of the left edge of a component relative to its parent.

Pascal

```
property Left: Integer;
```

C++

```
__property int Left;
```

Description

Use the Left property to determine where the left side of the control begins or to reposition the left side of the control.

If the control is contained in another control, the Left and Top properties are relative to the parent control. If the control is contained directly by the form, the property values are relative to the form. For forms, the value of the Left property is relative to the screen in pixels.

C++ Examples:

```
/*
Place a TTimer object in the form and enter Timer1Timer in
the OnTimer event.  Place other controls in the form and
change the active control at runtime.  The following event
handler responds to timer events by moving the active control
one pixel to the right every 100 miliseconds:
*/
void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  Timer1->Interval = 100;
  if (ActiveControl)
    ActiveControl->Left = ActiveControl->Left + 1;
}
```

Delphi Examples:

```
{
Place a TTimer object in the form and enter Timer1Timer in
the OnTimer event.  Place other controls in the form and
change the active control at runtime.  The following event
handler responds to timer events by moving the active control
one pixel to the right every 100 miliseconds:
}
procedure TForm1.Timer1Timer(Sender: TObject);
begin
  Timer1.Interval := 100;
  if ActiveControl <> nil then
    ActiveControl.Left := ActiveControl.Left + 1;
end;
```

3.1.3.4.11 TBoundLabel.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

Parent

BiDiMode

3.1.3.4.12 TBoundLabel.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

3.1.3.4.13 TBoundLabel.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

Font

Parent

ParentColor

ParentShowHint

3.1.3.4.14 TBoundLabel.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

3.1.3.4.15 TBoundLabel.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
```

```
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
```

```
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");

            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
```

```
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else

3.1.3.4.16 TBoundLabel.ShowAccelChar Property

Determines how an ampersand in the label text is displayed.

Pascal

```
property ShowAccelChar;
```

C++

```
__property ShowAccelChar;
```

Description

Set ShowAccelChar to true to allow the label to display an underlined accelerator key value. When ShowAccelChar is true, any character preceded by an ampersand (&) appears underlined. If the FocusControl property is set, the windowed control specified by the FocusControl property receives input focus when the user types that underlined character. To display an ampersand when ShowAccelChar is true, use two ampersands (&&) to stand for the single ampersand that is displayed.

Set ShowAccelChar to false to display the label text with all ampersands appearing as ampersands. When ShowAccelChar is false, the value of the FocusControl property is not used.

C++ Examples:

```
/*
This example uses two labels on a form. The first label has
a caption with an accelerator character in it. The second
label also includes an ampersand, but it does not appear as
```

```
an accelerator character.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Label1->ShowAccelChar = true;
  Label1->Caption = "An &Underlined character appears here";
  Label2->ShowAccelChar = false;
  Label2->Caption = "An ampersand (&) appears here";
}
```

Delphi Examples:

```
{
This example uses two labels on a form. The first label has
a caption with an accelerator character in it. The second
label also includes an ampersand, but it does not appear as
an accelerator character.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Label1.ShowAccelChar := True;
  Label1.Caption := 'An &Underlined character appears here';
  Label2.ShowAccelChar := False;
  Label2.Caption := 'An ampersand (&) appears here';
end;
```

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
```

```
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

3.1.3.4.18 TBoundLabel.Top Property

Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.

Pascal

```
property Top: Integer;
```

C++

```
__property int Top;
```

Description

Use Top to locate the top of the control or reposition the control to a different Y coordinate. The Top property, like the Left property, is the position of the control relative to its container. Thus, if a control is contained in a TPanel, the Left and Top properties are relative to the panel. If the control is contained directly by the form, it is relative to the form. For forms, the value of the Top property is relative to the screen in pixels.

C++ Examples:

```
/*
This example uses an updown control and a group box on a
form, with several controls contained within the group box.
When the updown control or is clicked, the controls within
the group box are moved in the appropriate direction.
*/
void __fastcall TForm1::UpDown1Click(TObject *Sender, TUDBtnType Button)
{
  int I;
  TControl *ChildControl;

  for (I = 0; I < GroupBox1->ControlCount; I++)
  {
    ChildControl = GroupBox1->Controls[I];
    if (Button == btNext)
      ChildControl->Top = ChildControl->Top + 15;
    else
      ChildControl->Top = ChildControl->Top - 15;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  const TColor colorarray[5] = {clYellow, clGreen, clBlue, clLime, clFuchsia};
  GroupBox1->Brush->Color = clRed;
  for (int i = 0; i < GroupBox1->ControlCount; i++)
    dynamic_cast<TWinControl *>(GroupBox1->Controls[i])->Brush->Color = colorarray[i];
}
```

Delphi Examples:

```
{
This example uses an updown control and a group box on a
form, with several controls contained within the group box.
When the updown control is clicked, the controls within
the group box are moved in the appropriate direction.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
const
  colorarray : Array[0..4] of TColor = (clYellow, clGreen, clBlue, clLime, clFuchsia);
begin
   GroupBox1.Brush.Color := clRed;
  for I:= 0 to GroupBox1.ControlCount -1 do
```

```
    begin
      TWinControl(GroupBox1.Controls[I]).Brush.Color := colorarray[I];
    end;
  end;

  procedure TForm1.UpDown1Click(Sender: TObject; Button: TUDBtnType);
  var
    I: Integer;
    ChildControl: TControl;
  begin
    for I:= 0 to GroupBox1.ControlCount -1 do
    begin
      ChildControl := GroupBox1.Controls[I];
      if Button = btNext then
        ChildControl.Top := ChildControl.Top + 15
      else
        ChildControl.Top := ChildControl.Top - 15;
    end;
  end;
```

Left

3.1.3.4.19 TBoundLabel.Transparent Property

Specifies whether controls that sit below the label on a form can be seen through the label.

Pascal

```
property Transparent;
```

C++

```
__property Transparent;
```

Description

Set Transparent to true to prevent the label from obscuring other controls on the form. For example, if the label is used to add text to a graphic, set Transparent to true so that the label does not stand out as a separate object.

Writing text so that the background is transparent is slower than writing text when Transparent is false. If the label is not obscuring a complicated image, performance can be improved by setting the background color of the label to match the object beneath it and setting Transparent to false.

ParentColor

3.1.3.4.20 TBoundLabel.Width Property

Specifies the horizontal size of the control or form in pixels.

Pascal

```
property Width: Integer;
```

C++

```
__property int Width;
```

Description

Use the Width property to read or change the width of the control.

Note: For tab sheet controls, changing this property at runtime has no effect.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
```

```
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane - a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
```

3.1.3.4.21 TBoundLabel.WordWrap Property

Specifies whether the label text wraps when it is too long for the width of the label.

Pascal

```
property WordWrap;
```

C++

```
__property WordWrap;
```

Description

Set WordWrap to true to allow the label to display multiple line of text. When WordWrap is true, text that is too wide for the label control wraps at the right margin and continues in additional lines.

Set WordWrap to false to limit the label to a single line. When WordWrap is false, text that is too wide for the label appears truncated.

3.1.3.5 TBoundLabel Events

The events of the TBoundLabel class are listed here.

Published Events

	Name	Description
	OnClick (see page 201)	Occurs when the user clicks the control.
	OnContextPopup (see page 203)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 203)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 204)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 207)	Occurs when the user drags an object over a control.

	OnEndDock (see page 210)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 210)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnMouseActivate (see page 211)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 212)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseMove (see page 214)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 217)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 219)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 220)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

3.1.3.5.1 TBoundLabel.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
```

```
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

3.1.3.5.2 TBoundLabel.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

3.1.3.5.3 TBoundLabel.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick

Responding to User Actions at Runtime

3.1.3.5.4 TBoundLabel.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
```

```
{
   Accept = Source->ClassNameIs("TLabel");
}

/*

3.1.3.5.5 TBoundLabel.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
type
  TForm1 = class(TForm)
    Panel1: TPanel;
    Label1: TLabel;
    procedure Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
      State: TDragState; var Accept: Boolean);
    procedure FormDragOver(Sender, Source: TObject; X, Y: Integer;
      State: TDragState; var Accept: Boolean);
    procedure FormDragDrop(Sender, Source: TObject; X, Y: Integer);
  private
    { Private declarations }
  public
    { Public declarations }
  end;

var
  Form1: TForm1;

implementation
```

```
{$R *.dfm}

procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;

3.1.3.5.7 TBoundLabel.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
```

```
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;

3.1.3.5.8 TBoundLabel.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants

to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

MouseCapture

3.1.3.5.9 TBoundLabel.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
```

```
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,

3.1.3.5.10 TBoundLabel.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
  property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

OnMouseDown

OnMouseMove

Responding to a Mouse-up Action

3.1.3.5.12 TBoundLabel.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDragOver

OnDockDrop

3.1.3.5.13 TBoundLabel.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

3.1.4 TButtonedEdit Class

TButtonedEdit is an edit control that has two embedded buttons.

Class Hierarchy

Pascal

```
TButtonedEdit = class(TCustomButtonedEdit);
```

C++

```
class TButtonedEdit : public TCustomButtonedEdit;
```

File

ExtCtrls

Description

Use a TButtonedEdit to add an edit control with two (optional) embedded buttons, one on either side of the text, to a form. TButtonedEdit uses the Images (see page 244) property to supply images from a TImageList to the embedded buttons, referenced by its LeftButton (see page 248) and RightButton (see page 261) properties. Use each button's ImageIndex, HotImageIndex, PressedImageIndex and DisabledImageIndex properties to specify images for each possible state.

C++ Examples:

```
/*
This example shows how to use the TButtonedEdit class. This example
implements a component like "TButtonedEdit search" that's to be
found in the tool pallete window.
Entering the control will enable the right button, left button will
display a MessageDlg and the right button will clear the input text.
*/
__fastcall TForm4::TForm4(TComponent* Owner)
    : TForm(Owner)
{
    //declaring an instance
    btnEdit = new TButtonedEdit(this);

    //setting the parent so it will autodetele
    btnEdit->Parent = this;

    //positioning
    btnEdit->Left = 10;
    btnEdit->Top = 10;

    //creating a TImageList and using it for the button
    TImageList* imList = new TImageList(this);
    Graphics::TBitmap* bmap = new Graphics::TBitmap();
    bmap->LoadFromFile("..\\littleB_16.bmp");
    imList->Add(bmap,NULL);
    bmap->LoadFromFile("..\\little_logo_16.bmp");
    imList->Add(bmap,NULL);
    btnEdit->Images = imList;

    //selecting the image for the left button and enabling it
    btnEdit->LeftButton->Visible = true;
    btnEdit->LeftButton->Enabled = true;
    btnEdit->LeftButton->ImageIndex = 0;
    btnEdit->LeftButton->DisabledImageIndex = 0;
    btnEdit->LeftButton->HotImageIndex = 0;

    //selecting the image for the right button
    //this will be enabled when the content changes
    btnEdit->RightButton->Enabled = true;
    btnEdit->RightButton->ImageIndex = 1;
    btnEdit->RightButton->DisabledImageIndex = 1;
    btnEdit->RightButton->HotImageIndex = 1;

    //selecting action for the buttoned edit to take
    btnEdit->OnEnter = btnEditEnter;
    btnEdit->OnRightButtonClick = btnEditRightClick;
    btnEdit->OnLeftButtonClick = btnEditLeftClick;

    //default text in the edit
    btnEdit->Text = "Default";

    btnEdit->Constraints->MinHeight = 16;
    btnEdit->Height = 16;

    //finally displaying the button
    btnEdit->Show();
```

```
}
//---------------------------------------------------------------------------

void __fastcall TForm4::btnEditEnter(TObject* Sender){
   btnEdit->Text = "";
   btnEdit->RightButton->Visible = true;
}

void __fastcall TForm4::btnEditRightClick(TObject* Sender){
   //resetting to default state
   btnEdit->Text = "Default";
   btnEdit->RightButton->Visible = false;
}

void __fastcall TForm4::btnEditLeftClick(TObject* Sender){
   MessageDlg("Left button pressed with: " + btnEdit->Text,
              mtInformation, TMsgDlgButtons() << mbOK, 0);

}
```

3.1.4.1 TButtonedEdit Members

The following tables list the members exposed by TButtonedEdit.

Protected Methods

	Name	Description
	DoSetTextHint (see page 676)	This is DoSetTextHint, a member of class TCustomButtonedEdit.
	GetEditButtonClass (see page 676)	This is GetEditButtonClass, a member of class TCustomButtonedEdit.
	Notification (see page 676)	Responds to notifications that components are being created or destroyed.
	UpdateEditMargins (see page 677)	Update the margins of the edit control to provide adequate space for the buttons.
	WndProc (see page 677)	Provides specific message responses for the control.

Public Methods

	Name	Description
	Create (see page 674)	Creates an instance of TCustomEdit.
	DefaultHandler (see page 675)	Provides message handling for all messages that the control does not fully process itself.
	Destroy (see page 675)	Destroys an instance of TWinControl.

Published Events

	Name	Description
	OnChange (see page 270)	Occurs when the text for the edit control may have changed.
	OnClick (see page 271)	Occurs when the user clicks the control.
	OnContextPopup (see page 273)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 273)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 274)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 277)	Occurs when the user drags an object over a control.
	OnEndDock (see page 280)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 280)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 281)	Occurs when a control receives the input focus.
	OnExit (see page 284)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 287)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 290)	Occurs when a key is pressed.
	OnKeyUp (see page 291)	Occurs when the user releases a key that has been pressed.
	OnLeftButtonClick (see page 293)	Occurs when the user clicks the LeftButton.
	OnMouseActivate (see page 296)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 297)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 299)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 300)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 300)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 302)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnRightButtonClick (see page 304)	Occurs when the user clicks the RightButton.
	OnStartDock (see page 307)	Occurs when the user begins to drag a control with a DragKind of dkDock.

	OnStartDrag (see page 308)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 227)	Determines how the control aligns within its container (parent control).
	Alignment (see page 230)	Determines how the text is aligned within the text edit control.
	Anchors (see page 231)	Specifies how the control is anchored to its parent.
	AutoSelect (see page 231)	Determines whether all the text in the edit control is automatically selected when the control gets focus.
	AutoSize (see page 232)	Determines whether the height of the edit control automatically resizes to accommodate the text.
	BevelEdges (see page 233)	Specifies which edges of the control are beveled.
	BevelInner (see page 233)	Specifies the cut of the inner bevel.
	BevelKind (see page 234)	Specifies the control's bevel style.
	BevelOuter (see page 234)	Specifies the cut of the outer bevel.
	BevelWidth (see page 234)	Specifies the width of the inner and outer bevels.
	BiDiMode (see page 235)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 235)	Determines whether the edit control has a single line border around the client area.
	CharCase (see page 236)	Determines the case of the text within the edit control.
	Color (see page 236)	Specifies the background color of the control.
	Constraints (see page 237)	Specifies the size constraints for the control.
	Ctl3D (see page 237)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 238)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 240)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 240)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 240)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 242)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 242)	Controls the attributes of text written on or in the control.
	HideSelection (see page 244)	Determines whether the visual indication of the selected text remains when focus shifts to another control.
	Images (see page 244)	Lists the images that can appear on the control's embedded buttons.
	ImeMode (see page 247)	Determines the behavior of the input method editor (IME).
	ImeName (see page 248)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	LeftButton (see page 248)	Specifies the control that implements the left embedded button.
	MaxLength (see page 252)	Specifies the maximum number of characters the user can enter into the edit control.
	NumbersOnly (see page 252)	Allows only numbers to be typed into the text edit.
	OEMConvert (see page 252)	Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.
	ParentBiDiMode (see page 253)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 253)	Determines where a control looks for its color information.
	ParentCtl3D (see page 254)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 254)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 254)	Determines where a control looks for its font information.
	ParentShowHint (see page 255)	Determines where a control looks to find out if its Help Hint should be shown.
	PasswordChar (see page 255)	Indicates the character, if any, to display in place of the actual characters typed in the control.
	PopupMenu (see page 256)	Identifies the pop-up menu associated with the control.
	ReadOnly (see page 261)	Determines whether the user can change the text of the edit control.
	RightButton (see page 261)	Specifies the control that implements the right embedded button.

	ShowHint (see page 264)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 266)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 266)	Determines if the user can tab to a control.
	Text (see page 267)	Contains a text string associated with the control.
	TextHint (see page 268)	A hint or message to be displayed when the Text property is empty.
	Visible (see page 268)	Determines whether the component appears onscreen.

3.1.4.2 TButtonedEdit Properties

The properties of the TButtonedEdit class are listed here.

Published Properties

	Name	Description
	Align (see page 227)	Determines how the control aligns within its container (parent control).
	Alignment (see page 230)	Determines how the text is aligned within the text edit control.
	Anchors (see page 231)	Specifies how the control is anchored to its parent.
	AutoSelect (see page 231)	Determines whether all the text in the edit control is automatically selected when the control gets focus.
	AutoSize (see page 232)	Determines whether the height of the edit control automatically resizes to accommodate the text.
	BevelEdges (see page 233)	Specifies which edges of the control are beveled.
	BevelInner (see page 233)	Specifies the cut of the inner bevel.
	BevelKind (see page 234)	Specifies the control's bevel style.
	BevelOuter (see page 234)	Specifies the cut of the outer bevel.
	BevelWidth (see page 234)	Specifies the width of the inner and outer bevels.
	BiDiMode (see page 235)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 235)	Determines whether the edit control has a single line border around the client area.
	CharCase (see page 236)	Determines the case of the text within the edit control.
	Color (see page 236)	Specifies the background color of the control.
	Constraints (see page 237)	Specifies the size constraints for the control.
	Ctl3D (see page 237)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DoubleBuffered (see page 238)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 240)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 240)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 240)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 242)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 242)	Controls the attributes of text written on or in the control.
	HideSelection (see page 244)	Determines whether the visual indication of the selected text remains when focus shifts to another control.
	Images (see page 244)	Lists the images that can appear on the control's embedded buttons.
	ImeMode (see page 247)	Determines the behavior of the input method editor (IME).
	ImeName (see page 248)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	LeftButton (see page 248)	Specifies the control that implements the left embedded button.
	MaxLength (see page 252)	Specifies the maximum number of characters the user can enter into the edit control.
	NumbersOnly (see page 252)	Allows only numbers to be typed into the text edit.
	OEMConvert (see page 252)	Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.
	ParentBiDiMode (see page 253)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 253)	Determines where a control looks for its color information.

	ParentCtl3D (see page 254)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 254)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 254)	Determines where a control looks for its font information.
	ParentShowHint (see page 255)	Determines where a control looks to find out if its Help Hint should be shown.
	PasswordChar (see page 255)	Indicates the character, if any, to display in place of the actual characters typed in the control.
	PopupMenu (see page 256)	Identifies the pop-up menu associated with the control.
	ReadOnly (see page 261)	Determines whether the user can change the text of the edit control.
	RightButton (see page 261)	Specifies the control that implements the right embedded button.
	ShowHint (see page 264)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 266)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 266)	Determines if the user can tab to a control.
	Text (see page 267)	Contains a text string associated with the control.
	TextHint (see page 268)	A hint or message to be displayed when the Text property is empty.
	Visible (see page 268)	Determines whether the component appears onscreen.

3.1.4.2.1 TButtonedEdit.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
```

```
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>

3.1.4.2.2 TButtonedEdit.Alignment Property

Determines how the text is aligned within the text edit control.

Pascal

```
property Alignment;
```

C++

```
__property Alignment;
```

Description

Use Alignment to change the way the text is formatted in the text edit control. Alignment can take one of the following values:

Value	Meaning
taLeftJustify	Align text to the left side of the control
taCenter	Center text horizontally in the control.
taRightJustify	Align text to the right side of the control.

SetAlignment

Text

Displaying and Editing Fields in an Edit Box

3.1.4.2.3 TButtonedEdit.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Align

3.1.4.2.4 TButtonedEdit.AutoSelect Property

Determines whether all the text in the edit control is automatically selected when the control gets focus.

Pascal

```
property AutoSelect;
```

C++

```
__property AutoSelect;
```

Description

Set AutoSelect to select all the text when the edit control gets focus. AutoSelect only applies to single-line edit controls.

Use AutoSelect when the user is more likely to replace the text in the edit control than to append to it.

SetSelTextBuf

3.1.4.2.5 TButtonedEdit.AutoSize Property

Determines whether the height of the edit control automatically resizes to accommodate the text.

Pascal

```
property AutoSize;
```

C++

```
__property AutoSize;
```

Description

Use AutoSize to make the edit control adjust its size automatically so the client area accommodates the height of the text. When AutoSize is false, the edit control has a fixed height. When AutoSize is true, the size of the control is readjusted whenever a change occurs that could affect the height of the control, such as a change to the font or border style.

Note: AutoSize only adjusts the height of the edit control. Even with AutoSize set to true, text in the edit control may appear truncated if it extends beyond the width of the control.

C++ Examples:

```
/*
This example uses an edit box and a button on a form. When
the user clicks the button, the font in the edit box
enlarges, and the edit box enlarges also to accommodate the
larger font size.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Edit1->AutoSize = true;
  Edit1->Font->Size = 20;
  Edit1->Text = "The edit box is taller now";
}
```

Delphi Examples:

```
{
{
This example uses an edit box and a button on a form. When
the user clicks the button, the font in the edit box
enlarges, and the edit box enlarges also to accommodate the
larger font size.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Edit1.AutoSize := True;
  Edit1.Font.Size := 20;
  Edit1.Text := 'The edit box is taller now';
end;
```

3.1.4.2.6 TButtonedEdit.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges;
```

C++

```
__property BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner

BevelOuter

BevelKind

3.1.4.2.7 TButtonedEdit.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner;
```

C++

```
__property BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges

BevelOuter

BevelKind

BevelWidth

BorderWidth

3.1.4.2.8 TButtonedEdit.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind;
```

C++

```
__property BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

BevelEdges

BevelOuter

BevelInner

BevelWidth

3.1.4.2.9 TButtonedEdit.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter;
```

C++

```
__property BevelOuter;
```

Description

Use BevelOuter to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges

BevelInner

BevelKind

BevelWidth

3.1.4.2.10 TButtonedEdit.BevelWidth Property

Specifies the width of the inner and outer bevels.

Pascal

```
property BevelWidth;
```

C++

```
__property BevelWidth;
```

Description

Use BevelWidth to specify the width, in pixels, of the inner and outer bevels.

See Also

BevelEdges

BevelInner

BevelKind

BevelOuter

3.1.4.2.11 TButtonedEdit.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

Including Bi-directional Functionality in Applications

3.1.4.2.12 TButtonedEdit.BorderStyle Property

Determines whether the edit control has a single line border around the client area.

Pascal

```
property BorderStyle;
```

C++

```
__property BorderStyle;
```

Description

Use BorderStyle to affect the sharpness with which the client area of the edit control stands out. BorderStyle can have a value of either bsSingle or bsNone. If BorderStyle is bsSingle, the edit control has a single-line border around the client area. If

BorderStyle is bsNone, there will be no border.

3.1.4.2.13 TButtonedEdit.CharCase Property

Determines the case of the text within the edit control.

Pascal

```
property CharCase;
```

C++

```
__property CharCase;
```

Description

Use CharCase to force the contents of the edit control to assume a particular case.

When CharCase is set to ecLowerCase or ecUpperCase, the case of characters is converted as the user types them into the edit control. Changing the CharCase property to ecLowerCase or ecUpperCase changes the actual contents of the text, not just the appearance. Any case information is lost and can't be recaptured by changing CharCase to ecNormal.

Text

3.1.4.2.14 TButtonedEdit.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
```

```
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor

3.1.4.2.15 TButtonedEdit.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

3.1.4.2.16 TButtonedEdit.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

BorderWidth

3.1.4.2.17 TButtonedEdit.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
```

```

DragMode

3.1.4.2.20 TButtonedEdit.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;

3.1.4.2.21 TButtonedEdit.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

3.1.4.2.22 TButtonedEdit.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var

3.1.4.2.23 TButtonedEdit.HideSelection Property

Determines whether the visual indication of the selected text remains when focus shifts to another control.

Pascal

```
property HideSelection;
```

C++

```
__property HideSelection;
```

Description

Set HideSelection to false to provide visual feedback of the selected portion of the text even when the edit control does not have focus. Set HideSelection to true to show the selection only when the edit control has focus. HideSelection does not affect the actual value of the selection, only the visual indication. Always setting HideSelection to false can make forms with many edit controls look too busy.

Lists the images that can appear on the control's embedded buttons.

Pascal

```
property Images: TImageList;
```

C++

```
__property TImageList Images;
```

Description

Images contains a list of images that can appear on the control's embedded buttons. If Images is unassigned, no images are displayed on the buttons.

Images in the list should be 16x16.

C++ Examples:

```
/*
This example shows how to use the TButtonedEdit class. This example
implements a component like "TButtonedEdit search" that's to be
found in the tool pallete window.
Entering the control will enable the right button, left button will
display a MessageDlg and the right button will clear the input text.
*/

3.1.4.2.25 TButtonedEdit.ImeMode Property

Determines the behavior of the input method editor (IME).

Pascal

```
property ImeMode;
```

C++

```
__property ImeMode;
```

Description

Set ImeMode to configure the way an IME processes user keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeMode allows a control to influence the type of conversion performed by the IME so that it is appropriate for the input expected by the control. For example, a control that only accepts numeric input might specify an ImeMode of imClose, as no conversion is necessary for numeric input.

Note: The value of ImeMode only takes effect when the control receives focus. To change the value of ImeMode when the control already has input focus, call the SetIme method.

3.1.4.2.26 TButtonedEdit.ImeName Property

Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

Pascal

```
property ImeName;
```

C++

```
__property ImeName;
```

Description

Set ImeName to specify which IME to use for converting keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeName must specify one of the IMEs that has been installed through the Windows control panel. The property inspector provides a drop-down list of all currently installed IMEs on the system. At runtime, applications can obtain a list of currently installed IMEs from the global Screen variable.

If ImeName specifies an unavailable IME, the IME that was active when the application started is used instead. No exception is generated.

Note: The value of ImeName only takes effect when the control receives focus. To change the value of ImeName after the control has input focus, call the SetIme method.

3.1.4.2.27 TButtonedEdit.LeftButton Property

Specifies the control that implements the left embedded button.

Pascal

```
property LeftButton: TEditButton;
```

C++

```
__property TEditButton LeftButton;
```

Description

Use LeftButton to work with the left button embedded in this edit control. Use this button's properties to specify images to correspond to the various states of the button, to disable the button, to toggle it's visiblity and to add a dropdown menu. At design time, expand the LeftButton property in the Object Inspector to set its properties.

C++ Examples:

```
/*
This example shows how to use the TButtonedEdit class. This example
implements a component like "TButtonedEdit search" that's to be
found in the tool pallete window.
Entering the control will enable the right button, left button will
display a MessageDlg and the right button will clear the input text.
*/
__fastcall TForm4::TForm4(TComponent* Owner)
    : TForm(Owner)
{
    //declaring an instance
    btnEdit = new TButtonedEdit(this);

    //setting the parent so it will autodetele
    btnEdit->Parent = this;

    //positioning
    btnEdit->Left = 10;
    btnEdit->Top = 10;

    //creating a TImageList and using it for the button
    TImageList* imList = new TImageList(this);
    Graphics::TBitmap* bmap = new Graphics::TBitmap();
    bmap->LoadFromFile("..\\littleB_16.bmp");
    imList->Add(bmap,NULL);
    bmap->LoadFromFile("..\\little_logo_16.bmp");
    imList->Add(bmap,NULL);
    btnEdit->Images = imList;

    //selecting the image for the left button and enabling it
    btnEdit->LeftButton->Visible = true;
    btnEdit->LeftButton->Enabled = true;
    btnEdit->LeftButton->ImageIndex = 0;
    btnEdit->LeftButton->DisabledImageIndex = 0;
    btnEdit->LeftButton->HotImageIndex = 0;

    //selecting the image for the right button
    //this will be enabled when the content changes
    btnEdit->RightButton->Enabled = true;
    btnEdit->RightButton->ImageIndex = 1;
    btnEdit->RightButton->DisabledImageIndex = 1;
    btnEdit->RightButton->HotImageIndex = 1;

    //selecting action for the buttoned edit to take
    btnEdit->OnEnter = btnEditEnter;
    btnEdit->OnRightButtonClick = btnEditRightClick;
    btnEdit->OnLeftButtonClick = btnEditLeftClick;

    //default text in the edit
    btnEdit->Text = "Default";

    btnEdit->Constraints->MinHeight = 16;
    btnEdit->Height = 16;

    //finally displaying the button
    btnEdit->Show();
```

```
}
//---------------------------------------------------------------------------

void __fastcall TForm4::btnEditEnter(TObject* Sender){
   btnEdit->Text = "";
   btnEdit->RightButton->Visible = true;
}

void __fastcall TForm4::btnEditRightClick(TObject* Sender){
   //resetting to default state

3.1.4.2.28 TButtonedEdit.MaxLength Property

Specifies the maximum number of characters the user can enter into the edit control.

Pascal

```
property MaxLength;
```

C++

```
__property MaxLength;
```

Description

Use MaxLength to limit the number of characters that can be entered into the edit control. A value of 0 indicates that there is no application-defined limit on the length.

Use MaxLength to limit the length of the text in an edit control if that text will be copied into a fixed-length buffer.

Note: Setting MaxLength will not truncate the existing text, it merely prevents the user from adding more text after reaching the limit of MaxLength characters.

Note: Even when MaxLength is 0, there may be limitations imposed by the operating system on the number of characters that may be entered into an edit control.

Note: The unit of MaxLength is characters (not bytes) if the application is using themes.

3.1.4.2.29 TButtonedEdit.NumbersOnly Property

Allows only numbers to be typed into the text edit.

Pascal

```
property NumbersOnly;
```

C++

```
__property NumbersOnly;
```

Description

Use NumbersOnly to prohibit entry of non-numeric characters in the textfield. Note, however, that a user can paste non-numeric characters in the textfield even when this property is set.

3.1.4.2.30 TButtonedEdit.OEMConvert Property

Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.

Pascal

```
property OEMConvert;
```

C++

```
__property OEMConvert;
```

Description

To ensure that any characters typed in the edit control can be unambiguously converted to the OEM character set, set OEMConvert to true. This causes all characters to be converted from ANSI to OEM and then back to ANSI as they are typed. Set OEMConvert to false to avoid the overhead of this conversion when it does not matter whether the text can be unambiguously mapped to an OEM string.

OEMConvert is most useful for edit controls used to enter file names when the application does not use Unicode file names.

Text

3.1.4.2.31 TButtonedEdit.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent

BiDiMode

3.1.4.2.32 TButtonedEdit.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

3.1.4.2.33 TButtonedEdit.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

3.1.4.2.34 TButtonedEdit.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

3.1.4.2.35 TButtonedEdit.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own

Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

Parent

ParentColor

ParentShowHint

3.1.4.2.36 TButtonedEdit.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

3.1.4.2.37 TButtonedEdit.PasswordChar Property

Indicates the character, if any, to display in place of the actual characters typed in the control.

Pascal

```
property PasswordChar;
```

C++

```
__property PasswordChar;
```

Description

Use the PasswordChar property to create an edit control that displays a special character in place of any entered text. If PasswordChar is set to the null character (ANSI character zero), the edit control displays its text normally. If PasswordChar is any other character, the edit control displays PasswordChar in place of each character typed. PasswordChar affects the appearance of the edit control only. The value of the Text property reflects the actual characters that are typed.

Text

3.1.4.2.38 TButtonedEdit.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
```

```
}

3.1.4.2.39 TButtonedEdit.ReadOnly Property

Determines whether the user can change the text of the edit control.

Pascal

```
property ReadOnly;
```

C++

```
__property ReadOnly;
```

Description

To restrict the edit control to display only, set the ReadOnly property to true. Set ReadOnly to false to allow the contents of the edit control to be edited.

Setting ReadOnly to true ensures that the text is not altered, while still allowing the user to select text. The selected text can then be manipulated by the application, or copied to the Clipboard.

GetSelTextBuf

3.1.4.2.40 TButtonedEdit.RightButton Property

Specifies the control that implements the right embedded button.

Pascal

```
property RightButton: TEditButton;
```

C++

```
__property TEditButton RightButton;
```

Description

Use RightButton to work with the right button embedded in this edit control. Use this button's properties to specify images to correspond to the various states of the button, to disable the button, to toggle it's visiblity and to add a dropdown menu. At design time, expand the RightButton property in the Object Inspector to set its properties.

C++ Examples:

```
/*
This example shows how to use the TButtonedEdit class. This example
implements a component like "TButtonedEdit search" that's to be
found in the tool pallete window.
Entering the control will enable the right button, left button will
display a MessageDlg and the right button will clear the input text.
*/
```

3.1.4.2.41 TButtonedEdit.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine

whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
```

```
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

Displaying Fly-over Help

3.1.4.2.42 TButtonedEdit.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

3.1.4.2.43 TButtonedEdit.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

3.1.4.2.44 TButtonedEdit.Text Property

Contains a text string associated with the control.

Pascal

```
property Text;
```

C++

```
__property Text;
```

Description

Use the Text property to read the Text of the control or specify a new string for the Text value. By default, Text is the control name. For edit controls and memos, the Text appears within the control. For combo boxes, the Text is the content of the edit control portion of the combo box.

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
*/
#include <memory>       //for STL auto_ptr class

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int Size = Edit1->GetTextLen(); //Get length of string in Edit1
  Size++;                         //Add room for null character
//  Char *Buffer = new Char[Size];  //Creates Buffer dynamic variable
  std::auto_ptr<Char> Buffer(new Char[Size]);
  Edit1->GetTextBuf(Buffer.get(),Size); //Puts Edit1->Text into Buffer
  Edit2->Text = Buffer.get();
}
/*
Note: the same thing could be accomplished more simply as follows:
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Edit2->Text = Edit1->Text;
}
```

Delphi Examples:

```
{
This example requires two edit boxes and a button.  This example
copies the text in an edit box into a null-terminated string, and
puts this string in another edit box when the user clicks the
button on the form.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Buffer: PChar;
  Size: Byte;
begin
  Size := Edit1.GetTextLen;       {Get length of string in Edit1}
  Inc(Size);                      {Add room for null character}
  GetMem(Buffer, Size);           {Creates Buffer dynamic variable}
  Edit1.GetTextBuf(Buffer,Size);  {Puts Edit1.Text into Buffer}
  Edit2.Text := StrPas(Buffer);   {Converts Buffer to a Pascal-style string}
  FreeMem(Buffer, Size);{Frees memory allocated to Buffer}
end;

{
Note: the same thing could be accomplished more simply as follows:
}
procedure TForm1.Button2Click(Sender: TObject);
begin
  Edit2.Text := Edit1.Text;
end;
```

Caption

Lines

3.1.4.2.45 TButtonedEdit.TextHint Property

A hint or message to be displayed when the Text property is empty.

Pascal

```
property TextHint;
```

C++

```
__property TextHint;
```

Description

Use TextHint to cue the user on what kind of entry is expected in the text field. Runtime themes must be enabled.

3.1.4.2.46 TButtonedEdit.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

3.1.4.3 TButtonedEdit Events

The events of the TButtonedEdit class are listed here.

Published Events

	Name	Description
	OnChange (see page 270)	Occurs when the text for the edit control may have changed.
	OnClick (see page 271)	Occurs when the user clicks the control.
	OnContextPopup (see page 273)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 273)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 274)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 277)	Occurs when the user drags an object over a control.
	OnEndDock (see page 280)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 280)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 281)	Occurs when a control receives the input focus.
	OnExit (see page 284)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 287)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 290)	Occurs when a key is pressed.
	OnKeyUp (see page 291)	Occurs when the user releases a key that has been pressed.
	OnLeftButtonClick (see page 293)	Occurs when the user clicks the LeftButton.
	OnMouseActivate (see page 296)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 297)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 299)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 300)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 300)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 302)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnRightButtonClick (see page 304)	Occurs when the user clicks the RightButton.
	OnStartDock (see page 307)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 308)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

3.1.4.3.1 TButtonedEdit.OnChange Event

Occurs when the text for the edit control may have changed.

Pascal

```
property OnChange;
```

C++

```
__property OnChange;
```

Description

Write an OnChange event handler to take specific action whenever the text for the edit control may have changed. Use the Modified property to see if a change actually occurred. The Text property of the edit control will already be updated to reflect any changes. This event provides the first opportunity to respond to modifications that the user types into the edit control.

See Also

Change

Text

3.1.4.3.2 TButtonedEdit.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
```

```
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}

3.1.4.3.3 TButtonedEdit.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

3.1.4.3.4 TButtonedEdit.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

OnClick

Responding to User Actions at Runtime

3.1.4.3.5 TButtonedEdit.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/
```

```
// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*

3.1.4.3.6 TButtonedEdit.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
```

```
  control was successfully dropped into and accepted by a
  another control.
  */
  void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
       int Y)
  {
    if (Sender->ClassNameIs("TLabel"))
    {
      AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
      if (Target)
        S = S + "accepted!";
      else
        S = S + "rejected.";
      Status->Caption = S;
    }
  }
```

Delphi Examples:

```
  {
  This code displays a message in a label named Status. The
  message displayed depends on whether the dragged label
  control was successfully dropped into and accepted by a
  another control.
  }
  procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
  var
    S: string;
  begin
    S := (Sender as TLabel).Name + ' was dropped... and ';
    if Target <> nil then
      S := S + 'accepted!'

3.1.4.3.9 TButtonedEdit.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter

event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)

3.1.4.3.10 TButtonedEdit.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
```

```
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

procedure TForm1.MaskEdit2Exit(Sender: TObject);
var
  net1, net2, host1, host2,
  netmask1, netmask2, hostmask1, hostmask2,
  sub_net1, sub_net2, sub_host1, sub_host2: Integer;

  IP, mask: String;

begin
  // extract the net and host address from the IP
  IP := MaskEdit1.Text;
  net1 := StrToInt(TrimRight(Copy(IP, 0, 3)));
  net2 := StrToInt(TrimRight(Copy(IP, 5, 3)));
  host1 := StrToInt(TrimRight(Copy(IP, 9, 3)));
  host2 := StrToInt(TrimRight(Copy(IP, 13, 3)));
```

```
    // a range test that you cannot validate through edit masks
    if ((net1 < 0) Or (net1 > 255) Or
        (net2 < 0) Or (net2 > 255) Or
        (host1 < 0) Or (host1 > 255) Or
        (host2 < 0) Or (host2 > 255)) then
      raise EArgumentException.Create('Not a valid IP address.');

    // extract the net and host mask from the subnet mask
    mask := MaskEdit2.Text;
    netmask1 := StrToInt(TrimRight(Copy(mask, 0, 3)));
    netmask2 := StrToInt(TrimRight(Copy(mask, 5, 3)));
    hostmask1 := StrToInt(TrimRight(Copy(mask, 9, 3)));
    hostmask2 := StrToInt(TrimRight(Copy(mask, 13, 3)));

    // a range test that you cannot validate through edit masks
    if ((netmask1 < 0) Or (netmask1 > 255) Or
        (netmask2 < 0) Or (netmask2 > 255) Or
        (hostmask1 < 0) Or (hostmask1 > 255) Or
        (hostmask2 < 0) Or (hostmask2 > 255)) then
      raise EArgumentException.Create('Not a valid subnet mask.');

    // compute the subnet address using bit-wise AND
    sub_net1 := net1 And netmask1;
    sub_net2 := net2 And netmask2;
    sub_host1 := host1 And hostmask1;
    sub_host2 := host2 And hostmask2;

    // display the subnet address
    MaskEdit3.Text :=
      IntToStr(sub_net1) + '.' + IntToStr(sub_net2) + '.' +
      IntToStr(sub_host1) + '.' + IntToStr(sub_host2);
  end;
  {
  This example uses an edit box and a memo control on a form.
  When either the edit box or the memo is the active control,
  it is colored yellow. When the active control becomes
  inactive, the color of the control returns to the Windows
  system color for a window.  These event handlers could also
  be shared.
  }
  procedure TForm1.Edit1Enter(Sender: TObject);
  begin
    Edit1.Color := clYellow;
  end;

  procedure TForm1.Edit1Exit(Sender: TObject);
  begin
    Edit1.Color := clWindow;
  end;

  procedure TForm1.Memo1Enter(Sender: TObject);
  begin
    Memo1.Color := clYellow;
  end;

  procedure TForm1.Memo1Exit(Sender: TObject);
  begin
    Memo1.Color := clWindow;
  end;

3.1.4.3.11 TButtonedEdit.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown;
```

C++

```
__property OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/

OnKeyPress

OnKeyUp

3.1.4.3.12 TButtonedEdit.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress;
```

C++

```
__property OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys

that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;

TEditButton (see page 835)

3.1.4.3.15 TButtonedEdit.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of

whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

MouseCapture

3.1.4.3.16 TButtonedEdit.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its

3.1.4.3.17 TButtonedEdit.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

3.1.4.3.18 TButtonedEdit.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

3.1.4.3.19 TButtonedEdit.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

MouseCapture

3.1.4.3.20 TButtonedEdit.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp;
```

C++

```
__property OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

3.1.4.3.22 TButtonedEdit.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDockDrop

3.1.4.3.23 TButtonedEdit.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

ExtCtrls

Description

TCategoryPanel is used to hold the set of display control legends for a particular display category.

See Also

TCategoryPanelGroup (see page 379)

3.1.5.1 TCategoryPanel Members

The following tables list the members exposed by TCategoryPanel.

Enumerations

	Name	Description
	THeaderState (see page 701)	THeaderState is the type of the HeaderState (see page 717) property for a category panel.

Protected Fields

	Name	Description
	FPanelSurface (see page 702)	This is FPanelSurface, a member of class TCustomCategoryPanel.

Protected Methods

	Name	Description
	AdjustClientRect (see page 804)	Adjusts the ClientRect property for the idiosyncrasies of the window.
	CalcRectBounds (see page 703)	Sets the rectangles used to display the text and glyphs of the category panel.
	CanAutoSize (see page 804)	Adjusts the way the panel responds to resize attempts.
	CreateParams (see page 805)	Initializes a window-creation parameter record passed in the Params parameter.

	DefineProperties (see page 703)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DrawCollapsedPanel (see page 704)	Displays the category panel in the collapsed state.
	DrawHeader (see page 704)	This is the overview for the DrawHeader method overload.
	DrawHeaderBackground (see page 705)	This is DrawHeaderBackground, a member of class TCustomCategoryPanel.
	DrawHeaderCaption (see page 705)	This is DrawHeaderCaption, a member of class TCustomCategoryPanel.
	DrawHeaderChevron (see page 705)	This is DrawHeaderChevron, a member of class TCustomCategoryPanel.
	GetCollapsedHeight (see page 706)	This is GetCollapsedHeight, a member of class TCustomCategoryPanel.
	Loaded (see page 707)	Initializes the control after it is loaded from a stream.
	Paint (see page 806)	Renders the image of the panel.
	ReadState (see page 707)	Prepares the control for having its properties assigned values from a stream.
	ResizeHeader (see page 708)	This is ResizeHeader, a member of class TCustomCategoryPanel.
	SetParent (see page 708)	Sets the parent of the control.
	SetParentBackground (see page 806)	This is SetParentBackground, a member of class TCustomPanel.
	UpdateControlOriginalParentSize (see page 709)	This is UpdateControlOriginalParentSize, a member of class TCustomCategoryPanel.
	UpdateHeader (see page 709)	This is UpdateHeader, a member of class TCustomCategoryPanel.
	WndProc (see page 709)	Provides specific message responses for the control.

Protected Properties

	Name	Description
	Alignment (see page 807)	Determines how the caption is aligned within the panel.
	BevelInner (see page 807)	Determines the style of the inner bevel of a panel.
	BevelOuter (see page 808)	Determines the style of the outer bevel of a panel.
	BevelWidth (see page 809)	Determines the width, in pixels, of both the inner and outer bevels of a panel.
	BorderStyle (see page 810)	Determines the style of the line drawn around the perimeter of the panel control.
	BorderWidth (see page 811)	Specifies the distance, in pixels, between the outer and inner bevels.
	HeaderHeight (see page 717)	Retrieves the HeaderHeight property associated with the parent TCustomCategoryPanelGroup (see page 718) HeaderHeight.
	ShowCaption (see page 814)	This is ShowCaption, a member of class TCustomPanel.
	VerticalAlignment (see page 814)	Sets the vertical position of the caption.

Public Methods

	Name	Description
	Collapse (see page 703)	Collapses the category panel.
	Create (see page 700)	Creates and initializes an instance of TCustomPanel.
	Create (see page 803)	Creates and initializes an instance of TCustomPanel (see page 802).
	Destroy (see page 700)	Destroys an instance of TCustomControl.
	Expand (see page 705)	Expands the category panel.
	GetChildren (see page 706)	Calls a specified procedure for every control in the category panel.
	GetControlsAlignment (see page 805)	Returns the alignment of text in the panel.
	GetTabOrderList (see page 706)	Builds a list of controls in tab order.
	SetBounds (see page 708)	Changes the position and size of the category panel in a single operation.

Public Properties

	Name	Description
	HeaderState (see page 717)	Shows the state of the header of category panel.
	PanelGroup (see page 717)	Indentifies the parent category panel group of the category panel.

Published Events

	Name	Description
	OnClick (see page 344)	Occurs when the user clicks the control.
	OnCollapse (see page 346)	Occurs immediately after a category panel is collapsed.
	OnContextPopup (see page 346)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

	OnDblClick (see page 347)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 347)	Occurs when another control is docked to the control.
	OnDockOver (see page 349)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 352)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 355)	Occurs when the user drags an object over a control.
	OnEndDock (see page 358)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 358)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 359)	Occurs when a control receives the input focus.
	OnExit (see page 362)	Occurs when the input focus shifts away from one control to another.
	OnExpand (see page 364)	Occurs immediately after a category panel is expanded.
	OnGetSiteInfo (see page 365)	Returns the control's docking information.
	OnMouseActivate (see page 367)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 368)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 370)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 370)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 371)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 373)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 375)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 376)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 376)	Occurs when the application tries to undock a control that is docked to the windowed control.

Published Properties

	Name	Description
	BiDiMode (see page 313)	Specifies the bi-directional mode for the control.
	Caption (see page 314)	Specifies a text string that identifies the control to the user.
	Collapsed (see page 316)	Specifies whether the category panel is collapsed.
	CollapsedHotImageIndex (see page 316)	Determines which image is displayed as the chevron when the category panel is collapsed and the mouse is hovering over the header.
	CollapsedImageIndex (see page 317)	Determines which image is displayed as the chevron when the category panel is collapsed and the mouse is not hovering over the header..
	CollapsedPressedImageIndex (see page 317)	Determines which image is displayed as the chevron when the category panel is collapsed and the left mouse button is pressed while the mouse hovers the header. .
	Color (see page 318)	Specifies the background color of the control.
	Ctl3D (see page 318)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DockSite (see page 319)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 320)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 322)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 322)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 322)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 324)	Controls whether the control responds to mouse, keyboard, and timer events.
	ExpandedHotImageIndex (see page 324)	Determines which image is displayed as the chevron when the category panel is expanded and the mouse is hovering over the header.
	ExpandedImageIndex (see page 325)	Determines which image is displayed as the chevron when the category panel is expanded and the mouse is not hovering over the header.
	ExpandedPressedImageIndex (see page 325)	Determines which image is displayed as the chevron when the category panel is collapsed and the left mouse button is pressed while the mouse hovers over the header.

	Font (see page 326)	Controls the attributes of text written on or in the control.
	FullRepaint (see page 327)	Determines how the panel repaints itself when it is resized.
	Height (see page 327)	Specifies the vertical size of the control in pixels.
	Left (see page 328)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Locked (see page 329)	Determines whether a panel that is used as a toolbar is replaced by a toolbar supplied by an OLE server.
	Padding (see page 329)	Specifies the padding of a control.
	ParentBackground (see page 330)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 330)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 330)	Determines where a control looks for its color information.
	ParentCtl3D (see page 331)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 331)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 332)	Determines where a control looks for its font information.
	ParentShowHint (see page 332)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 333)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 338)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 339)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 340)	Determines if the user can tab to a control.
	UseDockManager (see page 340)	Specifies whether the docking manager is used in drag-and-dock operations.
	Visible (see page 340)	Determines whether the component appears onscreen.
	Width (see page 342)	Specifies the horizontal size of the control or form in pixels.

3.1.5.2 TCategoryPanel Properties

The properties of the TCategoryPanel class are listed here.

Published Properties

	Name	Description
	BiDiMode (see page 313)	Specifies the bi-directional mode for the control.
	Caption (see page 314)	Specifies a text string that identifies the control to the user.
	Collapsed (see page 316)	Specifies whether the category panel is collapsed.
	CollapsedHotImageIndex (see page 316)	Determines which image is displayed as the chevron when the category panel is collapsed and the mouse is hovering over the header.
	CollapsedImageIndex (see page 317)	Determines which image is displayed as the chevron when the category panel is collapsed and the mouse is not hovering over the header..
	CollapsedPressedImageIndex (see page 317)	Determines which image is displayed as the chevron when the category panel is collapsed and the left mouse button is pressed while the mouse hovers the header. .
	Color (see page 318)	Specifies the background color of the control.
	Ctl3D (see page 318)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DockSite (see page 319)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 320)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 322)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 322)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 322)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 324)	Controls whether the control responds to mouse, keyboard, and timer events.
	ExpandedHotImageIndex (see page 324)	Determines which image is displayed as the chevron when the category panel is expanded and the mouse is hovering over the header.
	ExpandedImageIndex (see page 325)	Determines which image is displayed as the chevron when the category panel is expanded and the mouse is not hovering over the header.

	ExpandedPressedImageIndex (see page 325)	Determines which image is displayed as the chevron when the category panel is collapsed and the left mouse button is pressed while the mouse hovers over the header.
	Font (see page 326)	Controls the attributes of text written on or in the control.
	FullRepaint (see page 327)	Determines how the panel repaints itself when it is resized.
	Height (see page 327)	Specifies the vertical size of the control in pixels.
	Left (see page 328)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Locked (see page 329)	Determines whether a panel that is used as a toolbar is replaced by a toolbar supplied by an OLE server.
	Padding (see page 329)	Specifies the padding of a control.
	ParentBackground (see page 330)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 330)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 330)	Determines where a control looks for its color information.
	ParentCtl3D (see page 331)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 331)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 332)	Determines where a control looks for its font information.
	ParentShowHint (see page 332)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 333)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 338)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 339)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 340)	Determines if the user can tab to a control.
	UseDockManager (see page 340)	Specifies whether the docking manager is used in drag-and-dock operations.
	Visible (see page 340)	Determines whether the component appears onscreen.
	Width (see page 342)	Specifies the horizontal size of the control or form in pixels.

3.1.5.2.1 TCategoryPanel.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

UseRightToLeftAlignment

UseRightToLeftReading

UseRightToLeftScrollBar

Including Bi-directional Functionality in Applications

3.1.5.2.2 TCategoryPanel.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>
#include <memory>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
```

```
    TToolButton *button = new TToolButton(toolBar);  // The owner (toolBar) will clean this up.
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this); // The owner (this) will clean this up.
  myToolBar->Parent = this;
//  TStringList *captions = new TStringList();
  std::auto_ptr<TStringList> captions(new TStringList());

  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions.get());
//  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long to be the caption of this label';
end;
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
```

```
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
        Caption := ButtonCaptions[I];
        if (ButtonCaptions[I] = '|') then
          Style := tbsSeparator
        else
          Style := tbsButton;
      end;
    end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ToolBar1 := TToolBar.Create(Self);
  ToolBar1.Parent := Self;
  AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
  ToolBar1.ShowCaptions := True;
  ToolBar1.Height := 40;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  I: Integer;
begin
  for I := ToolBar1.ButtonCount - 1 downto 0 do
    ToolBar1.Buttons[I].Free;
  ToolBar1.Free;
end;
```

3.1.5.2.3 TCategoryPanel.Collapsed Property

Specifies whether the category panel is collapsed.

Pascal

```
property Collapsed: Boolean;
```

C++

```
__property Boolean Collapsed;
```

Description

Use Collapsed to determine if the category panel is in a collapsed state. It can also be used to cause the category panel to collapse or expand.

See Also

Collapse (see page 703)

Expand (see page 705)

3.1.5.2.4 TCategoryPanel.CollapsedHotImageIndex Property

Determines which image is displayed as the chevron when the category panel is collapsed and the mouse is hovering over the header.

Pascal

```
property CollapsedHotImageIndex: TImageIndex;
```

C++

```
__property TImageIndex CollapsedHotImageIndex;
```

Description

Set CollapsedHotImageIndex to associate the cheveron with one of the images in the Images property of the parent CategoryPanelGroup. The selected image will be displayed when the category panel is in the collapsed state while the mouse hovers over the header. This property has no effect if the HeaderStyle property of the parent panel group is set to hsThemed.

See Also

HeaderStyle (see page 734)

Images (see page 735)

3.1.5.2.5 TCategoryPanel.CollapsedImageIndex Property

Determines which image is displayed as the chevron when the category panel is collapsed and the mouse is not hovering over the header..

Pascal

```
property CollapsedImageIndex: TImageIndex;
```

C++

```
__property TImageIndex CollapsedImageIndex;
```

Description

Set CollapsedImageIndex to associate the cheveron with one of the images in the Images property of the parent CateogryPanelGroup. The selected image will be displayed when the category panel is in the collapsed state while the mouse is outside of the area of the header. This property has no effect if the HeaderStyle property of the parent panel group is set to hsThemed.

See Also

HeaderStyle (see page 734)

Images (see page 735)

3.1.5.2.6 TCategoryPanel.CollapsedPressedImageIndex Property

Determines which image is displayed as the chevron when the category panel is collapsed and the left mouse button is pressed while the mouse hovers the header. .

Pascal

```
property CollapsedPressedImageIndex: TImageIndex;
```

C++

```
__property TImageIndex CollapsedPressedImageIndex;
```

Description

Set CollapsedPressedImageIndex to associate the cheveron with one of the images in the Images property of the parent CateogryPanelGroup. The selected image will be displayed when the category panel is in the collapsed state while the left mouse button is pressed while the mouse hovers over the header. This property has no effect if the HeaderStyle property of the parent panel group is set to hsThemed.

See Also

HeaderStyle (see page 734)

Images (see page 735)

3.1.5.2.7 TCategoryPanel.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor

3.1.5.2.8 TCategoryPanel.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

ParentCtl3D

BevelKind

BevelInner

BevelOuter

BorderWidth

3.1.5.2.9 TCategoryPanel.DockSite Property

Specifies whether the control can be the target of drag-and-dock operations.

Pascal

```
property DockSite;
```

C++

```
__property DockSite;
```

Description

Set DockSite to true to allow other controls to be docked to this windowed control.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/
void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
      TWinControl *NewTarget, bool &Allow)
{
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if (Client->ClassNameIs("TDockableForm"))
    dynamic_cast<TDockableForm *>(Client)->DockSite = True;
  if ((DockClientCount == 2) && (NewTarget != this))        // Self?
    PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
}
procedure TConjoinDockHost.FormUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if Client is TDockableForm then
    TDockableForm(Client).DockSite := True;
  if (DockClientCount = 2) and (NewTarget <> Self) then
    PostMessage(Self.Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
end;
```

3.1.5.2.10 TCategoryPanel.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
```

```
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
```

```
    end;
  end;

3.1.5.2.11 TCategoryPanel.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

3.1.5.2.12 TCategoryPanel.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

3.1.5.2.13 TCategoryPanel.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
```

```
      else if htNowhere in HT then AttachMode := naAdd
      else if htOnIndent in HT then AttachMode := naInsert;
      TreeView1.Selected.MoveTo(AnItem, AttachMode);
    end;
  end;

  procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;

3.1.5.2.14 TCategoryPanel.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

3.1.5.2.15 TCategoryPanel.ExpandedHotImageIndex Property

Determines which image is displayed as the chevron when the category panel is expanded and the mouse is hovering over the header.

Pascal

```
property ExpandedHotImageIndex: TImageIndex;
```

C++

```
__property TImageIndex ExpandedHotImageIndex;
```

Description

Set ExpandedHotImageIndex to associate the cheveron with one of the images in the Images property of the parent CategoryPanelGroup. The selected image will be displayed when the category panel is in the expanded state while the mouse hovers over the header. This property has no effect if the HeaderStyle property of the parent panel group is set to hsThemed.

See Also

HeaderStyle (see page 734)

Images (see page 735)

3.1.5.2.16 TCategoryPanel.ExpandedImageIndex Property

Determines which image is displayed as the chevron when the category panel is expanded and the mouse is not hovering over the header.

Pascal

```
property ExpandedImageIndex: TImageIndex;
```

C++

```
__property TImageIndex ExpandedImageIndex;
```

Description

Set ExpandedImageIndex to associate the cheveron with one of the images in the Images property of the parent CateogryPanelGroup. The selected image will be displayed when the category panel is in the expanded state while the mouse is outside of the area of the header.

See Also

HeaderStyle (see page 734)

Images (see page 735)

3.1.5.2.17 TCategoryPanel.ExpandedPressedImageIndex Property

Determines which image is displayed as the chevron when the category panel is collapsed and the left mouse button is pressed while the mouse hovers over the header.

Pascal

```
property ExpandedPressedImageIndex: TImageIndex;
```

C++

```
__property TImageIndex ExpandedPressedImageIndex;
```

Description

Set CollapsedPressedImageIndex to associate the chevron with one of the images in the Images property of the parent CateogryPanelGroup. The selected image will be displayed when the category panel is in the collapsed state and the left mouse button is pressed while the mouse hovers over the header.

This property has no effect if the HeaderStyle property of the parent panel group is set to hsThemed.

See Also

HeaderStyle (see page 734)

3.1.5.2.18 TCategoryPanel.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
```

```
end;

3.1.5.2.19 TCategoryPanel.FullRepaint Property

Determines how the panel repaints itself when it is resized.

Pascal

```
property FullRepaint: Boolean;
```

C++

```
__property Boolean FullRepaint;
```

Description

FullRepaint controls how the panel responds when it is resized. When FullRepaint is true, the entire panel, including the beveled border repaints when the size changes. When FullRepaint is false, only the area inside the beveled border repaints.

See Also

Invalidate

3.1.5.2.20 TCategoryPanel.Height Property

Specifies the vertical size of the control in pixels.

Pascal

```
property Height;
```

C++

```
__property Height;
```

Description

Use the Height property to read or change the height of the control.

C++ Examples:

```
/*
This example needs only a blank form.  Three Rich Edit
controls are placed vertically on the form, each contain a
line of text, and the second form has HideSelection set to
false.  Try tabbing between the three Rich Edit controls and
observe the effect on the selected text.
*/
#include <ComCtrls.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int I = 0; I <= 2; I++)
  {
    TRichEdit *pRich = new TRichEdit(this);
    pRich->Parent = this;
    pRich->Top = pRich->Height * I;
    pRich->Text = "This text will take the focus.";
    pRich->SelStart = 0;
```

```
    pRich->SelLength = pRich->Text.Length();
    if (I == 1)
      pRich->HideSelection = false;
  }
}
```

Delphi Examples:

```
{
This example needs only a blank form. Three Rich Edit
controls are placed vertically on the form, each contain a
line of text, and the second form has HideSelection set to
false.  Try tabbing between the three Rich Edit controls and
observe the effect on the selected text.
}
uses ComCtrls;

procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  for I := 0 to 2 do
    with TRichEdit.Create(Self) do
    begin
      Parent := Self;
      Top := Height * I;
      Text := 'This text will take the focus.';
      SelStart := 0;
      SelLength := Length(Text);
      if (I = 1) then
        HideSelection := False;
    end;
end;
```

3.1.5.2.21 TCategoryPanel.Left Property

Specifies the horizontal coordinate of the left edge of a component relative to its parent.

Pascal

```
property Left;
```

C++

```
__property Left;
```

Description

Use the Left property to determine where the left side of the control begins or to reposition the left side of the control.

If the control is contained in another control, the Left and Top properties are relative to the parent control. If the control is contained directly by the form, the property values are relative to the form. For forms, the value of the Left property is relative to the screen in pixels.

C++ Examples:

```
/*
Place a TTimer object in the form and enter Timer1Timer in
the OnTimer event.  Place other controls in the form and
```

```
change the active control at runtime.  The following event
handler responds to timer events by moving the active control
one pixel to the right every 100 miliseconds:
*/
void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  Timer1->Interval = 100;
  if (ActiveControl)
    ActiveControl->Left = ActiveControl->Left + 1;
}
```

Delphi Examples:

```
{
Place a TTimer object in the form and enter Timer1Timer in
the OnTimer event.  Place other controls in the form and
change the active control at runtime.  The following event
handler responds to timer events by moving the active control
one pixel to the right every 100 miliseconds:
}
procedure TForm1.Timer1Timer(Sender: TObject);
begin
  Timer1.Interval := 100;
  if ActiveControl <> nil then
    ActiveControl.Left := ActiveControl.Left + 1;
end;
```

3.1.5.2.22 TCategoryPanel.Locked Property

Determines whether a panel that is used as a toolbar is replaced by a toolbar supplied by an OLE server.

Pascal

```
property Locked: Boolean;
```

C++

```
__property Boolean Locked;
```

Description

Set the Locked property to false when the panel is used as a toolbar by a TOleContainer component. Any panels aligned to a TOleContainer are assumed to be replaceable toolbars unless the Locked property is true. Prevent the panel from being replaced by an OLE server's toolbar by setting the panel's Locked property to true.

Note: An OLE application's toolbars must be in panels aligned to a side of the form (that is, their Align properties must be set to alTop, alBottom, alLeft, or alRight).

See Also

Align

TOleContainer (see page 5969)

3.1.5.2.23 TCategoryPanel.Padding Property

Specifies the padding of a control.

Pascal

```
property Padding;
```

C++

```
__property Padding;
```

Description

Use Padding to specify the padding of a control. This value is an instance of the class TPadding.

See Also

TPadding

3.1.5.2.24 TCategoryPanel.ParentBackground Property

Determines whether control uses parent's theme background.

Pascal

```
property ParentBackground;
```

C++

```
__property ParentBackground;
```

Description

If ParentBackground is true, the control uses the parent's theme background to draw its own background. ParentBackground has no effect unless XP themes are enabled.

3.1.5.2.25 TCategoryPanel.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent

BiDiMode

3.1.5.2.26 TCategoryPanel.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

3.1.5.2.27 TCategoryPanel.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

3.1.5.2.28 TCategoryPanel.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

3.1.5.2.29 TCategoryPanel.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

Parent

ParentColor

ParentShowHint

3.1.5.2.30 TCategoryPanel.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

3.1.5.2.31 TCategoryPanel.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
```

```
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
```

```
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
```

```
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

3.1.5.2.32 TCategoryPanel.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
```

```
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

3.1.5.2.33 TCategoryPanel.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

FindNextControl

TabStop

3.1.5.2.34 TCategoryPanel.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

TabOrder

3.1.5.2.35 TCategoryPanel.UseDockManager Property

Specifies whether the docking manager is used in drag-and-dock operations.

Pascal

```
property UseDockManager;
```

C++

```
__property UseDockManager;
```

Description

Use UseDockManager to get or set whether a docking manager is used in drag-and-dock operations.

The docking manager handles the positioning of docked controls and any painting of docking zones around those controls. If you do not use a docking manager, docked controls are aligned to the windowed control based on the closest edge to where they are released. When you do not use a docking manager, there is no region for a user to grab to automatically undock a docked control.

See Also

DockManager

3.1.5.2.36 TCategoryPanel.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
```

```
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.ActivePage.ClientWidth - Width);
        Left := Random(PageControl1.ActivePage.ClientHeight - Height);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

3.1.5.2.37 TCategoryPanel.Width Property

Specifies the horizontal size of the control or form in pixels.

Pascal

```
property Width;
```

C++

```
__property Width;
```

Description

Use the Width property to read or change the width of the control.

Note: For tab sheet controls, changing this property at runtime has no effect.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);
```

```
  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses

3.1.5.3 TCategoryPanel Events

The events of the TCategoryPanel class are listed here.

Published Events

	Name	Description
	OnClick (see page 344)	Occurs when the user clicks the control.
	OnCollapse (see page 346)	Occurs immediately after a category panel is collapsed.
	OnContextPopup (see page 346)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 347)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 347)	Occurs when another control is docked to the control.
	OnDockOver (see page 349)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 352)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 355)	Occurs when the user drags an object over a control.
	OnEndDock (see page 358)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 358)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 359)	Occurs when a control receives the input focus.
	OnExit (see page 362)	Occurs when the input focus shifts away from one control to another.
	OnExpand (see page 364)	Occurs immediately after a category panel is expanded.
	OnGetSiteInfo (see page 365)	Returns the control's docking information.
	OnMouseActivate (see page 367)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 368)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 370)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 370)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 371)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 373)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 375)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 376)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 376)	Occurs when the application tries to undock a control that is docked to the windowed control.

3.1.5.3.1 TCategoryPanel.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This

event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;
```

```
procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

3.1.5.3.2 TCategoryPanel.OnCollapse Event

Occurs immediately after a category panel is collapsed.

Pascal

```
property OnCollapse: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnCollapse;
```

Description

Write an OnCollapse event handler to perform special processing when a category panel is collapsed.

See Also

OnExpand (see page 718)

3.1.5.3.3 TCategoryPanel.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

3.1.5.3.4 TCategoryPanel.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

OnClick

Responding to User Actions at Runtime

3.1.5.3.5 TCategoryPanel.OnDockDrop Event

Occurs when another control is docked to the control.

Pascal

```
property OnDockDrop;
```

C++

```
__property OnDockDrop;
```

Description

Write code in the OnDockDrop event to perform actions when another control is docked on the control.

OnDockDrop can only occur if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
```

```
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;
```

OnDockOver

3.1.5.3.6 TCategoryPanel.OnDockOver Event

Occurs when another control is dragged over the control.

Pascal

```
property OnDockOver;
```

C++

```
__property OnDockOver;
```

Description

Write code in the OnDockOver event to indicate whether a dockable control that is dragged over the windowed control can be accepted as a dock client. OnDockOver occurs after the TDragDockObject has been initialized by an OnGetSiteInfo event.

OnDockOver occurs only if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
```

```
      ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;

TDragDockObject

3.1.5.3.7 TCategoryPanel.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
```

```
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.

TDragObject

3.1.5.3.8 TCategoryPanel.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

3.1.5.3.10 TCategoryPanel.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
```

```
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;

DragKind

3.1.5.3.11 TCategoryPanel.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter

event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

3.1.5.3.12 TCategoryPanel.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
```

```
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

procedure TForm1.MaskEdit2Exit(Sender: TObject);
var
  net1, net2, host1, host2,
  netmask1, netmask2, hostmask1, hostmask2,
  sub_net1, sub_net2, sub_host1, sub_host2: Integer;

  IP, mask: String;

begin
  // extract the net and host address from the IP
  IP := MaskEdit1.Text;

3.1.5.3.13 TCategoryPanel.OnExpand Event

Occurs immediately after a category panel is expanded.

Pascal

```
property OnExpand: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExpand;
```

Description

Write an OnExpand event handler to perform special processing when a category panel is expanded.

OnCollapse (see page 718)

3.1.5.3.14 TCategoryPanel.OnGetSiteInfo Event

Returns the control's docking information.

Pascal

```
property OnGetSiteInfo;
```

C++

```
__property OnGetSiteInfo;
```

Description

Write code in the OnGetSiteInfo event handler to initialize a TDragDockObject with information about where a dragged object can be docked, if at all. OnGetSiteInfo occurs before the OnDockOver event.

OnGetSiteInfo occurs only if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
```

```
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
```

```
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;

TDragDockObject

3.1.5.3.15 TCategoryPanel.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events.

This information is applicable to both VCL Win32 and VCL.NET.

MouseCapture

3.1.5.3.16 TCategoryPanel.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
```

```
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

3.1.5.3.17 TCategoryPanel.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

3.1.5.3.18 TCategoryPanel.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

3.1.5.3.19 TCategoryPanel.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

MouseCapture

3.1.5.3.20 TCategoryPanel.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp;
```

C++

```
__property OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
```

```
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else

3.1.5.3.21 TCategoryPanel.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDragOver

OnDockDrop

3.1.5.3.22 TCategoryPanel.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

3.1.5.3.23 TCategoryPanel.OnUnDock Event

Occurs when the application tries to undock a control that is docked to the windowed control.

Pascal

```
property OnUnDock;
```

C++

```
__property OnUnDock;
```

Description

Write an OnUnDock event handler to adjust the windowed control when a dock client is undocked. The OnUnDock event handler can make any necessary adjustments, or it can block the undock attempt by setting the Allow parameter to false.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/

3.1.6 TCategoryPanelGroup Class

TCategoryPanelGroup is a container for collapsible panels that are TCategoryPanel (see page 309) objects.

Class Hierarchy

Pascal

```
TCategoryPanelGroup = class(TCustomCategoryPanelGroup);
```

C++

```
class TCategoryPanelGroup : public TCustomCategoryPanelGroup;
```

File

ExtCtrls

Description

TCategoryPanelGroup is a container for collapsible panels that are TCategoryPanel (see page 309) objects. To add a new panel to TCategoryPanelGroup at design time, right-click the TCategoryPanelGroup object and choose New Panel. You can also collapse or expand all the panel in the same context menu by selecting Collapse All or Expand All. To collapse or expand and individual panel, you can toggle the Collapsed property in the object inspector for the desired TCateoryPanel object.

TCategoryPanel (see page 309)

3.1.6.1 TCategoryPanelGroup Members

The following tables list the members exposed by TCategoryPanelGroup.

Enumerations

	Name	Description
	THeaderStyle (see page 721)	Specifies the appearance of the headers of the the category panels.

Protected Methods

	Name	Description
	AdjustClientRect (see page 2557)	Adjusts the ClientRect property to exclude the scroll bars.
	AlignControls (see page 2557)	Aligns the controls in the scrolling windowed control.
	AutoScrollEnabled (see page 2558)	Indicates whether automatic scrolling is enabled.
	AutoScrollInView (see page 2558)	Scrolls a control into the visible area of the scrolling windowed control.
	ChangeScale (see page 2558)	Resizes the scrolling windowed control by a specific ratio.
	CreateParams (see page 2559)	Initializes the window creation parameters so that the entire window is not redrawn when the width or height of the client area changes.
	CreateWnd (see page 723)	Creates a Windows control corresponding to the TScrollingWinControl object.
	CreateWnd (see page 2559)	Creates a Windows control corresponding to the TScrollingWinControl (see page 2554) object.
	DoFlipChildren (see page 2560)	Flips the control's children.
	GetCategoryPanelClass (see page 723)	This is GetCategoryPanelClass, a member of class TCustomCategoryPanelGroup.
	Loaded (see page 724)	Initializes the control after it is loaded from a stream.
	Notification (see page 724)	Responds to notifications that components are being created or destroyed.
	ReorderPanels (see page 725)	This is ReorderPanels, a member of class TCustomCategoryPanelGroup.
	Resizing (see page 2561)	This is Resizing, a member of class TScrollingWinControl.
	WndProc (see page 725)	Provides specific message responses for the control.

Protected Properties

	Name	Description
	AutoScroll (see page 2561)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.

Public Methods

	Name	Description
	CollapseAll (see page 722)	Collapses all the category panels within the category panel group.
	Create (see page 720)	Creates and initializes a new TScrollingWinControl object.
	Create (see page 2555)	Creates and initializes a new TScrollingWinControl (see page 2554) object.
	CreatePanel (see page 722)	Creates a new category panel for the category panel group.
	Destroy (see page 721)	Removes the TScrollingWinControl object from memory.
	Destroy (see page 2556)	Removes the TScrollingWinControl (see page 2554) object from memory.
	DisableAutoRange (see page 2559)	Disables automatic scrolling.
	EnableAutoRange (see page 2560)	Reenables automatic scrolling.
	ExpandAll (see page 723)	Expands all the category panels within the category panel group.
	ScrollInView (see page 2561)	Scrolls a control into the visible area of the scrolling windowed control.

Public Properties

	Name	Description
	Panels (see page 735)	Lists the panels (TCategoryPanel (see page 309) objects) in the category panel group.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 2564)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 2564)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 418)	Occurs when an attempt is made to resize the control.
	OnClick (see page 419)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 421)	Adjust resize constraints.

	OnContextPopup (see page 421)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 422)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 422)	Occurs when another control is docked to the control.
	OnDockOver (see page 424)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 427)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 430)	Occurs when the user drags an object over a control.
	OnEndDock (see page 433)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 433)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 434)	Occurs when a control receives the input focus.
	OnExit (see page 437)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 439)	Returns the control's docking information.
	OnMouseActivate (see page 442)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 443)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 445)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 445)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 445)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 448)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 450)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 450)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 451)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 451)	Occurs immediately after the control is resized.
	OnStartDock (see page 452)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 452)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 453)	Occurs when the application tries to undock a control that is docked to the windowed control.

Published Properties

	Name	Description
	Align (see page 383)	Determines how the control aligns within its container (parent control).
	Anchors (see page 387)	Specifies how the control is anchored to its parent.
	BevelEdges (see page 387)	Specifies which edges of the control are beveled.
	BevelInner (see page 388)	Specifies the cut of the inner bevel.
	BevelKind (see page 388)	Specifies the control's bevel style.
	BevelOuter (see page 389)	Specifies the cut of the outer bevel.
	BevelWidth (see page 389)	Specifies the width of the inner and outer bevels.
	BiDiMode (see page 389)	Specifies the bi-directional mode for the control.
	ChevronAlignment (see page 390)	Determines how the chevron is aligned within the header of the category panels in this category panel group.
	ChevronColor (see page 390)	Specifies the color of the default chevron in the normal state.
	ChevronHotColor (see page 391)	Specifies the color of the default chevron in the hot state.
	Color (see page 391)	Specifies the background color of the control.
	Constraints (see page 392)	Specifies the size constraints for the control.
	Ctl3D (see page 393)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DockSite (see page 393)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 394)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 396)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 396)	Specifies whether the control is being dragged normally or for docking.

	DragMode (see page 397)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 398)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 399)	Controls the attributes of text written on or in the control.
	GradientBaseColor (see page 400)	Specifies the left or top color of the panel header in gradient style.
	GradientColor (see page 400)	Specifies the right or bottom color of the panel header in gradient style.
	GradientDirection (see page 400)	Specifies the direction of the gradient in the panel header.
	HeaderAlignment (see page 401)	Determines how the caption is aligned within the headers of the category panels in this category panel group.
	HeaderFont (see page 401)	Specifies the font of the caption of the headers of the panels.
	HeaderHeight (see page 401)	Specifies the height of the headers of the panels.
	HeaderImage (see page 402)	Specifies the image used for the background of the headers of the panels.
	HeaderStyle (see page 402)	Specifies the appearance of the headers of the the category panels.
	Height (see page 402)	Specifies the vertical size of the control in pixels.
	HorzScrollBar (see page 2562)	Represents the horizontal scroll bar for the scrolling windowed control.
	Images (see page 403)	Specifies an imagelist that can be used by the panels to replace the chevron. images.
	Padding (see page 404)	Specifies the padding of a control.
	ParentBackground (see page 404)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 404)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 405)	Determines where a control looks for its color information.
	ParentCtl3D (see page 405)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 406)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 406)	Determines where a control looks for its font information.
	ParentShowHint (see page 406)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 407)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 412)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 414)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 414)	Determines if the user can tab to a control.
	VertScrollBar (see page 2563)	Represents the vertical scroll bar for the scrolling windowed control.
	Visible (see page 415)	Determines whether the component appears onscreen.
	Width (see page 416)	Specifies the horizontal size of the control or form in pixels.

3.1.6.2 TCategoryPanelGroup Properties

The properties of the TCategoryPanelGroup class are listed here.

Published Properties

	Name	Description
	Align (see page 383)	Determines how the control aligns within its container (parent control).
	Anchors (see page 387)	Specifies how the control is anchored to its parent.
	BevelEdges (see page 387)	Specifies which edges of the control are beveled.
	BevelInner (see page 388)	Specifies the cut of the inner bevel.
	BevelKind (see page 388)	Specifies the control's bevel style.
	BevelOuter (see page 389)	Specifies the cut of the outer bevel.
	BevelWidth (see page 389)	Specifies the width of the inner and outer bevels.
	BiDiMode (see page 389)	Specifies the bi-directional mode for the control.
	ChevronAlignment (see page 390)	Determines how the chevron is aligned within the header of the category panels in this category panel group.
	ChevronColor (see page 390)	Specifies the color of the default chevron in the normal state.
	ChevronHotColor (see page 391)	Specifies the color of the default chevron in the hot state.
	Color (see page 391)	Specifies the background color of the control.
	Constraints (see page 392)	Specifies the size constraints for the control.

	Ctl3D (see page 393)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DockSite (see page 393)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 394)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 396)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 396)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 397)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 398)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 399)	Controls the attributes of text written on or in the control.
	GradientBaseColor (see page 400)	Specifies the left or top color of the panel header in gradient style.
	GradientColor (see page 400)	Specifies the right or bottom color of the panel header in gradient style.
	GradientDirection (see page 400)	Specifies the direction of the gradient in the panel header.
	HeaderAlignment (see page 401)	Determines how the caption is aligned within the headers of the category panels in this category panel group.
	HeaderFont (see page 401)	Specifies the font of the caption of the headers of the panels.
	HeaderHeight (see page 401)	Specifies the height of the headers of the panels.
	HeaderImage (see page 402)	Specifies the image used for the background of the headers of the panels.
	HeaderStyle (see page 402)	Specifies the appearance of the headers of the the category panels.
	Height (see page 402)	Specifies the vertical size of the control in pixels.
	Images (see page 403)	Specifies an imagelist that can be used by the panels to replace the chevron. images.
	Padding (see page 404)	Specifies the padding of a control.
	ParentBackground (see page 404)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 404)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 405)	Determines where a control looks for its color information.
	ParentCtl3D (see page 405)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 406)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 406)	Determines where a control looks for its font information.
	ParentShowHint (see page 406)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 407)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 412)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 414)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 414)	Determines if the user can tab to a control.
	Visible (see page 415)	Determines whether the component appears onscreen.
	Width (see page 416)	Specifies the horizontal size of the control or form in pixels.

3.1.6.2.1 TCategoryPanelGroup.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The

value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
```

```
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
```

```
    Split.MinSize := Form1.ClientWidth div 4;
    { Finally, create the last pane – a file list box }
    Files := TFileListBox.Create(Form1);
    Files.Parent := Form1;
    Files.Align := alClient;
    Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{

Parent

Anchors

3.1.6.2.2 TCategoryPanelGroup.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

3.1.6.2.3 TCategoryPanelGroup.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges;
```

C++

```
__property BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner

BevelOuter

BevelKind

3.1.6.2.4 TCategoryPanelGroup.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner;
```

C++

```
__property BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges

BevelOuter

BevelKind

BevelWidth

BorderWidth

3.1.6.2.5 TCategoryPanelGroup.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind;
```

C++

```
__property BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges

BevelOuter

BevelInner

BevelWidth

3.1.6.2.6 TCategoryPanelGroup.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter;
```

C++

```
__property BevelOuter;
```

Description

Use BevelOuter to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges

BevelInner

BevelKind

BevelWidth

3.1.6.2.7 TCategoryPanelGroup.BevelWidth Property

Specifies the width of the inner and outer bevels.

Pascal

```
property BevelWidth;
```

C++

```
__property BevelWidth;
```

Description

Use BevelWidth to specify the width, in pixels, of the inner and outer bevels.

See Also

BevelEdges

BevelInner

BevelKind

BevelOuter

3.1.6.2.8 TCategoryPanelGroup.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

3.1.6.2.9 TCategoryPanelGroup.ChevronAlignment Property

Determines how the chevron is aligned within the header of the category panels in this category panel group.

Pascal

```
property ChevronAlignment: TAlignment;
```

C++

```
__property TAlignment ChevronAlignment;
```

Description

Use the ChevronAlignment property to control the position of the chevron of the category panels within the category panel group. These are the possible values:

Value	Meaning
taLeftJustify	Align Chevron on the left side of the panel.
taCenter	Center the chevron on the panel.
taRightJustify	Align chevron on the right side of the panel.

3.1.6.2.10 TCategoryPanelGroup.ChevronColor Property

Specifies the color of the default chevron in the normal state.

Pascal

```
property ChevronColor: TColor;
```

C++

```
__property TColor ChevronColor;
```

Description

Use the ChevronColor property to select the color of the default normal chevron of the category panels in the category panel group. This property has no effect if the category panel overrides the default normal chevron with the CollapsedImageIndex property or the ExpandedImageIndex property.

See Also

THeaderState (see page 701)

CollapsedImageIndex (see page 715)

ExpandedImageIndex (see page 716)

3.1.6.2.11 TCategoryPanelGroup.ChevronHotColor Property

Specifies the color of the default chevron in the hot state.

Pascal

```
property ChevronHotColor: TColor;
```

C++

```
__property TColor ChevronHotColor;
```

Description

Use the ChevronHotColor property to select the color of the default hot chevron of the category panels in the category panel group. This property has no effect if the category panel overrides the default hot chevron color with the CollpasedHotImageIndex property or the ExpandedHotImageIndex property.

See Also

THeaderState (see page 701)

CollapsedImageIndex (see page 715)

ExpandedImageIndex (see page 716)

3.1.6.2.12 TCategoryPanelGroup.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
```

```
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor

3.1.6.2.13 TCategoryPanelGroup.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

OnCanResize

3.1.6.2.14 TCategoryPanelGroup.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

3.1.6.2.15 TCategoryPanelGroup.DockSite Property

Specifies whether the control can be the target of drag-and-dock operations.

Pascal

```
property DockSite;
```

C++

```
__property DockSite;
```

Description

Set DockSite to true to allow other controls to be docked to this windowed control.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/
void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
      TWinControl *NewTarget, bool &Allow)
{
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if (Client->ClassNameIs("TDockableForm"))
    dynamic_cast<TDockableForm *>(Client)->DockSite = True;
```

```
  if ((DockClientCount == 2) && (NewTarget != this))        // Self?
    PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
}
procedure TConjoinDockHost.FormUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if Client is TDockableForm then
    TDockableForm(Client).DockSite := True;
  if (DockClientCount = 2) and (NewTarget <> Self) then
    PostMessage(Self.Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
end;
```

3.1.6.2.16 TCategoryPanelGroup.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
```

```
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
```

```
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

3.1.6.2.17 TCategoryPanelGroup.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

3.1.6.2.18 TCategoryPanelGroup.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

3.1.6.2.19 TCategoryPanelGroup.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
```

```
    HT: THitTests;
  begin
    if TreeView1.Selected = nil then Exit;
    HT := TreeView1.GetHitTestInfoAt(X, Y);
    AnItem := TreeView1.GetNodeAt(X, Y);
    if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
    begin
      if (htOnItem in HT) or (htOnIcon in HT) then
        AttachMode := naAddChild
      else if htNowhere in HT then AttachMode := naAdd
      else if htOnIndent in HT then AttachMode := naInsert;
      TreeView1.Selected.MoveTo(AnItem, AttachMode);
    end;
  end;

  procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TTreeView;
  end;

3.1.6.2.20 TCategoryPanelGroup.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

3.1.6.2.21 TCategoryPanelGroup.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;

Displaying and Editing Text in a Memo Control

3.1.6.2.22 TCategoryPanelGroup.GradientBaseColor Property

Specifies the left or top color of the panel header in gradient style.

Pascal

```
property GradientBaseColor: TColor;
```

C++

```
__property TColor GradientBaseColor;
```

Description

Use the GradientBaseColor property to select the base gradient color for the panel header when HeaderStyle is set to hsGradient. If GradientDirection is set to gdHorizontal, GradientBaseColor represents the left color of the header. If GradientDirection is set to gdVertical, GradientBaseColor represents the top color of the header. This property has no effect if HeaderStyle is set to something other than hsGradient

See Also

HeaderStyle (see page 734)

3.1.6.2.23 TCategoryPanelGroup.GradientColor Property

Specifies the right or bottom color of the panel header in gradient style.

Pascal

```
property GradientColor: TColor;
```

C++

```
__property TColor GradientColor;
```

Description

Use the GradientColor property to select the gradient color for the panel header when HeaderStyle is set to hsGradient. If GradientDirection is set to gdHorizontal, GradientColor represents the right color of the header. If GradientDirection is set to gdVertical, GradientColor represents the bottom color of the header. This property has no effect if HeaderStyle is set to something other than hsGradient.

See Also

HeaderStyle (see page 734)

3.1.6.2.24 TCategoryPanelGroup.GradientDirection Property

Specifies the direction of the gradient in the panel header.

Pascal

```
property GradientDirection: TGradientDirection;
```

C++

```
__property TGradientDirection GradientDirection;
```

Description

Use the GradientDirection property to select the direction of the gradient header of the category panels in the category panel

group. The direction can either be horizontal or vertical. This property has no effect if HeaderStyle is set to something other than hsGradient.

See Also

HeaderStyle (see page 734)

3.1.6.2.25 TCategoryPanelGroup.HeaderAlignment Property

Determines how the caption is aligned within the headers of the category panels in this category panel group.

Pascal

```
property HeaderAlignment: TAlignment;
```

C++

```
__property TAlignment HeaderAlignment;
```

Description

Use the HeaderAlignment property to control the position of the caption of the category panels within the category panel group. These are the possible values:

Value	Meaning
taLeftJustify	Align caption on the left side of the header.
taCenter	Center the caption in the header.
taRightJustify	Align caption on the right side of the header.

3.1.6.2.26 TCategoryPanelGroup.HeaderFont Property

Specifies the font of the caption of the headers of the panels.

Pascal

```
property HeaderFont: TFont;
```

C++

```
__property TFont HeaderFont;
```

Description

Use the HeaderFont property to specify the font and font properties used to draw the caption of the headers of the category panels in the category panel group. The HeaderFont property has no effect when HeaderStyle is hsThemed.

3.1.6.2.27 TCategoryPanelGroup.HeaderHeight Property

Specifies the height of the headers of the panels.

Pascal

```
property HeaderHeight: Integer;
```

C++

```
__property int HeaderHeight;
```

Description

Use the HeaderHeight property to specify the height of the headers of the category panels in the category panel group.

3.1.6.2.28 TCategoryPanelGroup.HeaderImage Property

Specifies the image used for the background of the headers of the panels.

Pascal

```
property HeaderImage: TPicture;
```

C++

```
__property TPicture HeaderImage;
```

Description

Use the HeaderImage property to specify an image as the background for the headers of the category panels within the category panel group. This property has no effect if HeaderStyle is set to something other than hsImage.

See Also

HeaderStyle (see page 734)

3.1.6.2.29 TCategoryPanelGroup.HeaderStyle Property

Specifies the appearance of the headers of the the category panels.

Pascal

```
property HeaderStyle: THeaderStyle;
```

C++

```
__property THeaderStyle HeaderStyle;
```

Description

Use HeaderStyle to determine the appearance of headers of the category panels in the category panel group.

Value	Meaning
hsGradient	Header is a gradient determined by the GradientBaseColor, GradientColor, and GradientDirection properties.
hsImage	Header is the stretched image defined by the HeaderImage property. If HeaderImage is undefined, the hsGradient style will be used instead.
hsThemed	Header is defined by the system's theme. If runtime themes aren't enabled or supported, the hsGradient style will be used instead.

3.1.6.2.30 TCategoryPanelGroup.Height Property

Specifies the vertical size of the control in pixels.

Pascal

```
property Height;
```

C++

```
__property Height;
```

Description

Use the Height property to read or change the height of the control.

C++ Examples:

```
/*
```

```
This example needs only a blank form.  Three Rich Edit
controls are placed vertically on the form, each contain a
line of text, and the second form has HideSelection set to
false.  Try tabbing between the three Rich Edit controls and
observe the effect on the selected text.
*/
#include <ComCtrls.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int I = 0; I <= 2; I++)
  {
    TRichEdit *pRich = new TRichEdit(this);
    pRich->Parent = this;
    pRich->Top = pRich->Height * I;
    pRich->Text = "This text will take the focus.";
    pRich->SelStart = 0;
    pRich->SelLength = pRich->Text.Length();
    if (I == 1)
      pRich->HideSelection = false;
  }
}
```

Delphi Examples:

```
{
This example needs only a blank form. Three Rich Edit
controls are placed vertically on the form, each contain a
line of text, and the second form has HideSelection set to
false.  Try tabbing between the three Rich Edit controls and
observe the effect on the selected text.
}
uses ComCtrls;

procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  for I := 0 to 2 do
    with TRichEdit.Create(Self) do
    begin
      Parent := Self;
      Top := Height * I;
      Text := 'This text will take the focus.';
      SelStart := 0;
      SelLength := Length(Text);
      if (I = 1) then
        HideSelection := False;
    end;
end;
```

3.1.6.2.31 TCategoryPanelGroup.Images Property

Specifies an imagelist that can be used by the panels to replace the chevron. images.

Pascal

```
property Images: TImageList;
```

C++

```
__property TImageList Images;
```

Description

Use the images property to define a set of pictures that can be use by the category panels within the category panel group to replace the chevron.

See Also

ExpandedPressedImageIndex (see page 716)

3.1.6.2.32 TCategoryPanelGroup.Padding Property

Specifies the padding of a control.

Pascal

```
property Padding;
```

C++

```
__property Padding;
```

Description

Use Padding to specify the padding of a control. This value is an instance of the class TPadding.

See Also

TPadding

3.1.6.2.33 TCategoryPanelGroup.ParentBackground Property

Determines whether control uses parent's theme background.

Pascal

```
property ParentBackground;
```

C++

```
__property ParentBackground;
```

Description

If ParentBackground is true, the control uses the parent's theme background to draw its own background. ParentBackground has no effect unless XP themes are enabled.

3.1.6.2.34 TCategoryPanelGroup.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent

BiDiMode

3.1.6.2.35 TCategoryPanelGroup.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

ParentShowHint

3.1.6.2.36 TCategoryPanelGroup.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

3.1.6.2.37 TCategoryPanelGroup.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

3.1.6.2.38 TCategoryPanelGroup.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

See Also

Font

ParentColor

ParentShowHint

3.1.6.2.39 TCategoryPanelGroup.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

3.1.6.2.40 TCategoryPanelGroup.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
```

```
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
```

```
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)

    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
```

```
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then

    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
```

```
}

OnContextPopup

3.1.6.2.41 TCategoryPanelGroup.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
```

```
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

Displaying Fly-over Help

3.1.6.2.42 TCategoryPanelGroup.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

3.1.6.2.43 TCategoryPanelGroup.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

3.1.6.2.44 TCategoryPanelGroup.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;
```

```
procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);

3.1.6.2.45 TCategoryPanelGroup.Width Property

Specifies the horizontal size of the control or form in pixels.

Pascal

```
property Width;
```

C++

```
__property Width;
```

Description

Use the Width property to read or change the width of the control.

Note: For tab sheet controls, changing this property at runtime has no effect.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
```

```
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
```

Delphi Examples:

```
{

3.1.6.3 TCategoryPanelGroup Events

The events of the TCategoryPanelGroup class are listed here.

Published Events

	Name	Description
	OnCanResize (see page 418)	Occurs when an attempt is made to resize the control.
	OnClick (see page 419)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 421)	Adjust resize constraints.
	OnContextPopup (see page 421)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 422)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 422)	Occurs when another control is docked to the control.
	OnDockOver (see page 424)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 427)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 430)	Occurs when the user drags an object over a control.
	OnEndDock (see page 433)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 433)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 434)	Occurs when a control receives the input focus.
	OnExit (see page 437)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 439)	Returns the control's docking information.
	OnMouseActivate (see page 442)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 443)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 445)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 445)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 445)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 448)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 450)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 450)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 451)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 451)	Occurs immediately after the control is resized.
	OnStartDock (see page 452)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 452)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 453)	Occurs when the application tries to undock a control that is docked to the windowed control.

3.1.6.3.1 TCategoryPanelGroup.OnCanResize Event

Occurs when an attempt is made to resize the control.

Pascal

```
property OnCanResize;
```

C++

```
__property OnCanResize;
```

Description

Use OnCanResize to adjust the way a control is resized. If necessary, change the new width and height of the control in the OnCanResize event handler. The OnCanResize event handler also allows applications to indicate that the entire resize should be aborted.

If there is no OnCanResize event handler, or if the OnCanResize event handler indicates that the resize attempt can proceed, the OnCanResize event is followed immediately by an OnConstrainedResize event.

See Also

OnConstrainedResize

OnResize

3.1.6.3.2 TCategoryPanelGroup.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
```

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin

3.1.6.3.3 TCategoryPanelGroup.OnConstrainedResize Event

Adjust resize constraints.

Pascal

```
property OnConstrainedResize;
```

C++

```
__property OnConstrainedResize;
```

Description

Use OnConstrainedResize to adjust a control's constraints when an attempt is made to resize it. Upon entry to the OnConstrainedResize event handler, the parameters of the event handler are set to the corresponding properties of the control's Constraints object. The event handler can adjust those values before they are applied to the new height and width that is being applied to the control. (The CanAutoSize method or an OnCanResize event handler may already have adjusted this new height and width).

On exit from the OnConstrainedResize event handler, the constraints are applied to the attempted new height and width. Once the constraints are applied, the control's height and width are changed. After the control's height and width change, an OnResize event occurs to allow any final adjustments or responses.

Note: The OnConstrainedResize handler is called immediately after the OnCanResize handler.

Constraints

OnResize

CanAutoSize

3.1.6.3.4 TCategoryPanelGroup.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

3.1.6.3.5 TCategoryPanelGroup.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

OnClick

Responding to User Actions at Runtime

3.1.6.3.6 TCategoryPanelGroup.OnDockDrop Event

Occurs when another control is docked to the control.

Pascal

```
property OnDockDrop;
```

C++

```
__property OnDockDrop;
```

Description

Write code in the OnDockDrop event to perform actions when another control is docked on the control.

OnDockDrop can only occur if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

OnDockOver

3.1.6.3.7 TCategoryPanelGroup.OnDockOver Event

Occurs when another control is dragged over the control.

Pascal

```
property OnDockOver;
```

C++

```
__property OnDockOver;
```

Description

Write code in the OnDockOver event to indicate whether a dockable control that is dragged over the windowed control can be accepted as a dock client. OnDockOver occurs after the TDragDockObject has been initialized by an OnGetSiteInfo event.

OnDockOver occurs only if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

OnDockDrop

OnGetSiteInfo

TDragDockObject

3.1.6.3.8 TCategoryPanelGroup.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{

TDragObject

3.1.6.3.9 TCategoryPanelGroup.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.

OnStartDrag

DragKind

3.1.6.3.12 TCategoryPanelGroup.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter

event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{

3.1.6.3.13 TCategoryPanelGroup.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
```

```
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

procedure TForm1.MaskEdit2Exit(Sender: TObject);
var
  net1, net2, host1, host2,
  netmask1, netmask2, hostmask1, hostmask2,
  sub_net1, sub_net2, sub_host1, sub_host2: Integer;

begin
  // extract the net and host address from the IP
  IP := MaskEdit1.Text;
  net1 := StrToInt(TrimRight(Copy(IP, 0, 3)));
  net2 := StrToInt(TrimRight(Copy(IP, 5, 3)));
  host1 := StrToInt(TrimRight(Copy(IP, 9, 3)));
  host2 := StrToInt(TrimRight(Copy(IP, 13, 3)));

  // a range test that you cannot validate through edit masks
  if ((net1 < 0) Or (net1 > 255) Or
      (net2 < 0) Or (net2 > 255) Or
      (host1 < 0) Or (host1 > 255) Or
      (host2 < 0) Or (host2 > 255)) then
    raise EArgumentException.Create('Not a valid IP address.');

  // extract the net and host mask from the subnet mask
```

```
    mask := MaskEdit2.Text;
    netmask1 := StrToInt(TrimRight(Copy(mask, 0, 3)));
    netmask2 := StrToInt(TrimRight(Copy(mask, 5, 3)));
    hostmask1 := StrToInt(TrimRight(Copy(mask, 9, 3)));
    hostmask2 := StrToInt(TrimRight(Copy(mask, 13, 3)));

    // a range test that you cannot validate through edit masks
    if ((netmask1 < 0) Or (netmask1 > 255) Or
        (netmask2 < 0) Or (netmask2 > 255) Or
        (hostmask1 < 0) Or (hostmask1 > 255) Or
        (hostmask2 < 0) Or (hostmask2 > 255)) then
      raise EArgumentException.Create('Not a valid subnet mask.');

    // compute the subnet address using bit-wise AND
    sub_net1 := net1 And netmask1;
    sub_net2 := net2 And netmask2;
    sub_host1 := host1 And hostmask1;
    sub_host2 := host2 And hostmask2;

    // display the subnet address
    MaskEdit3.Text :=
      IntToStr(sub_net1) + '.' + IntToStr(sub_net2) + '.' +
      IntToStr(sub_host1) + '.' + IntToStr(sub_host2);
  end;
  {
  This example uses an edit box and a memo control on a form.
  When either the edit box or the memo is the active control,
  it is colored yellow. When the active control becomes
  inactive, the color of the control returns to the Windows
  system color for a window.  These event handlers could also
  be shared.
  }
  procedure TForm1.Edit1Enter(Sender: TObject);
  begin
    Edit1.Color := clYellow;
  end;

  procedure TForm1.Edit1Exit(Sender: TObject);
  begin
    Edit1.Color := clWindow;
  end;

  procedure TForm1.Memo1Enter(Sender: TObject);
  begin
    Memo1.Color := clYellow;
  end;

  procedure TForm1.Memo1Exit(Sender: TObject);
  begin
    Memo1.Color := clWindow;
  end;

3.1.6.3.14 TCategoryPanelGroup.OnGetSiteInfo Event

Returns the control's docking information.

Pascal

```
property OnGetSiteInfo;
```

C++

```
__property OnGetSiteInfo;
```

Description

Write code in the OnGetSiteInfo event handler to initialize a TDragDockObject with information about where a dragged object can be docked, if at all. OnGetSiteInfo occurs before the OnDockOver event.

OnGetSiteInfo occurs only if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;

TDragDockObject

3.1.6.3.15 TCategoryPanelGroup.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

MouseCapture

3.1.6.3.16 TCategoryPanelGroup.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
```

```
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```

3.1.6.3.17 TCategoryPanelGroup.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

3.1.6.3.18 TCategoryPanelGroup.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

3.1.6.3.19 TCategoryPanelGroup.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

property OnMouseUp;
```

C++

```
__property OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
```

```
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer);
begin
  StartX := X;
  StartY := Y;
end;

procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer);
begin
  Form1.Canvas.Rectangle(StartX, StartY, X, Y);
  StatusBar1.Panels[0].Text := '';
  StatusBar1.Panels[1].Text := '';
  StatusBar1.Panels[2].Text := '';
  StatusBar1.Panels[3].Text := '';
end;

procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
begin
  if ssLeft in Shift then { make sure button is down }
  begin
    if Y > StartY then
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
      end
    else
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
      end;
```

```
      if X > StartX then
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
        end
      else
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
        end;
    end;
  end;

Responding to a Mouse-up Action

3.1.6.3.21 TCategoryPanelGroup.OnMouseWheel Event

Occurs when the mouse wheel is rotated.

Pascal

```
property OnMouseWheel;
```

C++

```
__property OnMouseWheel;
```

Description

Write code in the OnMouseWheel event handler to respond to mouse wheel messages. If there is no OnMouseWheel event handler, or if the mouse wheel message is not handled in the OnMouseWheel event handler, then an OnMouseWheelUp or OnMouseWheelDown event occurs, depending on the direction the mouse wheel was rotated.

See Also

OnMouseWheelDown

OnMouseWheelUp

3.1.6.3.22 TCategoryPanelGroup.OnMouseWheelDown Event

Occurs when the mouse wheel is rotated downward.

Pascal

```
property OnMouseWheelDown;
```

C++

```
__property OnMouseWheelDown;
```

Description

Write code in the OnMouseWheelDown event handler to perform actions when the mouse wheel is rotated downward. OnMouseWheelDown occurs only if the message is not already handled in an OnMouseWheel event handler.

See Also

OnMouseWheel

OnMouseWheelUp

3.1.6.3.23 TCategoryPanelGroup.OnMouseWheelUp Event

Occurs when the mouse wheel is rotated upward.

Pascal

```
property OnMouseWheelUp;
```

C++

```
__property OnMouseWheelUp;
```

Description

Write code in the OnMouseWheelUp event handler to perform actions when the mouse wheel is rotated upward. OnMouseWheelUp occurs only if the message is not already handled in an OnMouseWheel event handler.

OnMouseWheelDown

OnMouseWheel

3.1.6.3.24 TCategoryPanelGroup.OnResize Event

Occurs immediately after the control is resized.

Pascal

```
property OnResize;
```

C++

```
__property OnResize;
```

Description

Use OnResize to make any final adjustments after a control is resized.

To modify the way a control responds when an attempt is made to resize it, use OnCanResize or OnConstrainedResize.

Note: Some controls call this event handler when the control is first created.

C++ Examples:

```
/*
The following code keeps the right edge on Button1 against
the right edge of Form1 when Form1 is resized.
*/
void __fastcall TForm1::FormResize(TObject *Sender)
{
  Button1->Left = Form1->ClientWidth - Button1->Width;
}
```

Delphi Examples:

```
{
The following code keeps the right edge on Button1 against
the right edge of Form1 when Form1 is resized.
}
procedure TForm1.FormResize(Sender: TObject);
begin
  Button1.Left := Form1.ClientWidth-Button1.Width;
end;
```

OnConstrainedResize

3.1.6.3.25 TCategoryPanelGroup.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDragOver

OnDockDrop

3.1.6.3.26 TCategoryPanelGroup.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it

contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

OnDragDrop

3.1.6.3.27 TCategoryPanelGroup.OnUnDock Event

Occurs when the application tries to undock a control that is docked to the windowed control.

Pascal

```
property OnUnDock;
```

C++

```
__property OnUnDock;
```

Description

Write an OnUnDock event handler to adjust the windowed control when a dock client is undocked. The OnUnDock event handler can make any necessary adjustments, or it can block the undock attempt by setting the Allow parameter to false.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/
void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
      TWinControl *NewTarget, bool &Allow)
{
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if (Client->ClassNameIs("TDockableForm"))
    dynamic_cast<TDockableForm *>(Client)->DockSite = True;
  if ((DockClientCount == 2) && (NewTarget != this))        // Self?
    PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
```

```
  UpdateCaption(Client);
}
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
}
```

```
procedure TConjoinDockHost.FormUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if Client is TDockableForm then
    TDockableForm(Client).DockSite := True;
  if (DockClientCount = 2) and (NewTarget <> Self) then
    PostMessage(Self.Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
end;
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;

3.1.7 TCategoryPanelSurface Class

Class Hierarchy

Pascal

```
TCategoryPanelSurface = class(TCustomTransparentControl);
```

C++

```
class TCategoryPanelSurface : public TCustomTransparentControl;
```

File

ExtCtrls

Description

This is class ExtCtrls.TCategoryPanelSurface.

3.1.7.1 TCategoryPanelSurface Members

The following tables list the members exposed by TCategoryPanelSurface.

Protected Methods

	Name	Description
	CreateParams (see page 457)	Initializes a window-creation parameter data structure.

Public Methods

	Name	Description
	Create (see page 456)	Creates an instance of TCustomControl.

3.1.7.2 TCategoryPanelSurface.Create Constructor

Creates an instance of TCustomControl.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCategoryPanelSurface(TComponent * AOwner);
```

Description

Calling Create constructs and initializes an instance of TCustomControl. However, you should never attempt to instantiate a TCustomControl. This class is intended solely as a base class from which other control classes descend and you should only call Create to instantiate one of these descendants. Controls placed on forms at design time are created automatically.

After calling the inherited constructor, Create initializes the control, including the following property settings:

Initializes a TCanvas object for its Canvas property.

When overriding Create, always call the inherited Create method first, then proceed with the control's initialization. Remember to specify the override directive when overriding the Create method.

Note: If a component's constructor allocates resources or memory, also override the destructor to free those resources.

3.1.7.3 TCategoryPanelSurface Methods

The methods of the TCategoryPanelSurface class are listed here.

Protected Methods

	Name	Description
	CreateParams (see page 457)	Initializes a window-creation parameter data structure.

3.1.7.3.1 TCategoryPanelSurface.CreateParams Method

Initializes a window-creation parameter data structure.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. Override CreateParams to customize the way a control creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

CreateParams fills in the parameter that is passed as the value of the Params parameter. This data structure holds information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function.

TWinControl implements CreateParams by setting all the fields of Params to generic base values. A number of the standard controls override CreateParams to change one or more of the default values in Params.

3.1.8 TCellCollection Class

A collection of TCellItem (see page 462) objects.

Class Hierarchy

Pascal

```
TCellCollection = class(TOwnedCollection);
```

C++

```
class TCellCollection : public TOwnedCollection;
```

File

ExtCtrls

Description

Use TCellCollection to represent all the cell items in a grid panel.

3.1.8.1 TCellCollection Members

The following tables list the members exposed by TCellCollection.

Protected Methods

	Name	Description
	GetAttr (see page 459)	Returns the name of a custom attribute that can be retrieved using the GetItemAttr method.
	GetAttrCount (see page 459)	Returns the number of custom attributes associated with items in the collection.
	GetItem (see page 460)	Returns a specified item in the collection.
	GetItemAttr (see page 460)	Returns the value of a custom attribute assigned to one of the collection's items.
	SetItem (see page 461)	This is SetItem, a member of class TCellCollection.
	Update (see page 461)	Updates the collection to reflect changes to its items.

Public Methods

	Name	Description
	Owner (see page 460)	Returns the Owner of the cell collection.

Public Properties

	Name	Description
	Items (see page 461)	Lists the items of the cell collection.

3.1.8.2 TCellCollection Methods

The methods of the TCellCollection class are listed here.

Protected Methods

	Name	Description
	GetAttr (see page 459)	Returns the name of a custom attribute that can be retrieved using the GetItemAttr method.
	GetAttrCount (see page 459)	Returns the number of custom attributes associated with items in the collection.

	GetItem (see page 460)	Returns a specified item in the collection.
V	GetItemAttr (see page 460)	Returns the value of a custom attribute assigned to one of the collection's items.
	SetItem (see page 461)	This is SetItem, a member of class TCellCollection.
V	Update (see page 461)	Updates the collection to reflect changes to its items.

Public Methods

	Name	Description
	Owner (see page 460)	Returns the Owner of the cell collection.

3.1.8.2.1 TCellCollection.GetAttr Method

Returns the name of a custom attribute that can be retrieved using the GetItemAttr method.

Pascal

```
function GetAttr(Index: Integer): string; override;
```

C++

```
virtual __fastcall UnicodeString GetAttr(int Index);
```

Description

TCollection descendants can associate user-defined attributes with the items in the collection. Each attribute has a name and, for each item in the collection, a value that is a string. The GetAttr method returns the name of an attribute.

Index identifies the attribute whose name is requested. This is a value between 0 and n-1, where n is the value returned by GetAttrCount.

As implemented by TCollection, GetAttr always returns an empty string, because TCollection defines no custom attributes.

See Also

GetAttrCount

GetItemAttr

3.1.8.2.2 TCellCollection.GetAttrCount Method

Returns the number of custom attributes associated with items in the collection.

Pascal

```
function GetAttrCount: Integer; override;
```

C++

```
virtual __fastcall int GetAttrCount();
```

Description

TCollection descendants can associate user-defined attributes with the items in the collection. Each attribute has a name and, for each item in the collection, a value that is a string. GetAttrCount returns the number of distinct attributes assigned to each item in the collection.

As implemented in TCollection, GetAttrCount always returns 0, because TCollection defines no custom attributes.

See Also

GetAttr

GetItemAttr

3.1.8.2.3 TCellCollection.GetItem Method

Returns a specified item in the collection.

Pascal

```
function GetItem(Index: Integer): TCellItem;
```

C++

```
__fastcall TCellItem GetItem(int Index);
```

Description

GetItem is the protected read implementation of the Items property.

See Also

Items

3.1.8.2.4 TCellCollection.GetItemAttr Method

Returns the value of a custom attribute assigned to one of the collection's items.

Pascal

```
function GetItemAttr(Index: Integer; ItemIndex: Integer): string; override;
```

C++

```
virtual __fastcall UnicodeString GetItemAttr(int Index, int ItemIndex);
```

Description

TCollection descendants can associate user-defined attributes with the items in the collection. Each attribute has a name and, for each item in the collection, a value that is a string. GetItemAttr returns the value of one of these attributes for a specified item in the collection.

Index identifies which attribute's value is desired. This is a value between 0 and n-1, where n is the value returned by GetAttrCount.

ItemIndex identifies the item whose attribute value is desired. This is an index into the Items property array.

As implemented in TCollection, GetItemAttr always returns an empty string, because TCollection defines no custom attributes.

See Also

GetAttr

GetAttrCount

3.1.8.2.5 TCellCollection.Owner Method

Returns the Owner of the cell collection.

Pascal

```
function Owner: TCustomGridPanel;
```

C++

```
__fastcall TCustomGridPanel Owner();
```

Description

Use the Owner method to obtain a reference to the list view that owns this cell collection.

3.1.8.2.6 TCellCollection.SetItem Method

Pascal

```
procedure SetItem(Index: Integer; Value: TCellItem);
```

C++

```
__fastcall SetItem(int Index, TCellItem Value);
```

Description

This is SetItem, a member of class TCellCollection.

3.1.8.2.7 TCellCollection.Update Method

Updates the collection to reflect changes to its items.

Pascal

```
procedure Update(Item: TCollectionItem); override;
```

C++

```
virtual __fastcall Update(TCollectionItem Item);
```

Description

Override Update in a descendant class to make any necessary changes when the items in the collection change. This method is called automatically when an update is complete.

Item identifies the item that changed. If the Item parameter is nil (Delphi) or NULL (C++), then the change affects more than one item in the collection.

As implemented in TCollection, Update does nothing. Descendant classes override this method to make any necessary adjustments.

Changed

3.1.8.3 TCellCollection Properties

The properties of the TCellCollection class are listed here.

Public Properties

	Name	Description
	Items (see page 461)	Lists the items of the cell collection.

3.1.8.3.1 TCellCollection.Items Property

Lists the items of the cell collection.

Pascal

```
property Items [Index: Integer]: TCellItem;
```

C++

```
__property TCellItem Items[int Index];
```

Description

Use the Items property to list the items of TCellCollection (see page 458).

3.1.9 TCellItem Class

Represents an item in a TCellCollection (see page 458).

Class Hierarchy

Pascal

```
TCellItem = class(TCollectionItem);
```

C++

```
class TCellItem : public TCollectionItem;
```

File

ExtCtrls

Description

The TCellItem class represents a cell on a grid panel.

3.1.9.1 TCellItem Members

The following tables list the members exposed by TCellItem.

Protected Methods

	Name	Description
	AssignTo (see page 463)	Copies the properties of an object to a destination object.
	SetSizeStyle (see page 464)	This is SetSizeStyle, a member of class TCellItem.
	SetValue (see page 464)	This is SetValue, a member of class TCellItem.

Protected Properties

	Name	Description
	AutoAdded (see page 464)	This is AutoAdded, a member of class TCellItem.
	Size (see page 465)	This is Size, a member of class TCellItem.

Public Methods

	Name	Description
	Create (see page 462)	Creates and initializes a TCollectionItem instance.

Published Properties

	Name	Description
	SizeStyle (see page 465)	Specifies the manner in which column size or row size is specified.
	Value (see page 465)	Sets the size of the cell item.

3.1.9.2 TCellItem.Create Constructor

Creates and initializes a TCollectionItem instance.

Pascal

```
constructor Create(Collection: TCollection); override;
```

C++

```
virtual __fastcall TCellItem(TCollection Collection);
```

Description

Do not call Create to instantiate a collection item. Instead, call the Add method of the collection to which the item should belong.

Collection identifies the TCollection instance to which the new item belongs.

Add

Collection

3.1.9.3 TCellItem Methods

The methods of the TCellItem class are listed here.

Protected Methods

	Name	Description
	AssignTo (see page 463)	Copies the properties of an object to a destination object.
	SetSizeStyle (see page 464)	This is SetSizeStyle, a member of class TCellItem.
	SetValue (see page 464)	This is SetValue, a member of class TCellItem.

3.1.9.3.1 TCellItem.AssignTo Method

Copies the properties of an object to a destination object.

Pascal

```
procedure AssignTo(Dest: TPersistent); override;
```

C++

```
virtual __fastcall AssignTo(TPersistent * Dest);
```

Description

Override the AssignTo method to extend the functionality of the Assign method of destination objects so that they handle newly created object classes. When defining a new object class, override the Assign method for every existing object class that should be able to copy its properties to the new class. Override the AssignTo method for every existing class to which the new class can copy.

The Assign method of TPersistent calls AssignTo if the descendant object does not succeed in copying the properties of a source object. The AssignTo method defined by TPersistent raises an EConvertError exception.

For example, given the following code in which A and B are instance variables:

```
A.Assign(B); {Delphi}
A->Assign(B); // C++
```

if A knows how to handle B, then it does so and returns. If A doesn't know how to handle B's type, execution will trickle to the TPersistent version of Assign, which calls:

```
B.AssignTo(A); {Delphi}
B->AssignTo(A); // C++
```

If B knows how to copy to A, the assignment succeeds. Otherwise, TPersistent raises an exception.

Assign

EConvertError

3.1.9.3.2 TCellItem.SetSizeStyle Method

Pascal

```
procedure SetSizeStyle(Value: TSizeStyle);
```

C++

```
__fastcall SetSizeStyle(TSizeStyle Value);
```

Description

This is SetSizeStyle, a member of class TCellItem.

3.1.9.3.3 TCellItem.SetValue Method

Pascal

```
procedure SetValue(Value: Double);
```

C++

```
__fastcall SetValue(Double Value);
```

Description

This is SetValue, a member of class TCellItem.

3.1.9.4 TCellItem Properties

The properties of the TCellItem class are listed here.

Protected Properties

	Name	Description
	AutoAdded (see page 464)	This is AutoAdded, a member of class TCellItem.
	Size (see page 465)	This is Size, a member of class TCellItem.

Published Properties

	Name	Description
	SizeStyle (see page 465)	Specifies the manner in which column size or row size is specified.
	Value (see page 465)	Sets the size of the cell item.

3.1.9.4.1 TCellItem.AutoAdded Property

Pascal

```
property AutoAdded: Boolean;
```

C++

```
__property Boolean AutoAdded;
```

Description

This is AutoAdded, a member of class TCellItem.

3.1.9.4.2 TCellItem.Size Property

Pascal

```
property Size: Integer;
```

C++

```
__property int Size;
```

Description

This is Size, a member of class TCellItem.

3.1.9.4.3 TCellItem.SizeStyle Property

Specifies the manner in which column size or row size is specified.

Pascal

```
property SizeStyle: TSizeStyle;
```

C++

```
__property TSizeStyle SizeStyle;
```

Description

Use the SizeStyle property to specify whether the size of the row or column in a grid is an absolute value, a percentage of the grid size, or generated automatically.

Style	Description
ssAbsolute	The number specified for the Value (see page 465) property is interpreted as the number of pixels for the row or column.
ssAuto	The number specified for the Value (see page 465) property is ignored, and the row or column is sized automatically.
ssPercent	The number specified for the Value (see page 465) property is interpreted as a percentage of the entire grid panel.

3.1.9.4.4 TCellItem.Value Property

Sets the size of the cell item.

Pascal

```
property Value: Double;
```

C++

```
__property Double Value;
```

Description

Use the Value property to specify the size of the column or row in the grid. This value can be set automatically or expressed as a percentage of the grid size or as an absolute value, depending on the SizeStyle (see page 465). For example, if SizeStyle (see page 465) is set to ssPercent, and you specify a value of 60, the column occupies approximately 60% of the grid panes width or a row occupies approximately 60% of the grid panel height.

3.1.10 TColorBox Class

TColorBox represents a combo box that lets users select a color.

Class Hierarchy

Pascal

```
TColorBox = class(TCustomColorBox);
```

C++

```
class TColorBox : public TCustomColorBox;
```

File

ExtCtrls

Description

Use TColorBox to provide the user with a drop-down combo box from which to select a color. Use the Style (see page 493) property to specify which colors the color box should list. Each color is displayed next to a small square that is drawn in the corresponding color.

Use the Selected (see page 491) property to access the color that the user selects. The Colors (see page 742) property provides access to the entire list of colors, while the ColorNames (see page 741) property lists their names.

TColorDialog

3.1.10.1 TColorBox Members

The following tables list the members exposed by TColorBox.

Protected Methods

	Name	Description
	CloseUp (see page 737)	Generates an OnCloseUp event.
	CreateWnd (see page 738)	Creates the window used to implement the color box.
	DrawItem (see page 738)	Renders an individual item in the color box.
	KeyDown (see page 738)	Generates an OnKeyDown event.
	KeyPress (see page 739)	Generates an OnKeyPress event.
	Loaded (see page 739)	Initializes the combo box after its form is loaded into memory.
	PickCustomColor (see page 740)	Displays the color selection dialog so that the user can select a custom color.
	PopulateList (see page 740)	Fills the color box with items that reflect the colors specified by the Style (see page 744) property.
	Select (see page 740)	Generates an OnSelect event.
	SetStyle (see page 741)	Sets the Style (see page 744) property.

Public Methods

	Name	Description
	Create (see page 737)	Creates a new TCustomColorBox (see page 735) object.

Public Properties

	Name	Description
R	ColorNames (see page 741)	Lists the names of the colors in the color box.
R	Colors (see page 742)	Lists the colors in the color box.

Published Events

	Name	Description
	OnChange (see page 497)	Occurs when the user changes the text displayed in the edit region.
	OnClick (see page 499)	Occurs when the user clicks the control.
	OnCloseUp (see page 501)	Occurs when the drop-down list closes up due to some user action.
	OnContextPopup (see page 501)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 502)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 502)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 505)	Occurs when the user drags an object over a control.
	OnDropDown (see page 508)	Occurs when the user opens the drop-down list.
	OnEndDock (see page 510)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 510)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 511)	Occurs when a control receives the input focus.
	OnExit (see page 514)	Occurs when the input focus shifts away from one control to another.
	OnGetColors (see page 516)	Occurs when the control is populated with colors.
	OnKeyDown (see page 517)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 520)	Occurs when a key is pressed.
	OnKeyUp (see page 521)	Occurs when the user releases a key that has been pressed.
	OnMouseEnter (see page 523)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 523)	Occurs when the user moves the mouse outside of a control.
	OnSelect (see page 524)	Occurs when the user selects a string in the drop-down list.
	OnStartDock (see page 524)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 525)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 469)	Determines how the control aligns within its container (parent control).
	Anchors (see page 472)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 473)	Positions to matching list items as you type.
	AutoDropDown (see page 474)	Specifies whether the drop-down list drops down automatically in response to user keystrokes.
	BevelEdges (see page 474)	Specifies which edges of the control are beveled.
	BevelInner (see page 475)	Specifies the cut of the inner bevel.
	BevelKind (see page 475)	Specifies the control's bevel style.
	BevelOuter (see page 476)	Specifies the cut of the outer bevel.
	BiDiMode (see page 476)	Specifies the bi-directional mode for the control.
	Color (see page 477)	Specifies the background color of the control.
	Constraints (see page 477)	Specifies the size constraints for the control.
	Ctl3D (see page 478)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefaultColorColor (see page 479)	Specifies the color displayed in the color box for clDefault.
	DoubleBuffered (see page 479)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DropDownCount (see page 481)	Specifies the maximum number of items displayed in the drop-down list.
	Enabled (see page 481)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 482)	Controls the attributes of text written on or in the control.

	ItemHeight (see page 483)	Specifies the height, in pixels, of the items in the drop-down list.
	NoneColorColor (see page 483)	Specifies the color displayed in the color box for clNone.
	ParentBiDiMode (see page 484)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 484)	Determines where a control looks for its color information.
	ParentCtl3D (see page 485)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 485)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 485)	Determines where a control looks for its font information.
	ParentShowHint (see page 486)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 486)	Identifies the pop-up menu associated with the control.
	Selected (see page 491)	Specifies the currently selected color.
	ShowHint (see page 492)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Style (see page 493)	Controls what colors are listed and how their names are formatted.
	TabOrder (see page 493)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 494)	Determines if the user can tab to a control.
	Visible (see page 494)	Determines whether the component appears onscreen.

3.1.10.2 TColorBox Properties

The properties of the TColorBox class are listed here.

Published Properties

	Name	Description
	Align (see page 469)	Determines how the control aligns within its container (parent control).
	Anchors (see page 472)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 473)	Positions to matching list items as you type.
	AutoDropDown (see page 474)	Specifies whether the drop-down list drops down automatically in response to user keystrokes.
	BevelEdges (see page 474)	Specifies which edges of the control are beveled.
	BevelInner (see page 475)	Specifies the cut of the inner bevel.
	BevelKind (see page 475)	Specifies the control's bevel style.
	BevelOuter (see page 476)	Specifies the cut of the outer bevel.
	BiDiMode (see page 476)	Specifies the bi-directional mode for the control.
	Color (see page 477)	Specifies the background color of the control.
	Constraints (see page 477)	Specifies the size constraints for the control.
	Ctl3D (see page 478)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefaultColorColor (see page 479)	Specifies the color displayed in the color box for clDefault.
	DoubleBuffered (see page 479)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DropDownCount (see page 481)	Specifies the maximum number of items displayed in the drop-down list.
	Enabled (see page 481)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 482)	Controls the attributes of text written on or in the control.
	ItemHeight (see page 483)	Specifies the height, in pixels, of the items in the drop-down list.
	NoneColorColor (see page 483)	Specifies the color displayed in the color box for clNone.
	ParentBiDiMode (see page 484)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 484)	Determines where a control looks for its color information.
	ParentCtl3D (see page 485)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 485)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 485)	Determines where a control looks for its font information.
	ParentShowHint (see page 486)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 486)	Identifies the pop-up menu associated with the control.

	Selected (see page 491)	Specifies the currently selected color.
	ShowHint (see page 492)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Style (see page 493)	Controls what colors are listed and how their names are formatted.
	TabOrder (see page 493)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 494)	Determines if the user can tab to a control.
	Visible (see page 494)	Determines whether the component appears onscreen.

3.1.10.2.1 TColorBox.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
```

```
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane - a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
}

Parent

Anchors

3.1.10.2.2 TColorBox.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other

aligned sibling controls as well as changes to the parent's size.

Parent

Align

3.1.10.2.3 TColorBox.AutoComplete Property

Positions to matching list items as you type.

Pascal

```
property AutoComplete;
```

C++

```
__property AutoComplete;
```

Description

AutoComplete will position to matching list values as you type, saving you keystrokes.

As you type, the ItemIndex property is updated with the list entry that matches the characters you have entered. As you type, different list entries may match, and ItemIndex changes accordingly.

There is a delay of AutoCompleteDelay milliseconds between the characters typed and the autocomplete operation.

C++ Examples:

```
/*
This is a very simple example showing how to create a comboBox, add to
it some choices, selecting a default value and getting the selected
value.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
//comboBox initialize
comb = new TComboBox(this);
comb->Parent = this;

//visual options
comb->Align = TAlign::alLeft;
comb->DoubleBuffered = true;
comb->AutoComplete = true;

//adding items to the combo box
comb->AddItem("firstChoice",NULL);
comb->AddItem("secondChoice",NULL);
comb->AddItem("thirdChoice",NULL);

//setting the default value
comb->ItemIndex = 1;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Button1Click(TObject *Sender)
{
MessageDlg("Selected text: " + comb->Text,
            mtInformation, TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This is a very simple example showing how to create a comboBox, add to
it some choices, selecting a default value and getting the selected
```

```
value.
}
procedure TForm3.Button1Click(Sender: TObject);
begin
  MessageDlg('Selected text: ' + comb.Text, mtInformation,
             mbYesNo, 0);
end;

procedure TForm3.FormCreate(Sender: TObject);
begin
  //initialize the combo box
  comb := TComboBox.Create(Self);
  comb.Parent := Self;

  //visual options
  comb.Align := alLeft;
  comb.DoubleBuffered := true;
  comb.AutoComplete := true;

  //adding items to the combo box
  comb.AddItem('firstChoice', nil);
  comb.AddItem('secondChoice', nil);
  comb.AddItem('thirdChoice', nil);

  //setting the default value
  comb.ItemIndex := 1;
end;
```

AutoCompleteDelay

3.1.10.2.4 TColorBox.AutoDropDown Property

Specifies whether the drop-down list drops down automatically in response to user keystrokes.

Pascal

```
property AutoDropDown;
```

C++

```
__property AutoDropDown;
```

Description

When AutoDropDown is true, the combo box automatically drops down its list when the user starts typing a string while the combo box has focus.

When AutoDropDown is false, the user must explicitly use the drop-down button to drop down the combo box list.

3.1.10.2.5 TColorBox.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges;
```

C++

```
__property BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner

BevelOuter

BevelKind

3.1.10.2.6 TColorBox.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner;
```

C++

```
__property BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges

BevelOuter

BevelKind

BevelWidth

BorderWidth

3.1.10.2.7 TColorBox.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind;
```

C++

```
__property BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges

BevelOuter

BevelInner

BevelWidth

3.1.10.2.8 TColorBox.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter;
```

C++

```
__property BevelOuter;
```

Description

Use BevelOuter to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges

BevelInner

BevelKind

BevelWidth

3.1.10.2.9 TColorBox.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

3.1.10.2.10 TColorBox.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor

3.1.10.2.11 TColorBox.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

Align

Anchors

OnConstrainedResize

OnCanResize

3.1.10.2.12 TColorBox.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

BorderWidth

3.1.10.2.13 TColorBox.DefaultColorColor Property

Specifies the color displayed in the color box for clDefault.

Pascal

```
property DefaultColorColor: TColor;
```

C++

```
__property TColor DefaultColorColor;
```

Description

Set DefaultColorColor to indicate what color the color box should use when drawing the icon for clDefault. This property only affects the color box if the Style property includes cbSystemColors and cbIncludeDefault.

Note: DefaultColorColor only affects the way clDefault appears in the color box. When you assign clDefault to a control, the control determines its own default color.

See Also

Colors (see page 742)

NoneColorColor (see page 743)

Style (see page 744)

3.1.10.2.14 TColorBox.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
```

```
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
```

```
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

3.1.10.2.15 TColorBox.DropDownCount Property

Specifies the maximum number of items displayed in the drop-down list.

Pascal

```
property DropDownCount;
```

C++

```
__property DropDownCount;
```

Description

By default, the drop-down list is long enough to contain eight items without requiring the user to scroll to see them all. To make the drop-down list smaller or larger, specify a number larger or smaller than eight as the DropDownCount value.

If the DropDownCount value is larger than the number of items in the Items property, the drop-down list will be just large enough to hold all the possible choices and no more. If the DropDownCount value is smaller then the number of item in the Items property, the drop down list will display a scroll bar.

Items

ItemCount

3.1.10.2.16 TColorBox.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

3.1.10.2.17 TColorBox.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

Displaying and Editing Text in a Memo Control

3.1.10.2.18 TColorBox.ItemHeight Property

Specifies the height, in pixels, of the items in the drop-down list.

Pascal

```
property ItemHeight;
```

C++

```
__property ItemHeight;
```

Description

Read ItemHeight to determine the height of the items in the drop-down list.

The effect of setting ItemHeight varies, depending on the type of combo box and the style. For example, TComboBox lets you set the item height only when Style is set to csOwnerDrawFixed or csOwnerDrawVariable. If Style is csOwnerDrawVariable, ItemHeight is the default height for drawing list items, but this value can be overridden by an OnMeasureItem event handler.

TComboBoxEx does not let you change the value of ItemHeight.

Note: Combo boxes that do not support changes to ItemHeight do not raise an exception when you attempt to change ItemHeight; they simply ignore the attempt.

OnMeasureItem

Style

3.1.10.2.19 TColorBox.NoneColorColor Property

Specifies the color displayed in the color box for clNone.

Pascal

```
property NoneColorColor: TColor;
```

C++

```
__property TColor NoneColorColor;
```

Description

Set NoneColorColor to indicate what color the color box should use when drawing the icon for clNone. This property only affects the color box if the Style property includes cbSystemColors and cbIncludeNone.

Note: NoneColorColor only affects the way clNone appears in the color box. When you assign clNone to a control, the control determines how to interpret clNone.

See Also

Colors (see page 742)

DefaultColorColor (see page 742)

Style (see page 744)

3.1.10.2.20 TColorBox.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent

BiDiMode

3.1.10.2.21 TColorBox.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

3.1.10.2.22 TColorBox.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

3.1.10.2.23 TColorBox.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

3.1.10.2.24 TColorBox.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

See Also

Font

Parent

ParentColor

ParentShowHint

3.1.10.2.25 TColorBox.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

3.1.10.2.26 TColorBox.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
```

```
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
```

```
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)

    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
```

```
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
```

```
  This example demonstrates how to add and delete menu items
  to a popup menu at runtime and assign an event handler to
  the OnClick event.  Place a TPopupMenu and three buttons on
  the form named "AddButton", "EditButton",  and
  "DestroyButton" and add OnClick events to all three buttons.
  Put the TPopupMenu in the PopupMenu property of the form.
  Place the PopupMenuItemsClick procedure in the TForm1 type
  declaration so that it can be used as the method call for
  the menu item OnClick event.

3.1.10.2.27 TColorBox.Selected Property

Specifies the currently selected color.

Pascal

```
property Selected: TColor;
```

C++

```
__property TColor Selected;
```

Description

Use Selected to get or set the selected color as a TColor value.

See Also

Colors (see page 742)

ItemIndex

3.1.10.2.28 TColorBox.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
```

```
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

3.1.10.2.29 TColorBox.Style Property

Controls what colors are listed and how their names are formatted.

Pascal

```
property Style: TColorBoxStyle;
```

C++

```
__property TColorBoxStyle Style;
```

Description

Use Style to configure what colors appear in the list and how the names appear. Style is a set that includes 0 or more of the TColorBoxStyles flags.

TColorDialog

3.1.10.2.30 TColorBox.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

3.1.10.2.31 TColorBox.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

3.1.10.2.32 TColorBox.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{

3.1.10.3 TColorBox Events

The events of the TColorBox class are listed here.

Published Events

	Name	Description
	OnChange (see page 497)	Occurs when the user changes the text displayed in the edit region.
	OnClick (see page 499)	Occurs when the user clicks the control.
	OnCloseUp (see page 501)	Occurs when the drop-down list closes up due to some user action.
	OnContextPopup (see page 501)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 502)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 502)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 505)	Occurs when the user drags an object over a control.
	OnDropDown (see page 508)	Occurs when the user opens the drop-down list.
	OnEndDock (see page 510)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 510)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 511)	Occurs when a control receives the input focus.
	OnExit (see page 514)	Occurs when the input focus shifts away from one control to another.
	OnGetColors (see page 516)	Occurs when the control is populated with colors.
	OnKeyDown (see page 517)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 520)	Occurs when a key is pressed.
	OnKeyUp (see page 521)	Occurs when the user releases a key that has been pressed.
	OnMouseEnter (see page 523)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 523)	Occurs when the user moves the mouse outside of a control.
	OnSelect (see page 524)	Occurs when the user selects a string in the drop-down list.
	OnStartDock (see page 524)	Occurs when the user begins to drag a control with a DragKind of dkDock.

	OnStartDrag (see page 525)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

3.1.10.3.1 TColorBox.OnChange Event

Occurs when the user changes the text displayed in the edit region.

Pascal

```
property OnChange;
```

C++

```
__property OnChange;
```

Description

Write an OnChange event handler to take specific action immediately after the user edits the text in the edit region or selects an item from the list. The Text property gives the new value in the edit region.

Note: OnChange only occurs in response to user actions. Changing the Text property programmatically does not trigger an OnChange event.

C++ Examples:

```
/*
This example requires a TPageControl already on the form.
Also, you must add pages to the TPageControl by right
clicking and selecting New Page.
The example code will allow the user to select the
ActivePage property through selection of a ComboBox item.
During the form create, the Combo Box control is loaded with
the names of each of the tabs, as well as the instance
pointers to the corresponding tab.  When the user selects
the Combo Box item, the associated TTabSheet object
contained in the Combo Box Objects array is used to set the
ActivePage property.  Select the Lines property of the
TRichEdit to enter a string.  Select the string before
justifying.
*/
void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{

OnCloseUp

3.1.10.3.2 TColorBox.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
```

```
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;

3.1.10.3.3 TColorBox.OnCloseUp Event

Occurs when the drop-down list closes up due to some user action.

Pascal

```
property OnCloseUp;
```

C++

```
__property OnCloseUp;
```

Description

Write an OnCloseUp event handler to implement special processing that needs to occur when the drop-down list closes up. For example, an OnCloseUp event handler can check whether the user changed the selected item while the list was dropped down and respond accordingly.

See Also

OnDropDown

DroppedDown

3.1.10.3.4 TColorBox.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

PopupMenu

AutoPopup (see page 4942)

3.1.10.3.5 TColorBox.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

OnClick

Responding to User Actions at Runtime

3.1.10.3.6 TColorBox.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
```

```
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);

3.1.10.3.7 TColorBox.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

3.1.10.3.8 TColorBox.OnDropDown Event

Occurs when the user opens the drop-down list.

Pascal

```
property OnDropDown;
```

C++

```
__property OnDropDown;
```

Description

Write an OnDropDown event handler to implement special processing that needs to occur only when the drop-down list is activated.

C++ Examples:

```
/*
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
*/
#include "Unit2.h"
#include "Unit3.h"

void __fastcall TForm1::ComboBox1DropDown(TObject *Sender)
{
  ComboBox1->Items->BeginUpdate(); // prevent repaints until done
  ComboBox1->Items->Clear(); // empty the list of any old values
  for (int i = 0; i < Screen->CustomFormCount; i++)
  {
    if ((reinterpret_cast<TForm1 *>(Screen->CustomForms[i]))->Visible)
      ComboBox1->Items->Add(Screen->CustomForms[i]->Caption);  // add form names
  }
  ComboBox1->Items->EndUpdate(); //reenable painting
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ComboBox1->Sorted = True; // make sure the form names are sorted
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Form2->Show();
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Form3->Show();
}
```

Delphi Examples:

```
{
This example fills the list of a combo box with the set of
open forms when the user drops down the list. The list is
regenerated every time the list is dropped down, so if the
application opens or closes forms, the combo box stays current.
}
procedure TForm1.ComboBox1DropDown(Sender: TObject);
var
  I: Integer;
begin
  with ComboBox1 do
  begin
    Items.BeginUpdate; { prevent repaints until done }
    Items.Clear; { empty the list of any old values }
    for I := 0 to Screen.CustomFormCount - 1 do
    begin
      if (Screen.CustomForms[I].Visible) then
        Items.Add(Screen.CustomForms[I].Caption); { add form name }
    end;
    Items.EndUpdate; {reenable painting }
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ComboBox1.Sorted := True; { make sure the form names are sorted }
end;

procedure TForm1.Button1Click(Sender: TObject);
```

```
begin
  Form2.Show;
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  Form3.Show;
end;
```

OnStartDock

3.1.10.3.10 TColorBox.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
```

```
    if (Sender->ClassNameIs("TLabel"))
    {
      AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
      if (Target)
        S = S + "accepted!";
      else
        S = S + "rejected.";
      Status->Caption = S;
    }
  }
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;

DragKind

3.1.10.3.11 TColorBox.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on

the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   (dynamic_cast<TEdit *>(myActiveControl))->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    (dynamic_cast<TRichEdit *>(myActiveControl))->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
```

```
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.

Using a Single Navigator for Multiple Datasets

3.1.10.3.12 TColorBox.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
```

```
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

procedure TForm1.MaskEdit2Exit(Sender: TObject);
var
  net1, net2, host1, host2,

        (hostmask2 < 0) Or (hostmask2 > 255)) then
      raise EArgumentException.Create('Not a valid subnet mask.');

    // compute the subnet address using bit-wise AND
    sub_net1 := net1 And netmask1;
    sub_net2 := net2 And netmask2;
    sub_host1 := host1 And hostmask1;
    sub_host2 := host2 And hostmask2;

    // display the subnet address
    MaskEdit3.Text :=
      IntToStr(sub_net1) + '.' + IntToStr(sub_net2) + '.' +
      IntToStr(sub_host1) + '.' + IntToStr(sub_host2);
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;

3.1.10.3.13 TColorBox.OnGetColors Event

Occurs when the control is populated with colors.

Pascal

```
property OnGetColors: TGetColorsEvent;
```

C++

```
__property TGetColorsEvent OnGetColors;
```

3.1.10.3.14 TColorBox.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown;
```

C++

```
__property OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
```

```
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

OnKeyPress

OnKeyUp

3.1.10.3.15 TColorBox.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress;
```

C++

```
__property OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an

OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

3.1.10.3.16 TColorBox.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp;
```

C++

```
__property OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to

3.1.10.3.17 TColorBox.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

3.1.10.3.18 TColorBox.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse

outside of a control when the parent top-level form is not active.

3.1.10.3.19 TColorBox.OnSelect Event

Occurs when the user selects a string in the drop-down list.

Pascal

```
property OnSelect;
```

C++

```
__property OnSelect;
```

Description

Write an OnSelect event handler to respond when the user changes the selected item in the drop-down list. OnSelect occurs after the selection has changed and the Text property reflects the new item.

ItemIndex

Text

3.1.10.3.20 TColorBox.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnEndDock

TDragDockObjectEx

DragKind

OnDragOver

OnDockDrop

3.1.10.3.21 TColorBox.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

3.1.11 TColorListBox Class

TColorListBox represents a list box that lets users select a color.

Class Hierarchy

Pascal

```
TColorListBox = class(TCustomColorListBox);
```

C++

```
class TColorListBox : public TCustomColorListBox;
```

File

ExtCtrls

Description

TCustomColorBox (see page 735) is the base class for TColorListBox and for combo boxes that display a list of colors. The list box displays a list of all the colors for which the Graphics (see page 2619) unit defines a constant. For a list of these colors, see TColor (see page 2878). Each color is displayed next to a small square that is drawn in the corresponding color.

Do not use TCustomColorBox (see page 735) in applications. It is intended to act as a base class for color selection controls. Rather, to add a list box control with selectable colors, use the TColorListBox component. To use a drop-down combo box that lets users select a color, use the TColorBox (see page 466) component, which appears on the Additional page of the component palette.

3.1.11.1 TColorListBox Members

The following tables list the members exposed by TColorListBox.

Protected Methods

	Name	Description
	CreateWnd (see page 746)	Creates a Windows control corresponding to the list box component.
	DrawItem (see page 747)	Generates an OnDrawItem event.
	KeyDown (see page 747)	Respond to key press events.
	KeyPress (see page 748)	Responds when the user presses a key.
	Loaded (see page 748)	Initializes the control after it is loaded from a stream.
	PickCustomColor (see page 749)	This is PickCustomColor, a member of class TCustomColorListBox.
	PopulateList (see page 749)	This is PopulateList, a member of class TCustomColorListBox.
	SetStyle (see page 749)	This is SetStyle, a member of class TCustomColorListBox.

Public Methods

	Name	Description
	Create (see page 746)	Instantiates a list box control.

Public Properties

	Name	Description
	ColorNames (see page 750)	This is ColorNames, a member of class TCustomColorListBox.
	Colors (see page 750)	This is Colors, a member of class TCustomColorListBox.

Published Events

	Name	Description
	OnClick (see page 555)	Occurs when the user clicks the control.
	OnContextPopup (see page 557)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 558)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 558)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 561)	Occurs when the user drags an object over a control.
	OnEndDock (see page 564)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 565)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 566)	Occurs when a control receives the input focus.
	OnExit (see page 568)	Occurs when the input focus shifts away from one control to another.
	OnGetColors (see page 571)	This is OnGetColors, a member of class TColorListBox.
	OnKeyDown (see page 571)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 575)	Occurs when a key is pressed.
	OnKeyUp (see page 576)	Occurs when the user releases a key that has been pressed.

	OnMouseActivate (see page 577)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 578)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 581)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 581)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 581)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 584)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 586)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 586)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 528)	Determines how the control aligns within its container (parent control).
	Anchors (see page 532)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 532)	Determines whether the user can give focus to items by typing in the list.
	BevelEdges (see page 533)	Specifies which edges of the control are beveled.
	BevelInner (see page 533)	Specifies the cut of the inner bevel.
	BevelKind (see page 533)	Specifies the control's bevel style.
	BevelOuter (see page 534)	Specifies the cut of the outer bevel.
	BiDiMode (see page 534)	Specifies the bi-directional mode for the control.
	Color (see page 535)	Sets the background color of the TColorListBox (see page 525) control.
	Constraints (see page 535)	Specifies the size constraints for the control.
	Ctl3D (see page 536)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefaultColorColor (see page 536)	This is DefaultColorColor, a member of class TColorListBox.
	DoubleBuffered (see page 536)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	Enabled (see page 538)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 539)	Controls the attributes of text written on or in the control.
	ItemHeight (see page 540)	Specifies the height in pixels of an item in an owner-draw list box.
	NoneColorColor (see page 540)	This is NoneColorColor, a member of class TColorListBox.
	ParentBiDiMode (see page 540)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 541)	Determines where a control looks for its color information.
	ParentCtl3D (see page 541)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 542)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 542)	Determines where a control looks for its font information.
	ParentShowHint (see page 542)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 543)	Identifies the pop-up menu associated with the control.
	Selected (see page 548)	Indicates whether a particular item is selected.
	ShowHint (see page 550)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Style (see page 551)	Determines whether the list box is standard or owner-draw and whether it is virtual.
	TabOrder (see page 552)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 553)	Determines if the user can tab to a control.
	Visible (see page 553)	Determines whether the component appears onscreen.

3.1.11.2 TColorListBox Properties

The properties of the TColorListBox class are listed here.

Published Properties

	Name	Description
	Align (see page 528)	Determines how the control aligns within its container (parent control).
	Anchors (see page 532)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 532)	Determines whether the user can give focus to items by typing in the list.
	BevelEdges (see page 533)	Specifies which edges of the control are beveled.
	BevelInner (see page 533)	Specifies the cut of the inner bevel.
	BevelKind (see page 533)	Specifies the control's bevel style.
	BevelOuter (see page 534)	Specifies the cut of the outer bevel.
	BiDiMode (see page 534)	Specifies the bi-directional mode for the control.
	Color (see page 535)	Sets the background color of the TColorListBox (see page 525) control.
	Constraints (see page 535)	Specifies the size constraints for the control.
	Ctl3D (see page 536)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefaultColorColor (see page 536)	This is DefaultColorColor, a member of class TColorListBox.
	DoubleBuffered (see page 536)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	Enabled (see page 538)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 539)	Controls the attributes of text written on or in the control.
	ItemHeight (see page 540)	Specifies the height in pixels of an item in an owner-draw list box.
	NoneColorColor (see page 540)	This is NoneColorColor, a member of class TColorListBox.
	ParentBiDiMode (see page 540)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 541)	Determines where a control looks for its color information.
	ParentCtl3D (see page 541)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 542)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 542)	Determines where a control looks for its font information.
	ParentShowHint (see page 542)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 543)	Identifies the pop-up menu associated with the control.
	Selected (see page 548)	Indicates whether a particular item is selected.
	ShowHint (see page 550)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Style (see page 551)	Determines whether the list box is standard or owner-draw and whether it is virtual.
	TabOrder (see page 552)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 553)	Determines if the user can tab to a control.
	Visible (see page 553)	Determines whether the component appears onscreen.

3.1.11.2.1 TColorListBox.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always

equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
```

```
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane – a file list box }
```

```
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
}

Parent

Anchors

3.1.11.2.2 TColorListBox.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

3.1.11.2.3 TColorListBox.AutoComplete Property

Determines whether the user can give focus to items by typing in the list.

Pascal

```
property AutoComplete;
```

C++

```
__property AutoComplete;
```

Description

Use AutoComplete to specify whether the list box automatically updates the ItemIndex property in response to user keystrokes. When AutoComplete is true, the item with focus changes to the first item that begins with the sequence of characters that the user typed. As the user types more characters, ItemIndex may change to a later item because the string to match becomes longer.

See Also

ItemIndex

3.1.11.2.4 TColorListBox.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges;
```

C++

```
__property BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner

BevelOuter

BevelKind

3.1.11.2.5 TColorListBox.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner;
```

C++

```
__property BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges

BevelOuter

BevelKind

BevelWidth

BorderWidth

3.1.11.2.6 TColorListBox.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind;
```

C++

```
__property BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

BevelEdges

BevelOuter

BevelInner

BevelWidth

3.1.11.2.7 TColorListBox.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter;
```

C++

```
__property BevelOuter;
```

Description

Use BevelOuter to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges

BevelInner

BevelKind

BevelWidth

3.1.11.2.8 TColorListBox.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

3.1.11.2.9 TColorListBox.Color Property

Sets the background color of the TColorListBox (see page 525) control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

The color property is set to white, by default.

3.1.11.2.10 TColorListBox.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

OnCanResize

3.1.11.2.11 TColorListBox.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

3.1.11.2.12 TColorListBox.DefaultColorColor Property

Pascal

```
property DefaultColorColor: TColor;
```

C++

```
__property TColor DefaultColorColor;
```

Description

This is DefaultColorColor, a member of class TColorListBox.

3.1.11.2.13 TColorListBox.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
```

```
  end;

  // This OnDragOver event handler permits the list box to
  // accept a dropped label:

  procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TLabel;
  end;

  // This OnDragDrop event handler implements the drop behavior.

  procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
  begin
    if (Sender is TListBox) and (Source is TLabel) then
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

3.1.11.2.14 TColorListBox.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

3.1.11.2.15 TColorListBox.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

3.1.11.2.16 TColorListBox.ItemHeight Property

Specifies the height in pixels of an item in an owner-draw list box.

Pascal

```
property ItemHeight;
```

C++

```
__property ItemHeight;
```

Description

Use ItemHeight to control the height of an item in a list box when the Style property is lbOwnerDrawFixed. The ItemHeight property can also affect the height of the list box itself. When the IntegralHeight property is true, the height of the list box is always an increment of the ItemHeight value.

If the Style property is lbStandard or lbOwnerDrawVariable, the value of ItemHeight is ignored.

3.1.11.2.17 TColorListBox.NoneColorColor Property

Pascal

```
property NoneColorColor: TColor;
```

C++

```
__property TColor NoneColorColor;
```

Description

This is NoneColorColor, a member of class TColorListBox.

3.1.11.2.18 TColorListBox.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent

BiDiMode

3.1.11.2.19 TColorListBox.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

3.1.11.2.20 TColorListBox.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

3.1.11.2.21 TColorListBox.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

3.1.11.2.22 TColorListBox.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

ParentShowHint

3.1.11.2.23 TColorListBox.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

3.1.11.2.24 TColorListBox.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
```

```
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/

3.1.11.2.25 TColorListBox.Selected Property

Indicates whether a particular item is selected.

Pascal

```
property Selected: TColor;
```

C++

```
__property TColor Selected;
```

Description

Use Selected to query the state of a particular item in the list box. If the item specified by the Index parameter is selected in the list box, the value of the Selected property is true. If the specified item is not selected, Selected is false. Set Selected to change the currently selected item.

The Index parameter is the item referenced by its position in the list box, with the first item having an Index value of 0.

An item is selected when the user highlights it. More than one item in the list box can be selected by setting the MultiSelect property to true. In this case, the Selected item is the one that has focus when the list box has input focus.

C++ Examples:

```
/*
This example uses a file listbox and a regular listbox on a
form. The following routine scans through the files listed
in the file listbox and lists the sizes of any selected
files to the regular list box.  To exercise the error
condition create a file in the Debug directory, start this
application and then delete the file.  Now try to list the
size of the deleted file.  Continue will continue listing
file sizes in a multiple selection that includes the deleted
file.  Break will stop.  Set the MultiSelect and
ExtendedSelect properties on the FileListBox.
*/
#include <stdio.h>     // for FILE, fopen, fstat, fileno, fread and fclose
#include <sys\stat.h>  // for fstat and the stat struct
```

```
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int i = 0; i < FileListBox1->Items->Count; i++)
  {
    if (FileListBox1->Selected[i])
    {
      if (!FileExists(FileListBox1->Items->Strings[i]))
      {
        MessageBeep(0);
        if (Application->MessageBox(
          String("File " + FileListBox1->Items->Strings[i] + "not found").t_str(),
          NULL,
          MB_OKCANCEL) == IDCANCEL)
          break;
        else
          continue;
      }
      FILE *F = fopen(AnsiString(FileListBox1->Items->Strings[i]).t_str(),"r");
      struct stat statbuf;
      fstat(fileno(F), &statbuf);
      ListBox1->Items->Add(
          FileListBox1->Items->Strings[i] + ": " + IntToStr(int(statbuf.st_size)));
      fclose(F);
    }
  }
}
```

Delphi Examples:

```
{
This example uses a file listbox and a regular listbox on a
form. The following routine scans through the files listed
in the file listbox and lists the sizes of any selected
files to the regular list box.  To exercise the error
condition create a file in the Debug directory, start this
application and then delete the file.  Now try to list the
size of the deleted file.  Set the MultiSelect and
ExtendedSelect properties on the FileListBox.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F: File;
  i, filehandle: Integer;
begin
  for i := 0 to (FileListBox1.Items.Count - 1) do begin
  try
    if FileListBox1.Selected[i] then
    begin
      if not FileExists(FileListBox1.Items.Strings[i]) then
      begin
        MessageDlg('File: ' + FileListBox1.Items.Strings[i] +
                   ' not found', mtError, [mbOk], 0);
        Continue;
      end;
      filehandle:=  FileOpen(FileListBox1.Items.Strings[i], fmOpenWrite);
      if (filehandle = -1) then
      begin
        MessageDlg('File: ' + FileListBox1.Items.Strings[i] +
                   ' cannot be opened with access mode fmOpenWrite.', mtError, [mbOk], 0);
        Continue;
      end
      else
        FileClose(filehandle);

      AssignFile(F, FileListBox1.Items.Strings[i]);
      Reset(F, 1);
```

```
        ListBox1.Items.Add(
          FileListBox1.Items.Strings[i] + ': ' + IntToStr(FileSize(F)));
        CloseFile(F);
      end;
    finally
    { do something here }
    end;
  end;
end;
```

3.1.11.2.26 TColorListBox.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
```

```
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';

Displaying Fly-over Help

3.1.11.2.27 TColorListBox.Style Property

Determines whether the list box is standard or owner-draw and whether it is virtual.

Pascal

```
property Style: TColorBoxStyle;
```

C++

```
__property TColorBoxStyle Style;
```

Description

Use Style to specify whether the list box is a standard list box that displays text strings, or an owner-draw list box that can display

graphical images. Owner-draw list boxes let you display items in some nonstandard way. In this case, you must write the code to paint items in the list box.

In addition, Style controls whether the list box is virtual, which means that items are supplied dynamically using event handlers. By default, Style is lbStandard, meaning that the list box is not virtual and it displays each item as a string.

3.1.11.2.28 TColorListBox.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

3.1.11.2.29 TColorListBox.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

3.1.11.2.30 TColorListBox.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
```

```
    {
      TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
      pPage->PageControl = PageControl1;
      pPage->Caption = AnsiString("Page") + IntToStr(i);
      TEdit *pEdit = new TEdit(this); // The owner will clean this up.
      pEdit->Parent = pPage;
      pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
      pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
    }
    PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);

3.1.11.3 TColorListBox Events

The events of the TColorListBox class are listed here.

Published Events

	Name	Description
	OnClick (see page 555)	Occurs when the user clicks the control.
	OnContextPopup (see page 557)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 558)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 558)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 561)	Occurs when the user drags an object over a control.
	OnEndDock (see page 564)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 565)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 566)	Occurs when a control receives the input focus.
	OnExit (see page 568)	Occurs when the input focus shifts away from one control to another.
	OnGetColors (see page 571)	This is OnGetColors, a member of class TColorListBox.
	OnKeyDown (see page 571)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 575)	Occurs when a key is pressed.
	OnKeyUp (see page 576)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 577)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 578)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 581)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 581)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 581)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 584)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 586)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 586)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

3.1.11.3.1 TColorListBox.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check

box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.

- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
```

```
    for i := 0 to 9 do
      with TTabSheet.Create(Self) do
      begin
        PageControl := PageControl1;
        Caption := 'TabSheet' + IntToStr(i);
        with TEdit.Create(Self) do
        begin
          Parent := PageControl1.Pages[i];
          Left := Random(PageControl1.ActivePage.ClientWidth - Width);
          Top := Random(PageControl1.ActivePage.ClientHeight - Height);
        end;
      end;
      PageControl1Change(Sender);
  end;

3.1.11.3.2 TColorListBox.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

3.1.11.3.3 TColorListBox.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

OnClick

Responding to User Actions at Runtime

3.1.11.3.4 TColorListBox.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
```

```
{
  Accept = Source->ClassNameIs("TLabel");
}

3.1.11.3.5 TColorListBox.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
```

```

DragKind

3.1.11.3.8 TColorListBox.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/

3.1.11.3.9 TColorListBox.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
```

```
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

procedure TForm1.MaskEdit2Exit(Sender: TObject);
var
  net1, net2, host1, host2,
  netmask1, netmask2, hostmask1, hostmask2,
  sub_net1, sub_net2, sub_host1, sub_host2: Integer;

  IP, mask: String;

begin
  // extract the net and host address from the IP
  IP := MaskEdit1.Text;
  net1 := StrToInt(TrimRight(Copy(IP, 0, 3)));
  net2 := StrToInt(TrimRight(Copy(IP, 5, 3)));
  host1 := StrToInt(TrimRight(Copy(IP, 9, 3)));
  host2 := StrToInt(TrimRight(Copy(IP, 13, 3)));

  // a range test that you cannot validate through edit masks
  if ((net1 < 0) Or (net1 > 255) Or
      (net2 < 0) Or (net2 > 255) Or
      (host1 < 0) Or (host1 > 255) Or
      (host2 < 0) Or (host2 > 255)) then
    raise EArgumentException.Create('Not a valid IP address.');

  // extract the net and host mask from the subnet mask
  mask := MaskEdit2.Text;
  netmask1 := StrToInt(TrimRight(Copy(mask, 0, 3)));
  netmask2 := StrToInt(TrimRight(Copy(mask, 5, 3)));
  hostmask1 := StrToInt(TrimRight(Copy(mask, 9, 3)));
  hostmask2 := StrToInt(TrimRight(Copy(mask, 13, 3)));

  // a range test that you cannot validate through edit masks
  if ((netmask1 < 0) Or (netmask1 > 255) Or
      (netmask2 < 0) Or (netmask2 > 255) Or
      (hostmask1 < 0) Or (hostmask1 > 255) Or
      (hostmask2 < 0) Or (hostmask2 > 255)) then
    raise EArgumentException.Create('Not a valid subnet mask.');

  // compute the subnet address using bit-wise AND
  sub_net1 := net1 And netmask1;
  sub_net2 := net2 And netmask2;
  sub_host1 := host1 And hostmask1;
  sub_host2 := host2 And hostmask2;

  // display the subnet address
  MaskEdit3.Text :=
    IntToStr(sub_net1) + '.' + IntToStr(sub_net2) + '.' +
    IntToStr(sub_host1) + '.' + IntToStr(sub_host2);
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;
```

```
procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

3.1.11.3.10 TColorListBox.OnGetColors Event

Pascal

```
property OnGetColors: TLBGetColorsEvent;
```

C++

```
__property TLBGetColorsEvent OnGetColors;
```

Description

This is OnGetColors, a member of class TColorListBox.

3.1.11.3.11 TColorListBox.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown;
```

C++

```
__property OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR

message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
Behavior is dependent on keyboard driver(USB, serial, etc).
*/

OnKeyPress

OnKeyUp

3.1.11.3.12 TColorListBox.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress;
```

C++

```
__property OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
```

```
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

OnKeyDown

OnKeyPress

3.1.11.3.14 TColorListBox.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

OnMouseMove

OnMouseUp

MouseCapture

3.1.11.3.15 TColorListBox.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
```

```
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.

3.1.11.3.16 TColorListBox.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

3.1.11.3.17 TColorListBox.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

3.1.11.3.18 TColorListBox.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

MouseCapture

3.1.11.3.19 TColorListBox.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp;
```

C++

```
__property OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

3.1.11.3.20 TColorListBox.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

TDragDockObjectEx

DragKind

OnDragOver

OnDockDrop

3.1.11.3.21 TColorListBox.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

3.1.12 TColumnCollection Class

Controls the **Collection Editor** for columns within a grid panel.

Class Hierarchy

Pascal

```
TColumnCollection = class(TCellCollection);
```

C++

```
class TColumnCollection : public TCellCollection;
```

File

ExtCtrls

Description

TColumnCollection controls the **Collection Editor** for columns within a grid panel.

Collection Editor

3.1.12.1 TColumnCollection Members

The following tables list the members exposed by TColumnCollection.

Protected Methods

	Name	Description
	GetAttr (see page 459)	Returns the name of a custom attribute that can be retrieved using the GetItemAttr method.
	GetAttrCount (see page 459)	Returns the number of custom attributes associated with items in the collection.
	GetItem (see page 460)	Returns a specified item in the collection.
	GetItemAttr (see page 589)	Returns the value of a custom attribute assigned to one of the collection's items.
	Notify (see page 589)	Responds when items are added to or removed from the collection.
	SetItem (see page 461)	This is SetItem, a member of class TCellCollection.
	Update (see page 461)	Updates the collection to reflect changes to its items.

Public Methods

	Name	Description
	Add (see page 589)	Adds a column to the grid panel.
	Create (see page 588)	This is Create, a member of class TColumnCollection.
	Owner (see page 460)	Returns the Owner of the cell collection.

Public Properties

	Name	Description
	Items (see page 461)	Lists the items of the cell collection.

3.1.12.2 TColumnCollection.Create Constructor

Pascal

```
constructor Create(AOwner: TPersistent);
```

C++

```
__fastcall TColumnCollection(TPersistent * AOwner);
```

Description

This is Create, a member of class TColumnCollection.

3.1.12.3 TColumnCollection Methods

The methods of the TColumnCollection class are listed here.

Protected Methods

	Name	Description
	GetItemAttr (see page 589)	Returns the value of a custom attribute assigned to one of the collection's items.
	Notify (see page 589)	Responds when items are added to or removed from the collection.

Public Methods

	Name	Description
	Add (see page 589)	Adds a column to the grid panel.

3.1.12.3.1 TColumnCollection.Add Method

Adds a column to the grid panel.

Pascal

```
function Add: TColumnItem;
```

C++

```
__fastcall TColumnItem Add();
```

Description

Use the Add method to add a new column to the grid panel.

3.1.12.3.2 TColumnCollection.GetItemAttr Method

Returns the value of a custom attribute assigned to one of the collection's items.

Pascal

```
function GetItemAttr(Index: Integer; ItemIndex: Integer): string; override;
```

C++

```
virtual __fastcall UnicodeString GetItemAttr(int Index, int ItemIndex);
```

Description

TCollection descendants can associate user-defined attributes with the items in the collection. Each attribute has a name and, for each item in the collection, a value that is a string. GetItemAttr returns the value of one of these attributes for a specified item in the collection.

Index identifies which attribute's value is desired. This is a value between 0 and n-1, where n is the value returned by GetAttrCount.

ItemIndex identifies the item whose attribute value is desired. This is an index into the Items property array.

As implemented in TCollection, GetItemAttr always returns an empty string, because TCollection defines no custom attributes.

See Also

GetAttr

GetAttrCount

3.1.12.3.3 TColumnCollection.Notify Method

Responds when items are added to or removed from the collection.

Pascal

```
procedure Notify(Item: TCollectionItem; Action: TCollectionNotification); override;
```

C++

```
virtual __fastcall Notify(TCollectionItem Item, TCollectionNotification Action);
```

Description

Notify is called automatically when the items in the collection change.

Item is the item that was just added to or that is about to be removed from the collection.

Action indicates whether item was added, is about to be removed, or is about to be deleted:

As implemented in TCollection, Notify calls Added when Action is cnAdded and calls Deleting when Action is cnDeleting. TCollection ignores the cnExtracting action. Descendant classes can override Notify to modify this behavior.

3.1.13 TColumnItem Class

Class Hierarchy

Pascal

```
TColumnItem = class(TCellItem);
```

C++

```
class TColumnItem : public TCellItem;
```

File

ExtCtrls

Description

This is class ExtCtrls.TColumnItem.

3.1.14 TControlBar Class

TControlBar manages the layout of toolbar components.

Class Hierarchy

Pascal

```
TControlBar = class(TCustomControlBar);
```

C++

```
class TControlBar : public TCustomControlBar;
```

File

ExtCtrls

Description

Use TControlBar as a docking site for toolbar components. Control bars contain child controls (usually TToolBar objects) that can be moved and resized independently. As with a cool bar, each child control resides on its own individual band that the user positions by dragging its sizing grip.

Tip: When docking TToolBar objects to a control bar, you may find it useful to use TToolDockObject.

Note: If you want to use TActionToolBar on a TControlBar component, you should set the AutoSize (see page 599) property to **False**. When the AutoSize (see page 599) property is set to True (default), the TActionToolBar control wraps its controls

and expands itself in size, accordingly. This does not allow the TActionToolBar component to display properly on a TControlBar component. When the AutoSize (see page 599) property is set to **False**, the TActionToolBar hides items on the end of the bar and displays a dropdown button that provides access to those items. The control displays in the proper size.

TToolBar

3.1.14.1 TControlBar Members

The following tables list the members exposed by TControlBar.

Protected Methods

	Name	Description
	AlignControls (see page 757)	Aligns controls in the control bar.
	CanAutoSize (see page 757)	Indicates how the control can be resized.
	CreateParams (see page 758)	Sets the control bar's window flags.
	DoBandMove (see page 758)	Generates an OnBandMove (see page 772) event.
	DoBandPaint (see page 758)	Generates an OnBandPaint (see page 772) event.
	DoBeginBandMove (see page 759)	This is DoBeginBandMove, a member of class TCustomControlBar.
	DockOver (see page 759)	Generates an OnDockOver event and ensures proper docking of floating controls.
	DoEndBandMove (see page 759)	This is DoEndBandMove, a member of class TCustomControlBar.
	DoPaletteChange (see page 760)	Prepares the control bar to realize a new palette.
	DragControl (see page 760)	Starts a drag operation on a control band.
	GetControlInfo (see page 761)	Generates an OnBandInfo (see page 771) event.
	GetPalette (see page 762)	Returns the handle to a palette for use by the control.
	GetSiteInfo (see page 762)	Generates an OnGetSiteInfo event
	HitTest (see page 763)	Returns the control at the specified coordinates.
	MouseDown (see page 763)	Handles mouse button clicks.
	MouseMove (see page 763)	Handles mouse movements.
	MouseUp (see page 764)	Handles releasing of a mouse button.
	Paint (see page 764)	Paints the control bar.
	PaintControlFrame (see page 765)	Paints a control band's frame.

Public Methods

	Name	Description
	Create (see page 755)	Creates and initializes an instance of TCustomControlBar (see page 754).
	Destroy (see page 756)	Destroys the TCustomControlBar (see page 754) instance.
	FlipChildren (see page 761)	Reverses the positions of child controls.
	StickControls (see page 765)	Places controls in their final positions after a control is moved in or dropped on the control bar.

Public Properties

	Name	Description
	Canvas (see page 602)	Specifies the TCanvas object that presents a drawing surface for the control.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 623)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 624)	Occurs when an object with custom alignment is aligned.
	OnBandDrag (see page 624)	Occurs when the user starts a drag operation on a specified control.
	OnBandInfo (see page 625)	Occurs when the control bar adjusts the docking position of a band.
	OnBandMove (see page 625)	Occurs when a control band is moving.

	OnBandPaint (see page 626)	Occurs when a control band is painted.
	OnBeginBandMove (see page 626)	This is OnBeginBandMove, a member of class TControlBar.
	OnCanResize (see page 626)	Occurs when an attempt is made to resize the control.
	OnClick (see page 627)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 628)	Adjust resize constraints.
	OnContextPopup (see page 629)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 630)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 630)	Occurs when another control is docked to the control.
	OnDockOver (see page 632)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 634)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 637)	Occurs when the user drags an object over a control.
	OnEndBandMove (see page 640)	This is OnEndBandMove, a member of class TControlBar.
	OnEndDock (see page 640)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 641)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 642)	Occurs when a control receives the input focus.
	OnExit (see page 644)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 647)	Returns the control's docking information.
	OnMouseActivate (see page 649)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 650)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 652)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 653)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 653)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 655)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnPaint (see page 657)	Occurs when the control bar is painted.
	OnResize (see page 658)	Occurs immediately after the control is resized.
	OnStartDock (see page 659)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 659)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 660)	Occurs when the application tries to undock a control that is docked to the windowed control.

Published Properties

	Name	Description
	Align (see page 594)	Determines how the control aligns within its container (parent control).
	Anchors (see page 597)	Specifies how the control is anchored to its parent.
	AutoDock (see page 598)	Determines whether the control bar temporarily docks drag clients to provide visual feedback.
	AutoDrag (see page 598)	Specifies whether control bands can be undocked by dragging.
	AutoSize (see page 599)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 599)	Specifies which edges of the control are beveled.
	BevelInner (see page 600)	Specifies the cut of the inner bevel.
	BevelKind (see page 600)	Specifies the control's bevel style.
	BevelOuter (see page 601)	Specifies the cut of the outer bevel.
	BevelWidth (see page 601)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 601)	Specifies the width of the control's border.
	Color (see page 604)	Specifies the background color of the control.
	Constraints (see page 604)	Specifies the size constraints for the control.
	CornerEdge (see page 605)	The size of the cornering for the edge of the bands.
	DockSite (see page 605)	Specifies whether the control can be the target of drag-and-dock operations.

	DragCursor (see page 606)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 607)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 607)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	DrawingStyle (see page 609)	This is DrawingStyle, a member of class TControlBar.
	Enabled (see page 609)	Controls whether the control responds to mouse, keyboard, and timer events.
	GradientDirection (see page 609)	Horizontal or Vertical.
	GradientEndColor (see page 609)	Stores the color that the gradient is painted with when it ends.
	GradientStartColor (see page 610)	Stores the color that the gradient is painted when it starts.
	ParentBackground (see page 610)	Determines whether control uses parent's theme background.
	ParentColor (see page 610)	Determines where a control looks for its color information.
	ParentCtl3D (see page 611)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 611)	Determines where a control looks for its font information.
	ParentShowHint (see page 612)	Determines where a control looks to find out if its Help Hint should be shown.
	Picture (see page 612)	Specifies the control bar's picture.
	PopupMenu (see page 612)	Identifies the pop-up menu associated with the control.
	RowSize (see page 617)	Specifies the height of the control bar's rows.
	RowSnap (see page 618)	Specifies whether controls are snapped to the control bar's rows when docked.
	ShowHint (see page 618)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 620)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 620)	Determines if the user can tab to a control.
	Visible (see page 621)	Determines whether the component appears onscreen.

3.1.14.2 TControlBar Properties

The properties of the TControlBar class are listed here.

Public Properties

	Name	Description
	Canvas (see page 602)	Specifies the TCanvas object that presents a drawing surface for the control.

Published Properties

	Name	Description
	Align (see page 594)	Determines how the control aligns within its container (parent control).
	Anchors (see page 597)	Specifies how the control is anchored to its parent.
	AutoDock (see page 598)	Determines whether the control bar temporarily docks drag clients to provide visual feedback.
	AutoDrag (see page 598)	Specifies whether control bands can be undocked by dragging.
	AutoSize (see page 599)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 599)	Specifies which edges of the control are beveled.
	BevelInner (see page 600)	Specifies the cut of the inner bevel.
	BevelKind (see page 600)	Specifies the control's bevel style.
	BevelOuter (see page 601)	Specifies the cut of the outer bevel.
	BevelWidth (see page 601)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 601)	Specifies the width of the control's border.
	Color (see page 604)	Specifies the background color of the control.
	Constraints (see page 604)	Specifies the size constraints for the control.
	CornerEdge (see page 605)	The size of the cornering for the edge of the bands.
	DockSite (see page 605)	Specifies whether the control can be the target of drag-and-dock operations.
	DragCursor (see page 606)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 607)	Specifies whether the control is being dragged normally or for docking.

	DragMode (see page 607)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	DrawingStyle (see page 609)	This is DrawingStyle, a member of class TControlBar.
	Enabled (see page 609)	Controls whether the control responds to mouse, keyboard, and timer events.
	GradientDirection (see page 609)	Horizontal or Vertical.
	GradientEndColor (see page 609)	Stores the color that the gradient is painted with when it ends.
	GradientStartColor (see page 610)	Stores the color that the gradient is painted when it starts.
	ParentBackground (see page 610)	Determines whether control uses parent's theme background.
	ParentColor (see page 610)	Determines where a control looks for its color information.
	ParentCtl3D (see page 611)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 611)	Determines where a control looks for its font information.
	ParentShowHint (see page 612)	Determines where a control looks to find out if its Help Hint should be shown.
	Picture (see page 612)	Specifies the control bar's picture.
	PopupMenu (see page 612)	Identifies the pop-up menu associated with the control.
	RowSize (see page 617)	Specifies the height of the control bar's rows.
	RowSnap (see page 618)	Specifies whether controls are snapped to the control bar's rows when docked.
	ShowHint (see page 618)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 620)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 620)	Determines if the user can tab to a control.
	Visible (see page 621)	Determines whether the component appears onscreen.

3.1.14.2.1 TControlBar.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
```

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};
```

```
void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane - a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
}

Parent

Anchors

3.1.14.2.2 TControlBar.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

3.1.14.2.3 TControlBar.AutoDock Property

Determines whether the control bar temporarily docks drag clients to provide visual feedback.

Pascal

```
property AutoDock: Boolean;
```

C++

```
__property Boolean AutoDock;
```

Description

If AutoDock is true (the default), when a dockable object is dragged over the control bar, the control bar temporarily docks the object so that the user can see the impact of the drag operation. That is, the user can see the dock position and how other docked controls will be repositioned to make room. When the user releases the mouse, the dragged object is docked at the current spot, and any temporary dockings are canceled. However, if the user cancels the drag-and-dock operation, the dragged object reverts to its last temporary dock site rather than to its location at the start of the drag operation.

If AutoDock is false, the control bar does not temporarily dock dragged objects. Instead, the user only sees the dragging rectangle as it passes over the control bar, with no feedback as to the adjustments the control bar would make if the dragged object were released.

See Also

DockClients

DockSite

OnDockOver

3.1.14.2.4 TControlBar.AutoDrag Property

Specifies whether control bands can be undocked by dragging.

Pascal

```
property AutoDrag: Boolean;
```

C++

```
__property Boolean AutoDrag;
```

Description

Use AutoDrag to specify whether control bands are automatically undocked when the user drags them. If AutoDrag is true, control bands (TToolBar objects) are undocked when dragged off the control bar. Otherwise, control bands are kept within the control bar.

See Also

DragMode

OnBandDrag (see page 771)

onbandmove (see page 772)

3.1.14.2.5 TControlBar.AutoSize Property

Specifies whether the control sizes itself automatically to accommodate its contents.

Pascal

```
property AutoSize;
```

C++

```
__property AutoSize;
```

Description

Use AutoSize to specify whether the control sizes itself automatically. When AutoSize is true, the control resizes automatically when its contents change.

By default, AutoSize is false.

See Also

Constraints

CanAutoSize

3.1.14.2.6 TControlBar.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges;
```

C++

```
__property BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner

BevelOuter

BevelKind

3.1.14.2.7 TControlBar.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner;
```

C++

```
__property BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges

BevelOuter

BevelKind

BevelWidth

BorderWidth

3.1.14.2.8 TControlBar.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind;
```

C++

```
__property BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges

BevelOuter

BevelInner

BevelWidth

3.1.14.2.9 TControlBar.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter;
```

C++

```
__property BevelOuter;
```

Description

Use BevelOuter to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges

BevelInner

BevelKind

BevelWidth

3.1.14.2.10 TControlBar.BevelWidth Property

Specifies the width of the inner and outer bevels.

Pascal

```
property BevelWidth;
```

C++

```
__property BevelWidth;
```

Description

Use BevelWidth to specify the width, in pixels, of the inner and outer bevels.

See Also

BevelEdges

BevelInner

BevelKind

BevelOuter

3.1.14.2.11 TControlBar.BorderWidth Property

Specifies the width of the control's border.

Pascal

```
property BorderWidth;
```

C++

```
__property BorderWidth;
```

Description

Use BorderWidth to get or set the width of the control's border. Graphics or text drawn by the control is clipped to the area within the border.

See Also

ClientRect

BevelOuter

3.1.14.2.12 TControlBar.Canvas Property

Specifies the TCanvas object that presents a drawing surface for the control.

Pascal

```
property Canvas;
```

C++

```
__property Canvas;
```

Description

Use the properties of the TCanvas object to draw or paint on the surface of the control. Canvas encapsulates a Windows device context, providing all the tools and methods needed for drawing and painting.

Canvas is a protected property that is usually redeclared as public in descendants of TCustomControl.

C++ Examples:

```
/*
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
*/
void __fastcall TForm1::DrawGrid1DrawCell(
  TObject *Sender, int ACol, int ARow, TRect &Rect, TGridDrawState State)
{
  long index = ARow * DrawGrid1->ColCount + ACol;
  DrawGrid1->Canvas->Brush->Color = clBackground;
  DrawGrid1->Canvas->FillRect(Rect);
  if (State.Contains(gdFocused))
  {
    DrawGrid1->Canvas->DrawFocusRect(Rect);
    Label1->Caption = "Cell " + IntToStr(int(index)) + " has the focus.";
  }
  ImageList1->Draw(
    DrawGrid1->Canvas, Rect.Left, Rect.Top, index, True);
}

void __fastcall TForm1::DrawGrid1SelectCell(TObject *Sender, int ACol, int ARow,
      bool &CanSelect)
{
  CanSelect= True;
}
/*
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
```

```
TControl and has a public Canvas property.
*/
{
  TPoint APoint = Point(X, Y);
  int Index = ListBox1->ItemAtPos(APoint, True);
  TStringGrid *myStringGrid;
  TClass ClassRef = ListBox1->Items->Objects[Index]->ClassType();
  if (String(ClassRef->ClassName()) == "TStringGrid")
  {
    myStringGrid = dynamic_cast<TStringGrid *>(ListBox1->Items->Objects[Index]);
    // make sure we are using the TControls canvas and not the from's!
    myStringGrid->Canvas->MoveTo(myStringGrid->ClientRect.Left, myStringGrid->ClientRect.Top);
    myStringGrid->Canvas->LineTo(myStringGrid->ClientRect.Right,
myStringGrid->ClientRect.Bottom);
    myStringGrid = NULL;
  }
}
```

Delphi Examples:

```
{
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
}
procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
  Rect: TRect; State: TGridDrawState);
var
  index: Integer;
begin
  index := ARow * DrawGrid1.ColCount + ACol;
  DrawGrid1.Canvas.Brush.Color := clWhite;
  DrawGrid1.Canvas.FillRect(Rect);
  if (gdFocused in State) then
  begin
    DrawGrid1.Canvas.DrawFocusRect(Rect);
    Label1.Caption:= 'Cell ' + InttoStr(index) + ' has the focus.';
  end;
  ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
end;

procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
  var CanSelect: Boolean);
begin
  CanSelect:= True;
end;
{
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
}
  if (ListBox1.Items.Objects[Index] is TStringGrid) then
  begin
    myStringGrid:= (ListBox1.Items.Objects[Index] as TStringGrid);
    with myStringGrid.ClientRect do
    begin // make sure we are using the TControl's canvas and not the form's!
      myStringGrid.Canvas.MoveTo(Left, Top);
      myStringGrid.Canvas.LineTo(Right, Bottom);
    end;
  myStringGrid:= nil;
  end;
```

See Also

Paint

3.1.14.2.13 TControlBar.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{

3.1.14.2.14 TControlBar.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

3.1.14.2.15 TControlBar.CornerEdge Property

The size of the cornering for the edge of the bands.

Pascal

```
property CornerEdge: TCornerEdge;
```

C++

```
__property TCornerEdge CornerEdge;
```

Description

This property stores the size of the cornering for the edge of the bands.

3.1.14.2.16 TControlBar.DockSite Property

Specifies whether the control can be the target of drag-and-dock operations.

Pascal

```
property DockSite;
```

C++

```
__property DockSite;
```

Description

Set DockSite to true to allow other controls to be docked to this windowed control.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/
void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
      TWinControl *NewTarget, bool &Allow)
{
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if (Client->ClassNameIs("TDockableForm"))
    dynamic_cast<TDockableForm *>(Client)->DockSite = True;
  if ((DockClientCount == 2) && (NewTarget != this))        // Self?
    PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
}
procedure TConjoinDockHost.FormUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if Client is TDockableForm then
    TDockableForm(Client).DockSite := True;
  if (DockClientCount = 2) and (NewTarget <> Self) then
    PostMessage(Self.Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
end;
```

3.1.14.2.17 TControlBar.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor;
```

C++

```
__property DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor

DragKind

DragMode

3.1.14.2.18 TControlBar.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

3.1.14.2.19 TControlBar.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
```

```
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;

3.1.14.2.20 TControlBar.DrawingStyle Property

Pascal

```
property DrawingStyle: TBandDrawingStyle;
```

C++

```
__property TBandDrawingStyle DrawingStyle;
```

Description

This is DrawingStyle, a member of class TControlBar.

3.1.14.2.21 TControlBar.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

3.1.14.2.22 TControlBar.GradientDirection Property

Horizontal or Vertical.

Pascal

```
property GradientDirection: TGradientDirection;
```

C++

```
__property TGradientDirection GradientDirection;
```

Description

Stores the direction of the gradient as Horizontal or Vertical.

3.1.14.2.23 TControlBar.GradientEndColor Property

Stores the color that the gradient is painted with when it ends.

Pascal

```
property GradientEndColor: TColor;
```

C++

```
__property TColor GradientEndColor;
```

Description

Use this property to store the color that you want to use to end your drawing. (This blends with the start color.)

3.1.14.2.24 TControlBar.GradientStartColor Property

Stores the color that the gradient is painted when it starts.

Pascal

```
property GradientStartColor: TColor;
```

C++

```
__property TColor GradientStartColor;
```

Description

Use this property to store the color that you want to use to initialize the drawing.

3.1.14.2.25 TControlBar.ParentBackground Property

Determines whether control uses parent's theme background.

Pascal

```
property ParentBackground;
```

C++

```
__property ParentBackground;
```

Description

If ParentBackground is true, the control uses the parent's theme background to draw its own background. ParentBackground has no effect unless XP themes are enabled.

3.1.14.2.26 TControlBar.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

3.1.14.2.27 TControlBar.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

3.1.14.2.28 TControlBar.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

ParentColor

ParentShowHint

3.1.14.2.29 TControlBar.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

3.1.14.2.30 TControlBar.Picture Property

Specifies the control bar's picture.

Pascal

```
property Picture: TPicture;
```

C++

```
__property TPicture Picture;
```

Description

Use Picture to specify the control bar's picture. The picture is tiled across the control bar.

3.1.14.2.31 TControlBar.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)

3.1.14.2.32 TControlBar.RowSize Property

Specifies the height of the control bar's rows.

Pascal

```
property RowSize: TRowSize;
```

C++

```
__property TRowSize RowSize;
```

Description

Use RowSize to specify the height, in pixels, of the control bar's rows.

See Also

CanAutoSize (see page 757)

AutoSize

ClientHeight

3.1.14.2.33 TControlBar.RowSnap Property

Specifies whether controls are snapped to the control bar's rows when docked.

Pascal

```
property RowSnap: Boolean;
```

C++

```
__property Boolean RowSnap;
```

Description

Use RowSnap to specify whether controls are snapped to the control bar's rows when docked. Controls that are snapped have their Top and Height properties set automatically to correspond to the control bar's rows.

3.1.14.2.34 TControlBar.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

3.1.14.2.35 TControlBar.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

3.1.14.2.36 TControlBar.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

3.1.14.2.37 TControlBar.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
```

```
  edit control placed somewhere on the client area of the
  sheet.  Unchecking the checkbox will cause the client area
  (not the tab area) of the Tab Control to become invisible.
  }
  procedure TForm1.CheckBox1Click(Sender: TObject);
  begin
    PageControl1.ActivePage.Visible := CheckBox1.Checked;
  end;

  procedure TForm1.PageControl1Change(Sender: TObject);
  begin
    CheckBox1.Checked := PageControl1.ActivePage.Visible;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  var
    i: Integer;
  begin
    for i := 0 to 9 do
      with TTabSheet.Create(Self) do
      begin
        PageControl := PageControl1;
        Caption := 'TabSheet' + IntToStr(i);
        with TEdit.Create(Self) do
        begin
          Parent := PageControl1.Pages[i];
          Left := Random(PageControl1.ActivePage.ClientWidth - Width);
          Top := Random(PageControl1.ActivePage.ClientHeight - Height);
        end;
      end;
      PageControl1Change(Sender);
  end;
```

3.1.14.3 TControlBar Events

The events of the TControlBar class are listed here.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 623)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 624)	Occurs when an object with custom alignment is aligned.
	OnBandDrag (see page 624)	Occurs when the user starts a drag operation on a specified control.
	OnBandInfo (see page 625)	Occurs when the control bar adjusts the docking position of a band.
	OnBandMove (see page 625)	Occurs when a control band is moving.
	OnBandPaint (see page 626)	Occurs when a control band is painted.
	OnBeginBandMove (see page 626)	This is OnBeginBandMove, a member of class TControlBar.
	OnCanResize (see page 626)	Occurs when an attempt is made to resize the control.
	OnClick (see page 627)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 628)	Adjust resize constraints.
	OnContextPopup (see page 629)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

	OnDblClick (see page 630)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 630)	Occurs when another control is docked to the control.
	OnDockOver (see page 632)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 634)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 637)	Occurs when the user drags an object over a control.
	OnEndBandMove (see page 640)	This is OnEndBandMove, a member of class TControlBar.
	OnEndDock (see page 640)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 641)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 642)	Occurs when a control receives the input focus.
	OnExit (see page 644)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 647)	Returns the control's docking information.
	OnMouseActivate (see page 649)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 650)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 652)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 653)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 653)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 655)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnPaint (see page 657)	Occurs when the control bar is painted.
	OnResize (see page 658)	Occurs immediately after the control is resized.
	OnStartDock (see page 659)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 659)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 660)	Occurs when the application tries to undock a control that is docked to the windowed control.

3.1.14.3.1 TControlBar.OnAlignInsertBefore Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignInsertBefore;
```

C++

```
__property OnAlignInsertBefore;
```

Description

OnAlignInsertBefore occurs for each pair of child controls with an Align property of **alCustom**.

It can determine the order in which custom-aligned child controls are placed. OnAlignInsertBefore returns true if **C2** should be presented before **C1**, and false otherwise. It holds a TAlignInsertBeforeEvent type.

CustomAlignInsertBefore triggers the OnAlignInsertBefore event. If this event is defined, CustomAlignInsertBefore returns the value returned by OnAlignInsertBefore. Defining this event allows users to define the order of control alignment without overriding CustomAlignInsertBefore.

CustomAlignInsertBefore

Align

TAlignInsertBeforeEvent

3.1.14.3.2 TControlBar.OnAlignPosition Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignPosition;
```

C++

```
__property OnAlignPosition;
```

Description

OnAlignPosition occurs when child controls with an Align property of **alCustom** are aligned.

CustomAlignPosition triggers the OnAlignPosition event. If this event is defined, CustomAlignPosition uses the alignment parameters it obtains from OnAlignPosition. Defining this event allows users to set the alignment parameters without overriding CustomAlignPosition. It holds a TAlignPositionEvent type.

These are the parameters:

Parameter	Meaning
NewLeft | NewTop | NewWidth | NewHeight	Location and size of child control, as determined by container's size and the Anchors TControl_Anchors constraints for the control. OnAlignPosition can modify these values to reposition the control.
AlignRect	The client area in which the control is aligned. OnAlignPosition can modify this value.
AlignInfo	Alignment information in a TAlignInfo.
As implemented in TWinControl, OnAlignPosition does nothing.

TAlignPositionEvent

3.1.14.3.3 TControlBar.OnBandDrag Event

Occurs when the user starts a drag operation on a specified control.

Pascal

```
property OnBandDrag: TBandDragEvent;
```

C++

```
__property TBandDragEvent OnBandDrag;
```

Description

Use OnBandDrag to conditionally allow the user to start dragging a control in the control bar.

The event handler indicates the control that the user is trying to drag. Change its Drag parameter to false to prevent the drag operation. If Drag remains true on exit from the event handler, the drag operation proceeds.

OnStartDock

onbandmove (see page 772)

3.1.14.3.4 TControlBar.OnBandInfo Event

Occurs when the control bar adjusts the docking position of a band.

Pascal

```
property OnBandInfo: TBandInfoEvent;
```

C++

```
__property TBandInfoEvent OnBandInfo;
```

Description

Write code in the OnBandInfo event handler to provide information to the control bar that it can use when arranging its bands. The OnBandInfo event handler has several parameters that can be used to return information about how the band should be positioned, including its size, inset, and number of rows.

Width

3.1.14.3.5 TControlBar.OnBandMove Event

Occurs when a control band is moving.

Pascal

```
property OnBandMove: TBandMoveEvent;
```

C++

```
__property TBandMoveEvent OnBandMove;
```

Description

Write an OnBandMove event handler to perform actions when a band is moving.

Use OnBandMove to specify the destination rectangle for the band. For example, adjust the destination rectangle so that its right edge matches the right edge of the control bar. This means the control extends to the control bar's right edge no matter where it is moved.

See Also

AutoDrag (see page 766)

RowSnap (see page 770)

3.1.14.3.6 TControlBar.OnBandPaint Event

Occurs when a control band is painted.

Pascal

```
property OnBandPaint: TBandPaintEvent;
```

C++

```
__property TBandPaintEvent OnBandPaint;
```

Description

Write an OnBandPaint event handler to customize the way the control bar draws its bands. From the event handler, you can draw to the control bar's canvas, using the dimensions of the band that are passed in as the ARect parameter. You can change the dimensions so that the automatically drawn frame and grabber appear in a different portion of the control bar (for example, indented slightly). You can suppress the automatic painting of the frame or grabber by removing options from the Options parameter.

OnPaint (see page 773)

3.1.14.3.7 TControlBar.OnBeginBandMove Event

Pascal

```
property OnBeginBandMove: TBeginBandMoveEvent;
```

C++

```
__property TBeginBandMoveEvent OnBeginBandMove;
```

Description

This is OnBeginBandMove, a member of class TControlBar.

3.1.14.3.8 TControlBar.OnCanResize Event

Occurs when an attempt is made to resize the control.

Pascal

```
property OnCanResize;
```

C++

```
__property OnCanResize;
```

Description

Use OnCanResize to adjust the way a control is resized. If necessary, change the new width and height of the control in the OnCanResize event handler. The OnCanResize event handler also allows applications to indicate that the entire resize should be aborted.

If there is no OnCanResize event handler, or if the OnCanResize event handler indicates that the resize attempt can proceed, the OnCanResize event is followed immediately by an OnConstrainedResize event.

See Also

OnConstrainedResize

SetBounds

OnResize

3.1.14.3.9 TControlBar.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
```

```
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

3.1.14.3.10 TControlBar.OnConstrainedResize Event

Adjust resize constraints.

Pascal

```
property OnConstrainedResize;
```

C++

```
__property OnConstrainedResize;
```

Description

Use OnConstrainedResize to adjust a control's constraints when an attempt is made to resize it. Upon entry to the OnConstrainedResize event handler, the parameters of the event handler are set to the corresponding properties of the control's Constraints object. The event handler can adjust those values before they are applied to the new height and width that is being applied to the control. (The CanAutoSize method or an OnCanResize event handler may already have adjusted this new height and width).

On exit from the OnConstrainedResize event handler, the constraints are applied to the attempted new height and width. Once the constraints are applied, the control's height and width are changed. After the control's height and width change, an OnResize event occurs to allow any final adjustments or responses.

Note: The OnConstrainedResize handler is called immediately after the OnCanResize handler.

OnResize

CanAutoSize

3.1.14.3.11 TControlBar.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple

times for each context menu invocation.

3.1.14.3.12 TControlBar.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

OnClick

Responding to User Actions at Runtime

3.1.14.3.13 TControlBar.OnDockDrop Event

Occurs when another control is docked to the control.

Pascal

```
property OnDockDrop;
```

C++

```
__property OnDockDrop;
```

Description

Write code in the OnDockDrop event to perform actions when another control is docked on the control.

OnDockDrop can only occur if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
```

```
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
```

```
      //Modify the DockRect to preview dock area.
      ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
      ARect.BottomRight := LeftDockPanel.ClientToScreen(
        Point(Self.ClientWidth div 3, LeftDockPanel.Height));
      Source.DockRect := ARect;
    end;
  end;

  procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
    NewTarget: TWinControl; var Allow: Boolean);
  begin
    //OnUnDock gets called BEFORE the client is undocked, in order to optionally
    //disallow the undock. DockClientCount is never 0 when called from this event.
    if (Sender as TPanel).DockClientCount = 1 then
      ShowDockPanel(Sender as TPanel, False, nil);
  end;

  procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
    DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
    var CanDock: Boolean);
  begin
    //if CanDock is true, the panel will not automatically draw the preview rect.
    CanDock := DockClient is TDockableForm;
  end;
```

OnDockOver

3.1.14.3.14 TControlBar.OnDockOver Event

Occurs when another control is dragged over the control.

Pascal

```
property OnDockOver;
```

C++

```
__property OnDockOver;
```

Description

Write code in the OnDockOver event to indicate whether a dockable control that is dragged over the windowed control can be accepted as a dock client. OnDockOver occurs after the TDragDockObject has been initialized by an OnGetSiteInfo event.

OnDockOver occurs only if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
```

```
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
```

```
      //Modify the DockRect to preview dock area.
      ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
      ARect.BottomRight := LeftDockPanel.ClientToScreen(
        Point(Self.ClientWidth div 3, LeftDockPanel.Height));
      Source.DockRect := ARect;
    end;
  end;

  procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
    NewTarget: TWinControl; var Allow: Boolean);
  begin
    //OnUnDock gets called BEFORE the client is undocked, in order to optionally
    //disallow the undock. DockClientCount is never 0 when called from this event.
    if (Sender as TPanel).DockClientCount = 1 then
      ShowDockPanel(Sender as TPanel, False, nil);
  end;

  procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
    DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
    var CanDock: Boolean);
  begin
    //if CanDock is true, the panel will not automatically draw the preview rect.
    CanDock := DockClient is TDockableForm;
  end;
```

TDragDockObject

3.1.14.3.15 TControlBar.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
```

```
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
type

3.1.14.3.16 TControlBar.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
```

```
  label control to be dropped on a panel control and stops the
  dragging of the label as soon as the user drags the label
  onto the panel:
  Note: Set the label's DragMode property to dmAutomatic.
  */
  void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

  {
    reinterpret_cast<TForm1 *>(Source)->Left = X;
    reinterpret_cast<TForm1 *>(Source)->Top = Y;
  }

  void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
            TDragState State, bool &Accept)
  {
    Accept = Source->ClassNameIs("TLabel");
  }

  void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
            TDragState State, bool &Accept)
  {
    Accept = false;
    if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
      dynamic_cast<TLabel *>(Source)->EndDrag(false);
  }
  /*
  This code comes from an application that contains a list box
  and three labels, each with a different font and color.  The
  DragMode property for each of the labels is dmAutomatic.

3.1.14.3.17 TControlBar.OnEndBandMove Event

Pascal

```
property OnEndBandMove: TEndBandMoveEvent;
```

C++

```
__property TEndBandMoveEvent OnEndBandMove;
```

Description

This is OnEndBandMove, a member of class TControlBar.

3.1.14.3.18 TControlBar.OnEndDock Event

Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

Pascal

```
property OnEndDock;
```

C++

```
__property OnEndDock;
```

Description

Use OnEndDock to specify actions or special processing that when a drag-and-dock operation stops.

3.1.14.3.19 TControlBar.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{

3.1.14.3.20 TControlBar.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
```

```
  FontDialog1->Options << fdApplyButton;

Using a Single Navigator for Multiple Datasets

3.1.14.3.21 TControlBar.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.

}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
```

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

procedure TForm1.MaskEdit2Exit(Sender: TObject);
var
  net1, net2, host1, host2,
  netmask1, netmask2, hostmask1, hostmask2,
  sub_net1, sub_net2, sub_host1, sub_host2: Integer;

  IP, mask: String;

begin
  // extract the net and host address from the IP
  IP := MaskEdit1.Text;
  net1 := StrToInt(TrimRight(Copy(IP, 0, 3)));
  net2 := StrToInt(TrimRight(Copy(IP, 5, 3)));
  host1 := StrToInt(TrimRight(Copy(IP, 9, 3)));
  host2 := StrToInt(TrimRight(Copy(IP, 13, 3)));

  // a range test that you cannot validate through edit masks
  if ((net1 < 0) Or (net1 > 255) Or
      (net2 < 0) Or (net2 > 255) Or
      (host1 < 0) Or (host1 > 255) Or
      (host2 < 0) Or (host2 > 255)) then
    raise EArgumentException.Create('Not a valid IP address.');

  // extract the net and host mask from the subnet mask
  mask := MaskEdit2.Text;
  netmask1 := StrToInt(TrimRight(Copy(mask, 0, 3)));
  netmask2 := StrToInt(TrimRight(Copy(mask, 5, 3)));
  hostmask1 := StrToInt(TrimRight(Copy(mask, 9, 3)));
  hostmask2 := StrToInt(TrimRight(Copy(mask, 13, 3)));

  // a range test that you cannot validate through edit masks
  if ((netmask1 < 0) Or (netmask1 > 255) Or
      (netmask2 < 0) Or (netmask2 > 255) Or
      (hostmask1 < 0) Or (hostmask1 > 255) Or
      (hostmask2 < 0) Or (hostmask2 > 255)) then
    raise EArgumentException.Create('Not a valid subnet mask.');

  // compute the subnet address using bit-wise AND
  sub_net1 := net1 And netmask1;
  sub_net2 := net2 And netmask2;
  sub_host1 := host1 And hostmask1;
  sub_host2 := host2 And hostmask2;
```

```
    // display the subnet address
    MaskEdit3.Text :=
      IntToStr(sub_net1) + '.' + IntToStr(sub_net2) + '.' +
      IntToStr(sub_host1) + '.' + IntToStr(sub_host2);
  end;
  {
  This example uses an edit box and a memo control on a form.
  When either the edit box or the memo is the active control,
  it is colored yellow. When the active control becomes
  inactive, the color of the control returns to the Windows
  system color for a window.  These event handlers could also
  be shared.
  }
  procedure TForm1.Edit1Enter(Sender: TObject);
  begin
    Edit1.Color := clYellow;
  end;

  procedure TForm1.Edit1Exit(Sender: TObject);
  begin
    Edit1.Color := clWindow;
  end;

  procedure TForm1.Memo1Enter(Sender: TObject);
  begin
    Memo1.Color := clYellow;
  end;

  procedure TForm1.Memo1Exit(Sender: TObject);
  begin
    Memo1.Color := clWindow;
  end;

ActiveControl (see page 2145)

3.1.14.3.22 TControlBar.OnGetSiteInfo Event

Returns the control's docking information.

Pascal

```
property OnGetSiteInfo;
```

C++

```
__property OnGetSiteInfo;
```

Description

Write code in the OnGetSiteInfo event handler to initialize a TDragDockObject with information about where a dragged object can be docked, if at all. OnGetSiteInfo occurs before the OnDockOver event.

OnGetSiteInfo occurs only if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
```

```
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
```

```
    Source: TDragDockObject; X, Y: Integer; State: TDragState;
    var Accept: Boolean);
  var
    ARect: TRect;
  begin
    Accept := Source.Control is TDockableForm;
    if Accept then
    begin
      //Modify the DockRect to preview dock area.
      ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
      ARect.BottomRight := LeftDockPanel.ClientToScreen(
        Point(Self.ClientWidth div 3, LeftDockPanel.Height));
      Source.DockRect := ARect;
    end;
  end;

  procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
    NewTarget: TWinControl; var Allow: Boolean);
  begin
    //OnUnDock gets called BEFORE the client is undocked, in order to optionally
    //disallow the undock. DockClientCount is never 0 when called from this event.
    if (Sender as TPanel).DockClientCount = 1 then
      ShowDockPanel(Sender as TPanel, False, nil);
  end;

  procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
    DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
    var CanDock: Boolean);
  begin
    //if CanDock is true, the panel will not automatically draw the preview rect.
    CanDock := DockClient is TDockableForm;
  end;
```

TDragDockObject

3.1.14.3.23 TControlBar.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is

over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

3.1.14.3.24 TControlBar.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
```

```
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,

3.1.14.3.25 TControlBar.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
  property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

3.1.14.3.26 TControlBar.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

3.1.14.3.27 TControlBar.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
```

```
  released, the rectangle appears on the form's canvas. Its
  top-left and bottom-right corners are defined by the
  location of the mouse pointer when the user pressed and
  released the mouse button.  While the user drags the mouse,
  the location of the top, left, bottom, and right sides of
  the rectangle are displayed in the status bar.
  }
  procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
  Y: Integer);
  begin
    StartX := X;
    StartY := Y;
  end;

  procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
  Integer);
  begin
    Form1.Canvas.Rectangle(StartX, StartY, X, Y);
    StatusBar1.Panels[0].Text := '';
    StatusBar1.Panels[1].Text := '';
    StatusBar1.Panels[2].Text := '';
    StatusBar1.Panels[3].Text := '';
  end;

  procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
  begin
    if ssLeft in Shift then { make sure button is down }
    begin
      if Y > StartY then
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
        end
      else
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
        end;
      if X > StartX then
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
        end
      else
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
        end;
    end;
  end;
```

3.1.14.3.29 TControlBar.OnPaint Event

Occurs when the control bar is painted.

Pascal

```
  property OnPaint: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnPaint;
```

Description

Write an OnPaint event handler to change the way the control bar is rendered. When a control bar receives a Windows paint message, it first draws the background picture, if any, and then generates an OnPaint event. After the OnPaint event exits, the control bar generates an OnBandPaint event for each band, finally rendering the grabbers and frames for each band.

Use the Canvas property to draw the control bar's image. Use the ClientRect property to obtain the dimensions on which to draw.

If the custom drawing is intended to change the appearance of individual bands, use the OnBandPaint event instead.

3.1.14.3.30 TControlBar.OnResize Event

Occurs immediately after the control is resized.

Pascal

```
property OnResize;
```

C++

```
__property OnResize;
```

Description

Use OnResize to make any final adjustments after a control is resized.

To modify the way a control responds when an attempt is made to resize it, use OnCanResize or OnConstrainedResize.

Note: Some controls call this event handler when the control is first created.

C++ Examples:

```
/*
The following code keeps the right edge on Button1 against
the right edge of Form1 when Form1 is resized.
*/
void __fastcall TForm1::FormResize(TObject *Sender)
{
  Button1->Left = Form1->ClientWidth - Button1->Width;
}
```

Delphi Examples:

```
{
The following code keeps the right edge on Button1 against
the right edge of Form1 when Form1 is resized.
}
procedure TForm1.FormResize(Sender: TObject);
begin
  Button1.Left := Form1.ClientWidth-Button1.Width;
end;
```

3.1.14.3.31 TControlBar.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDragOver

OnDockDrop

3.1.14.3.32 TControlBar.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it

contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

3.1.14.3.33 TControlBar.OnUnDock Event

Occurs when the application tries to undock a control that is docked to the windowed control.

Pascal

```
property OnUnDock;
```

C++

```
__property OnUnDock;
```

Description

Write an OnUnDock event handler to adjust the windowed control when a dock client is undocked. The OnUnDock event handler can make any necessary adjustments, or it can block the undock attempt by setting the Allow parameter to false.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/
void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
      TWinControl *NewTarget, bool &Allow)
{
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if (Client->ClassNameIs("TDockableForm"))
    dynamic_cast<TDockableForm *>(Client)->DockSite = True;
  if ((DockClientCount == 2) && (NewTarget != this))        // Self?
    PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
```

```
  UpdateCaption(Client);
}
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
}
```

```
procedure TConjoinDockHost.FormUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if Client is TDockableForm then
    TDockableForm(Client).DockSite := True;
  if (DockClientCount = 2) and (NewTarget <> Self) then
    PostMessage(Self.Handle, WM_CLOSE, 0, 0);

ExtCtrls

Description

This is class ExtCtrls.TControlCollection.

3.1.15.1 TControlCollection Members

The following tables list the members exposed by TControlCollection.

Protected Methods

	Name	Description
	GetControl (see page 665)	This is GetControl, a member of class TControlCollection.
	GetControlItem (see page 665)	This is GetControlItem, a member of class TControlCollection.
	GetItem (see page 665)	Returns a specified item in the collection.
	SetControl (see page 666)	This is SetControl, a member of class TControlCollection.
	SetItem (see page 666)	This is SetItem, a member of class TControlCollection.
V	Update (see page 667)	Updates the collection to reflect changes to its items.

Public Methods

	Name	Description
	Add (see page 664)	Creates a new TCollectionItem instance and adds it to the Items array.
	AddControl (see page 665)	This is AddControl, a member of class TControlCollection.
	Create (see page 664)	This is Create, a member of class TControlCollection.
	IndexOf (see page 666)	This is IndexOf, a member of class TControlCollection.
	Owner (see page 666)	Returns the Owner of the collection.
	RemoveControl (see page 666)	This is RemoveControl, a member of class TControlCollection.

Public Properties

	Name	Description
R	ControlItems (see page 667)	This is ControlItems, a member of class TControlCollection.
	Controls (see page 668)	This is Controls, a member of class TControlCollection.
	Items (see page 668)	Lists the items in the collection.

3.1.15.2 TControlCollection.Create Constructor

Pascal

```
constructor Create(AOwner: TPersistent);
```

C++

```
__fastcall TControlCollection(TPersistent * AOwner);
```

Description

This is Create, a member of class TControlCollection.

3.1.15.3 TControlCollection Methods

The methods of the TControlCollection class are listed here.

Protected Methods

	Name	Description
	GetControl (see page 665)	This is GetControl, a member of class TControlCollection.
	GetControlItem (see page 665)	This is GetControlItem, a member of class TControlCollection.
	GetItem (see page 665)	Returns a specified item in the collection.
	SetControl (see page 666)	This is SetControl, a member of class TControlCollection.
	SetItem (see page 666)	This is SetItem, a member of class TControlCollection.
V	Update (see page 667)	Updates the collection to reflect changes to its items.

Public Methods

	Name	Description
	Add (see page 664)	Creates a new TCollectionItem instance and adds it to the Items array.
	AddControl (see page 665)	This is AddControl, a member of class TControlCollection.
	IndexOf (see page 666)	This is IndexOf, a member of class TControlCollection.
	Owner (see page 666)	Returns the Owner of the collection.
	RemoveControl (see page 666)	This is RemoveControl, a member of class TControlCollection.

3.1.15.3.1 TControlCollection.Add Method

Creates a new TCollectionItem instance and adds it to the Items array.

Pascal

```
function Add: TControlItem;
```

C++

```
__fastcall TControlItem Add();
```

Description

Call Add to create an item in the collection. The new item is placed at the end of the Items array.

Add returns the new collection item.

Create

Delete

3.1.15.3.2 TControlCollection.AddControl Method

Pascal

```
procedure AddControl(AControl: TControl; AColumn: Integer = -1; ARow: Integer = -1);
```

C++

```
__fastcall AddControl(TControl * AControl, int AColumn = -1, int ARow = -1);
```

Description

This is AddControl, a member of class TControlCollection.

3.1.15.3.3 TControlCollection.GetControl Method

Pascal

```
function GetControl(AColumn: Integer; ARow: Integer): TControl;
```

C++

```
__fastcall TControl * GetControl(int AColumn, int ARow);
```

Description

This is GetControl, a member of class TControlCollection.

3.1.15.3.4 TControlCollection.GetControlItem Method

Pascal

```
function GetControlItem(AColumn: Integer; ARow: Integer): TControlItem;
```

C++

```
__fastcall TControlItem GetControlItem(int AColumn, int ARow);
```

Description

This is GetControlItem, a member of class TControlCollection.

3.1.15.3.5 TControlCollection.GetItem Method

Returns a specified item in the collection.

Pascal

```
function GetItem(Index: Integer): TControlItem;
```

C++

```
__fastcall TControlItem GetItem(int Index);
```

Description

GetItem is the protected read implementation of the Items property.

See Also

Items

3.1.15.3.6 TControlCollection.IndexOf Method

Pascal

```
function IndexOf(AControl: TControl): Integer;
```

C++

```
__fastcall int IndexOf(TControl * AControl);
```

Description

This is IndexOf, a member of class TControlCollection.

3.1.15.3.7 TControlCollection.Owner Method

Returns the Owner of the collection.

Pascal

```
function Owner: TCustomGridPanel;
```

C++

```
__fastcall TCustomGridPanel Owner();
```

Description

Call Owner to obtain a reference to the object that owns this collection. Typically, the owner uses the collection to implement one of its properties.

3.1.15.3.8 TControlCollection.RemoveControl Method

Pascal

```
procedure RemoveControl(AControl: TControl);
```

C++

```
__fastcall RemoveControl(TControl * AControl);
```

Description

This is RemoveControl, a member of class TControlCollection.

3.1.15.3.9 TControlCollection.SetControl Method

Pascal

```
procedure SetControl(AColumn: Integer; ARow: Integer; Value: TControl);
```

C++

```
__fastcall SetControl(int AColumn, int ARow, TControl * Value);
```

Description

This is SetControl, a member of class TControlCollection.

3.1.15.3.10 TControlCollection.SetItem Method

Pascal

```
procedure SetItem(Index: Integer; Value: TControlItem);
```

C++

```
__fastcall SetItem(int Index, TControlItem Value);
```

Description

This is SetItem, a member of class TControlCollection.

3.1.15.3.11 TControlCollection.Update Method

Updates the collection to reflect changes to its items.

Pascal

```
procedure Update(Item: TCollectionItem); override;
```

C++

```
virtual __fastcall Update(TCollectionItem Item);
```

Description

Override Update in a descendant class to make any necessary changes when the items in the collection change. This method is called automatically when an update is complete.

Item identifies the item that changed. If the Item parameter is nil (Delphi) or NULL (C++), then the change affects more than one item in the collection.

As implemented in TCollection, Update does nothing. Descendant classes override this method to make any necessary adjustments.

3.1.15.4 TControlCollection Properties

The properties of the TControlCollection class are listed here.

Public Properties

	Name	Description
	ControlItems (see page 667)	This is ControlItems, a member of class TControlCollection.
	Controls (see page 668)	This is Controls, a member of class TControlCollection.
	Items (see page 668)	Lists the items in the collection.

3.1.15.4.1 TControlCollection.ControlItems Property

Pascal

```
property ControlItems [AColumn, ARow: Integer]: TControlItem;
```

C++

```
__property TControlItem ControlItems[int AColumn, ARow];
```

Description

This is ControlItems, a member of class TControlCollection.

3.1.15.4.2 TControlCollection.Controls Property

Pascal

```
property Controls [AColumn, ARow: Integer]: TControl;
```

C++

```
__property TControl * Controls[int AColumn, ARow];
```

Description

This is Controls, a member of class TControlCollection.

3.1.15.4.3 TControlCollection.Items Property

Lists the items in the collection.

Pascal

```
property Items [Index: Integer]: TControlItem;
```

C++

```
__property TControlItem Items[int Index];
```

Description

Use Items to access individual items in the collection. The value of the Index parameter corresponds to the Index property of TCollectionItem. It represents the position of the item in the collection.

File

ExtCtrls

Description

This is class ExtCtrls.TControlItem.

3.1.16.1 TControlItem Members

The following tables list the members exposed by TControlItem.

Protected Methods

	Name	Description
	AssignTo (see page 670)	Copies the properties of an object to a destination object.
	InternalSetLocation (see page 671)	This is InternalSetLocation, a member of class TControlItem.

Protected Properties

	Name	Description
	GridPanel (see page 672)	This is GridPanel, a member of class TControlItem.
	Pushed (see page 672)	This is Pushed, a member of class TControlItem.

Public Methods

	Name	Description
	Create (see page 669)	Creates and initializes a TCollectionItem instance.
	Destroy (see page 669)	Destroys the TCollectionItem instance and frees its memory.
	SetLocation (see page 671)	This is SetLocation, a member of class TControlItem.

Published Properties

	Name	Description
	Column (see page 672)	This is Column, a member of class TControlItem.
	ColumnSpan (see page 672)	This is ColumnSpan, a member of class TControlItem.
	Control (see page 672)	This is Control, a member of class TControlItem.
	Row (see page 673)	This is Row, a member of class TControlItem.
	RowSpan (see page 673)	This is RowSpan, a member of class TControlItem.

3.1.16.2 TControlItem.Create Constructor

Creates and initializes a TCollectionItem instance.

Pascal

```
constructor Create(Collection: TCollection); override;
```

C++

```
virtual __fastcall TControlItem(TCollection Collection);
```

Description

Do not call Create to instantiate a collection item. Instead, call the Add method of the collection to which the item should belong.

Collection identifies the TCollection instance to which the new item belongs.

See Also

Add

Collection

3.1.16.3 TControlItem.Destroy Destructor

Destroys the TCollectionItem instance and frees its memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TControlItem();
```

Description

Destroy is called indirectly by TCollection's Clear or Delete method.

3.1.16.4 TControlItem Methods

The methods of the TControlItem class are listed here.

Protected Methods

	Name	Description
	AssignTo (see page 670)	Copies the properties of an object to a destination object.
	InternalSetLocation (see page 671)	This is InternalSetLocation, a member of class TControlItem.

Public Methods

	Name	Description
	SetLocation (see page 671)	This is SetLocation, a member of class TControlItem.

3.1.16.4.1 TControlItem.AssignTo Method

Copies the properties of an object to a destination object.

Pascal

```
procedure AssignTo(Dest: TPersistent); override;
```

C++

```
virtual __fastcall AssignTo(TPersistent * Dest);
```

Description

Override the AssignTo method to extend the functionality of the Assign method of destination objects so that they handle newly created object classes. When defining a new object class, override the Assign method for every existing object class that should be able to copy its properties to the new class. Override the AssignTo method for every existing class to which the new class can copy.

The Assign method of TPersistent calls AssignTo if the descendant object does not succeed in copying the properties of a source object. The AssignTo method defined by TPersistent raises an EConvertError exception.

For example, given the following code in which A and B are instance variables:

```
A.Assign(B); {Delphi}
A->Assign(B); // C++
```

if A knows how to handle B, then it does so and returns. If A doesn't know how to handle B's type, execution will trickle to the TPersistent version of Assign, which calls:

```
B.AssignTo(A); {Delphi}
B->AssignTo(A); // C++
```

If B knows how to copy to A, the assignment succeeds. Otherwise, TPersistent raises an exception.

3.1.16.4.2 TControlItem.InternalSetLocation Method

Pascal

```
procedure InternalSetLocation(AColumn: Integer; ARow: Integer; APushed: Boolean; MoveExisting:
Boolean);
```

C++

```
__fastcall InternalSetLocation(int AColumn, int ARow, Boolean APushed, Boolean MoveExisting);
```

Description

This is InternalSetLocation, a member of class TControlItem.

3.1.16.4.3 TControlItem.SetLocation Method

Pascal

```
procedure SetLocation(AColumn: Integer; ARow: Integer; APushed: Boolean = False);
```

C++

```
__fastcall SetLocation(int AColumn, int ARow, Boolean APushed = False);
```

Description

This is SetLocation, a member of class TControlItem.

3.1.16.5 TControlItem Properties

The properties of the TControlItem class are listed here.

Protected Properties

	Name	Description
R	GridPanel (see page 672)	This is GridPanel, a member of class TControlItem.
R	Pushed (see page 672)	This is Pushed, a member of class TControlItem.

Published Properties

	Name	Description
	Column (see page 672)	This is Column, a member of class TControlItem.
	ColumnSpan (see page 672)	This is ColumnSpan, a member of class TControlItem.
	Control (see page 672)	This is Control, a member of class TControlItem.
	Row (see page 673)	This is Row, a member of class TControlItem.
	RowSpan (see page 673)	This is RowSpan, a member of class TControlItem.

3.1.16.5.1 TControlItem.Column Property

Pascal

```
property Column: Integer;
```

C++

```
__property int Column;
```

Description

This is Column, a member of class TControlItem.

3.1.16.5.2 TControlItem.ColumnSpan Property

Pascal

```
property ColumnSpan: TCellSpan;
```

C++

```
__property TCellSpan ColumnSpan;
```

Description

This is ColumnSpan, a member of class TControlItem.

3.1.16.5.3 TControlItem.Control Property

Pascal

```
property Control: TControl;
```

C++

```
__property TControl * Control;
```

Description

This is Control, a member of class TControlItem.

3.1.16.5.4 TControlItem.GridPanel Property

Pascal

```
property GridPanel: TCustomGridPanel;
```

C++

```
__property TCustomGridPanel GridPanel;
```

Description

This is GridPanel, a member of class TControlItem.

3.1.16.5.5 TControlItem.Pushed Property

Pascal

```
property Pushed: Boolean;
```

C++

```
__property Boolean Pushed;
```

Description

This is Pushed, a member of class TControlItem.

3.1.16.5.6 TControlItem.Row Property

Pascal

```
property Row: Integer;
```

C++

```
__property int Row;
```

Description

This is Row, a member of class TControlItem.

3.1.16.5.7 TControlItem.RowSpan Property

Pascal

```
property RowSpan: TCellSpan;
```

C++

```
__property TCellSpan RowSpan;
```

Description

This is RowSpan, a member of class TControlItem.

3.1.17 TCustomButtonedEdit Class

TCustomButtonedEditis the base class for edit controls that contain embedded buttons.

Class Hierarchy

Pascal

```
TCustomButtonedEdit = class(TCustomEdit);
```

C++

```
class TCustomButtonedEdit : public TCustomEdit;
```

File

ExtCtrls

Description

A TCustomButtonedEdit is the base class for edit controls that have associated buttons. This class introduces new properties for managing buttons that sit to the sides of the edit control.

This class contains an Images (see page 682) property that holds an TImagelist that displays on the LeftButton (see page 685) and RightButton (see page 688) to indicate state. LeftButton (see page 685) and RightButton (see page 688) properties contain indexes into the Images (see page 682) TImageList to specify which image to use for which state. OnLeftButtonClick (see page 692) and OnRightButtonClick (see page 695) are event handlers for the buttons.

Do not create instances of TCustomButtonedEdit. Use TCustomButtonedEdit as a base class when declaring edit controls that include buttons. Properties and methods of TCustomButtonedEdit provide basic behavior that descendant classes inherit as well as behavior that components can override to customize their behavior.

See Also

Images (see page 682)

LeftButton (see page 685)

RightButton (see page 688)

NumbersOnly (see page 252)

TextHint (see page 268)

TEditButton (see page 835)

3.1.17.1 TCustomButtonedEdit Members

The following tables list the members exposed by TCustomButtonedEdit.

Protected Methods

	Name	Description
	DoSetTextHint (see page 676)	This is DoSetTextHint, a member of class TCustomButtonedEdit.
	GetEditButtonClass (see page 676)	This is GetEditButtonClass, a member of class TCustomButtonedEdit.
	Notification (see page 676)	Responds to notifications that components are being created or destroyed.
	UpdateEditMargins (see page 677)	Update the margins of the edit control to provide adequate space for the buttons.
	WndProc (see page 677)	Provides specific message responses for the control.

Public Events

	Name	Description
	OnLeftButtonClick (see page 692)	Occurs when the user clicks the LeftButton (see page 685).
	OnRightButtonClick (see page 695)	Occurs when the user clicks the RightButton (see page 688).

Public Methods

	Name	Description
	Create (see page 674)	Creates an instance of TCustomEdit.
	DefaultHandler (see page 675)	Provides message handling for all messages that the control does not fully process itself.
	Destroy (see page 675)	Destroys an instance of TWinControl.

Public Properties

	Name	Description
	Images (see page 682)	Lists the images that can appear on the control's embedded buttons.
	LeftButton (see page 685)	Specifies the control that implements the left embedded button.
	RightButton (see page 688)	Specifies the control that implements the right embedded button.

3.1.17.2 TCustomButtonedEdit.Create Constructor

Creates an instance of TCustomEdit.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomButtonedEdit(TComponent * AOwner);
```

Description

Call Create to create and initialize an instance of TCustomEdit.

AOwner is another component, typically the form, that is responsible for freeing the edit control. It becomes the value of the Owner property.

Derived objects that override the Create method should call the inherited Create before performing any additional initialization.

See Also

Owner

3.1.17.3 TCustomButtonedEdit.Destroy Destructor

Destroys an instance of TWinControl.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomButtonedEdit();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the TWinControl reference is not nil, and only then calls Destroy.

System::TObject::Free

Destroy

3.1.17.4 TCustomButtonedEdit Methods

The methods of the TCustomButtonedEdit class are listed here.

Protected Methods

	Name	Description
	DoSetTextHint (see page 676)	This is DoSetTextHint, a member of class TCustomButtonedEdit.
	GetEditButtonClass (see page 676)	This is GetEditButtonClass, a member of class TCustomButtonedEdit.
	Notification (see page 676)	Responds to notifications that components are being created or destroyed.
	UpdateEditMargins (see page 677)	Update the margins of the edit control to provide adequate space for the buttons.
	WndProc (see page 677)	Provides specific message responses for the control.

Public Methods

	Name	Description
	DefaultHandler (see page 675)	Provides message handling for all messages that the control does not fully process itself.

3.1.17.4.1 TCustomButtonedEdit.DefaultHandler Method

Provides message handling for all messages that the control does not fully process itself.

Pascal

```
procedure DefaultHandler(var Message); override;
```

C++

```
virtual __fastcall DefaultHandler( Message);
```

Description

Override DefaultHandler to change the default message handling for the edit control. The Message parameter can be cast to a TMessage type, to obtain the WParam, LParam, and Result of the message. If the Result of the message is non-zero, the message has already been handled. Set the Result field to a non-zero value to prevent further processing of the message by the inherited method.

Note: In Delphi, calling inherited in a message-handling method results in a call to the ancestor's DefaultHandler method if that ancestor does not specify a handler for the message being handled.

WindowProc

DefWndProc

TMessage

3.1.17.4.2 TCustomButtonedEdit.DoSetTextHint Method

Pascal

```
procedure DoSetTextHint(const Value: string); override;
```

C++

```
virtual __fastcall DoSetTextHint(const UnicodeString Value);
```

Description

This is DoSetTextHint, a member of class TCustomButtonedEdit.

3.1.17.4.3 TCustomButtonedEdit.GetEditButtonClass Method

Pascal

```
function GetEditButtonClass: TEditButtonClass; dynamic;
```

C++

```
__fastcall TEditButtonClass GetEditButtonClass();
```

Description

This is GetEditButtonClass, a member of class TCustomButtonedEdit.

3.1.17.4.4 TCustomButtonedEdit.Notification Method

Responds to notifications that components are being created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification allows TControl to update its PopupMenu property when the pop-up menu it refers to is destroyed.

Override the Notification method to respond to notifications that other components are about to be destroyed or have just been created. Use the Notification method to update controls that rely on other objects. Remove references to objects that are going away so that the control does not refer to objects that have been destroyed. For example, data-aware objects override the Notification method to update themselves when their data source is removed. Some objects respond to notifications that other objects of a specific type are being created. For example, the session component sets the Session property of new data-aware controls to itself when the AutoSessionName property is true.

By default, components pass along the notification to their owned components, if any.

See Also

PopupMenu

Notification

3.1.17.4.5 TCustomButtonedEdit.UpdateEditMargins Method

Update the margins of the edit control to provide adequate space for the buttons.

Pascal

```
procedure UpdateEditMargins; dynamic;
```

C++

```
__fastcall UpdateEditMargins();
```

Description

Use UpdateEditMargins to set the margins of the edit control to provide adequate space for the buttons. The LeftButton (see page 685) or the RightButton (see page 688) must be visible for this to occur.

See Also

TEditButton (see page 835)

3.1.17.4.6 TCustomButtonedEdit.WndProc Method

Provides specific message responses for the control.

Pascal

```
procedure WndProc(var Message: TMessage); override;
```

C++

```
virtual __fastcall WndProc(TMessage Message);
```

Description

Override WndProc to change the initial Windows message handler for the control. The WindowProc property is initialized to point to the WndProc method.

WndProc for TWinControl overrides the inherited method to define responses for focus, mouse, and keyboard messages. It sends all others to its inherited WndProc.

When overriding WndProc to provide specialized responses to messages, call the inherited WndProc at the end to dispatch any unhandled messages.

C++ Examples:

```
/*
This example shows how to use the WndProc method and the
WindowProc property to subclass a custom control's window
procedure.  This example subclasses the window procedure of
a TListBox descendant to respond to a user-defined message
called WM_STYLEMESSAGE. The subclassed window procedure can
be turned on or off by pressing a radio button.
*/

3.1.17.5 TCustomButtonedEdit Properties

The properties of the TCustomButtonedEdit class are listed here.

Public Properties

	Name	Description
	Images (see page 682)	Lists the images that can appear on the control's embedded buttons.
	LeftButton (see page 685)	Specifies the control that implements the left embedded button.
	RightButton (see page 688)	Specifies the control that implements the right embedded button.

3.1.17.5.1 TCustomButtonedEdit.Images Property

Lists the images that can appear on the control's embedded buttons.

Pascal

```
property Images: TImageList;
```

C++

```
__property TImageList Images;
```

Description

Images contains a list of images that can appear on the control's embedded buttons. If Images is unassigned, no images are displayed on the buttons.

Images in the list should be 16x16.

C++ Examples:

```
/*
This example shows how to use the TButtonedEdit class. This example
implements a component like "TButtonedEdit search" that's to be
found in the tool pallete window.
Entering the control will enable the right button, left button will
display a MessageDlg and the right button will clear the input text.
*/
__fastcall TForm4::TForm4(TComponent* Owner)
    : TForm(Owner)
{
    //declaring an instance
    btnEdit = new TButtonedEdit(this);

    //setting the parent so it will autodetele
    btnEdit->Parent = this;

    //positioning
    btnEdit->Left = 10;
    btnEdit->Top = 10;

    //creating a TImageList and using it for the button
    TImageList* imList = new TImageList(this);
    Graphics::TBitmap* bmap = new Graphics::TBitmap();
    bmap->LoadFromFile("..\\littleB_16.bmp");
    imList->Add(bmap,NULL);
    bmap->LoadFromFile("..\\little_logo_16.bmp");
    imList->Add(bmap,NULL);
    btnEdit->Images = imList;
```

```
    //selecting the image for the left button and enabling it
    btnEdit->LeftButton->Visible = true;
    btnEdit->LeftButton->Enabled = true;
    btnEdit->LeftButton->ImageIndex = 0;
    btnEdit->LeftButton->DisabledImageIndex = 0;
    btnEdit->LeftButton->HotImageIndex = 0;

    //selecting the image for the right button
    //this will be enabled when the content changes
    btnEdit->RightButton->Enabled = true;

3.1.17.5.2 TCustomButtonedEdit.LeftButton Property

Specifies the control that implements the left embedded button.

Pascal

```
property LeftButton: TEditButton;
```

C++

```
__property TEditButton LeftButton;
```

Description

Use LeftButton to work with the left button embedded in this edit control. Use this button's properties to specify images to correspond to the various states of the button, to disable the button, to toggle it's visiblity and to add a dropdown menu. At design time, expand the LeftButton property in the Object Inspector to set its properties.

C++ Examples:

```
/*
This example shows how to use the TButtonedEdit class. This example
implements a component like "TButtonedEdit search" that's to be
found in the tool pallete window.
Entering the control will enable the right button, left button will
display a MessageDlg and the right button will clear the input text.

3.1.17.6 TCustomButtonedEdit Events

The events of the TCustomButtonedEdit class are listed here.

Public Events

	Name	Description
	OnLeftButtonClick (see page 692)	Occurs when the user clicks the LeftButton (see page 685).
	OnRightButtonClick (see page 695)	Occurs when the user clicks the RightButton (see page 688).

3.1.17.6.1 TCustomButtonedEdit.OnLeftButtonClick Event

Occurs when the user clicks the LeftButton (see page 685).

Pascal

```
property OnLeftButtonClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnLeftButtonClick;
```

Description

Use the OnLeftButtonClick event handler to respond when the user clicks the LeftButton (see page 685) of the control.

C++ Examples:

```
/*
This example shows how to use the TButtonedEdit class. This example
implements a component like "TButtonedEdit search" that's to be
found in the tool pallete window.
Entering the control will enable the right button, left button will
display a MessageDlg and the right button will clear the input text.

3.1.18 TCustomCategoryPanel Class

TCustomCategoryPanel is a base class for the TCategoryPanel (see page 309) class.

Class Hierarchy

Pascal

```
TCustomCategoryPanel = class(TCustomPanel);
```

C++

```
class TCustomCategoryPanel : public TCustomPanel;
```

File

ExtCtrls

Description

TCustomCategoryPanel is a base class for the TCategoryPanel (see page 309) class. All of the class members for TCategoryPanel (see page 309) originate in TCustomCategoryPanel.

See Also

TCustomCategoryPanelGroup (see page 718)

3.1.18.1 TCustomCategoryPanel Members

The following tables list the members exposed by TCustomCategoryPanel.

Enumerations

	Name	Description
	THeaderState (see page 701)	THeaderState is the type of the HeaderState (see page 717) property for a category panel.

Protected Fields

	Name	Description
	FPanelSurface (see page 702)	This is FPanelSurface, a member of class TCustomCategoryPanel.

Protected Methods

	Name	Description
	AdjustClientRect (see page 804)	Adjusts the ClientRect property for the idiosyncrasies of the window.

	CalcRectBounds (see page 703)	Sets the rectangles used to display the text and glyphs of the category panel.
	CanAutoSize (see page 804)	Adjusts the way the panel responds to resize attempts.
	CreateParams (see page 805)	Initializes a window-creation parameter record passed in the Params parameter.
	DefineProperties (see page 703)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DrawCollapsedPanel (see page 704)	Displays the category panel in the collapsed state.
	DrawHeader (see page 704)	This is the overview for the DrawHeader method overload.
	DrawHeaderBackground (see page 705)	This is DrawHeaderBackground, a member of class TCustomCategoryPanel.
	DrawHeaderCaption (see page 705)	This is DrawHeaderCaption, a member of class TCustomCategoryPanel.
	DrawHeaderChevron (see page 705)	This is DrawHeaderChevron, a member of class TCustomCategoryPanel.
	GetCollapsedHeight (see page 706)	This is GetCollapsedHeight, a member of class TCustomCategoryPanel.
	Loaded (see page 707)	Initializes the control after it is loaded from a stream.
	Paint (see page 806)	Renders the image of the panel.
	ReadState (see page 707)	Prepares the control for having its properties assigned values from a stream.
	ResizeHeader (see page 708)	This is ResizeHeader, a member of class TCustomCategoryPanel.
	SetParent (see page 708)	Sets the parent of the control.
	SetParentBackground (see page 806)	This is SetParentBackground, a member of class TCustomPanel.
	UpdateControlOriginalParentSize (see page 709)	This is UpdateControlOriginalParentSize, a member of class TCustomCategoryPanel.
	UpdateHeader (see page 709)	This is UpdateHeader, a member of class TCustomCategoryPanel.
	WndProc (see page 709)	Provides specific message responses for the control.

Protected Properties

	Name	Description
	Alignment (see page 807)	Determines how the caption is aligned within the panel.
	BevelInner (see page 807)	Determines the style of the inner bevel of a panel.
	BevelOuter (see page 808)	Determines the style of the outer bevel of a panel.
	BevelWidth (see page 809)	Determines the width, in pixels, of both the inner and outer bevels of a panel.
	BorderStyle (see page 810)	Determines the style of the line drawn around the perimeter of the panel control.
	BorderWidth (see page 811)	Specifies the distance, in pixels, between the outer and inner bevels.
	Color (see page 812)	Specifies the background color of the control.
	FullRepaint (see page 813)	Determines how the panel repaints itself when it is resized.
R	HeaderHeight (see page 717)	Retrieves the HeaderHeight property associated with the parent TCustomCategoryPanelGroup (see page 718) HeaderHeight.
	Locked (see page 813)	Determines whether a panel that is used as a toolbar is replaced by a toolbar supplied by an OLE server.
	ParentColor (see page 814)	Determines where a control looks for its color information.
	ShowCaption (see page 814)	This is ShowCaption, a member of class TCustomPanel.
	VerticalAlignment (see page 814)	Sets the vertical position of the caption.

Public Events

	Name	Description
	OnCollapse (see page 718)	Occurs immediately after a category panel is collapsed.
	OnExpand (see page 718)	Occurs immediately after a category panel is expanded.

Public Methods

	Name	Description
	Collapse (see page 703)	Collapses the category panel.
	Create (see page 700)	Creates and initializes an instance of TCustomPanel.
	Destroy (see page 700)	Destroys an instance of TCustomControl.
	Expand (see page 705)	Expands the category panel.
	GetChildren (see page 706)	Calls a specified procedure for every control in the category panel.
	GetControlsAlignment (see page 805)	Returns the alignment of text in the panel.
	GetTabOrderList (see page 706)	Builds a list of controls in tab order.
	SetBounds (see page 708)	Changes the position and size of the category panel in a single operation.

Public Properties

	Name	Description
	Collapsed (see page 714)	Specifies whether the category panel is collapsed.
	CollapsedHotImageIndex (see page 714)	Determines which image is displayed as the chevron when the category panel is collapsed and the mouse is hovering over the header.
	CollapsedImageIndex (see page 715)	Determines which image is displayed as the chevron when the category panel is collapsed and the mouse is not hovering over the header..
	CollapsedPressedImageIndex (see page 715)	Determines which image is displayed as the chevron when the category panel is collapsed and the left mouse button is pressed while the mouse hovers the header. .
	ExpandedHotImageIndex (see page 716)	Determines which image is displayed as the chevron when the category panel is expanded and the mouse is hovering over the header.
	ExpandedImageIndex (see page 716)	Determines which image is displayed as the chevron when the category panel is expanded and the mouse is not hovering over the header.
	ExpandedPressedImageIndex (see page 716)	Determines which image is displayed as the chevron when the category panel is collapsed and the left mouse button is pressed while the mouse hovers over the header.
R	HeaderState (see page 717)	Shows the state of the header of category panel.
	PanelGroup (see page 717)	Indentifies the parent category panel group of the category panel.
	ParentBackground (see page 813)	Determines whether control uses parent's theme background.

3.1.18.2 TCustomCategoryPanel.Create Constructor

Creates and initializes an instance of TCustomPanel.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomCategoryPanel(TComponent * AOwner);
```

Description

Call Create to instantiate a panel at runtime. Panels placed in forms at design time do not need to be explicitly created because they are created automatically.

AOwner is the component, typically a form, that is responsible for freeing the panel.

See Also

Owner

3.1.18.3 TCustomCategoryPanel.Destroy Destructor

Destroys an instance of TCustomControl.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomCategoryPanel();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the control is not nil, and only then calls Destroy.

Applications should only free controls explicitly when the constructor was called without assigning an owner to the control.

As the control is destroyed, it:

Destroys the TCanvas object in its Canvas property.

Override Destroy to free any memory or resources allocated in the Create method. When declaring a Destroy method in a descendant control type, always add the override directive to the declaration and call the inherited Destroy as the last statement in the redeclared method.

When a control is created, Delphi automatically provides exception handling around the constructor call. The destructor is called if an exception escapes from the constructor. This means that the destructor code must be prepared to clean up a partially constructed instance. Check all data fields for zero before disposing of their contents.

3.1.18.4 TCustomCategoryPanel Enumerations

The enumerations of the TCustomCategoryPanel class are listed here.

Enumerations

	Name	Description
	THeaderState (see page 701)	THeaderState is the type of the HeaderState (see page 717) property for a category panel.

3.1.18.4.1 ExtCtrls.TCustomCategoryPanel.THeaderState Enumeration

THeaderState is the type of the HeaderState (see page 717) property for a category panel.

Pascal

```
THeaderState = (
  hsNormal,
  hsHot,
  hsPressed
);
```

C++

```
enum THeaderState {
  hsNormal,
  hsHot,
  hsPressed
};
```

File

ExtCtrls

Description

These are the possible value of the THeaderState type:

Value	Meaning
hsNormal	Mouse cursor is not hovering over header
hsHot	Mouse cursor is hovering over header

hsPressed	Mouse cursor is hovering over header and left mouse button is depressed

3.1.18.5 TCustomCategoryPanel Fields

The fields of the TCustomCategoryPanel class are listed here.

Protected Fields

	Name	Description
	FPanelSurface (see page 702)	This is FPanelSurface, a member of class TCustomCategoryPanel.

3.1.18.5.1 TCustomCategoryPanel.FPanelSurface Field

Pascal

```
FPanelSurface: TCategoryPanelSurface;
```

C++

```
TCategoryPanelSurface FPanelSurface;
```

Description

This is FPanelSurface, a member of class TCustomCategoryPanel.

3.1.18.6 TCustomCategoryPanel Methods

The methods of the TCustomCategoryPanel class are listed here.

Protected Methods

	Name	Description
	CalcRectBounds (see page 703)	Sets the rectangles used to display the text and glyphs of the category panel.
	DefineProperties (see page 703)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DrawCollapsedPanel (see page 704)	Displays the category panel in the collapsed state.
	DrawHeader (see page 704)	This is the overview for the DrawHeader method overload.
	DrawHeaderBackground (see page 705)	This is DrawHeaderBackground, a member of class TCustomCategoryPanel.
	DrawHeaderCaption (see page 705)	This is DrawHeaderCaption, a member of class TCustomCategoryPanel.
	DrawHeaderChevron (see page 705)	This is DrawHeaderChevron, a member of class TCustomCategoryPanel.
	GetCollapsedHeight (see page 706)	This is GetCollapsedHeight, a member of class TCustomCategoryPanel.
	Loaded (see page 707)	Initializes the control after it is loaded from a stream.
	ReadState (see page 707)	Prepares the control for having its properties assigned values from a stream.
	ResizeHeader (see page 708)	This is ResizeHeader, a member of class TCustomCategoryPanel.
	SetParent (see page 708)	Sets the parent of the control.
	UpdateControlOriginalParentSize (see page 709)	This is UpdateControlOriginalParentSize, a member of class TCustomCategoryPanel.
	UpdateHeader (see page 709)	This is UpdateHeader, a member of class TCustomCategoryPanel.
	WndProc (see page 709)	Provides specific message responses for the control.

Public Methods

	Name	Description
	Collapse (see page 703)	Collapses the category panel.
	Expand (see page 705)	Expands the category panel.
	GetChildren (see page 706)	Calls a specified procedure for every control in the category panel.
	GetTabOrderList (see page 706)	Builds a list of controls in tab order.

	SetBounds (see page 708)	Changes the position and size of the category panel in a single operation.

3.1.18.6.1 TCustomCategoryPanel.CalcRectBounds Method

Sets the rectangles used to display the text and glyphs of the category panel.

Pascal

```
procedure CalcRectBounds; virtual;
```

C++

```
virtual __fastcall CalcRectBounds();
```

Description

Changes the position and size of the glyph rect and text used in the DrawHeaderChevron (see page 705) and UpdateButtonState methods by using the themes, header and group images information.

See Also

DrawHeaderChevron (see page 705)

3.1.18.6.2 TCustomCategoryPanel.Collapse Method

Collapses the category panel.

Pascal

```
procedure Collapse;
```

C++

```
__fastcall Collapse();
```

Description

Collapse is called automatically when the user clicks on the header of an expanded category panel. This function will set the Collapsed (see page 714) property to true.

See Also

Collapsed (see page 714)

3.1.18.6.3 TCustomCategoryPanel.DefineProperties Method

Provides methods to read and write the IsControl property to a stream such as a form file.

Pascal

```
procedure DefineProperties(Filer: TFiler); override;
```

C++

```
virtual __fastcall DefineProperties(TFiler Filer);
```

Description

DefineProperties is called automatically by the streaming system that loads and saves VCL components. It allows persistent objects to read and write properties that are not published. Published properties are loaded and stored automatically.

DefineProperties uses the methods of the filer passed as the Filer parameter to assign methods that can load and save the IsControl property.

Override DefineProperties to persist unpublished properties. Call the DefineBinaryProperty or DefineProperty method of the Filer

parameter to assign methods that load or save property values.

Note: When overriding this method, call the parent class's DefineProperties method first.

See Also

DefineBinaryProperty

DefineProperty

DefineProperties

IsControl

3.1.18.6.4 TCustomCategoryPanel.DrawCollapsedPanel Method

Displays the category panel in the collapsed state.

Pascal

```
procedure DrawCollapsedPanel(ACanvas: TCanvas); virtual;
```

C++

```
virtual __fastcall DrawCollapsedPanel(TCanvas ACanvas);
```

Description

Displays the category panel in the collapsed state.

3.1.18.6.5 DrawHeader Method

This is the overview for the DrawHeader method overload.

Overload List

	Name	Description
	TCustomCategoryPanel.DrawHeader () (see page 704)	This is DrawHeader, a member of class TCustomCategoryPanel.
	TCustomCategoryPanel.DrawHeader (HDC) (see page 704)	This is DrawHeader, a member of class TCustomCategoryPanel.

3.1.18.6.5.1 TCustomCategoryPanel.DrawHeader Method ()

Pascal

```
procedure DrawHeader; virtual; overload;
```

C++

```
virtual __fastcall DrawHeader();
```

Description

This is DrawHeader, a member of class TCustomCategoryPanel.

3.1.18.6.5.2 TCustomCategoryPanel.DrawHeader Method (HDC)

Pascal

```
procedure DrawHeader(DC: HDC); virtual; overload;
```

C++

```
virtual __fastcall DrawHeader(HDC DC);
```

Description

This is DrawHeader, a member of class TCustomCategoryPanel.

3.1.18.6.6 TCustomCategoryPanel.DrawHeaderBackground Method

Pascal

```
procedure DrawHeaderBackground(ACanvas: TCanvas); virtual;
```

C++

```
virtual __fastcall DrawHeaderBackground(TCanvas ACanvas);
```

Description

This is DrawHeaderBackground, a member of class TCustomCategoryPanel.

3.1.18.6.7 TCustomCategoryPanel.DrawHeaderCaption Method

Pascal

```
procedure DrawHeaderCaption(ACanvas: TCanvas); virtual;
```

C++

```
virtual __fastcall DrawHeaderCaption(TCanvas ACanvas);
```

Description

This is DrawHeaderCaption, a member of class TCustomCategoryPanel.

3.1.18.6.8 TCustomCategoryPanel.DrawHeaderChevron Method

Pascal

```
procedure DrawHeaderChevron(ACanvas: TCanvas); virtual;
```

C++

```
virtual __fastcall DrawHeaderChevron(TCanvas ACanvas);
```

Description

This is DrawHeaderChevron, a member of class TCustomCategoryPanel.

3.1.18.6.9 TCustomCategoryPanel.Expand Method

Expands the category panel.

Pascal

```
procedure Expand;
```

C++

```
__fastcall Expand();
```

Description

Expand is called automatically when the user clicks on the header of a collapsed category panel. This function will set the Collapsed (see page 714) property to false.

See Also

Collapse (see page 703)

Collapsed (see page 714)

3.1.18.6.10 TCustomCategoryPanel.GetChildren Method

Calls a specified procedure for every control in the category panel.

Pascal

```
procedure GetChildren(Proc: TGetChildProc; Root: TComponent); override;
```

C++

```
virtual __fastcall GetChildren(TGetChildProc Proc, TComponent * Root);
```

Description

GetChildren is called by the streaming system that loads and saves components. Applications seldom need to call this routine.

GetChildren executes the callback specified by the Proc parameter for every child control listed by the Controls property.

Override GetChildren to limit or augment which child controls are saved with the control. When overriding GetChildren, call the procedure passed as the Proc parameter for every child control that should be saved.

The **Proc** parameter defines the callback.

The **Root** parameter is ignored.

3.1.18.6.11 TCustomCategoryPanel.GetCollapsedHeight Method

Pascal

```
function GetCollapsedHeight: Integer; virtual;
```

C++

```
virtual __fastcall int GetCollapsedHeight();
```

Description

This is GetCollapsedHeight, a member of class TCustomCategoryPanel.

3.1.18.6.12 TCustomCategoryPanel.GetTabOrderList Method

Builds a list of controls in tab order.

Pascal

```
procedure GetTabOrderList(List: TList); override;
```

C++

```
virtual __fastcall GetTabOrderList(TList List);
```

Description

Call GetTabOrderList to construct a list of child controls in tab order.

GetTabOrderList iterates through the control's internal tab-order list, adding each of the child controls to List, including any controls contained in those controls. The result is a list of all the controls and their owned controls, in tab order.

The FindNextControl method calls GetTabOrderList to build a complete list of the controls that FindNextControl uses to locate

the next control in the tab order.

If the category panel is collapsed, GetTabOrderList returns an empty list.

3.1.18.6.13 TCustomCategoryPanel.Loaded Method

Initializes the control after it is loaded from a stream.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Do not call Loaded. The VCL streaming system calls Loaded automatically after the control's form is loaded into memory so that the control can complete any initializations that depend on other objects in the form.

Loaded overrides the inherited method in order to initialize the control from its associated Action. To change the properties the control copies from its action, override the ActionChange method.

See Also

Loaded

Action

ActionChange

3.1.18.6.14 TCustomCategoryPanel.ReadState Method

Prepares the control for having its properties assigned values from a stream.

Pascal

```
procedure ReadState(Reader: TReader); override;
```

C++

```
virtual __fastcall ReadState(TReader Reader);
```

Description

Override ReadState to change the preparations the control makes as it readies itself to have its property values assigned from a stream. For example, a control might destroy temporary internal data structures or objects before new instances are loaded from the stream. Be sure to include a call to the inherited method when overriding ReadState.

As implemented in TWinControl, ReadState disables control alignment until all the child controls have been read from the stream, calls the inherited ReadState method, and re-enables the alignment of all the controls. The method then builds the tab order list of controls and synchronizes its visibility with that of its parent control.

See Also

Parent

ReadState

3.1.18.6.15 TCustomCategoryPanel.ResizeHeader Method

Pascal

```
procedure ResizeHeader(OldHeight: Integer; NewHeight: Integer);
```

C++

```
__fastcall ResizeHeader(int OldHeight, int NewHeight);
```

Description

This is ResizeHeader, a member of class TCustomCategoryPanel.

3.1.18.6.16 TCustomCategoryPanel.SetBounds Method

Changes the position and size of the category panel in a single operation.

Pascal

```
procedure SetBounds(ALeft: Integer; ATop: Integer; AWidth: Integer; AHeight: Integer);
override;
```

C++

```
virtual __fastcall SetBounds(int ALeft, int ATop, int AWidth, int AHeight);
```

Description

Changes the position and size of the category panel within the constraints of the category panel group. SetBounds will not allow the height to be less than the header height of the category panel. Other category panels within the same category panel group will be adjusted accordingly. By calling SetBounds instead of adjusting the **LeftTop**, **Width**, and **Height** individually, you ensure that the panel will not repaint between changes.

3.1.18.6.17 TCustomCategoryPanel.SetParent Method

Sets the parent of the control.

Pascal

```
procedure SetParent(AParent: TWinControl); override;
```

C++

```
virtual __fastcall SetParent(TWinControl * AParent);
```

Description

SetParent is the protected implementation of the Parent property. Override SetParent to execute additional code when the value of the Parent property changes.

The AParent parameter specifies the new parent of the control.

If the control already has a parent, SetParent removes the control from that parent's list of controls by calling the parent's RemoveControl method. If AParent is not nil (Delphi) or NULL (C++), SetParent calls its InsertControl method to add the control to its list of controls.

The TControl destructor calls SetParent(nil (Delphi) or NULL (C++)) to remove the control from its parent's control list before destroying the component.

Destroy

InsertControl

Parent

RemoveControl

3.1.18.6.18 TCustomCategoryPanel.UpdateControlOriginalParentSize Method

Pascal

```
procedure UpdateControlOriginalParentSize(AControl: TControl; var AOriginalParentSize:
TPoint); override;
```

C++

```
virtual __fastcall UpdateControlOriginalParentSize(TControl * AControl, TPoint
AOriginalParentSize);
```

Description

This is UpdateControlOriginalParentSize, a member of class TCustomCategoryPanel.

3.1.18.6.19 TCustomCategoryPanel.UpdateHeader Method

Pascal

```
procedure UpdateHeader;
```

C++

```
__fastcall UpdateHeader();
```

Description

This is UpdateHeader, a member of class TCustomCategoryPanel.

3.1.18.6.20 TCustomCategoryPanel.WndProc Method

Provides specific message responses for the control.

Pascal

```
procedure WndProc(var Message: TMessage); override;
```

C++

```
virtual __fastcall WndProc(TMessage Message);
```

Description

Override WndProc to change the initial Windows message handler for the control. The WindowProc property is initialized to point to the WndProc method.

WndProc for TWinControl overrides the inherited method to define responses for focus, mouse, and keyboard messages. It sends all others to its inherited WndProc.

When overriding WndProc to provide specialized responses to messages, call the inherited WndProc at the end to dispatch any unhandled messages.

C++ Examples:

```
/*
This example shows how to use the WndProc method and the
WindowProc property to subclass a custom control's window
procedure.  This example subclasses the window procedure of
a TListBox descendant to respond to a user-defined message
```

```
  called WM_STYLEMESSAGE. The subclassed window procedure can
  be turned on or off by pressing a radio button.
  */
  class TMyListBoxDescendant : public TListBox
  {
  __published:    // IDE-managed Components
      void __fastcall SubClassWndProc(Messages::TMessage &Message);
      void __fastcall ToggleSubClass(bool On);
      void __fastcall OnDrawItemProc(
        TWinControl *Control, int Index, const TRect &Rect,

  SubClassRadioGroup1->Items->Add("WndProc");
  SubClassRadioGroup1->ItemIndex = 2;
}
```

Delphi Examples:

```
{
This example shows how to use the WndProc method and the
WindowProc property to subclass a custom control's window
procedure.  This example subclasses the window procedure of
a TListBox descendant to respond to a user-defined message
called WM_STYLEMESSAGE. The subclassed window procedure can
be turned on or off by pressing a radio button.
}

type

3.1.18.7 TCustomCategoryPanel Properties

The properties of the TCustomCategoryPanel class are listed here.

Protected Properties

	Name	Description
	HeaderHeight (see page 717)	Retrieves the HeaderHeight property associated with the parent TCustomCategoryPanelGroup (see page 718) HeaderHeight.

Public Properties

	Name	Description
	Collapsed (see page 714)	Specifies whether the category panel is collapsed.
	CollapsedHotImageIndex (see page 714)	Determines which image is displayed as the chevron when the category panel is collapsed and the mouse is hovering over the header.
	CollapsedImageIndex (see page 715)	Determines which image is displayed as the chevron when the category panel is collapsed and the mouse is not hovering over the header..
	CollapsedPressedImageIndex (see page 715)	Determines which image is displayed as the chevron when the category panel is collapsed and the left mouse button is pressed while the mouse hovers the header. .
	ExpandedHotImageIndex (see page 716)	Determines which image is displayed as the chevron when the category panel is expanded and the mouse is hovering over the header.
	ExpandedImageIndex (see page 716)	Determines which image is displayed as the chevron when the category panel is expanded and the mouse is not hovering over the header.
	ExpandedPressedImageIndex (see page 716)	Determines which image is displayed as the chevron when the category panel is collapsed and the left mouse button is pressed while the mouse hovers over the header.
R	HeaderState (see page 717)	Shows the state of the header of category panel.
	PanelGroup (see page 717)	Indentifies the parent category panel group of the category panel.

3.1.18.7.1 TCustomCategoryPanel.Collapsed Property

Specifies whether the category panel is collapsed.

Pascal

```
property Collapsed: Boolean;
```

C++

```
__property Boolean Collapsed;
```

Description

Use Collapsed to determine if the category panel is in a collapsed state. It can also be used to cause the category panel to collapse or expand.

See Also

Collapse (see page 703)

Expand (see page 705)

3.1.18.7.2 TCustomCategoryPanel.CollapsedHotImageIndex Property

Determines which image is displayed as the chevron when the category panel is collapsed and the mouse is hovering over the header.

Pascal

```
property CollapsedHotImageIndex: TImageIndex;
```

C++

```
__property TImageIndex CollapsedHotImageIndex;
```

Description

Set CollapsedHotImageIndex to associate the cheveron with one of the images in the Images property of the parent CategoryPanelGroup. The selected image will be displayed when the category panel is in the collapsed state while the mouse hovers over the header. This property has no effect if the HeaderStyle property of the parent panel group is set to hsThemed.

See Also

HeaderStyle (see page 734)

Images (see page 735)

3.1.18.7.3 TCustomCategoryPanel.CollapsedImageIndex Property

Determines which image is displayed as the chevron when the category panel is collapsed and the mouse is not hovering over the header..

Pascal

```
property CollapsedImageIndex: TImageIndex;
```

C++

```
__property TImageIndex CollapsedImageIndex;
```

Description

Set CollapsedImageIndex to associate the cheveron with one of the images in the Images property of the parent CateogryPanelGroup. The selected image will be displayed when the category panel is in the collapsed state while the mouse is outside of the area of the header. This property has no effect if the HeaderStyle property of the parent panel group is set to hsThemed.

See Also

HeaderStyle (see page 734)

Images (see page 735)

3.1.18.7.4 TCustomCategoryPanel.CollapsedPressedImageIndex Property

Determines which image is displayed as the chevron when the category panel is collapsed and the left mouse button is pressed while the mouse hovers the header. .

Pascal

```
property CollapsedPressedImageIndex: TImageIndex;
```

C++

```
__property TImageIndex CollapsedPressedImageIndex;
```

Description

Set CollapsedPressedImageIndex to associate the cheveron with one of the images in the Images property of the parent CateogryPanelGroup. The selected image will be displayed when the category panel is in the collapsed state while the left mouse button is pressed while the mouse hovers over the header. This property has no effect if the HeaderStyle property of the parent panel group is set to hsThemed.

See Also

HeaderStyle (see page 734)

Images (see page 735)

3.1.18.7.5 TCustomCategoryPanel.ExpandedHotImageIndex Property

Determines which image is displayed as the chevron when the category panel is expanded and the mouse is hovering over the header.

Pascal

```
property ExpandedHotImageIndex: TImageIndex;
```

C++

```
__property TImageIndex ExpandedHotImageIndex;
```

Description

Set ExpandedHotImageIndex to associate the cheveron with one of the images in the Images property of the parent CategoryPanelGroup. The selected image will be displayed when the category panel is in the expanded state while the mouse hovers over the header. This property has no effect if the HeaderStyle property of the parent panel group is set to hsThemed.

See Also

HeaderStyle (see page 734)

Images (see page 735)

3.1.18.7.6 TCustomCategoryPanel.ExpandedImageIndex Property

Determines which image is displayed as the chevron when the category panel is expanded and the mouse is not hovering over the header.

Pascal

```
property ExpandedImageIndex: TImageIndex;
```

C++

```
__property TImageIndex ExpandedImageIndex;
```

Description

Set ExpandedImageIndex to associate the cheveron with one of the images in the Images property of the parent CateogryPanelGroup. The selected image will be displayed when the category panel is in the expanded state while the mouse is outside of the area of the header.

See Also

HeaderStyle (see page 734)

Images (see page 735)

3.1.18.7.7 TCustomCategoryPanel.ExpandedPressedImageIndex Property

Determines which image is displayed as the chevron when the category panel is collapsed and the left mouse button is pressed while the mouse hovers over the header.

Pascal

```
property ExpandedPressedImageIndex: TImageIndex;
```

C++

```
__property TImageIndex ExpandedPressedImageIndex;
```

Description

Set CollapsedPressedImageIndex (see page 715) to associate the chevron with one of the images in the Images property of the parent CateogryPanelGroup. The selected image will be displayed when the category panel is in the collapsed state and the left mouse button is pressed while the mouse hovers over the header.

This property has no effect if the HeaderStyle property of the parent panel group is set to hsThemed.

See Also

HeaderStyle (see page 734)

Images (see page 735)

3.1.18.7.8 TCustomCategoryPanel.HeaderHeight Property

Retrieves the HeaderHeight property associated with the parent TCustomCategoryPanelGroup (see page 718) HeaderHeight.

Pascal

```
property HeaderHeight: Integer;
```

C++

```
__property int HeaderHeight;
```

Description

HeaderHeight is a read-only property used to access the HeaderHeight property of the parent category panel group.

3.1.18.7.9 TCustomCategoryPanel.HeaderState Property

Shows the state of the header of category panel.

Pascal

```
property HeaderState: THeaderState;
```

C++

```
__property THeaderState HeaderState;
```

Description

Use HeaderState to determine the current state of the header of the category panel. This is a read-only property.

Value	Meaning
hsNormal	Mouse cursor is not hovering over header .
hsHot	Mouse cursor is hovering over header.
hsPressed	Mouse cursor is hovering over header and left mouse button is depressed.

3.1.18.7.10 TCustomCategoryPanel.PanelGroup Property

Indentifies the parent category panel group of the category panel.

Pascal

```
property PanelGroup: TCustomCategoryPanelGroup;
```

C++

```
__property TCustomCategoryPanelGroup PanelGroup;
```

Description

Use the PanelGroup property to get or set the parent panel group of this category panel. The category panel will adopt properties of the new category panel group (e.g. Width, HeaderHeight (see page 717), Images).

3.1.18.8 TCustomCategoryPanel Events

The events of the TCustomCategoryPanel class are listed here.

Public Events

	Name	Description
	OnCollapse (see page 718)	Occurs immediately after a category panel is collapsed.
	OnExpand (see page 718)	Occurs immediately after a category panel is expanded.

3.1.18.8.1 TCustomCategoryPanel.OnCollapse Event

Occurs immediately after a category panel is collapsed.

Pascal

```
property OnCollapse: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnCollapse;
```

Description

Write an OnCollapse event handler to perform special processing when a category panel is collapsed.

See Also

OnExpand (see page 718)

3.1.18.8.2 TCustomCategoryPanel.OnExpand Event

Occurs immediately after a category panel is expanded.

Pascal

```
property OnExpand: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExpand;
```

Description

Write an OnExpand event handler to perform special processing when a category panel is expanded.

See Also

OnCollapse (see page 718)

3.1.19 TCustomCategoryPanelGroup Class

Class Hierarchy

Pascal

```
TCustomCategoryPanelGroup = class(TScrollingWinControl);
```

C++

```
class TCustomCategoryPanelGroup : public TScrollingWinControl;
```

File

ExtCtrls

Description

This is class ExtCtrls.TCustomCategoryPanelGroup.

3.1.19.1 TCustomCategoryPanelGroup Members

The following tables list the members exposed by TCustomCategoryPanelGroup.

Enumerations

	Name	Description
	THeaderStyle (see page 721)	Specifies the appearance of the headers of the the category panels.

Protected Methods

	Name	Description
	AdjustClientRect (see page 2557)	Adjusts the ClientRect property to exclude the scroll bars.
	AlignControls (see page 2557)	Aligns the controls in the scrolling windowed control.
	AutoScrollEnabled (see page 2558)	Indicates whether automatic scrolling is enabled.
	AutoScrollInView (see page 2558)	Scrolls a control into the visible area of the scrolling windowed control.
	ChangeScale (see page 2558)	Resizes the scrolling windowed control by a specific ratio.
	CreateParams (see page 2559)	Initializes the window creation parameters so that the entire window is not redrawn when the width or height of the client area changes.
	CreateWnd (see page 723)	Creates a Windows control corresponding to the TScrollingWinControl object.
	DoFlipChildren (see page 2560)	Flips the control's children.
	GetCategoryPanelClass (see page 723)	This is GetCategoryPanelClass, a member of class TCustomCategoryPanelGroup.
	Loaded (see page 724)	Initializes the control after it is loaded from a stream.
	Notification (see page 724)	Responds to notifications that components are being created or destroyed.
	ReorderPanels (see page 725)	This is ReorderPanels, a member of class TCustomCategoryPanelGroup.
	Resizing (see page 2561)	This is Resizing, a member of class TScrollingWinControl.
	WndProc (see page 725)	Provides specific message responses for the control.

Protected Properties

	Name	Description
	AutoScroll (see page 2561)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.

Public Methods

	Name	Description
	CollapseAll (see page 722)	Collapses all the category panels within the category panel group.
	Create (see page 720)	Creates and initializes a new TScrollingWinControl object.
	CreatePanel (see page 722)	Creates a new category panel for the category panel group.
	Destroy (see page 721)	Removes the TScrollingWinControl object from memory.
	DisableAutoRange (see page 2559)	Disables automatic scrolling.
	EnableAutoRange (see page 2560)	Reenables automatic scrolling.
	ExpandAll (see page 723)	Expands all the category panels within the category panel group.
	ScrollInView (see page 2561)	Scrolls a control into the visible area of the scrolling windowed control.

Public Properties

	Name	Description
	ChevronAlignment (see page 730)	Determines how the chevron is aligned within the header of the category panels in this category panel group.
	ChevronColor (see page 730)	Specifies the color of the default chevron in the normal state.
	ChevronHotColor (see page 731)	Specifies the color of the default chevron in the hot state.
	Color (see page 731)	Specifies the background color of the control.
	GradientBaseColor (see page 732)	Specifies the left or top color of the panel header in gradient style.
	GradientColor (see page 732)	Specifies the right or bottom color of the panel header in gradient style.
	GradientDirection (see page 733)	Specifies the direction of the gradient in the panel header.
	HeaderAlignment (see page 733)	Determines how the caption is aligned within the headers of the category panels in this category panel group.
	HeaderFont (see page 733)	Specifies the font of the caption of the headers of the panels.
	HeaderHeight (see page 734)	Specifies the height of the headers of the panels.
	HeaderImage (see page 734)	Specifies the image used for the background of the headers of the panels.
	HeaderStyle (see page 734)	Specifies the appearance of the headers of the the category panels.
	Images (see page 735)	Specifies an imagelist that can be used by the panels to replace the chevron. images.
R	Panels (see page 735)	Lists the panels (TCategoryPanel (see page 309) objects) in the category panel group.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 2564)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 2564)	Occurs when an object with custom alignment is aligned.

Published Properties

	Name	Description
	HorzScrollBar (see page 2562)	Represents the horizontal scroll bar for the scrolling windowed control.
	VertScrollBar (see page 2563)	Represents the vertical scroll bar for the scrolling windowed control.

3.1.19.2 TCustomCategoryPanelGroup.Create Constructor

Creates and initializes a new TScrollingWinControl object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomCategoryPanelGroup(TComponent * AOwner);
```

Description

Use Create to create and initialize a new TScrollingWinControl object.

AOwner is a TComponent object that owns the scrolling windowed control.

See Also

AutoScroll (see page 2561)

HorzScrollBar (see page 2562)

Create

VertScrollBar (see page 2563)

3.1.19.3 TCustomCategoryPanelGroup.Destroy Destructor

Removes the TScrollingWinControl object from memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomCategoryPanelGroup();
```

Description

Do not call Destroy.TScrollingWinControl Instead, call Free, which calls DestroyWinControl if the TScrollingWinControl object is not nil.

See Also

Destroy

System::TObject::Free

3.1.19.4 TCustomCategoryPanelGroup Enumerations

The enumerations of the TCustomCategoryPanelGroup class are listed here.

Enumerations

	Name	Description
	THeaderStyle (see page 721)	Specifies the appearance of the headers of the the category panels.

3.1.19.4.1 ExtCtrls.TCustomCategoryPanelGroup.THeaderStyle Enumeration

Specifies the appearance of the headers of the the category panels.

Pascal

```
THeaderStyle = (
  hsGradient,
  hsImage,
  hsThemed
);
```

C++

```
enum THeaderStyle {
  hsGradient,
  hsImage,
  hsThemed
};
```

File

ExtCtrls

Description

THeaderStyle is the type of the HeaderStyle (see page 734) property for a category panel group. These are the possible values of the THeaderStyle type:

Value	Meaning
hsGradient	Header is a gradient determined by the GradientBaseColor (see page 732), GradientColor (see page 732), and GradientDirection (see page 733) properties.
hsImage	Header is the stretched image defined by the HeaderImage (see page 734) property. If HeaderImage (see page 734) is undefined, the hsGradient style will be used instead.
hsThemed	Header is defined by the system's theme. If runtime themes aren't enabled or supported, the hsGradient style will be used instead.

3.1.19.5 TCustomCategoryPanelGroup Methods

The methods of the TCustomCategoryPanelGroup class are listed here.

Protected Methods

	Name	Description
	CreateWnd (see page 723)	Creates a Windows control corresponding to the TScrollingWinControl object.
	GetCategoryPanelClass (see page 723)	This is GetCategoryPanelClass, a member of class TCustomCategoryPanelGroup.
	Loaded (see page 724)	Initializes the control after it is loaded from a stream.
	Notification (see page 724)	Responds to notifications that components are being created or destroyed.
	ReorderPanels (see page 725)	This is ReorderPanels, a member of class TCustomCategoryPanelGroup.
	WndProc (see page 725)	Provides specific message responses for the control.

Public Methods

	Name	Description
	CollapseAll (see page 722)	Collapses all the category panels within the category panel group.
	CreatePanel (see page 722)	Creates a new category panel for the category panel group.
	ExpandAll (see page 723)	Expands all the category panels within the category panel group.

3.1.19.5.1 TCustomCategoryPanelGroup.CollapseAll Method

Collapses all the category panels within the category panel group.

Pascal

```
procedure CollapseAll;
```

C++

```
__fastcall CollapseAll();
```

Description

Call CollapseAll to collapse all the category panels within the category panel group.

See Also

Collapse (see page 703)

ExpandAll (see page 723)

3.1.19.5.2 TCustomCategoryPanelGroup.CreatePanel Method

Creates a new category panel for the category panel group.

Pascal

```
function CreatePanel(AOwner: TComponent): TCustomCategoryPanel;
```

C++

```
__fastcall TCustomCategoryPanel CreatePanel(TComponent * AOwner);
```

Description

Call CreatePanel to create a TCategoryPanel (see page 309) object and assign it to the panel group.

AOwner is the owner of the TCustomCategoryPanel (see page 698) object and is responsible for freeing that object during cleanup.

3.1.19.5.3 TCustomCategoryPanelGroup.CreateWnd Method

Creates a Windows control corresponding to the TScrollingWinControl object.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the control is first created or when the window must be destroyed and recreated to reflect property changes.

See Also

CreateWnd

DestroyWnd

3.1.19.5.4 TCustomCategoryPanelGroup.ExpandAll Method

Expands all the category panels within the category panel group.

Pascal

```
procedure ExpandAll;
```

C++

```
__fastcall ExpandAll();
```

Description

Call ExpandAll to expand all the category panels within the category panel group.

See Also

Expand (see page 705)

CollapseAll (see page 722)

3.1.19.5.5 TCustomCategoryPanelGroup.GetCategoryPanelClass Method

Pascal

```
function GetCategoryPanelClass: TCategoryPanelClass; virtual;
```

C++

```
virtual __fastcall TCategoryPanelClass GetCategoryPanelClass();
```

Description

This is GetCategoryPanelClass, a member of class TCustomCategoryPanelGroup.

3.1.19.5.6 TCustomCategoryPanelGroup.Loaded Method

Initializes the control after it is loaded from a stream.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Do not call Loaded. The VCL streaming system calls Loaded automatically after the control's form is loaded into memory so that the control can complete any initializations that depend on other objects in the form.

Loaded overrides the inherited method in order to initialize the control from its associated Action. To change the properties the control copies from its action, override the ActionChange method.

See Also

Loaded

Action

ActionChange

3.1.19.5.7 TCustomCategoryPanelGroup.Notification Method

Responds to notifications that components are being created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification allows TControl to update its PopupMenu property when the pop-up menu it refers to is destroyed.

Override the Notification method to respond to notifications that other components are about to be destroyed or have just been created. Use the Notification method to update controls that rely on other objects. Remove references to objects that are going away so that the control does not refer to objects that have been destroyed. For example, data-aware objects override the Notification method to update themselves when their data source is removed. Some objects respond to notifications that other objects of a specific type are being created. For example, the session component sets the Session property of new data-aware controls to itself when the AutoSessionName property is true.

By default, components pass along the notification to their owned components, if any.

PopupMenu

Notification

3.1.19.5.8 TCustomCategoryPanelGroup.ReorderPanels Method

Pascal

```
procedure ReorderPanels; dynamic;
```

C++

```
__fastcall ReorderPanels();
```

Description

This is ReorderPanels, a member of class TCustomCategoryPanelGroup.

3.1.19.5.9 TCustomCategoryPanelGroup.WndProc Method

Provides specific message responses for the control.

Pascal

```
procedure WndProc(var Message: TMessage); override;
```

C++

```
virtual __fastcall WndProc(TMessage Message);
```

Description

Override WndProc to change the initial Windows message handler for the control. The WindowProc property is initialized to point to the WndProc method.

WndProc for TWinControl overrides the inherited method to define responses for focus, mouse, and keyboard messages. It sends all others to its inherited WndProc.

When overriding WndProc to provide specialized responses to messages, call the inherited WndProc at the end to dispatch any unhandled messages.

C++ Examples:

```
/*
This example shows how to use the WndProc method and the
WindowProc property to subclass a custom control's window
procedure.  This example subclasses the window procedure of
a TListBox descendant to respond to a user-defined message
called WM_STYLEMESSAGE. The subclassed window procedure can
be turned on or off by pressing a radio button.
*/
class TMyListBoxDescendant : public TListBox
{
__published:    // IDE-managed Components

```

Delphi Examples:

```
{
This example shows how to use the WndProc method and the
WindowProc property to subclass a custom control's window
procedure.  This example subclasses the window procedure of
a TListBox descendant to respond to a user-defined message
called WM_STYLEMESSAGE. The subclassed window procedure can
be turned on or off by pressing a radio button.
}

3.1.19.6 TCustomCategoryPanelGroup Properties

The properties of the TCustomCategoryPanelGroup class are listed here.

Public Properties

	Name	Description
	ChevronAlignment (see page 730)	Determines how the chevron is aligned within the header of the category panels in this category panel group.
	ChevronColor (see page 730)	Specifies the color of the default chevron in the normal state.
	ChevronHotColor (see page 731)	Specifies the color of the default chevron in the hot state.
	Color (see page 731)	Specifies the background color of the control.
	GradientBaseColor (see page 732)	Specifies the left or top color of the panel header in gradient style.
	GradientColor (see page 732)	Specifies the right or bottom color of the panel header in gradient style.
	GradientDirection (see page 733)	Specifies the direction of the gradient in the panel header.

	HeaderAlignment (see page 733)	Determines how the caption is aligned within the headers of the category panels in this category panel group.
	HeaderFont (see page 733)	Specifies the font of the caption of the headers of the panels.
	HeaderHeight (see page 734)	Specifies the height of the headers of the panels.
	HeaderImage (see page 734)	Specifies the image used for the background of the headers of the panels.
	HeaderStyle (see page 734)	Specifies the appearance of the headers of the the category panels.
	Images (see page 735)	Specifies an imagelist that can be used by the panels to replace the chevron. images.
R	Panels (see page 735)	Lists the panels (TCategoryPanel (see page 309) objects) in the category panel group.

3.1.19.6.1 TCustomCategoryPanelGroup.ChevronAlignment Property

Determines how the chevron is aligned within the header of the category panels in this category panel group.

Pascal

```
property ChevronAlignment: TAlignment;
```

C++

```
__property TAlignment ChevronAlignment;
```

Description

Use the ChevronAlignment property to control the position of the chevron of the category panels within the category panel group. These are the possible values:

Value	Meaning
taLeftJustify	Align Chevron on the left side of the panel.
taCenter	Center the chevron on the panel.
taRightJustify	Align chevron on the right side of the panel.

3.1.19.6.2 TCustomCategoryPanelGroup.ChevronColor Property

Specifies the color of the default chevron in the normal state.

Pascal

```
property ChevronColor: TColor;
```

C++

```
__property TColor ChevronColor;
```

Description

Use the ChevronColor property to select the color of the default normal chevron of the category panels in the category panel group. This property has no effect if the category panel overrides the default normal chevron with the CollapsedImageIndex property or the ExpandedImageIndex property.

See Also

THeaderState (see page 701)

CollapsedImageIndex (see page 715)

ExpandedImageIndex (see page 716)

3.1.19.6.3 TCustomCategoryPanelGroup.ChevronHotColor Property

Specifies the color of the default chevron in the hot state.

Pascal

```
property ChevronHotColor: TColor;
```

C++

```
__property TColor ChevronHotColor;
```

Description

Use the ChevronHotColor property to select the color of the default hot chevron of the category panels in the category panel group. This property has no effect if the category panel overrides the default hot chevron color with the CollpasedHotImageIndex property or the ExpandedHotImageIndex property.

See Also

THeaderState (see page 701)

CollapsedImageIndex (see page 715)

ExpandedImageIndex (see page 716)

3.1.19.6.4 TCustomCategoryPanelGroup.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
```

```
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor

3.1.19.6.5 TCustomCategoryPanelGroup.GradientBaseColor Property

Specifies the left or top color of the panel header in gradient style.

Pascal

```
property GradientBaseColor: TColor;
```

C++

```
__property TColor GradientBaseColor;
```

Description

Use the GradientBaseColor property to select the base gradient color for the panel header when HeaderStyle (see page 734) is set to hsGradient. If GradientDirection (see page 733) is set to gdHorizontal, GradientBaseColor represents the left color of the header. If GradientDirection (see page 733) is set to gdVertical, GradientBaseColor represents the top color of the header. This property has no effect if HeaderStyle (see page 734) is set to something other than hsGradient

See Also

HeaderStyle (see page 734)

3.1.19.6.6 TCustomCategoryPanelGroup.GradientColor Property

Specifies the right or bottom color of the panel header in gradient style.

Pascal

```
property GradientColor: TColor;
```

C++

```
__property TColor GradientColor;
```

Description

Use the GradientColor property to select the gradient color for the panel header when HeaderStyle (see page 734) is set to hsGradient. If GradientDirection (see page 733) is set to gdHorizontal, GradientColor represents the right color of the header. If GradientDirection (see page 733) is set to gdVertical, GradientColor represents the bottom color of the header. This property has no effect if HeaderStyle (see page 734) is set to something other than hsGradient.

See Also

HeaderStyle (see page 734)

3.1.19.6.7 TCustomCategoryPanelGroup.GradientDirection Property

Specifies the direction of the gradient in the panel header.

Pascal

```
property GradientDirection: TGradientDirection;
```

C++

```
__property TGradientDirection GradientDirection;
```

Description

Use the GradientDirection property to select the direction of the gradient header of the category panels in the category panel group. The direction can either be horizontal or vertical. This property has no effect if HeaderStyle (see page 734) is set to something other than hsGradient.

See Also

HeaderStyle (see page 734)

3.1.19.6.8 TCustomCategoryPanelGroup.HeaderAlignment Property

Determines how the caption is aligned within the headers of the category panels in this category panel group.

Pascal

```
property HeaderAlignment: TAlignment;
```

C++

```
__property TAlignment HeaderAlignment;
```

Description

Use the HeaderAlignment property to control the position of the caption of the category panels within the category panel group. These are the possible values:

Value	Meaning
taLeftJustify	Align caption on the left side of the header.
taCenter	Center the caption in the header.
taRightJustify	Align caption on the right side of the header.

3.1.19.6.9 TCustomCategoryPanelGroup.HeaderFont Property

Specifies the font of the caption of the headers of the panels.

Pascal

```
property HeaderFont: TFont;
```

C++

```
__property TFont HeaderFont;
```

Description

Use the HeaderFont property to specify the font and font properties used to draw the caption of the headers of the category panels in the category panel group. The HeaderFont property has no effect when HeaderStyle (see page 734) is hsThemed.

3.1.19.6.10 TCustomCategoryPanelGroup.HeaderHeight Property

Specifies the height of the headers of the panels.

Pascal

```
property HeaderHeight: Integer;
```

C++

```
__property int HeaderHeight;
```

Description

Use the HeaderHeight property to specify the height of the headers of the category panels in the category panel group.

3.1.19.6.11 TCustomCategoryPanelGroup.HeaderImage Property

Specifies the image used for the background of the headers of the panels.

Pascal

```
property HeaderImage: TPicture;
```

C++

```
__property TPicture HeaderImage;
```

Description

Use the HeaderImage property to specify an image as the background for the headers of the category panels within the category panel group. This property has no effect if HeaderStyle (see page 734) is set to something other than hsImage.

See Also

HeaderStyle (see page 734)

3.1.19.6.12 TCustomCategoryPanelGroup.HeaderStyle Property

Specifies the appearance of the headers of the the category panels.

Pascal

```
property HeaderStyle: THeaderStyle;
```

C++

```
__property THeaderStyle HeaderStyle;
```

Description

Use HeaderStyle to determine the appearance of headers of the category panels in the category panel group.

Value	Meaning
hsGradient	Header is a gradient determined by the GradientBaseColor (see page 732), GradientColor (see page 732), and GradientDirection (see page 733) properties.
hsImage	Header is the stretched image defined by the HeaderImage (see page 734) property. If HeaderImage (see page 734) is undefined, the hsGradient style will be used instead.
hsThemed	Header is defined by the system's theme. If runtime themes aren't enabled or supported, the hsGradient style will be used instead.

3.1.19.6.13 TCustomCategoryPanelGroup.Images Property

Specifies an imagelist that can be used by the panels to replace the chevron. images.

Pascal

```
property Images: TImageList;
```

C++

```
__property TImageList Images;
```

Description

Use the images property to define a set of pictures that can be use by the category panels within the category panel group to replace the chevron.

See Also

CollapsedHotImageIndex (see page 714)

CollapsedImageIndex (see page 715)

CollapsedPressedImageIndex (see page 715)

ExpandedHotImageIndex (see page 716)

ExpandedImageIndex (see page 716)

ExpandedPressedImageIndex (see page 716)

3.1.19.6.14 TCustomCategoryPanelGroup.Panels Property

Lists the panels (TCategoryPanel (see page 309) objects) in the category panel group.

Pascal

```
property Panels: TList;
```

C++

```
__property TList Panels;
```

Description

Use Panels to access the list of category panels within the category panel group.

3.1.20 TCustomColorBox Class

TCustomColorBox represents a combo box that lets users select a color.

Class Hierarchy

Pascal

```
TCustomColorBox = class(TCustomComboBox);
```

C++

```
class TCustomColorBox : public TCustomComboBox;
```

File

ExtCtrls

Description

TCustomColorBox is the base class for drop-down combo boxes that display a list of colors. The combo box displays a list of all the colors for which the Graphics (see page 2619) unit defines a constant. For a list of these colors, see TColor (see page 2878). Each color is displayed next to a small square that is drawn in the corresponding color.

Do not use TCustomColorBox in applications. It is intended to act as a base class for color selection controls. Rather, to add a drop-down combo box that lets users select a color, use the TColorBox (see page 466) component, which appears on the Additional page of the component palette.

See Also

TComboBox

TColorDialog

TColorBox (see page 466)

3.1.20.1 TCustomColorBox Members

The following tables list the members exposed by TCustomColorBox.

Protected Methods

	Name	Description
	CloseUp (see page 737)	Generates an OnCloseUp event.
	CreateWnd (see page 738)	Creates the window used to implement the color box.
	DrawItem (see page 738)	Renders an individual item in the color box.
	KeyDown (see page 738)	Generates an OnKeyDown event.
	KeyPress (see page 739)	Generates an OnKeyPress event.
	Loaded (see page 739)	Initializes the combo box after its form is loaded into memory.
	PickCustomColor (see page 740)	Displays the color selection dialog so that the user can select a custom color.
	PopulateList (see page 740)	Fills the color box with items that reflect the colors specified by the Style (see page 744) property.
	Select (see page 740)	Generates an OnSelect event.
	SetStyle (see page 741)	Sets the Style (see page 744) property.

Public Events

	Name	Description
	OnGetColors (see page 744)	Occurs when the control is populated with colors.

Public Methods

	Name	Description
	Create (see page 737)	Creates a new TCustomColorBox (see page 735) object.

Public Properties

	Name	Description
	ColorNames (see page 741)	Lists the names of the colors in the color box.
	Colors (see page 742)	Lists the colors in the color box.
	DefaultColorColor (see page 742)	Specifies the color displayed in the color box for clDefault (see page 2903).
	NoneColorColor (see page 743)	Specifies the color displayed in the color box for clNone (see page 2914).
	Selected (see page 743)	Specifies the currently selected color.
	Style (see page 744)	Controls what colors are listed and how their names are formatted.

3.1.20.2 TCustomColorBox.Create Constructor

Creates a new TCustomColorBox (see page 735) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomColorBox(TComponent * AOwner);
```

Description

Call Create to instantiate a color box at runtime. TCustomColorBox (see page 735) objects placed on a form at design time are created automatically.

AOwner specifies the owner of the color box. This component (typically the form) is responsible for freeing the color box.

See Also

Owner

3.1.20.3 TCustomColorBox Methods

The methods of the TCustomColorBox class are listed here.

Protected Methods

	Name	Description
	CloseUp (see page 737)	Generates an OnCloseUp event.
	CreateWnd (see page 738)	Creates the window used to implement the color box.
	DrawItem (see page 738)	Renders an individual item in the color box.
	KeyDown (see page 738)	Generates an OnKeyDown event.
	KeyPress (see page 739)	Generates an OnKeyPress event.
	Loaded (see page 739)	Initializes the combo box after its form is loaded into memory.
	PickCustomColor (see page 740)	Displays the color selection dialog so that the user can select a custom color.
	PopulateList (see page 740)	Fills the color box with items that reflect the colors specified by the Style (see page 744) property.
	Select (see page 740)	Generates an OnSelect event.
	SetStyle (see page 741)	Sets the Style (see page 744) property.

3.1.20.3.1 TCustomColorBox.CloseUp Method

Generates an OnCloseUp event.

Pascal

```
procedure CloseUp; override;
```

C++

```
virtual __fastcall CloseUp();
```

Description

Applications can't call this protected method. It is called automatically when the drop-down list of the combo box closes.

CloseUp generates an OnCloseUp event so that applications can respond when the list closes.

See Also

OnCloseUp

3.1.20.3.2 TCustomColorBox.CreateWnd Method

Creates the window used to implement the color box.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

Applications can't call this protected method. It is called automatically when the color box is first created or when the window must be destroyed and recreated to reflect property changes.

TCustomColorBox (see page 735) overrides the inherited CreateWnd method to populate the combo box with the colors specified by the Style (see page 744) property.

See Also

CreateWnd

Style (see page 744)

3.1.20.3.3 TCustomColorBox.DrawItem Method

Renders an individual item in the color box.

Pascal

```
procedure DrawItem(Index: Integer; Rect: TRect; State: TOwnerDrawState); override;
```

C++

```
virtual __fastcall DrawItem(int Index, TRect Rect, TOwnerDrawState State);
```

Description

Applications can't call this protected method. It is called automatically when the color box needs to paint one of the items in the list. DrawItem draws a small box that displays the color that the item represents, followed by the name of the color.

Index is the index of the item to draw, where 0 specifies the first item, 1 specifies the second item, and so on.

Rect indicates the boundaries of the item on the color box's canvas, in client coordinates.

State indicates state information that can affect the way the item is drawn. In TCustomColorBox (see page 735), DrawItem uses State to determine whether an item is selected, but ignores all other state information.

See Also

Items

3.1.20.3.4 TCustomColorBox.KeyDown Method

Generates an OnKeyDown event.

Pascal

```
procedure KeyDown(var Key: Word; Shift: TShiftState); override;
```

C++

```
virtual __fastcall KeyDown(Word Key, TShiftState Shift);
```

Description

Applications can't call this protected method. It is called automatically when the user first presses a key while the color box has focus.

Key is the key code of the key that was pressed.

Shift indicates the state of the Ctrl, Shift, and Alt keys when Key was pressed.

TCustomColorBox (see page 735) overrides the inherited KeyDown method to prepare for the selection of a new color. It then calls the inherited method, which generates an OnKeyDown event.

See Also

OnKeyDown

3.1.20.3.5 TCustomColorBox.KeyPress Method

Generates an OnKeyPress event.

Pascal

```
procedure KeyPress(var Key: Char); override;
```

C++

```
virtual __fastcall KeyPress(Char Key);
```

Description

Applications can't call this protected method. It is called automatically when the user presses a key while the color box has focus.

Key is the key code of the key that was pressed.

TCustomColorBox (see page 735) overrides the inherited KeyPress method to display a color selection dialog if the user presses the Enter key while the custom color item has focus. Otherwise, KeyPress calls the inherited method, which generates an OnKeyPress event.

OnKeyPress

TColorDialog

3.1.20.3.6 TCustomColorBox.Loaded Method

Initializes the combo box after its form is loaded into memory.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Do not call the protected Loaded method. The component streaming system calls this method after it loads the combo box's form

from a stream.

TCustomCombo overrides the inherited method to select the item specified by the ItemIndex property once the form is fully loaded.

See Also

Loaded

ItemIndex

3.1.20.3.7 TCustomColorBox.PickCustomColor Method

Displays the color selection dialog so that the user can select a custom color.

Pascal

```
function PickCustomColor: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean PickCustomColor();
```

Description

Applications can't call this protected method. It is called automatically when the user selects the custom color item. PickCustomColor displays the color selection dialog, with the selected color initialized to the last-selected custom color. If the user selects a color in this dialog, PickCustomColor updates the image of the item to display the selected color and returns true. If the user cancels from the color selection dialog, PickCustomColor returns false.

Override PickCustomColor to provide a different response when the user selects the custom color item.

See Also

TColorDialog

3.1.20.3.8 TCustomColorBox.PopulateList Method

Fills the color box with items that reflect the colors specified by the Style (see page 744) property.

Pascal

```
procedure PopulateList;
```

C++

```
__fastcall PopulateList();
```

Description

Applications can't call this protected method. It is called automatically when the color box needs to fill itself with items. (For example, when the color box is first created or when the Style (see page 744) property changes)

PopulateList fills the color box with the items indicated by the Style (see page 744) property.

See Also

Style (see page 744)

3.1.20.3.9 TCustomColorBox.Select Method

Generates an OnSelect event.

Pascal

```
procedure Select; override;
```

C++

```
virtual __fastcall Select();
```

Description

Applications can't call this protected method. It is called automatically when the user selects a color.

TCustomColorBox (see page 735) overrides the inherited method to display a color selection dialog if the user selects the custom color item. After checking for a custom color, TCustomColorBox (see page 735) calls the inherited method, which generates an OnSelect event.

See Also

OnSelect

3.1.20.3.10 TCustomColorBox.SetStyle Method

Sets the Style (see page 744) property.

Pascal

```
procedure SetStyle(AStyle: TColorBoxStyle); reintroduce;
```

C++

```
__fastcall SetStyle(TColorBoxStyle AStyle);
```

Description

SetStyle is the protected write implementation of the Style (see page 744) property. It repopulates the list to reflect the new value of Style (see page 744), and disables the color box if the new value for Style (see page 744) results in an empty color box.

See Also

Style (see page 744)

3.1.20.4 TCustomColorBox Properties

The properties of the TCustomColorBox class are listed here.

Public Properties

	Name	Description
	ColorNames (see page 741)	Lists the names of the colors in the color box.
	Colors (see page 742)	Lists the colors in the color box.
	DefaultColorColor (see page 742)	Specifies the color displayed in the color box for clDefault (see page 2903).
	NoneColorColor (see page 743)	Specifies the color displayed in the color box for clNone (see page 2914).
	Selected (see page 743)	Specifies the currently selected color.
	Style (see page 744)	Controls what colors are listed and how their names are formatted.

3.1.20.4.1 TCustomColorBox.ColorNames Property

Lists the names of the colors in the color box.

Pascal

```
property ColorNames [Index: Integer]: string;
```

C++

```
__property UnicodeString ColorNames[int Index];
```

Description

Use ColorNames to obtain the name of one of the colors listed in the color box.

Index is the index of the name, where 0 is the index of the first color in the box, 1 is the index of the second color, and so on.

The value of each name is either the name of a color constant defined in the Graphics (see page 2619) unit (such as clBlack (see page 2899)), or it is the name of the color with the "cl" stripped off (Black). The Style (see page 744) property determines which name is used for each color.

The Style (see page 744) property also controls which colors are included in the list.

See Also

Colors (see page 742)

Items

ItemIndex

Style (see page 744)

3.1.20.4.2 TCustomColorBox.Colors Property

Lists the colors in the color box.

Pascal

```
property Colors [Index: Integer]: TColor;
```

C++

```
__property TColor Colors[int Index];
```

Description

Use Colors to obtain the value of a color in the color box.

Index is the index of the color, where 0 is the index of the first color in the box, 1 is the index of the second color, and so on.

Note: The Style (see page 744) property controls which colors are included in the list.

See Also

ColorNames (see page 741)

Selected (see page 743)

DefaultColorColor (see page 742)

NoneColorColor (see page 743)

Style (see page 744)

3.1.20.4.3 TCustomColorBox.DefaultColorColor Property

Specifies the color displayed in the color box for clDefault (see page 2903).

Pascal

```
property DefaultColorColor: TColor;
```

C++

```
__property TColor DefaultColorColor;
```

Description

Set DefaultColorColor to indicate what color the color box should use when drawing the icon for clDefault (see page 2903). This property only affects the color box if the Style (see page 744) property includes cbSystemColors and cbIncludeDefault.

Note: DefaultColorColor only affects the way clDefault (see page 2903) appears in the color box. When you assign clDefault (see page 2903) to a control, the control determines its own default color.

See Also

Colors (see page 742)

NoneColorColor (see page 743)

Style (see page 744)

3.1.20.4.4 TCustomColorBox.NoneColorColor Property

Specifies the color displayed in the color box for clNone (see page 2914).

Pascal

```
property NoneColorColor: TColor;
```

C++

```
__property TColor NoneColorColor;
```

Description

Set NoneColorColor to indicate what color the color box should use when drawing the icon for clNone (see page 2914). This property only affects the color box if the Style (see page 744) property includes cbSystemColors and cbIncludeNone.

Note: NoneColorColor only affects the way clNone (see page 2914) appears in the color box. When you assign clNone (see page 2914) to a control, the control determines how to interpret clNone (see page 2914).

See Also

Colors (see page 742)

DefaultColorColor (see page 742)

Style (see page 744)

3.1.20.4.5 TCustomColorBox.Selected Property

Specifies the currently selected color.

Pascal

```
property Selected: TColor;
```

C++

```
__property TColor Selected;
```

Description

Use Selected to get or set the selected color as a TColor (see page 2878) value.

See Also

Colors (see page 742)

ItemIndex

3.1.20.4.6 TCustomColorBox.Style Property

Controls what colors are listed and how their names are formatted.

Pascal

```
property Style: TColorBoxStyle;
```

C++

```
__property TColorBoxStyle Style;
```

Description

Use Style to configure what colors appear in the list and how the names appear. Style is a set that includes 0 or more of the TColorBoxStyles (see page 1541) flags.

See Also

DefaultColorColor (see page 742)

NoneColorColor (see page 743)

3.1.20.5 TCustomColorBox Events

The events of the TCustomColorBox class are listed here.

Public Events

	Name	Description
	OnGetColors (see page 744)	Occurs when the control is populated with colors.

3.1.20.5.1 TCustomColorBox.OnGetColors Event

Occurs when the control is populated with colors.

Pascal

```
property OnGetColors: TGetColorsEvent;
```

C++

```
__property TGetColorsEvent OnGetColors;
```

3.1.21 TCustomColorListBox Class

Class Hierarchy

Pascal

```
TCustomColorListBox = class(TCustomListBox);
```

C++

```
class TCustomColorListBox : public TCustomListBox;
```

File

ExtCtrls

Description

This is class ExtCtrls.TCustomColorListBox.

3.1.21.1 TCustomColorListBox Members

The following tables list the members exposed by TCustomColorListBox.

Protected Methods

	Name	Description
	CreateWnd (see page 746)	Creates a Windows control corresponding to the list box component.
	DrawItem (see page 747)	Generates an OnDrawItem event.
	KeyDown (see page 747)	Respond to key press events.
	KeyPress (see page 748)	Responds when the user presses a key.
	Loaded (see page 748)	Initializes the control after it is loaded from a stream.
	PickCustomColor (see page 749)	This is PickCustomColor, a member of class TCustomColorListBox.
	PopulateList (see page 749)	This is PopulateList, a member of class TCustomColorListBox.
	SetStyle (see page 749)	This is SetStyle, a member of class TCustomColorListBox.

Public Events

	Name	Description
	OnGetColors (see page 753)	This is OnGetColors, a member of class TCustomColorListBox.

Public Methods

	Name	Description
	Create (see page 746)	Instantiates a list box control.

Public Properties

	Name	Description
	ColorNames (see page 750)	This is ColorNames, a member of class TCustomColorListBox.
	Colors (see page 750)	This is Colors, a member of class TCustomColorListBox.
	DefaultColorColor (see page 750)	This is DefaultColorColor, a member of class TCustomColorListBox.
	NoneColorColor (see page 750)	This is NoneColorColor, a member of class TCustomColorListBox.
	Selected (see page 751)	Indicates whether a particular item is selected.
	Style (see page 753)	Determines whether the list box is standard or owner-draw and whether it is virtual.

3.1.21.2 TCustomColorListBox.Create Constructor

Instantiates a list box control.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomColorListBox(TComponent * AOwner);
```

Description

Call Create to instantiate a list box control at runtime. For list boxes created at design time, Create is called automatically.AOwner is the component that is responsible for freeing the list box. It becomes the value of the Owner property. If AOwner is nil, the caller is responsible for explicitly freeing the control.

See Also

Owner

3.1.21.3 TCustomColorListBox Methods

The methods of the TCustomColorListBox class are listed here.

Protected Methods

	Name	Description
	CreateWnd (see page 746)	Creates a Windows control corresponding to the list box component.
	DrawItem (see page 747)	Generates an OnDrawItem event.
	KeyDown (see page 747)	Respond to key press events.
	KeyPress (see page 748)	Responds when the user presses a key.
	Loaded (see page 748)	Initializes the control after it is loaded from a stream.
	PickCustomColor (see page 749)	This is PickCustomColor, a member of class TCustomColorListBox.
	PopulateList (see page 749)	This is PopulateList, a member of class TCustomColorListBox.
	SetStyle (see page 749)	This is SetStyle, a member of class TCustomColorListBox.

3.1.21.3.1 TCustomColorListBox.CreateWnd Method

Creates a Windows control corresponding to the list box component.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the list box must be displayed. CreateWnd calls the inherited CreateWnd method, which calls

CreateParams to initialize the window-creation parameters.

CreateWindowHandle to create the window handle for the control.

CreateWnd additionally sets up the list box position, tabs, items, and columns.

See Also

Columns

CreateHandle

CreateParams

CreateWindowHandle

CreateWnd

ItemIndex

Items

TabWidth

TopIndex

3.1.21.3.2 TCustomColorListBox.DrawItem Method

Generates an OnDrawItem event.

Pascal

```
procedure DrawItem(Index: Integer; Rect: TRect; State: TOwnerDrawState); override;
```

C++

```
virtual __fastcall DrawItem(int Index, TRect Rect, TOwnerDrawState State);
```

Description

DrawItem is called whenever a visual aspect of an owner-draw list box changes. The list box calls DrawItem for each visible item in its list, passing the index of the item in the Index parameter.

By default, the DrawItem method for a list box calls any event handler attached to the component's OnDrawItem event. If there is no handler attached, DrawItem fills the rectangle passed in Rect and draws any text associated with the indexed item. The default drawing ignores the State parameter, although State is passed along to attached event handlers.

See Also

ItemHeight

MeasureItem

OnDrawItem

OnMeasureItem

Style

3.1.21.3.3 TCustomColorListBox.KeyDown Method

Respond to key press events.

Pascal

```
procedure KeyDown(var Key: Word; Shift: TShiftState); override;
```

C++

```
virtual __fastcall KeyDown(Word Key, TShiftState Shift);
```

Description

When a windowed control receives a key-down message (WM_KEYDOWN) from Windows, its message handler calls the DoKeyDown method. If DoKeyDown determines that the control should, in fact, process the character, it calls KeyDown, passing the key code and shift-key state in the Key and Shift parameters, respectively.

KeyDown calls any event handler attached to the OnKeyDown event. Override KeyDown to provide other responses in addition to the event-handler call.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use WinAPI virtual key codes to determine the key pressed. For more information, search for virtual key codes in the Win32 Developer's Reference (WIN32.HLP).

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

Either KeyDown or the OnKeyDown event handler it calls can suppress further processing of a key by setting the Key parameter to zero.

See Also

KeyUp

OnKeyDown

DoKeyDown

DoKeyPress

DoKeyUp

3.1.21.3.4 TCustomColorListBox.KeyPress Method

Responds when the user presses a key.

Pascal

```
procedure KeyPress(var Key: Char); override;
```

C++

```
virtual __fastcall KeyPress(Char Key);
```

Description

KeyPress is called automatically when the list box receives a key-press message (WM_CHAR). It generates an OnKeyPress event, and then, if the AutoComplete property is true, updates ItemIndex to reflect the next character that the user typed.

The Key parameter is the character represented by the key that is pressed, not a Windows virtual key code.

See Also

OnKeyPress

3.1.21.3.5 TCustomColorListBox.Loaded Method

Initializes the control after it is loaded from a stream.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Do not call Loaded. The VCL streaming system calls Loaded automatically after the control's form is loaded into memory so that the control can complete any initializations that depend on other objects in the form.

Loaded overrides the inherited method in order to initialize the control from its associated Action. To change the properties the control copies from its action, override the ActionChange method.

See Also

Loaded

Action

ActionChange

3.1.21.3.6 TCustomColorListBox.PickCustomColor Method

Pascal

```
function PickCustomColor: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean PickCustomColor();
```

Description

This is PickCustomColor, a member of class TCustomColorListBox.

3.1.21.3.7 TCustomColorListBox.PopulateList Method

Pascal

```
procedure PopulateList;
```

C++

```
__fastcall PopulateList();
```

Description

This is PopulateList, a member of class TCustomColorListBox.

3.1.21.3.8 TCustomColorListBox.SetStyle Method

Pascal

```
procedure SetStyle(AStyle: TColorBoxStyle); reintroduce;
```

C++

```
__fastcall SetStyle(TColorBoxStyle AStyle);
```

Description

This is SetStyle, a member of class TCustomColorListBox.

3.1.21.4 TCustomColorListBox Properties

The properties of the TCustomColorListBox class are listed here.

Public Properties

	Name	Description
	ColorNames (see page 750)	This is ColorNames, a member of class TCustomColorListBox.
	Colors (see page 750)	This is Colors, a member of class TCustomColorListBox.
	DefaultColorColor (see page 750)	This is DefaultColorColor, a member of class TCustomColorListBox.
	NoneColorColor (see page 750)	This is NoneColorColor, a member of class TCustomColorListBox.
	Selected (see page 751)	Indicates whether a particular item is selected.
	Style (see page 753)	Determines whether the list box is standard or owner-draw and whether it is virtual.

3.1.21.4.1 TCustomColorListBox.ColorNames Property

Pascal

```
property ColorNames [Index: Integer]: string;
```

C++

```
__property UnicodeString ColorNames[int Index];
```

Description

This is ColorNames, a member of class TCustomColorListBox.

3.1.21.4.2 TCustomColorListBox.Colors Property

Pascal

```
property Colors [Index: Integer]: TColor;
```

C++

```
__property TColor Colors[int Index];
```

Description

This is Colors, a member of class TCustomColorListBox.

3.1.21.4.3 TCustomColorListBox.DefaultColorColor Property

Pascal

```
property DefaultColorColor: TColor;
```

C++

```
__property TColor DefaultColorColor;
```

Description

This is DefaultColorColor, a member of class TCustomColorListBox.

3.1.21.4.4 TCustomColorListBox.NoneColorColor Property

Pascal

```
property NoneColorColor: TColor;
```

C++

```
__property TColor NoneColorColor;
```

Description

This is NoneColorColor, a member of class TCustomColorListBox.

3.1.21.4.5 TCustomColorListBox.Selected Property

Indicates whether a particular item is selected.

Pascal

```
property Selected: TColor;
```

C++

```
__property TColor Selected;
```

Description

Use Selected to query the state of a particular item in the list box. If the item specified by the Index parameter is selected in the list box, the value of the Selected property is true. If the specified item is not selected, Selected is false. Set Selected to change the currently selected item.

The Index parameter is the item referenced by its position in the list box, with the first item having an Index value of 0.

An item is selected when the user highlights it. More than one item in the list box can be selected by setting the MultiSelect property to true. In this case, the Selected item is the one that has focus when the list box has input focus.

C++ Examples:

```
/*
This example uses a file listbox and a regular listbox on a
form. The following routine scans through the files listed
in the file listbox and lists the sizes of any selected
files to the regular list box.  To exercise the error
condition create a file in the Debug directory, start this
application and then delete the file.  Now try to list the
size of the deleted file.  Continue will continue listing
file sizes in a multiple selection that includes the deleted
file.  Break will stop.  Set the MultiSelect and
ExtendedSelect properties on the FileListBox.
*/
#include <stdio.h>     // for FILE, fopen, fstat, fileno, fread and fclose
#include <sys\stat.h>  // for fstat and the stat struct

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int i = 0; i < FileListBox1->Items->Count; i++)
  {
    if (FileListBox1->Selected[i])
    {
      if (!FileExists(FileListBox1->Items->Strings[i]))
      {
        MessageBeep(0);
        if (Application->MessageBox(
          String("File " + FileListBox1->Items->Strings[i] + "not found").t_str(),
          NULL,
          MB_OKCANCEL) == IDCANCEL)
          break;
        else
          continue;
      }
      FILE *F = fopen(AnsiString(FileListBox1->Items->Strings[i]).t_str(),"r");
      struct stat statbuf;
      fstat(fileno(F), &statbuf);
      ListBox1->Items->Add(
```

```
          FileListBox1->Items->Strings[i] + ": " + IntToStr(int(statbuf.st_size)));
        fclose(F);
      }
    }
  }
```

Delphi Examples:

```
{
This example uses a file listbox and a regular listbox on a
form. The following routine scans through the files listed
in the file listbox and lists the sizes of any selected
files to the regular list box.  To exercise the error
condition create a file in the Debug directory, start this
application and then delete the file.  Now try to list the
size of the deleted file.  Set the MultiSelect and
ExtendedSelect properties on the FileListBox.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F: File;
  i, filehandle: Integer;
begin
  for i := 0 to (FileListBox1.Items.Count - 1) do begin
  try
    if FileListBox1.Selected[i] then
    begin
      if not FileExists(FileListBox1.Items.Strings[i]) then
      begin
        MessageDlg('File: ' + FileListBox1.Items.Strings[i] +
                   ' not found', mtError, [mbOk], 0);
        Continue;
      end;
      filehandle:=  FileOpen(FileListBox1.Items.Strings[i], fmOpenWrite);
      if (filehandle = -1) then
      begin
        MessageDlg('File: ' + FileListBox1.Items.Strings[i] +
                   ' cannot be opened with access mode fmOpenWrite.', mtError, [mbOk], 0);
        Continue;
      end
      else
        FileClose(filehandle);

      AssignFile(F, FileListBox1.Items.Strings[i]);
      Reset(F, 1);
      ListBox1.Items.Add(
        FileListBox1.Items.Strings[i] + ': ' + IntToStr(FileSize(F)));
      CloseFile(F);
    end;
   finally
   { do something here }
   end;
  end;
end;
```

3.1.21.4.6 TCustomColorListBox.Style Property

Determines whether the list box is standard or owner-draw and whether it is virtual.

Pascal

```
property Style: TColorBoxStyle;
```

C++

```
__property TColorBoxStyle Style;
```

Description

Use Style to specify whether the list box is a standard list box that displays text strings, or an owner-draw list box that can display graphical images. Owner-draw list boxes let you display items in some nonstandard way. In this case, you must write the code to paint items in the list box.

In addition, Style controls whether the list box is virtual, which means that items are supplied dynamically using event handlers. By default, Style is lbStandard, meaning that the list box is not virtual and it displays each item as a string.

3.1.21.5 TCustomColorListBox Events

The events of the TCustomColorListBox class are listed here.

Public Events

	Name	Description
	OnGetColors (see page 753)	This is OnGetColors, a member of class TCustomColorListBox.

3.1.21.5.1 TCustomColorListBox.OnGetColors Event

Pascal

```
property OnGetColors: TLBGetColorsEvent;
```

C++

```
__property TLBGetColorsEvent OnGetColors;
```

Description

This is OnGetColors, a member of class TCustomColorListBox.

3.1.22 TCustomControlBar Class

TCustomControlBar is the base class for control bar components.

Class Hierarchy

Pascal

```
TCustomControlBar = class(TCustomControl);
```

C++

```
class TCustomControlBar : public TCustomControl;
```

File

ExtCtrls

Description

Use TCustomControlBar as a base class when defining control bar components. Control bars are designed to manage the layout of toolbar controls, although they can contain other controls as well. They provide a convenient docking site in applications that have dockable toolbars.

Do not create instances of TCustomControlBar. To add a control bar to a form, use TControlBar (see page 590) instead.

See Also

TControlBar (see page 590)

TToolBar

3.1.22.1 TCustomControlBar Members

The following tables list the members exposed by TCustomControlBar.

Protected Events

	Name	Description
	OnBandDrag (see page 771)	Occurs when the user starts a drag operation on a specified control.
	OnBandInfo (see page 771)	Occurs when the control bar adjusts the docking position of a band.
	OnBandMove (see page 772)	Occurs when a control band is moving.
	OnBandPaint (see page 772)	Occurs when a control band is painted.
	OnBeginBandMove (see page 773)	This is OnBeginBandMove, a member of class TCustomControlBar.
	OnEndBandMove (see page 773)	This is OnEndBandMove, a member of class TCustomControlBar.
	OnPaint (see page 773)	Occurs when the control bar is painted.

Protected Methods

	Name	Description
	AlignControls (see page 757)	Aligns controls in the control bar.
	CanAutoSize (see page 757)	Indicates how the control can be resized.
	CreateParams (see page 758)	Sets the control bar's window flags.
	DoBandMove (see page 758)	Generates an OnBandMove (see page 772) event.
	DoBandPaint (see page 758)	Generates an OnBandPaint (see page 772) event.
	DoBeginBandMove (see page 759)	This is DoBeginBandMove, a member of class TCustomControlBar.
	DockOver (see page 759)	Generates an OnDockOver event and ensures proper docking of floating controls.

	DoEndBandMove (see page 759)	This is DoEndBandMove, a member of class TCustomControlBar.
	DoPaletteChange (see page 760)	Prepares the control bar to realize a new palette.
V	DragControl (see page 760)	Starts a drag operation on a control band.
V	GetControlInfo (see page 761)	Generates an OnBandInfo (see page 771) event.
V	GetPalette (see page 762)	Returns the handle to a palette for use by the control.
V	GetSiteInfo (see page 762)	Generates an OnGetSiteInfo event
	HitTest (see page 763)	Returns the control at the specified coordinates.
V	MouseDown (see page 763)	Handles mouse button clicks.
V	MouseMove (see page 763)	Handles mouse movements.
V	MouseUp (see page 764)	Handles releasing of a mouse button.
V	Paint (see page 764)	Paints the control bar.
V	PaintControlFrame (see page 765)	Paints a control band's frame.

Protected Properties

	Name	Description
	AutoDock (see page 766)	Determines whether the control bar temporarily docks drag clients to provide visual feedback.
	AutoDrag (see page 766)	Specifies whether control bands can be undocked by dragging.
	AutoSize (see page 767)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelKind (see page 767)	Specifies the control's bevel style.
	CornerEdge (see page 768)	This is CornerEdge, a member of class TCustomControlBar.
	DockSite (see page 768)	Specifies whether the control can be the target of drag-and-dock operations.
	DrawingStyle (see page 769)	This is DrawingStyle, a member of class TCustomControlBar.
	GradientDirection (see page 769)	This is GradientDirection, a member of class TCustomControlBar.
	GradientEndColor (see page 769)	This is GradientEndColor, a member of class TCustomControlBar.
	GradientStartColor (see page 769)	This is GradientStartColor, a member of class TCustomControlBar.
	RowSize (see page 770)	Specifies the height of the control bar's rows.
	RowSnap (see page 770)	Specifies whether controls are snapped to the control bar's rows when docked.

Public Methods

	Name	Description
V	Create (see page 755)	Creates and initializes an instance of TCustomControlBar (see page 754).
V	Destroy (see page 756)	Destroys the TCustomControlBar (see page 754) instance.
V	FlipChildren (see page 761)	Reverses the positions of child controls.
V	StickControls (see page 765)	Places controls in their final positions after a control is moved in or dropped on the control bar.

Public Properties

	Name	Description
	Picture (see page 770)	Specifies the control bar's picture.

3.1.22.2 TCustomControlBar.Create Constructor

Creates and initializes an instance of TCustomControlBar (see page 754).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomControlBar(TComponent * AOwner);
```

Description

Call Create to instantiate a control bar at runtime. Control bars added to forms at design time are created automatically.

AOwner is a component, typically the form, that is responsible for freeing the control bar instance. It becomes the value of the Owner property.

See Also

Owner

3.1.22.3 TCustomControlBar.Destroy Destructor

Destroys the TCustomControlBar (see page 754) instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomControlBar();
```

Description

Do not call Destroy. Instead, call Free.

Destroy frees the memory allocated for the TCustomControlBar (see page 754) properties.

See Also

System::TObject::Free

3.1.22.4 TCustomControlBar Methods

The methods of the TCustomControlBar class are listed here.

Protected Methods

	Name	Description
	AlignControls (see page 757)	Aligns controls in the control bar.
	CanAutoSize (see page 757)	Indicates how the control can be resized.
	CreateParams (see page 758)	Sets the control bar's window flags.
	DoBandMove (see page 758)	Generates an OnBandMove (see page 772) event.
	DoBandPaint (see page 758)	Generates an OnBandPaint (see page 772) event.
	DoBeginBandMove (see page 759)	This is DoBeginBandMove, a member of class TCustomControlBar.
	DockOver (see page 759)	Generates an OnDockOver event and ensures proper docking of floating controls.
	DoEndBandMove (see page 759)	This is DoEndBandMove, a member of class TCustomControlBar.
	DoPaletteChange (see page 760)	Prepares the control bar to realize a new palette.
	DragControl (see page 760)	Starts a drag operation on a control band.
	GetControlInfo (see page 761)	Generates an OnBandInfo (see page 771) event.
	GetPalette (see page 762)	Returns the handle to a palette for use by the control.
	GetSiteInfo (see page 762)	Generates an OnGetSiteInfo event
	HitTest (see page 763)	Returns the control at the specified coordinates.
	MouseDown (see page 763)	Handles mouse button clicks.
	MouseMove (see page 763)	Handles mouse movements.
	MouseUp (see page 764)	Handles releasing of a mouse button.
	Paint (see page 764)	Paints the control bar.
	PaintControlFrame (see page 765)	Paints a control band's frame.

Public Methods

	Name	Description
	FlipChildren (see page 761)	Reverses the positions of child controls.

	StickControls (see page 765)	Places controls in their final positions after a control is moved in or dropped on the control bar.

3.1.22.4.1 TCustomControlBar.AlignControls Method

Aligns controls in the control bar.

Pascal

```
procedure AlignControls(AControl: TControl; var ARect: TRect); override;
```

C++

```
virtual __fastcall AlignControls(TControl * AControl, TRect ARect);
```

Description

Use AlignControls to align all controls within an area of the control bar. The alignment of child controls is based on their Align property.

AControl is a child control that takes precedence in alignment over other, similarly-aligned controls. This parameter can be nil (Delphi) or NULL (C++).

Rect specifies the area in which to align the controls.

TCustomControlBar (see page 754) overrides the inherited method to enforce the alignment of child controls in a manner appropriate to a control bar. AlignControls determines the best alignment for each control according to its size and the available space.

3.1.22.4.2 TCustomControlBar.CanAutoSize Method

Indicates how the control can be resized.

Pascal

```
function CanAutoSize(var NewWidth: Integer; var NewHeight: Integer): Boolean; override;
```

C++

```
virtual __fastcall Boolean CanAutoSize(int NewWidth, int NewHeight);
```

Description

CanAutoSize is called automatically when the AutoSize property is true and an attempt is made to resize the control. It allows controls to implement the AutoSize property before the resize sequence that begins with the OnCanResize and OnConstrainedResize events and ends with the OnResize event.

When CanAutoSize is called, the NewWidth and NewHeight parameters indicate the proposed new dimensions of the control. CanAutoSize adjusts these values so that the control's size adjusts to its contents. If the adjustment results in values of NewWidth and NewHeight that differ from the control's current width and height, CanAutoSize returns true, indicating that the resize sequence should proceed. If, after adjustment, NewWidth and NewHeight equal Width and Height, CanAutoSize returns false, and the resize sequence is aborted.

As implemented in TWinControl, CanAutoSize returns true, adjusting NewWidth and NewHeight so that all the control's children fit.

See Also

Constraints

ConstrainedResize

AdjustSize

3.1.22.4.3 TCustomControlBar.CreateParams Method

Sets the control bar's window flags.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. CreateParams fills in the parameter record that is passed as the value of the Params parameter. This data structure holds information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function.

In TCustomControlBar (see page 754), CreateParams overrides the inherited method in order to turn off the CS_HREDRAW and CS_VREDRAW windows flags.

See Also

CreateWnd

CreateWindowHandle

3.1.22.4.4 TCustomControlBar.DoBandMove Method

Generates an OnBandMove (see page 772) event.

Pascal

```
procedure DoBandMove(Control: TControl; var ARect: TRect); virtual;
```

C++

```
virtual __fastcall DoBandMove(TControl * Control, TRect ARect);
```

Description

Do not call DoBandMove. It is called automatically when a band is moved in the control bar.

Control is the band that is about to be moved.

ARect is the area to which the control is about to be moved. This value can be changed by the OnBandMove (see page 772) event handler.

Override DoBandMove to perform actions in addition to calling the OnBandMove (see page 772) event handler when a band is moved.

See Also

onbandmove (see page 772)

3.1.22.4.5 TCustomControlBar.DoBandPaint Method

Generates an OnBandPaint (see page 772) event.

Pascal

```
procedure DoBandPaint(Control: TControl; Canvas: TCanvas; var ARect: TRect; var Options:
TBandPaintOptions); virtual;
```

C++

```
virtual __fastcall DoBandPaint(TControl * Control, TCanvas Canvas, TRect ARect,
TBandPaintOptions Options);
```

Description

Do not call DoBandPaint. It is called automatically for each band when the control bar is painted. Override DoBandPaint to provide class-specific paint code for the bands or to suppress the OnBandPaint (see page 772) event.

Control is the control (usually a tool bar) whose band is about to be painted.

Canvas is the control bar's canvas. This is the canvas to use for drawing the band.

ARect is the dimensions of the band on the canvas. The OnBandPaint (see page 772) event handler can change this value to alter where the frame and grabber are drawn.

Options specifies which parts of the band should be drawn after DoBandPaint exits.

See Also

OnBandPaint (see page 772)

3.1.22.4.6 TCustomControlBar.DoBeginBandMove Method

Pascal

```
function DoBeginBandMove(Control: TControl): Boolean; dynamic;
```

C++

```
__fastcall Boolean DoBeginBandMove(TControl * Control);
```

Description

This is DoBeginBandMove, a member of class TCustomControlBar.

3.1.22.4.7 TCustomControlBar.DockOver Method

Generates an OnDockOver event and ensures proper docking of floating controls.

Pascal

```
procedure DockOver(Source: TDragDockObject; X: Integer; Y: Integer; State: TDragState; var
Accept: Boolean); override;
```

C++

```
virtual __fastcall DockOver(TDragDockObject Source, int X, int Y, TDragState State, Boolean
Accept);
```

Description

DockOver overrides the inherited method to ensure proper docking of floating controls that are accepted by the OnDockOver event handler.

See Also

OnDockOver

3.1.22.4.8 TCustomControlBar.DoEndBandMove Method

Pascal

```
procedure DoEndBandMove(Control: TControl); dynamic;
```

C++

```
__fastcall DoEndBandMove(TControl * Control);
```

Description

This is DoEndBandMove, a member of class TCustomControlBar.

3.1.22.4.9 TCustomControlBar.DoPaletteChange Method

Prepares the control bar to realize a new palette.

Pascal

```
function DoPaletteChange: Boolean;
```

C++

```
__fastcall Boolean DoPaletteChange();
```

Description

Call DoPaletteChange to prepare the control bar to realize a new palette. DoPaletteChange returns true if the control bar should be redrawn to reflect the new palette, and false otherwise.

DoPaletteChange is called when the Picture (see page 770) property changes.

See Also

picture (see page 770)

getpalette (see page 762)

3.1.22.4.10 TCustomControlBar.DragControl Method

Starts a drag operation on a control band.

Pascal

```
function DragControl(AControl: TControl; X: Integer; Y: Integer; KeepCapture: Boolean =
False): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean DragControl(TControl * AControl, int X, int Y, Boolean KeepCapture
= False);
```

Description

Call DragControl to start a drag operation on a control band.

If AutoDrag (see page 766) is true, DragControl is called automatically when a control is undocked from the control bar.

AControl is the control on the band that should be dragged.

X and Y are the current positions of the mouse pointer.

KeepCapture indicates whether the control bar should capture the mouse when processing the drag.

See Also

AutoDrag (see page 766)

Capture

3.1.22.4.11 TCustomControlBar.FlipChildren Method

Reverses the positions of child controls.

Pascal

```
procedure FlipChildren(AllLevels: Boolean); override;
```

C++

```
virtual __fastcall FlipChildren(Boolean AllLevels);
```

Description

Call FlipChildren to flip the control's children; that is, to move children on the left side of the control to the right side and vice versa. FlipChildren reverses the position of all child controls and adjusts their Align properties, if necessary, to enforce the new position.

AllLevels specifies whether FlipChildren should be called recursively on the control's children.

FlipChildren can be used to reverse the layout of an application when it is running in Middle Eastern locales where users read from right to left instead of left to right: Call UseRightToLeftAlignment to determine whether the BiDiMode property dictates a reversal of alignment based on the system locale.

Note: FlipChildren does the same thing as the Flip Children command on the control's context menu in the IDE.

See Also

BiDiMode

UseRightToLeftAlignment

3.1.22.4.12 TCustomControlBar.GetControlInfo Method

Generates an OnBandInfo (see page 771) event.

Pascal

```
procedure GetControlInfo(AControl: TControl; var Insets: TRect; var PreferredSize: Integer;
var RowCount: Integer); virtual;
```

C++

```
virtual __fastcall GetControlInfo(TControl * AControl, TRect Insets, int PreferredSize, int
RowCount);
```

Description

GetControlInfo is called automatically when the control bar needs to arrange the position of its bands. It generates an OnBandInfo (see page 771) event to obtain information about a control band.

AControl is the control associated with the band being positioned.

Insets returns the margin between the edges of the control and the edges of its band.

PreferredSize returns the control's preferred width. (The control's width is reduced if it can't fit inside the control bar.)

RowCount returns the number of control rows that the control spans in the control bar.

See Also

OnBandInfo (see page 771)

3.1.22.4.13 TCustomControlBar.GetPalette Method

Returns the handle to a palette for use by the control.

Pascal

```
function GetPalette: HPALETTE; override;
```

C++

```
virtual __fastcall HPALETTE GetPalette();
```

Description

As implemented in TControl, GetPalette returns a null handle, indicating that the control does not have a palette. Override GetPalette to implement derived objects that use a palette. Create a palette handle for the control by a call to the Windows API function CreatePalette. GetPalette should return the palette handle for the control.

Specifying the palette for a control tells the application that the control's palette needs to be realized and designates the palette to use for realization.

GetPalette is called only if the run-time video mode requires color palette support, for example, in 256-color mode.

See Also

PaletteChanged

3.1.22.4.14 TCustomControlBar.GetSiteInfo Method

Generates an OnGetSiteInfo event

Pascal

```
procedure GetSiteInfo(Client: TControl; var InfluenceRect: TRect; MousePos: TPoint; var
CanDock: Boolean); override;
```

C++

```
virtual __fastcall GetSiteInfo(TControl * Client, TRect InfluenceRect, TPoint MousePos,
Boolean CanDock);
```

Description

GetSiteInfo is called automatically during drag-and-dock operations to initialize a TDragDockObject with information about where a dragged object can be docked, if at all.

Client is a potential docking client.

InfluenceRect returns the area in which the client would be docked.

MousePos is the current mouse position.

CanDock returns whether the client can dock to the windowed control.

As implemented in TWinControl, GetSiteInfo generates an influence rectangle equal to BoundsRect expanded by 10 pixels on every side, and then calls the OnGetSiteInfo event handler.

See Also

OnGetSiteInfo

BoundsRect

3.1.22.4.15 TCustomControlBar.HitTest Method

Returns the control at the specified coordinates.

Pascal

```
function HitTest(X: Integer; Y: Integer): TControl;
```

C++

```
__fastcall TControl * HitTest(int X, int Y);
```

Description

Call HitTest to get the control at the specified coordinates.

X and Y are the coordinates.

See Also

MouseDown (see page 763)

3.1.22.4.16 TCustomControlBar.MouseDown Method

Handles mouse button clicks.

Pascal

```
procedure MouseDown(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer);
override;
```

C++

```
virtual __fastcall MouseDown(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

MouseDown is called automatically when the user clicks the control bar with the mouse. After generating an OnMouseDown event, MouseDown determines whether a band is being dragged and if so, computes its position.

Button indicates which button was clicked.

Shift indicates the state of the Alt, Ctrl, and Shift keys and the state of the mouse buttons.

X and Y are the position where the mouse was clicked.

See Also

OnMouseDown

HitTest (see page 763)

3.1.22.4.17 TCustomControlBar.MouseMove Method

Handles mouse movements.

Pascal

```
procedure MouseMove(Shift: TShiftState; X: Integer; Y: Integer); override;
```

C++

```
virtual __fastcall MouseMove(TShiftState Shift, int X, int Y);
```

Description

MouseMove generates an OnMouseMove event and then performs special processing if a control is being undocked from the

control bar or moved within the control bar.

Shift indicates the state of the Alt, Ctrl, and Shift keys and the state of the mouse buttons.

X and Y are the current position of the mouse.

See Also

OnMouseMove

AutoDrag (see page 766)

3.1.22.4.18 TCustomControlBar.MouseUp Method

Handles releasing of a mouse button.

Pascal

```
procedure MouseUp(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer); override;
```

C++

```
virtual __fastcall MouseUp(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

MouseUp handles the dropping of a control onto the control bar and, once the control (if any) is docked, generates an OnMouseUp event.

Button indicates which button was released.

Shift indicates the state of the Alt, Ctrl, and Shift keys and the state of the mouse buttons.

X and Y are the position where the mouse was released.

See Also

OnMouseUp

3.1.22.4.19 TCustomControlBar.Paint Method

Paints the control bar.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

Paint is called automatically when the control bar needs to paint itself.

To customize the painting, either override the Paint method, or specify options in the OnPaint (see page 773) and OnBandPaint (see page 772) event handlers.

See Also

OnPaint (see page 773)

onbandpaint (see page 772)

PaintControlFrame (see page 765)

3.1.22.4.20 TCustomControlBar.PaintControlFrame Method

Paints a control band's frame.

Pascal

```
procedure PaintControlFrame(Canvas: TCanvas; AControl: TControl; var ARect: TRect); virtual;
```

C++

```
virtual __fastcall PaintControlFrame(TCanvas Canvas, TControl * AControl, TRect ARect);
```

Description

The Paint (see page 764) method calls PaintControlFrame for each band to render its image. PaintControlFrame generates an OnBandPaint (see page 772) event, and then draws the frame and grabber for the band, depending on the values returned by the event handler.

Canvas is the control bar's canvas.

AControl is the control on the band to be painted.

ARect indicates the dimensions of the band.

See Also

OnPaint (see page 773)

onbandpaint (see page 772)

PaintControlFrame

3.1.22.4.21 TCustomControlBar.StickControls Method

Places controls in their final positions after a control is moved in or dropped on the control bar.

Pascal

```
procedure StickControls; virtual;
```

C++

```
virtual __fastcall StickControls();
```

Description

Override StickControls to specify how controls are set in their final positions after a control is moved in or dropped on the control bar.

See Also

rowsnap (see page 770)

3.1.22.5 TCustomControlBar Properties

The properties of the TCustomControlBar class are listed here.

Protected Properties

	Name	Description
	AutoDock (see page 766)	Determines whether the control bar temporarily docks drag clients to provide visual feedback.
	AutoDrag (see page 766)	Specifies whether control bands can be undocked by dragging.

	AutoSize (see page 767)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelKind (see page 767)	Specifies the control's bevel style.
	CornerEdge (see page 768)	This is CornerEdge, a member of class TCustomControlBar.
	DockSite (see page 768)	Specifies whether the control can be the target of drag-and-dock operations.
	DrawingStyle (see page 769)	This is DrawingStyle, a member of class TCustomControlBar.
	GradientDirection (see page 769)	This is GradientDirection, a member of class TCustomControlBar.
	GradientEndColor (see page 769)	This is GradientEndColor, a member of class TCustomControlBar.
	GradientStartColor (see page 769)	This is GradientStartColor, a member of class TCustomControlBar.
	RowSize (see page 770)	Specifies the height of the control bar's rows.
	RowSnap (see page 770)	Specifies whether controls are snapped to the control bar's rows when docked.

Public Properties

	Name	Description
	Picture (see page 770)	Specifies the control bar's picture.

3.1.22.5.1 TCustomControlBar.AutoDock Property

Determines whether the control bar temporarily docks drag clients to provide visual feedback.

Pascal

```
property AutoDock: Boolean;
```

C++

```
__property Boolean AutoDock;
```

Description

If AutoDock is true (the default), when a dockable object is dragged over the control bar, the control bar temporarily docks the object so that the user can see the impact of the drag operation. That is, the user can see the dock position and how other docked controls will be repositioned to make room. When the user releases the mouse, the dragged object is docked at the current spot, and any temporary dockings are canceled. However, if the user cancels the drag-and-dock operation, the dragged object reverts to its last temporary dock site rather than to its location at the start of the drag operation.

If AutoDock is false, the control bar does not temporarily dock dragged objects. Instead, the user only sees the dragging rectangle as it passes over the control bar, with no feedback as to the adjustments the control bar would make if the dragged object were released.

See Also

DockClients

DockSite

OnDockOver

3.1.22.5.2 TCustomControlBar.AutoDrag Property

Specifies whether control bands can be undocked by dragging.

Pascal

```
property AutoDrag: Boolean;
```

C++

```
__property Boolean AutoDrag;
```

Description

Use AutoDrag to specify whether control bands are automatically undocked when the user drags them. If AutoDrag is true, control bands (TToolBar objects) are undocked when dragged off the control bar. Otherwise, control bands are kept within the control bar.

See Also

DragMode

OnBandDrag (see page 771)

onbandmove (see page 772)

3.1.22.5.3 TCustomControlBar.AutoSize Property

Specifies whether the control sizes itself automatically to accommodate its contents.

Pascal

```
property AutoSize;
```

C++

```
__property AutoSize;
```

Description

Use AutoSize to specify whether the control sizes itself automatically. When AutoSize is true, the control resizes automatically when its contents change.

By default, AutoSize is false.

See Also

Constraints

CanAutoSize

3.1.22.5.4 TCustomControlBar.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind;
```

C++

```
__property BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges

BevelOuter

BevelInner

BevelWidth

3.1.22.5.5 TCustomControlBar.CornerEdge Property

Pascal

```
property CornerEdge: TCornerEdge;
```

C++

```
__property TCornerEdge CornerEdge;
```

Description

This is CornerEdge, a member of class TCustomControlBar.

3.1.22.5.6 TCustomControlBar.DockSite Property

Specifies whether the control can be the target of drag-and-dock operations.

Pascal

```
property DockSite;
```

C++

```
__property DockSite;
```

Description

Set DockSite to true to allow other controls to be docked to this windowed control.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/
void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
      TWinControl *NewTarget, bool &Allow)
{
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if (Client->ClassNameIs("TDockableForm"))
    dynamic_cast<TDockableForm *>(Client)->DockSite = True;
  if ((DockClientCount == 2) && (NewTarget != this))        // Self?
    PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
```

```
}
procedure TConjoinDockHost.FormUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if Client is TDockableForm then
    TDockableForm(Client).DockSite := True;
  if (DockClientCount = 2) and (NewTarget <> Self) then
    PostMessage(Self.Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
end;
```

3.1.22.5.7 TCustomControlBar.DrawingStyle Property

Pascal

```
property DrawingStyle: TBandDrawingStyle;
```

C++

```
__property TBandDrawingStyle DrawingStyle;
```

Description

This is DrawingStyle, a member of class TCustomControlBar.

3.1.22.5.8 TCustomControlBar.GradientDirection Property

Pascal

```
property GradientDirection: TGradientDirection;
```

C++

```
__property TGradientDirection GradientDirection;
```

Description

This is GradientDirection, a member of class TCustomControlBar.

3.1.22.5.9 TCustomControlBar.GradientEndColor Property

Pascal

```
property GradientEndColor: TColor;
```

C++

```
__property TColor GradientEndColor;
```

Description

This is GradientEndColor, a member of class TCustomControlBar.

3.1.22.5.10 TCustomControlBar.GradientStartColor Property

Pascal

```
property GradientStartColor: TColor;
```

C++

```
__property TColor GradientStartColor;
```

Description

This is GradientStartColor, a member of class TCustomControlBar.

3.1.22.5.11 TCustomControlBar.Picture Property

Specifies the control bar's picture.

Pascal

```
property Picture: TPicture;
```

C++

```
__property TPicture Picture;
```

Description

Use Picture to specify the control bar's picture. The picture is tiled across the control bar.

See Also

OnBandPaint (see page 772)

OnPaint (see page 773)

3.1.22.5.12 TCustomControlBar.RowSize Property

Specifies the height of the control bar's rows.

Pascal

```
property RowSize: TRowSize;
```

C++

```
__property TRowSize RowSize;
```

Description

Use RowSize to specify the height, in pixels, of the control bar's rows.

See Also

CanAutoSize (see page 757)

AutoSize

OnBandInfo (see page 771)

ClientHeight

3.1.22.5.13 TCustomControlBar.RowSnap Property

Specifies whether controls are snapped to the control bar's rows when docked.

Pascal

```
property RowSnap: Boolean;
```

C++

```
__property Boolean RowSnap;
```

Description

Use RowSnap to specify whether controls are snapped to the control bar's rows when docked. Controls that are snapped have

their Top and Height properties set automatically to correspond to the control bar's rows.

StickControls (see page 765)

Height

Top

3.1.22.6 TCustomControlBar Events

The events of the TCustomControlBar class are listed here.

Protected Events

	Name	Description
	OnBandDrag (see page 771)	Occurs when the user starts a drag operation on a specified control.
	OnBandInfo (see page 771)	Occurs when the control bar adjusts the docking position of a band.
	OnBandMove (see page 772)	Occurs when a control band is moving.
	OnBandPaint (see page 772)	Occurs when a control band is painted.
	OnBeginBandMove (see page 773)	This is OnBeginBandMove, a member of class TCustomControlBar.
	OnEndBandMove (see page 773)	This is OnEndBandMove, a member of class TCustomControlBar.
	OnPaint (see page 773)	Occurs when the control bar is painted.

3.1.22.6.1 TCustomControlBar.OnBandDrag Event

Occurs when the user starts a drag operation on a specified control.

Pascal

```
property OnBandDrag: TBandDragEvent;
```

C++

```
__property TBandDragEvent OnBandDrag;
```

Description

Use OnBandDrag to conditionally allow the user to start dragging a control in the control bar.

The event handler indicates the control that the user is trying to drag. Change its Drag parameter to false to prevent the drag operation. If Drag remains true on exit from the event handler, the drag operation proceeds.

See Also

OnStartDock

onbandmove (see page 772)

3.1.22.6.2 TCustomControlBar.OnBandInfo Event

Occurs when the control bar adjusts the docking position of a band.

Pascal

```
property OnBandInfo: TBandInfoEvent;
```

C++

```
__property TBandInfoEvent OnBandInfo;
```

Description

Write code in the OnBandInfo event handler to provide information to the control bar that it can use when arranging its bands. The OnBandInfo event handler has several parameters that can be used to return information about how the band should be positioned, including its size, inset, and number of rows.

See Also

TBDockHeight

onbandmove (see page 772)

LRDockWidth

Height

Width

3.1.22.6.3 TCustomControlBar.OnBandMove Event

Occurs when a control band is moving.

Pascal

```
property OnBandMove: TBandMoveEvent;
```

C++

```
__property TBandMoveEvent OnBandMove;
```

Description

Write an OnBandMove event handler to perform actions when a band is moving.

Use OnBandMove to specify the destination rectangle for the band. For example, adjust the destination rectangle so that its right edge matches the right edge of the control bar. This means the control extends to the control bar's right edge no matter where it is moved.

See Also

AutoDrag (see page 766)

RowSnap (see page 770)

3.1.22.6.4 TCustomControlBar.OnBandPaint Event

Occurs when a control band is painted.

Pascal

```
property OnBandPaint: TBandPaintEvent;
```

C++

```
__property TBandPaintEvent OnBandPaint;
```

Description

Write an OnBandPaint event handler to customize the way the control bar draws its bands. From the event handler, you can draw to the control bar's canvas, using the dimensions of the band that are passed in as the ARect parameter. You can change the dimensions so that the automatically drawn frame and grabber appear in a different portion of the control bar (for example, indented slightly). You can suppress the automatic painting of the frame or grabber by removing options from the Options parameter.

See Also

OnPaint (see page 773)

3.1.22.6.5 TCustomControlBar.OnBeginBandMove Event

Pascal

```
property OnBeginBandMove: TBeginBandMoveEvent;
```

C++

```
__property TBeginBandMoveEvent OnBeginBandMove;
```

Description

This is OnBeginBandMove, a member of class TCustomControlBar.

3.1.22.6.6 TCustomControlBar.OnEndBandMove Event

Pascal

```
property OnEndBandMove: TEndBandMoveEvent;
```

C++

```
__property TEndBandMoveEvent OnEndBandMove;
```

Description

This is OnEndBandMove, a member of class TCustomControlBar.

3.1.22.6.7 TCustomControlBar.OnPaint Event

Occurs when the control bar is painted.

Pascal

```
property OnPaint: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnPaint;
```

Description

Write an OnPaint event handler to change the way the control bar is rendered. When a control bar receives a Windows paint message, it first draws the background picture, if any, and then generates an OnPaint event. After the OnPaint event exits, the control bar generates an OnBandPaint (see page 772) event for each band, finally rendering the grabbers and frames for each band.

Use the Canvas property to draw the control bar's image. Use the ClientRect property to obtain the dimensions on which to draw.

If the custom drawing is intended to change the appearance of individual bands, use the OnBandPaint (see page 772) event instead.

3.1.23 TCustomFlowPanel Class

The base class for all flow panel components.

Class Hierarchy

Pascal

```
TCustomFlowPanel = class(TCustomPanel);
```

C++

```
class TCustomFlowPanel : public TCustomPanel;
```

File

ExtCtrls

Description

Use TCustomFlowPanel as a base class when defining flow panels that include other controls as constituent parts.

See Also

TFlowPanel (see page 857)

3.1.23.1 TCustomFlowPanel Members

The following tables list the members exposed by TCustomFlowPanel.

Protected Methods

	Name	Description
	AdjustClientRect (see page 804)	Adjusts the ClientRect property for the idiosyncrasies of the window.
	AlignControls (see page 776)	Aligns any controls for which the control is the parent within a specified area of the control.
	CanAutoSize (see page 804)	Adjusts the way the panel responds to resize attempts.
	CreateParams (see page 805)	Initializes a window-creation parameter record passed in the Params parameter.
	Paint (see page 806)	Renders the image of the panel.
	SetParentBackground (see page 806)	This is SetParentBackground, a member of class TCustomPanel.

Protected Properties

	Name	Description
	Alignment (see page 807)	Determines how the caption is aligned within the panel.
	BevelInner (see page 807)	Determines the style of the inner bevel of a panel.
	BevelOuter (see page 808)	Determines the style of the outer bevel of a panel.
	BevelWidth (see page 809)	Determines the width, in pixels, of both the inner and outer bevels of a panel.
	BorderStyle (see page 810)	Determines the style of the line drawn around the perimeter of the panel control.
	BorderWidth (see page 811)	Specifies the distance, in pixels, between the outer and inner bevels.
	Color (see page 812)	Specifies the background color of the control.
	FullRepaint (see page 813)	Determines how the panel repaints itself when it is resized.
	Locked (see page 813)	Determines whether a panel that is used as a toolbar is replaced by a toolbar supplied by an OLE server.
	ParentColor (see page 814)	Determines where a control looks for its color information.
	ShowCaption (see page 814)	This is ShowCaption, a member of class TCustomPanel.
	VerticalAlignment (see page 814)	Sets the vertical position of the caption.

Public Methods

	Name	Description
	Create (see page 775)	Creates and initializes an instance of TCustomPanel.
	Destroy (see page 775)	Destroys an instance of TCustomControl.
	GetChildren (see page 776)	Calls a specified method for each child of the control.
	GetControlIndex (see page 777)	This is GetControlIndex, a member of class TCustomFlowPanel.
	GetControlsAlignment (see page 805)	Returns the alignment of text in the panel.
	SetControlIndex (see page 777)	This is SetControlIndex, a member of class TCustomFlowPanel.

Public Properties

	Name	Description
	AutoWrap (see page 778)	Specifies whether controls are automatically wrapped to fit on the flow panel.
	FlowStyle (see page 778)	Specifies the starting point and direction for controls added to a flow panel.
	ParentBackground (see page 813)	Determines whether control uses parent's theme background.

3.1.23.2 TCustomFlowPanel.Create Constructor

Creates and initializes an instance of TCustomPanel.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomFlowPanel(TComponent * AOwner);
```

Description

Call Create to instantiate a panel at runtime. Panels placed in forms at design time do not need to be explicitly created because they are created automatically.

AOwner is the component, typically a form, that is responsible for freeing the panel.

See Also

Owner

3.1.23.3 TCustomFlowPanel.Destroy Destructor

Destroys an instance of TCustomControl.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomFlowPanel();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the control is not nil, and only then calls Destroy.

Applications should only free controls explicitly when the constructor was called without assigning an owner to the control.

As the control is destroyed, it:

Destroys the TCanvas object in its Canvas property.

Override Destroy to free any memory or resources allocated in the Create method. When declaring a Destroy method in a descendant control type, always add the override directive to the declaration and call the inherited Destroy as the last statement in the redeclared method.

When a control is created, Delphi automatically provides exception handling around the constructor call. The destructor is called if an exception escapes from the constructor. This means that the destructor code must be prepared to clean up a partially constructed instance. Check all data fields for zero before disposing of their contents.

Create

3.1.23.4 TCustomFlowPanel Methods

The methods of the TCustomFlowPanel class are listed here.

Protected Methods

	Name	Description
	AlignControls (see page 776)	Aligns any controls for which the control is the parent within a specified area of the control.

Public Methods

	Name	Description
	GetChildren (see page 776)	Calls a specified method for each child of the control.
	GetControlIndex (see page 777)	This is GetControlIndex, a member of class TCustomFlowPanel.
	SetControlIndex (see page 777)	This is SetControlIndex, a member of class TCustomFlowPanel.

3.1.23.4.1 TCustomFlowPanel.AlignControls Method

Aligns any controls for which the control is the parent within a specified area of the control.

Pascal

```
procedure AlignControls(AControl: TControl; var Rect: TRect); override;
```

C++

```
virtual __fastcall AlignControls(TControl * AControl, TRect Rect);
```

Description

Use AlignControls to align all controls within an area of a form, panel, group box, scroll box, or any container control. Specify the area in which to align the controls as the value of the Rect parameter.

AlignControls uses the Align property value for each child control to determine how to align it. The AControl parameter can be nil (Delphi) or NULL (C++). If you specify a control in AControl, that control takes precedence in alignment over other, similarly-aligned controls.

See Also

Align

3.1.23.4.2 TCustomFlowPanel.GetChildren Method

Calls a specified method for each child of the control.

Pascal

```
procedure GetChildren(Proc: TGetChildProc; Root: TComponent); override;
```

C++

```
virtual __fastcall GetChildren(TGetChildProc Proc, TComponent * Root);
```

Description

GetChildren is called by the streaming system that loads and saves components. Applications seldom need to call this routine.

GetChildren executes the callback specified by the Proc parameter for every child control listed by the Controls property that lists the Root parameter as its Owner.

Override GetChildren to limit or augment which child controls are saved with the control. When overriding GetChildren, call the procedure passed as the Proc parameter for every child control that should be saved. The Root parameter indicates the component (usually a form) that owns the control.

Controls

Owner

3.1.23.4.3 TCustomFlowPanel.GetControlIndex Method

Pascal

```
function GetControlIndex(AControl: TControl): Integer;
```

C++

```
__fastcall int GetControlIndex(TControl * AControl);
```

Description

This is GetControlIndex, a member of class TCustomFlowPanel.

3.1.23.4.4 TCustomFlowPanel.SetControlIndex Method

Pascal

```
procedure SetControlIndex(AControl: TControl; Index: Integer);
```

C++

```
__fastcall SetControlIndex(TControl * AControl, int Index);
```

Description

This is SetControlIndex, a member of class TCustomFlowPanel.

3.1.23.5 TCustomFlowPanel Properties

The properties of the TCustomFlowPanel class are listed here.

Public Properties

	Name	Description
	AutoWrap (see page 778)	Specifies whether controls are automatically wrapped to fit on the flow panel.
	FlowStyle (see page 778)	Specifies the starting point and direction for controls added to a flow panel.

3.1.23.5.1 TCustomFlowPanel.AutoWrap Property

Specifies whether controls are automatically wrapped to fit on the flow panel.

Pascal

```
property AutoWrap: Boolean;
```

C++

```
__property Boolean AutoWrap;
```

Description

If set to True, a new control is automatically placed in a location on the flow panel in which it is visible. If set to False, a new control continues in the same direction as the previous control, even if it would no longer be visible on the panel. You can increase the size of the panel to view controls that are not automatically wrapped to the next line or column.

3.1.23.5.2 TCustomFlowPanel.FlowStyle Property

Specifies the starting point and direction for controls added to a flow panel.

Pascal

```
property FlowStyle: TFlowStyle;
```

C++

```
__property TFlowStyle FlowStyle;
```

Description

Use FlowStyle to set the starting position for the first control added to a flow panel, as well as the subsequent position for additional controls.

Flow Style	Description
BottomTopLeftRight	The first control is at the bottom left corner of the panel. Subsequent controls are added from bottom to top and then from left to right.
BottomTopRightLeft	The first control is at the bottom right corner of the panel. Subsequent controls are added from bottom to top and then from right to left.
LeftRightBottomTop	The first control is at the bottom left corner of the panel. Subsequent controls are added from left to right and then from bottom to top.
LeftRightTopBottom	The first control is at the top left corner of the panel. Subsequent controls are added from left to right and then from top to bottom. This is the default setting.
RightLeftBottomTop	The first control is at the bottom right corner of the panel. Subsequent controls are added from right to left and then from bottom to top.
RightLeftTopBottom	The first control is at the top right corner of the panel. Subsequent controls are added from right to left and then from top to bottom.
TopBottomLeftRight	The first control is at the top left corner of the panel. Subsequent controls are added from top to bottom and then from left to right.
TopBottomRightLeft	The first control is at the top right corner of the panel. Subsequent controls are added from top to bottom and then from right to left.

C++ Examples:

```
//
//This example demonstrates the use of Flow panel to automatically
//align a set of controls and the different methods that can be used for that.
```

```
//A Stack is used to control the order of destruction of buttons.
//
void __fastcall TForm2::btAButtonClick(TObject *Sender)
{
    TButton *thisButton;
    TButton *lastButton;
    String temp;

    /* Sender is a TButton, cast it */
    thisButton = dynamic_cast<TButton*>(Sender);

    if (m_Stack->Count() > 0)
    {
        /* If there are buttons in stack, peek it */
        lastButton = dynamic_cast<TButton*>(m_Stack->Peek());

        /* Change the captions of this button and the last one */
        temp = thisButton->Caption;
        thisButton->Caption = lastButton->Caption;
        lastButton->Caption = temp;
    }
}

void __fastcall TForm2::btAddButtonClick(TObject *Sender)
{
    /* Create a new button */
    TButton *button = new TButton(m_FlowPane);

    button->Parent = m_FlowPane;
    button->Caption = IntToStr(m_Stack->Count());
    button->OnClick = btAButtonClick;

    /* Push the button to the stack */
    m_Stack->Push(button);
}

void __fastcall TForm2::btReArrangeClick(TObject *Sender)
{
    /* Change the current flow style (rotate them) */
    TFlowStyle newFlowStyle = m_FlowPane->FlowStyle;

    if (newFlowStyle == fsBottomTopRightLeft)
        newFlowStyle = fsLeftRightTopBottom;
    else
        newFlowStyle = newFlowStyle + 1;

    m_FlowPane->FlowStyle = newFlowStyle;
}

void __fastcall TForm2::btRemoveButtonClick(TObject *Sender)
{
    TButton *button;

    if (m_Stack->Count() > 0)
    {
        /* if the stack is not empty, pop the last button */
        button = dynamic_cast<TButton*>(m_Stack->Pop());
        delete button;
    }
}

void __fastcall TForm2::FormCreate(TObject *Sender)
{
    /* Create a new TFlowPanel pane and align it to client */
    m_FlowPane = new TFlowPanel(this);
    m_FlowPane->Parent = this;
```

```
    m_FlowPane->Align = alClient;

    /* Set the initial flowing style */
    m_FlowPane->FlowStyle = fsLeftRightTopBottom;

    /* Create the button stack */
    m_Stack = new TObjectStack();
}

void __fastcall TForm2::FormDestroy(TObject *Sender)
{
    /* Destroy the stack also */
    delete m_Stack;
}
```

Delphi Examples:

```
{
This example demonstrates the use of Flow panel to automatically
align a set of controls and the different methods that can be used for that.
A Stack is used to control the order of destruction of buttons.
}
procedure TForm2.btAButtonClick(Sender: TObject);
var
  ThisButton : TButton;
  LastButton : TButton;
  Temp       : String;
begin
  { Sender is a TButton, cast it }
  ThisButton := Sender as TButton;

  if FStack.Count > 0 then
  begin
    { If there are buttons in stack, peek it }
    LastButton := FStack.Peek() as TButton;

    { Change the captions of this button and the last one }
    Temp := ThisButton.Caption;
    ThisButton.Caption := LastButton.Caption;
    LastButton.Caption := Temp;
  end;
end;

procedure TForm2.btAddButtonClick(Sender: TObject);
var
  Button : TButton;
begin
  { Create a new button }
  Button := TButton.Create(FFlowPane);
  Button.Parent := FFlowPane;
  Button.Caption := IntToStr(FStack.Count);
  Button.OnClick := btAButtonClick;

  { Push the button to the stack }
  FStack.Push(Button);
end;

procedure TForm2.btReArrangeClick(Sender: TObject);
var
  NewFlowStyle : TFlowStyle;
begin
  { Chnage the flow order (rotate) }
  NewFlowStyle := FFlowPane.FlowStyle;

  if NewFlowStyle = fsBottomTopRightLeft then
     NewFlowStyle := fsLeftRightTopBottom
  else
```

```
    Inc(NewFlowStyle);

  FFlowPane.FlowStyle := NewFlowStyle;
end;

procedure TForm2.btRemoveButtonClick(Sender: TObject);
var
  Button : TButton;
begin
  if FStack.Count > 0 then
  begin
    { if the stack is not empty, pop the last button }
    Button := FStack.Pop() as TButton;
    Button.Free();
  end;
end;

procedure TForm2.FormCreate(Sender: TObject);
begin
  { Create a new TFlowPanel pane and align it to client }
  FFlowPane := TFlowPanel.Create(Self);
  FFlowPane.Parent := Self;
  FFlowPane.Align := alClient;

  { Set the initial flowing style }
  FFlowPane.FlowStyle := fsLeftRightTopBottom;

  { Create the button stack }
  FStack := TObjectStack.Create();
end;

procedure TForm2.FormDestroy(Sender: TObject);
begin
  { Destroy the stack also }
  FStack.Free();
end;
```

3.1.24 TCustomGridPanel Class

The base class for all grid panel components.

Class Hierarchy

Pascal

```
TCustomGridPanel = class(TCustomPanel);
```

C++

```
class TCustomGridPanel : public TCustomPanel;
```

File

ExtCtrls

Description

Use TCustomGridPanel as a base class when defining grid panels that include other controls as constituent parts.

See Also

TGridPanel (see page 941)

3.1.24.1 TCustomGridPanel Members

The following tables list the members exposed by TCustomGridPanel.

Protected Methods

	Name	Description
	AdjustClientRect (see page 804)	Adjusts the ClientRect property for the idiosyncrasies of the window.
	AlignControls (see page 784)	Aligns any controls for which the control is the parent within a specified area of the control.
	AutoAddColumn (see page 785)	This is AutoAddColumn, a member of class TCustomGridPanel.
	AutoAddRow (see page 785)	This is AutoAddRow, a member of class TCustomGridPanel.
	CanAutoSize (see page 804)	Adjusts the way the panel responds to resize attempts.
	CellIndexToCell (see page 785)	This is CellIndexToCell, a member of class TCustomGridPanel.
	CellToCellIndex (see page 785)	This is CellToCellIndex, a member of class TCustomGridPanel.
	CreateParams (see page 805)	Initializes a window-creation parameter record passed in the Params parameter.
	Loaded (see page 786)	Initializes the control after it is loaded from a stream.
	Paint (see page 787)	Renders the image of the panel.
	RemoveEmptyAutoAddColumns (see page 787)	This is RemoveEmptyAutoAddColumns, a member of class TCustomGridPanel.
	RemoveEmptyAutoAddRows (see page 787)	This is RemoveEmptyAutoAddRows, a member of class TCustomGridPanel.
	SetParentBackground (see page 806)	This is SetParentBackground, a member of class TCustomPanel.
	UpdateControlOriginalParentSize (see page 788)	This is UpdateControlOriginalParentSize, a member of class TCustomGridPanel.

Protected Properties

	Name	Description
	Alignment (see page 807)	Determines how the caption is aligned within the panel.
	BevelInner (see page 807)	Determines the style of the inner bevel of a panel.
	BevelOuter (see page 808)	Determines the style of the outer bevel of a panel.
	BevelWidth (see page 809)	Determines the width, in pixels, of both the inner and outer bevels of a panel.
	BorderStyle (see page 810)	Determines the style of the line drawn around the perimeter of the panel control.
	BorderWidth (see page 811)	Specifies the distance, in pixels, between the outer and inner bevels.
	Color (see page 812)	Specifies the background color of the control.
	FullRepaint (see page 813)	Determines how the panel repaints itself when it is resized.
	Locked (see page 813)	Determines whether a panel that is used as a toolbar is replaced by a toolbar supplied by an OLE server.
	ParentColor (see page 814)	Determines where a control looks for its color information.
	ShowCaption (see page 814)	This is ShowCaption, a member of class TCustomPanel.
	VerticalAlignment (see page 814)	Sets the vertical position of the caption.

Public Methods

	Name	Description
	Create (see page 783)	Creates and initializes an instance of TCustomPanel.
	Destroy (see page 783)	Destroys an instance of TCustomControl.
	GetChildren (see page 785)	Calls a specified method for each child of the control.
	GetControlsAlignment (see page 805)	Returns the alignment of text in the panel.
	IsColumnEmpty (see page 786)	This is IsColumnEmpty, a member of class TCustomGridPanel.
	IsRowEmpty (see page 786)	This is IsRowEmpty, a member of class TCustomGridPanel.

Public Properties

	Name	Description
	CellCount (see page 788)	This is CellCount, a member of class TCustomGridPanel.
	CellRect (see page 788)	Returns the screen coordinates of a cell in the grid.
	CellSize (see page 789)	This is CellSize, a member of class TCustomGridPanel.
	ColumnCollection (see page 789)	Sets the number and size of the columns on the grid panel.
	ColumnSpanIndex (see page 789)	This is ColumnSpanIndex, a member of class TCustomGridPanel.

	ControlCollection (see page 789)	This is ControlCollection, a member of class TCustomGridPanel.
	ExpandStyle (see page 790)	Specifies whether rows or columns are added to a filled grid panel to accommodate additional controls.
	ParentBackground (see page 813)	Determines whether control uses parent's theme background.
	RowCollection (see page 790)	Sets the number and size of the rows on the grid panel.
R	RowSpanIndex (see page 790)	This is RowSpanIndex, a member of class TCustomGridPanel.

3.1.24.2 TCustomGridPanel.Create Constructor

Creates and initializes an instance of TCustomPanel.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomGridPanel(TComponent * AOwner);
```

Description

Call Create to instantiate a panel at runtime. Panels placed in forms at design time do not need to be explicitly created because they are created automatically.

AOwner is the component, typically a form, that is responsible for freeing the panel.

See Also

Owner

3.1.24.3 TCustomGridPanel.Destroy Destructor

Destroys an instance of TCustomControl.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomGridPanel();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the control is not nil, and only then calls Destroy.

Applications should only free controls explicitly when the constructor was called without assigning an owner to the control.

As the control is destroyed, it:

Destroys the TCanvas object in its Canvas property.

Override Destroy to free any memory or resources allocated in the Create method. When declaring a Destroy method in a descendant control type, always add the override directive to the declaration and call the inherited Destroy as the last statement in the redeclared method.

When a control is created, Delphi automatically provides exception handling around the constructor call. The destructor is called if an exception escapes from the constructor. This means that the destructor code must be prepared to clean up a partially constructed instance. Check all data fields for zero before disposing of their contents.

3.1.24.4 TCustomGridPanel Methods

The methods of the TCustomGridPanel class are listed here.

Protected Methods

	Name	Description
	AlignControls (see page 784)	Aligns any controls for which the control is the parent within a specified area of the control.
	AutoAddColumn (see page 785)	This is AutoAddColumn, a member of class TCustomGridPanel.
	AutoAddRow (see page 785)	This is AutoAddRow, a member of class TCustomGridPanel.
	CellIndexToCell (see page 785)	This is CellIndexToCell, a member of class TCustomGridPanel.
	CellToCellIndex (see page 785)	This is CellToCellIndex, a member of class TCustomGridPanel.
	Loaded (see page 786)	Initializes the control after it is loaded from a stream.
	Paint (see page 787)	Renders the image of the panel.
	RemoveEmptyAutoAddColumns (see page 787)	This is RemoveEmptyAutoAddColumns, a member of class TCustomGridPanel.
	RemoveEmptyAutoAddRows (see page 787)	This is RemoveEmptyAutoAddRows, a member of class TCustomGridPanel.
	UpdateControlOriginalParentSize (see page 788)	This is UpdateControlOriginalParentSize, a member of class TCustomGridPanel.

Public Methods

	Name	Description
	GetChildren (see page 785)	Calls a specified method for each child of the control.
	IsColumnEmpty (see page 786)	This is IsColumnEmpty, a member of class TCustomGridPanel.
	IsRowEmpty (see page 786)	This is IsRowEmpty, a member of class TCustomGridPanel.

3.1.24.4.1 TCustomGridPanel.AlignControls Method

Aligns any controls for which the control is the parent within a specified area of the control.

Pascal

```
procedure AlignControls(AControl: TControl; var Rect: TRect); override;
```

C++

```
virtual __fastcall AlignControls(TControl * AControl, TRect Rect);
```

Description

Use AlignControls to align all controls within an area of a form, panel, group box, scroll box, or any container control. Specify the area in which to align the controls as the value of the Rect parameter.

AlignControls uses the Align property value for each child control to determine how to align it. The AControl parameter can be nil (Delphi) or NULL (C++). If you specify a control in AControl, that control takes precedence in alignment over other, similarly-aligned controls.

See Also

Align

3.1.24.4.2 TCustomGridPanel.AutoAddColumn Method

Pascal

```
function AutoAddColumn: TColumnItem;
```

C++

```
__fastcall TColumnItem AutoAddColumn();
```

Description

This is AutoAddColumn, a member of class TCustomGridPanel.

3.1.24.4.3 TCustomGridPanel.AutoAddRow Method

Pascal

```
function AutoAddRow: TRowItem;
```

C++

```
__fastcall TRowItem AutoAddRow();
```

Description

This is AutoAddRow, a member of class TCustomGridPanel.

3.1.24.4.4 TCustomGridPanel.CellIndexToCell Method

Pascal

```
procedure CellIndexToCell(AIndex: Integer; var AColumn: Integer; var ARow: Integer);
```

C++

```
__fastcall CellIndexToCell(int AIndex, int AColumn, int ARow);
```

Description

This is CellIndexToCell, a member of class TCustomGridPanel.

3.1.24.4.5 TCustomGridPanel.CellToCellIndex Method

Pascal

```
function CellToCellIndex(AColumn: Integer; ARow: Integer): Integer;
```

C++

```
__fastcall int CellToCellIndex(int AColumn, int ARow);
```

Description

This is CellToCellIndex, a member of class TCustomGridPanel.

3.1.24.4.6 TCustomGridPanel.GetChildren Method

Calls a specified method for each child of the control.

Pascal

```
procedure GetChildren(Proc: TGetChildProc; Root: TComponent); override;
```

C++

```
virtual __fastcall GetChildren(TGetChildProc Proc, TComponent * Root);
```

Description

GetChildren is called by the streaming system that loads and saves components. Applications seldom need to call this routine.

GetChildren executes the callback specified by the Proc parameter for every child control listed by the Controls property that lists the Root parameter as its Owner.

Override GetChildren to limit or augment which child controls are saved with the control. When overriding GetChildren, call the procedure passed as the Proc parameter for every child control that should be saved. The Root parameter indicates the component (usually a form) that owns the control.

See Also

Controls

Owner

3.1.24.4.7 TCustomGridPanel.IsColumnEmpty Method

Pascal

```
function IsColumnEmpty(AColumn: Integer): Boolean;
```

C++

```
__fastcall Boolean IsColumnEmpty(int AColumn);
```

Description

This is IsColumnEmpty, a member of class TCustomGridPanel.

3.1.24.4.8 TCustomGridPanel.IsRowEmpty Method

Pascal

```
function IsRowEmpty(ARow: Integer): Boolean;
```

C++

```
__fastcall Boolean IsRowEmpty(int ARow);
```

Description

This is IsRowEmpty, a member of class TCustomGridPanel.

3.1.24.4.9 TCustomGridPanel.Loaded Method

Initializes the control after it is loaded from a stream.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Do not call Loaded. The VCL streaming system calls Loaded automatically after the control's form is loaded into memory so that the control can complete any initializations that depend on other objects in the form.

Loaded overrides the inherited method in order to initialize the control from its associated Action. To change the properties the control copies from its action, override the ActionChange method.

See Also

Loaded

Action

ActionChange

3.1.24.4.10 TCustomGridPanel.Paint Method

Renders the image of the panel.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

Override the Paint method to change the way the panel is drawn. The Paint method for TCustomPanel draws the bevels of the panel, sets the brush and font for the panel, and fills in the interior of the panel. Finally, Paint writes the value of Caption on the panel.

See Also

BevelInner (see page 807)

BevelOuter (see page 808)

Brush

Caption

Canvas

3.1.24.4.11 TCustomGridPanel.RemoveEmptyAutoAddColumns Method

Pascal

```
procedure RemoveEmptyAutoAddColumns;
```

C++

```
__fastcall RemoveEmptyAutoAddColumns();
```

Description

This is RemoveEmptyAutoAddColumns, a member of class TCustomGridPanel.

3.1.24.4.12 TCustomGridPanel.RemoveEmptyAutoAddRows Method

Pascal

```
procedure RemoveEmptyAutoAddRows;
```

C++

```
__fastcall RemoveEmptyAutoAddRows();
```

Description

This is RemoveEmptyAutoAddRows, a member of class TCustomGridPanel.

3.1.24.4.13 TCustomGridPanel.UpdateControlOriginalParentSize Method

Pascal

```
procedure UpdateControlOriginalParentSize(AControl: TControl; var AOriginalParentSize:
TPoint); override;
```

C++

```
virtual __fastcall UpdateControlOriginalParentSize(TControl * AControl, TPoint
AOriginalParentSize);
```

Description

This is UpdateControlOriginalParentSize, a member of class TCustomGridPanel.

3.1.24.5 TCustomGridPanel Properties

The properties of the TCustomGridPanel class are listed here.

Public Properties

	Name	Description
R	CellCount (see page 788)	This is CellCount, a member of class TCustomGridPanel.
R	CellRect (see page 788)	Returns the screen coordinates of a cell in the grid.
R	CellSize (see page 789)	This is CellSize, a member of class TCustomGridPanel.
	ColumnCollection (see page 789)	Sets the number and size of the columns on the grid panel.
R	ColumnSpanIndex (see page 789)	This is ColumnSpanIndex, a member of class TCustomGridPanel.
	ControlCollection (see page 789)	This is ControlCollection, a member of class TCustomGridPanel.
	ExpandStyle (see page 790)	Specifies whether rows or columns are added to a filled grid panel to accommodate additional controls.
	RowCollection (see page 790)	Sets the number and size of the rows on the grid panel.
R	RowSpanIndex (see page 790)	This is RowSpanIndex, a member of class TCustomGridPanel.

3.1.24.5.1 TCustomGridPanel.CellCount Property

Pascal

```
property CellCount: Integer;
```

C++

```
__property int CellCount;
```

Description

This is CellCount, a member of class TCustomGridPanel.

3.1.24.5.2 TCustomGridPanel.CellRect Property

Returns the screen coordinates of a cell in the grid.

Pascal

```
property CellRect [AColumn, ARow: Integer]: TRect;
```

C++

```
__property TRect CellRect[int AColumn, ARow];
```

Description

Use the CellRect property to return the screen coordinates of a cell in the grid.

3.1.24.5.3 TCustomGridPanel.CellSize Property

Pascal

```
property CellSize [AColumn, ARow: Integer]: TPoint;
```

C++

```
__property TPoint CellSize[int AColumn, ARow];
```

Description

This is CellSize, a member of class TCustomGridPanel.

3.1.24.5.4 TCustomGridPanel.ColumnCollection Property

Sets the number and size of the columns on the grid panel.

Pascal

```
property ColumnCollection: TColumnCollection;
```

C++

```
__property TColumnCollection ColumnCollection;
```

Description

Use the ColumnCollection property to set the number of columns as well as the size of each column. You can use the SizeStyle property to specify whether column sizes are based on a percentage of the available width, based on an absolute value, or automatically sized.

3.1.24.5.5 TCustomGridPanel.ColumnSpanIndex Property

Pascal

```
property ColumnSpanIndex [AColumn, ARow: Integer]: Integer;
```

C++

```
__property int ColumnSpanIndex[int AColumn, ARow];
```

Description

This is ColumnSpanIndex, a member of class TCustomGridPanel.

3.1.24.5.6 TCustomGridPanel.ControlCollection Property

Pascal

```
property ControlCollection: TControlCollection;
```

C++

```
__property TControlCollection ControlCollection;
```

Description

This is ControlCollection, a member of class TCustomGridPanel.

3.1.24.5.7 TCustomGridPanel.ExpandStyle Property

Specifies whether rows or columns are added to a filled grid panel to accommodate additional controls.

Pascal

```
property ExpandStyle: TExpandStyle;
```

C++

```
__property TExpandStyle ExpandStyle;
```

Description

Use the ExpandStyle property to specify how a grid panel is expanded when each cell of the grid contains a control, and a new control is added.

3.1.24.5.8 TCustomGridPanel.RowCollection Property

Sets the number and size of the rows on the grid panel.

Pascal

```
property RowCollection: TRowCollection;
```

C++

```
__property TRowCollection RowCollection;
```

Description

Use the RowCollection property to set the number of rows as well as the size of each row. You can use the SizeStyle property to specify whether row sizes are based on a percentage of the available width, based on an absolute value, or automatically sized.

3.1.24.5.9 TCustomGridPanel.RowSpanIndex Property

Pascal

```
property RowSpanIndex [AColumn, ARow: Integer]: Integer;
```

C++

```
__property int RowSpanIndex[int AColumn, ARow];
```

Description

This is RowSpanIndex, a member of class TCustomGridPanel.

3.1.25 TCustomLabeledEdit Class

TCustomLabeledEdit is the base class for edit controls that have an integrated label.

Class Hierarchy

Pascal

```
TCustomLabeledEdit = class(TCustomEdit);
```

C++

```
class TCustomLabeledEdit : public TCustomEdit;
```

File

ExtCtrls

Description

TCustomLabeledEdit is the base class for edit controls that have an associated label. This class introduces new properties for managing a label that sits on one side of the edit control.

Do not create instances of TCustomLabeledEdit. Use TCustomLabeledEdit as a base class when declaring edit controls that include a label. Properties and methods of TCustomLabeledEdit provide basic behavior that descendant classes inherit as well as behavior that components can override to customize their behavior.

See Also

TEdit

TLabeledEdit (see page 1100)

TBoundLabel (see page 174)

3.1.25.1 TCustomLabeledEdit Members

The following tables list the members exposed by TCustomLabeledEdit.

Protected Methods

	Name	Description
	CMBidimodechanged (see page 792)	Responds when the BiDiMode property changes.
	CMEnabledchanged (see page 793)	Responds when the Enabled property changes.
	CMVisiblechanged (see page 793)	Responds when the Visible property changes.
V	Notification (see page 793)	Responds to notifications when objects are created or destroyed.
V	SetName (see page 794)	Sets the name of the control.
V	SetParent (see page 795)	Sets the value of the Parent property.

Public Methods

	Name	Description
V	Create (see page 791)	Creates an instance of TCustomLabeledEdit (see page 790).
V	SetBounds (see page 794)	Sets the windowed control's boundary properties all at once.
	SetupInternalLabel (see page 795)	Initializes the control that implements the EditLabel (see page 796) property.

Public Properties

	Name	Description
R	EditLabel (see page 796)	Specifies the control that implements the label.
	LabelPosition (see page 796)	Specifies the position of the label relative to the edit control.
	LabelSpacing (see page 796)	Specifies the distance, in pixels, between the label and the edit region.

3.1.25.2 TCustomLabeledEdit.Create Constructor

Creates an instance of TCustomLabeledEdit (see page 790).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomLabeledEdit(TComponent * AOwner);
```

Description

Call Create to instantiate a labeled edit control. AOwner specifies a component, typically the form, that is responsible for freeing the labeled edit control.

See Also

Owner

3.1.25.3 TCustomLabeledEdit Methods

The methods of the TCustomLabeledEdit class are listed here.

Protected Methods

	Name	Description
	CMBidimodechanged (see page 792)	Responds when the BiDiMode property changes.
	CMEnabledchanged (see page 793)	Responds when the Enabled property changes.
	CMVisiblechanged (see page 793)	Responds when the Visible property changes.
V	Notification (see page 793)	Responds to notifications when objects are created or destroyed.
V	SetName (see page 794)	Sets the name of the control.
V	SetParent (see page 795)	Sets the value of the Parent property.

Public Methods

	Name	Description
V	SetBounds (see page 794)	Sets the windowed control's boundary properties all at once.
	SetupInternalLabel (see page 795)	Initializes the control that implements the EditLabel (see page 796) property.

3.1.25.3.1 TCustomLabeledEdit.CMBidimodechanged Method

Responds when the BiDiMode property changes.

Pascal

```
procedure CMBidimodechanged(var Message: TMessage); message CM_BIDIMODECHANGED;
```

C++

```
__fastcall CMBidimodechanged(TMessage Message);
```

Description

CMBidimodechanged is called automatically when an application changes the BiDiMode property.

Message is a CM_BIDIMODECHANGED message that notifies the labeled edit of the change.

The labeled edit control responds by changing the BiDiMode property of the associated label to the value of its own BiDiMode property.

See Also

BiDiMode

EditLabel (see page 796)

3.1.25.3.2 TCustomLabeledEdit.CMEnabledchanged Method

Responds when the Enabled property changes.

Pascal

```
procedure CMEnabledchanged(var Message: TMessage); message CM_ENABLEDCHANGED;
```

C++

```
__fastcall CMEnabledchanged(TMessage Message);
```

Description

CMEnabledchanged is called automatically when an application changes the Enabled property.

Message is a CM_ENABLEDCHANGED message that notifies the labeled edit of the change.

The labeled edit control responds by changing the Enabled property of the associated label to the value of its own Enabled property.

See Also

Enabled

EditLabel (see page 796)

3.1.25.3.3 TCustomLabeledEdit.CMVisiblechanged Method

Responds when the Visible property changes.

Pascal

```
procedure CMVisiblechanged(var Message: TMessage); message CM_VISIBLECHANGED;
```

C++

```
__fastcall CMVisiblechanged(TMessage Message);
```

Description

CMVisiblechanged is called automatically when an application changes the Visible property.

Message is a CM_VISIBLECHANGED message that notifies the labeled edit of the change.

The labeled edit control responds by changing the Visible property of the associated label to the value of its own Visible property.

See Also

Visible

EditLabel (see page 796)

3.1.25.3.4 TCustomLabeledEdit.Notification Method

Responds to notifications when objects are created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

This protected method is called automatically immediately after objects are created and immediately before they are destroyed. TCustomLabeledEdit (see page 790) overrides this method to update the EditLabel (see page 796) property when it receives a notification that the label component is about to be destroyed.

AComponent is the component that was just created or that is about to be destroyed.

Operation indicates whether the notification indicates the creation or destruction of AComponent.

See Also

EditLabel (see page 796)

3.1.25.3.5 TCustomLabeledEdit.SetBounds Method

Sets the windowed control's boundary properties all at once.

Pascal

```
procedure SetBounds(ALeft: Integer; ATop: Integer; AWidth: Integer; AHeight: Integer);
override;
```

C++

```
virtual __fastcall SetBounds(int ALeft, int ATop, int AWidth, int AHeight);
```

Description

Use SetBounds to change all of the control's boundary properties at once. The same effect can be achieved by setting the Left, Top, Width, and Height properties separately. By setting all four properties at once, SetBounds ensures that the control will not repaint between changes

Specify the values for the Left, Top, Width, and Height properties as the value of the ALeft, ATop, AWidth, and AHeight parameters, respectively.

See Also

Height

Left

Top

Width

3.1.25.3.6 TCustomLabeledEdit.SetName Method

Sets the name of the control.

Pascal

```
procedure SetName(const Value: TComponentName); override;
```

C++

```
virtual __fastcall SetName(const TComponentName Value);
```

Description

SetName is the protected write implementation of the Name property. TControl updates the Text or Caption property, if appropriate, after changing the value of Name.

Override SetName to execute additional code when the value of the Name property changes.

See Also

Name

Caption

Text

3.1.25.3.7 TCustomLabeledEdit.SetParent Method

Sets the value of the Parent property.

Pascal

```
procedure SetParent(AParent: TWinControl); override;
```

C++

```
virtual __fastcall SetParent(TWinControl * AParent);
```

Description

SetParent is the protected property setter for the Parent property. TCustomLabeledEdit (see page 790) overrides SetParent to ensure that the label has the same parent as the edit control.

See Also

Parent

EditLabel (see page 796)

3.1.25.3.8 TCustomLabeledEdit.SetupInternalLabel Method

Initializes the control that implements the EditLabel (see page 796) property.

Pascal

```
procedure SetupInternalLabel;
```

C++

```
__fastcall SetupInternalLabel();
```

Description

Applications do not need to call SetupInternalLabel because this method is called when you set the EditLabel (see page 796) property.

SetupInternalLabel ensures that there is a control to implement the EditLabel (see page 796) property, adds the labeled edit control to the list of components that should be notified when the label is freed, and sets the label's FocusControl property to the labeled edit control.

See Also

EditLabel (see page 796)

FocusControl

3.1.25.4 TCustomLabeledEdit Properties

The properties of the TCustomLabeledEdit class are listed here.

Public Properties

	Name	Description
	EditLabel (see page 796)	Specifies the control that implements the label.
	LabelPosition (see page 796)	Specifies the position of the label relative to the edit control.
	LabelSpacing (see page 796)	Specifies the distance, in pixels, between the label and the edit region.

3.1.25.4.1 TCustomLabeledEdit.EditLabel Property

Specifies the control that implements the label.

Pascal

```
property EditLabel: TBoundLabel;
```

C++

```
__property TBoundLabel EditLabel;
```

Description

Use EditLabel to work with the label that is associated with this labeled edit control. Use this label's properties to specify the caption that appears on the label, the position of the caption within the label, the font used to write that caption, and so on. At design time, expand the EditLabel property in the Object Inspector to set its properties.

See Also

LabelPosition (see page 796)

LabelSpacing (see page 796)

3.1.25.4.2 TCustomLabeledEdit.LabelPosition Property

Specifies the position of the label relative to the edit control.

Pascal

```
property LabelPosition: TLabelPosition;
```

C++

```
__property TLabelPosition LabelPosition;
```

Description

Set LabelPosition to indicate where the label sits relative to the edit control.

See Also

EditLabel (see page 796)

LabelSpacing (see page 796)

3.1.25.4.3 TCustomLabeledEdit.LabelSpacing Property

Specifies the distance, in pixels, between the label and the edit region.

Pascal

```
property LabelSpacing: Integer;
```

C++

```
__property int LabelSpacing;
```

Description

Set LabelSpacing to indicate the distance, in pixels, between the label and the edit control.

See Also

EditLabel (see page 796)

LabelPosition (see page 796)

3.1.26 TCustomLinkLabel Class

Base class for label containing HTML link.

Class Hierarchy

Pascal

```
TCustomLinkLabel = class(TWinControl);
```

C++

```
class TCustomLinkLabel : public TWinControl;
```

File

ExtCtrls

Description

TLinkLabel (see page 1167) is the base class for a label that can contain HTML tags, including a link. The OnLinkClick (see page 802) event is triggered by clicking the link.

See Also

TLinkLabel (see page 1167)

OnLinkClick (see page 802)

TSysLinkEvent (see page 1555)

TSysLinkType (see page 1546)

3.1.26.1 TCustomLinkLabel Members

The following tables list the members exposed by TCustomLinkLabel.

Protected Methods

	Name	Description
	CreateParams (see page 799)	Initializes a window-creation parameter data structure.
	CreateWnd (see page 799)	Creates the underlying window.
	SetAutoSize (see page 800)	This is SetAutoSize, a member of class TCustomLinkLabel.
	UseThemes (see page 800)	This is UseThemes, a member of class TCustomLinkLabel.

Public Events

	Name	Description
	OnLinkClick (see page 802)	Event for click on TCustomLinkLabel (see page 797) HTML link.

Public Methods

	Name	Description
	Create (see page 798)	Creates an instance of TWinControl.

Public Nested Types

Name	Description
TLinkAlignment (see page 801)	This is nested type ExtCtrls.TCustomLinkLabel.TLinkAlignment.

Public Properties

	Name	Description
	Alignment (see page 800)	This is Alignment, a member of class TCustomLinkLabel.
	AutoSize (see page 800)	Specifies whether the control sizes itself automatically to accommodate its contents.
	UseVisualStyle (see page 801)	This is UseVisualStyle, a member of class TCustomLinkLabel.

3.1.26.2 TCustomLinkLabel.Create Constructor

Creates an instance of TWinControl.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomLinkLabel(TComponent * AOwner);
```

Description

Call Create to construct and initialize a new control and insert the newly-constructed control into its owner, as specified by the AOwner parameter. Create inserts the control in the owner by calling the owner's InsertComponent method.

Most controls override Create to initialize their unique properties. Objects that override the Create method must always call the inherited Create method first, and then proceed with the component-specific initialization. Specify the override directive when overriding the Create method.

If a component's Create method allocates resources or memory, override the Destroy method to free those resources.

Brush

TabOrder

CreateParented

InsertComponent

Create

Owner

3.1.26.3 TCustomLinkLabel Methods

The methods of the TCustomLinkLabel class are listed here.

Protected Methods

	Name	Description
	CreateParams (see page 799)	Initializes a window-creation parameter data structure.

	CreateWnd (see page 799)	Creates the underlying window.
	SetAutoSize (see page 800)	This is SetAutoSize, a member of class TCustomLinkLabel.
	UseThemes (see page 800)	This is UseThemes, a member of class TCustomLinkLabel.

3.1.26.3.1 TCustomLinkLabel.CreateParams Method

Initializes a window-creation parameter data structure.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. Override CreateParams to customize the way a control creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

CreateParams fills in the parameter that is passed as the value of the Params parameter. This data structure holds information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function.

TWinControl implements CreateParams by setting all the fields of Params to generic base values. A number of the standard controls override CreateParams to change one or more of the default values in Params.

See Also

CreateWindowHandle

CreateWnd

AddBiDiModeExStyle

3.1.26.3.2 TCustomLinkLabel.CreateWnd Method

Creates the underlying window.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the control is first created or when the underlying screen object must be destroyed and recreated to reflect property changes. Override CreateWnd to pass additional initialization messages to the screen object when it is created.

See Also

CreateParams

CreateWindowHandle

Perform

DestroyWnd

3.1.26.3.3 TCustomLinkLabel.SetAutoSize Method

Pascal

```
procedure SetAutoSize(Value: Boolean); override;
```

C++

```
virtual __fastcall SetAutoSize(Boolean Value);
```

Description

This is SetAutoSize, a member of class TCustomLinkLabel.

3.1.26.3.4 TCustomLinkLabel.UseThemes Method

Pascal

```
function UseThemes: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean UseThemes();
```

Description

This is UseThemes, a member of class TCustomLinkLabel.

3.1.26.4 TCustomLinkLabel Properties

The properties of the TCustomLinkLabel class are listed here.

Public Properties

	Name	Description
	Alignment (see page 800)	This is Alignment, a member of class TCustomLinkLabel.
	AutoSize (see page 800)	Specifies whether the control sizes itself automatically to accommodate its contents.
	UseVisualStyle (see page 801)	This is UseVisualStyle, a member of class TCustomLinkLabel.

3.1.26.4.1 TCustomLinkLabel.Alignment Property

Pascal

```
property Alignment: TLinkAlignment;
```

C++

```
__property TLinkAlignment Alignment;
```

Description

This is Alignment, a member of class TCustomLinkLabel.

3.1.26.4.2 TCustomLinkLabel.AutoSize Property

Specifies whether the control sizes itself automatically to accommodate its contents.

Pascal

```
property AutoSize: Boolean;
```

C++

```
__property Boolean AutoSize;
```

Description

Use AutoSize to specify whether the control sizes itself automatically. When AutoSize is true, the control resizes automatically when its contents change.

By default, AutoSize is false.

See Also

Constraints

CanAutoSize

3.1.26.4.3 TCustomLinkLabel.UseVisualStyle Property

Pascal

```
property UseVisualStyle: Boolean;
```

C++

```
__property Boolean UseVisualStyle;
```

Description

This is UseVisualStyle, a member of class TCustomLinkLabel.

3.1.26.5 TCustomLinkLabel Nested Types

The nested types of the TCustomLinkLabel class are listed here.

Public Nested Types

Name	Description
TLinkAlignment (see page 801)	This is nested type ExtCtrls.TCustomLinkLabel.TLinkAlignment.

3.1.26.5.1 TCustomLinkLabel.TLinkAlignment Nested Type

Pascal

```
TLinkAlignment = taLeftJustify..taRightJustify;
```

C++

```
taLeftJustify..taRightJustify TLinkAlignment;
```

Description

This is nested type ExtCtrls.TCustomLinkLabel.TLinkAlignment.

3.1.26.6 TCustomLinkLabel Events

The events of the TCustomLinkLabel class are listed here.

Public Events

	Name	Description
	OnLinkClick (see page 802)	Event for click on TCustomLinkLabel (see page 797) HTML link.

3.1.26.6.1 TCustomLinkLabel.OnLinkClick Event

Event for click on TCustomLinkLabel (see page 797) HTML link.

Pascal

```
property OnLinkClick: TSysLinkEvent;
```

C++

```
__property TSysLinkEvent OnLinkClick;
```

Description

OnLinkClick is triggered by a click on a TCustomLinkLabel (see page 797)'s HTML link. The event identifies the link URI and link type.

See Also

TCustomLinkLabel (see page 797)

TSysLinkEvent (see page 1555)

TSysLinkType (see page 1546)

3.1.27 TCustomPanel Class

TCustomPanel is the base class for all panel components.

Class Hierarchy

Pascal

```
TCustomPanel = class(TCustomControl);
```

C++

```
class TCustomPanel : public TCustomControl;
```

File

ExtCtrls

Description

Use TCustomPanel as a base class when defining objects that include other controls as constituent parts. Panel components are controls can contain other controls, grouping them together.

When a panel is aligned with the form using the Align property, it maintains the same relative position to the form even when the form is resized. For example, a panel can be aligned so that it always remains on the top of the form, even when the user changes the shape and size of the form. This makes panels useful for implementing components that act like tool bars or status bars. For example, construct a tool bar or tool palette by adding speed buttons that execute commands or set modes to a panel .

See Also

TForm (see page 2241)

TPanel (see page 1326)

TCustomFrame (see page 2237)

TGroupBox

3.1.27.1 TCustomPanel Members

The following tables list the members exposed by TCustomPanel.

Protected Methods

	Name	Description
	AdjustClientRect (see page 804)	Adjusts the ClientRect property for the idiosyncrasies of the window.
	CanAutoSize (see page 804)	Adjusts the way the panel responds to resize attempts.
	CreateParams (see page 805)	Initializes a window-creation parameter record passed in the Params parameter.
	Paint (see page 806)	Renders the image of the panel.
	SetParentBackground (see page 806)	This is SetParentBackground, a member of class TCustomPanel.

Protected Properties

	Name	Description
	Alignment (see page 807)	Determines how the caption is aligned within the panel.
	BevelInner (see page 807)	Determines the style of the inner bevel of a panel.
	BevelOuter (see page 808)	Determines the style of the outer bevel of a panel.
	BevelWidth (see page 809)	Determines the width, in pixels, of both the inner and outer bevels of a panel.
	BorderStyle (see page 810)	Determines the style of the line drawn around the perimeter of the panel control.
	BorderWidth (see page 811)	Specifies the distance, in pixels, between the outer and inner bevels.
	Color (see page 812)	Specifies the background color of the control.
	FullRepaint (see page 813)	Determines how the panel repaints itself when it is resized.
	Locked (see page 813)	Determines whether a panel that is used as a toolbar is replaced by a toolbar supplied by an OLE server.
	ParentColor (see page 814)	Determines where a control looks for its color information.
	ShowCaption (see page 814)	This is ShowCaption, a member of class TCustomPanel.
	VerticalAlignment (see page 814)	Sets the vertical position of the caption.

Public Methods

	Name	Description
	Create (see page 803)	Creates and initializes an instance of TCustomPanel (see page 802).
	GetControlsAlignment (see page 805)	Returns the alignment of text in the panel.

Public Properties

	Name	Description
	ParentBackground (see page 813)	Determines whether control uses parent's theme background.

3.1.27.2 TCustomPanel.Create Constructor

Creates and initializes an instance of TCustomPanel (see page 802).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomPanel(TComponent * AOwner);
```

Description

Call Create to instantiate a panel at runtime. Panels placed in forms at design time do not need to be explicitly created because they are created automatically.

AOwner is the component, typically a form, that is responsible for freeing the panel.

See Also

Owner

3.1.27.3 TCustomPanel Methods

The methods of the TCustomPanel class are listed here.

Protected Methods

	Name	Description
	AdjustClientRect (see page 804)	Adjusts the ClientRect property for the idiosyncrasies of the window.
	CanAutoSize (see page 804)	Adjusts the way the panel responds to resize attempts.
	CreateParams (see page 805)	Initializes a window-creation parameter record passed in the Params parameter.
	Paint (see page 806)	Renders the image of the panel.
	SetParentBackground (see page 806)	This is SetParentBackground, a member of class TCustomPanel.

Public Methods

	Name	Description
	GetControlsAlignment (see page 805)	Returns the alignment of text in the panel.

3.1.27.3.1 TCustomPanel.AdjustClientRect Method

Adjusts the ClientRect property for the idiosyncrasies of the window.

Pascal

```
procedure AdjustClientRect(var Rect: TRect); override;
```

C++

```
virtual __fastcall AdjustClientRect(TRect Rect);
```

Description

AdjustClientRect is called internally when the panel needs accurate information on where to place child controls within the client area. AdjustClientRect reduces ClientRect by the width of the inner and outer bevels so that child objects are not placed on the beveled region.

See Also

ClientRect

Controls

3.1.27.3.2 TCustomPanel.CanAutoSize Method

Adjusts the way the panel responds to resize attempts.

Pascal

```
function CanAutoSize(var NewWidth: Integer; var NewHeight: Integer): Boolean; override;
```

C++

```
virtual __fastcall Boolean CanAutoSize(int NewWidth, int NewHeight);
```

Description

CanAutoSize is called automatically when the AutoSize property is true and an attempt is made to resize the panel. It allows the

panel to implement the AutoSize property before the resize sequence that begins with the OnCanResize and OnConstrainedResize events and ends with the OnResize event.

When CanAutoSize is called, the NewWidth and NewHeight parameters indicate the proposed new dimensions of the panel. CanAutoSize adjusts these values so that the panel's size adjusts to its contents. If the adjustment results in values of NewWidth and NewHeight that differ from the panel's current width and height, CanAutoSize returns true, indicating that the resize sequence should proceed. If, after adjustment, NewWidth and NewHeight equal Width and Height, CanAutoSize returns false, and the resize sequence is aborted.

See Also

AutoSize

AdjustSize

ConstrainedResize

OnCanResize

3.1.27.3.3 TCustomPanel.CreateParams Method

Initializes a window-creation parameter record passed in the Params parameter.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

CreateParams is called automatically to initialize the window-creation parameters whenever the window for the panel needs to be created. CreateParams overrides the inherited method to implement the BorderStyle (see page 810) property.

See Also

BorderStyle (see page 810)

CreateParams

3.1.27.3.4 TCustomPanel.GetControlsAlignment Method

Returns the alignment of text in the panel.

Pascal

```
function GetControlsAlignment: TAlignment; override;
```

C++

```
virtual __fastcall TAlignment GetControlsAlignment();
```

Description

GetControlsAlignment returns the value of the Alignment (see page 807) property.

See Also

Alignment (see page 807)

UseRightToLeftAlignment

3.1.27.3.5 TCustomPanel.Paint Method

Renders the image of the panel.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

Override the Paint method to change the way the panel is drawn. The Paint method for TCustomPanel (see page 802) draws the bevels of the panel, sets the brush and font for the panel, and fills in the interior of the panel. Finally, Paint writes the value of Caption on the panel.

See Also

BevelInner (see page 807)

BevelOuter (see page 808)

Brush

Caption

Canvas

3.1.27.3.6 TCustomPanel.SetParentBackground Method

Pascal

```
procedure SetParentBackground(Value: Boolean); override;
```

C++

```
virtual __fastcall SetParentBackground(Boolean Value);
```

Description

This is SetParentBackground, a member of class TCustomPanel.

3.1.27.4 TCustomPanel Properties

The properties of the TCustomPanel class are listed here.

Protected Properties

	Name	Description
	Alignment (see page 807)	Determines how the caption is aligned within the panel.
	BevelInner (see page 807)	Determines the style of the inner bevel of a panel.
	BevelOuter (see page 808)	Determines the style of the outer bevel of a panel.
	BevelWidth (see page 809)	Determines the width, in pixels, of both the inner and outer bevels of a panel.
	BorderStyle (see page 810)	Determines the style of the line drawn around the perimeter of the panel control.
	BorderWidth (see page 811)	Specifies the distance, in pixels, between the outer and inner bevels.
	Color (see page 812)	Specifies the background color of the control.
	FullRepaint (see page 813)	Determines how the panel repaints itself when it is resized.
	Locked (see page 813)	Determines whether a panel that is used as a toolbar is replaced by a toolbar supplied by an OLE server.
	ParentColor (see page 814)	Determines where a control looks for its color information.

	ShowCaption (see page 814)	This is ShowCaption, a member of class TCustomPanel.
	VerticalAlignment (see page 814)	Sets the vertical position of the caption.

Public Properties

	Name	Description
	ParentBackground (see page 813)	Determines whether control uses parent's theme background.

3.1.27.4.1 TCustomPanel.Alignment Property

Determines how the caption is aligned within the panel.

Pascal

```
property Alignment: TAlignment;
```

C++

```
__property TAlignment Alignment;
```

Description

Use the Alignment property to specify if the caption of a panel appears on the left, right, or center of the panel. For example, to use a panel as a status bar that displays the TApplication (see page 1924). ::Hint property as the panel's Caption property, set Alignment to taLeftJustify to place the hint text on the left side of the panel.

Note: Use the VerticalAlignment (see page 814) property to control the vertical position of the caption.

See Also

Hint (see page 1976)

Caption

3.1.27.4.2 TCustomPanel.BevelInner Property

Determines the style of the inner bevel of a panel.

Pascal

```
property BevelInner: TPanelBevel;
```

C++

```
__property TPanelBevel BevelInner;
```

Description

Use BevelInner to provide the panel with a three-dimensional beveled look. A panel component has two bevels, an outer bevel drawn next to the border of the control, and an inner bevel drawn inside the outer bevel, separated by the number of pixels specified in the BorderWidth (see page 811) property. The width of the bevels, if they are drawn, is the BevelWidth (see page 809) property.

C++ Examples:

```
/*
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
*/
void __fastcall TForm1::CreateStatusLineClick(TObject *Sender)
{
```

```
  Panel1->Align = alBottom;
  Panel1->BevelInner = bvLowered;
  Panel1->BevelOuter = bvRaised;
  Panel1->BorderWidth = 1;
  Panel1->BevelWidth = 1;
}
```

Delphi Examples:

```
{
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
}
procedure TForm1.CreateStatusLineClick(Sender: TObject);
begin
  with Panel1 do
  begin
    Align := alBottom;
    BevelInner := bvLowered;
    BevelOuter := bvRaised;
    BorderWidth := 1;
    BevelWidth := 1;
  end;
end;
```

See Also

BevelOuter (see page 808)

BevelWidth (see page 809)

BorderWidth (see page 811)

3.1.27.4.3 TCustomPanel.BevelOuter Property

Determines the style of the outer bevel of a panel.

Pascal

```
property BevelOuter: TPanelBevel;
```

C++

```
__property TPanelBevel BevelOuter;
```

Description

Use BevelOuter to provide the panel with a three-dimensional beveled look. A panel component has two bevels, an outer bevel drawn next to the border of the control, and an inner bevel drawn inside the outer bevel, separated by the number of pixels specified in the BorderWidth (see page 811) property. The width of the outer bevel is specified in the BevelWidth (see page 809) property in pixels.

C++ Examples:

```
/*
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
*/
void __fastcall TForm1::CreateStatusLineClick(TObject *Sender)
```

```
{
  Panel1->Align = alBottom;
  Panel1->BevelInner = bvLowered;
  Panel1->BevelOuter = bvRaised;
  Panel1->BorderWidth = 1;
  Panel1->BevelWidth = 1;
}
```

Delphi Examples:

```
{
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
}
procedure TForm1.CreateStatusLineClick(Sender: TObject);
begin
  with Panel1 do
  begin
    Align := alBottom;
    BevelInner := bvLowered;
    BevelOuter := bvRaised;
    BorderWidth := 1;
    BevelWidth := 1;
  end;
end;
```

See Also

BevelInner (see page 807)

BevelWidth (see page 809)

BorderWidth (see page 811)

3.1.27.4.4 TCustomPanel.BevelWidth Property

Determines the width, in pixels, of both the inner and outer bevels of a panel.

Pascal

```
property BevelWidth: TBevelWidth;
```

C++

```
__property TBevelWidth BevelWidth;
```

Description

Use BevelWidth to specify how wide the inner or outer bevel should be. Do not confuse BevelWidth, which is the width of the bevels, with BorderWidth (see page 811), which is the space between the bevels.

If both the BevelInner (see page 807) and BevelOuter (see page 808) properties are bvNone, BevelWidth has no effect. To remove both bevels, set the BevelInner (see page 807) and BevelOuter (see page 808) properties to bvNone, rather than setting the BevelWidth to 0, as this involves less overhead when painting.

C++ Examples:

```
/*
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
```

```
  BorderWidth properties.
  */
  void __fastcall TForm1::CreateStatusLineClick(TObject *Sender)
  {
    Panel1->Align = alBottom;
    Panel1->BevelInner = bvLowered;
    Panel1->BevelOuter = bvRaised;
    Panel1->BorderWidth = 1;
    Panel1->BevelWidth = 1;
  }
```

Delphi Examples:

```
  {
  This example uses a panel component and a button named
  CreateStatusLine on a form. The code moves the panel to the
  bottom of the form when the user clicks the button and gives
  the panel the appearance of a status line by changing the
  value of the BevelInner, BevelOuter, BevelWidth, and
  BorderWidth properties.
  }
  procedure TForm1.CreateStatusLineClick(Sender: TObject);
  begin
    with Panel1 do
    begin
      Align := alBottom;
      BevelInner := bvLowered;
      BevelOuter := bvRaised;
      BorderWidth := 1;
      BevelWidth := 1;
    end;
  end;
```

See Also

BevelInner (see page 807)

BevelOuter (see page 808)

BorderWidth (see page 811)

3.1.27.4.5 TCustomPanel.BorderStyle Property

Determines the style of the line drawn around the perimeter of the panel control.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Use BorderStyle to specify whether the panel has a single line drawn around it. These are the possible values:

Value	Meaning
bsNone	No visible border
bsSingle	Single-line border

Do not confuse the line drawn around the panel with the BorderWidth (see page 811) of the panel. The BorderWidth (see page 811) of the panel is the distance between the outer and inner bevels.

See Also

BorderWidth (see page 811)

3.1.27.4.6 TCustomPanel.BorderWidth Property

Specifies the distance, in pixels, between the outer and inner bevels.

Pascal

```
property BorderWidth: TBorderWidth;
```

C++

```
__property TBorderWidth BorderWidth;
```

Description

Use BorderWidth to specify how wide the border around the panel should be. A value of 0 (zero) means no border should appear.

The border of a panel is the area between the outer and inner bevels. It is visible only if the inner bevel is raised or lowered, but affects the inset of the caption within the panel even if BevelInner (see page 807) is bvNone. If the Alignment (see page 807) property is not taCenter, the Caption will be aligned to the inner edge of the border. This edge is BorderWidth pixels in from the outer bevel if BevelInner (see page 807) is bvNone. It is the inner edge of the inner bevel otherwise.

Do not confuse the border of the panel with line drawn around the panel itself. The line around the panel is specified by the BorderStyle (see page 810) property.

C++ Examples:

```
/*
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
*/
void __fastcall TForm1::CreateStatusLineClick(TObject *Sender)
{
  Panel1->Align = alBottom;
  Panel1->BevelInner = bvLowered;
  Panel1->BevelOuter = bvRaised;
  Panel1->BorderWidth = 1;
  Panel1->BevelWidth = 1;
}
```

Delphi Examples:

```
{
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
}
procedure TForm1.CreateStatusLineClick(Sender: TObject);
begin
  with Panel1 do
  begin
    Align := alBottom;
    BevelInner := bvLowered;
    BevelOuter := bvRaised;
    BorderWidth := 1;
```

```
    BevelWidth := 1;
  end;
end;
```

See Also

Alignment (see page 807)

BevelInner (see page 807)

BevelOuter (see page 808)

BorderStyle (see page 810)

Caption

3.1.27.4.7 TCustomPanel.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor

3.1.27.4.8 TCustomPanel.FullRepaint Property

Determines how the panel repaints itself when it is resized.

Pascal

```
property FullRepaint: Boolean;
```

C++

```
__property Boolean FullRepaint;
```

Description

FullRepaint controls how the panel responds when it is resized. When FullRepaint is true, the entire panel, including the beveled border repaints when the size changes. When FullRepaint is false, only the area inside the beveled border repaints.

See Also

Invalidate

3.1.27.4.9 TCustomPanel.Locked Property

Determines whether a panel that is used as a toolbar is replaced by a toolbar supplied by an OLE server.

Pascal

```
property Locked: Boolean;
```

C++

```
__property Boolean Locked;
```

Description

Set the Locked property to false when the panel is used as a toolbar by a TOleContainer component. Any panels aligned to a TOleContainer are assumed to be replaceable toolbars unless the Locked property is true. Prevent the panel from being replaced by an OLE server's toolbar by setting the panel's Locked property to true.

Note: An OLE application's toolbars must be in panels aligned to a side of the form (that is, their Align properties must be set to alTop, alBottom, alLeft, or alRight).

See Also

Align

TOleContainer (see page 5969)

3.1.27.4.10 TCustomPanel.ParentBackground Property

Determines whether control uses parent's theme background.

Pascal

```
property ParentBackground;
```

C++

```
__property ParentBackground;
```

Description

If ParentBackground is true, the control uses the parent's theme background to draw its own background. ParentBackground has no effect unless XP themes are enabled.

3.1.27.4.11 TCustomPanel.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

ParentShowHint

3.1.27.4.12 TCustomPanel.ShowCaption Property

Pascal

```
property ShowCaption: Boolean;
```

C++

```
__property Boolean ShowCaption;
```

Description

This is ShowCaption, a member of class TCustomPanel.

3.1.27.4.13 TCustomPanel.VerticalAlignment Property

Sets the vertical position of the caption.

Pascal

```
property VerticalAlignment: TVerticalAlignment;
```

C++

```
__property TVerticalAlignment VerticalAlignment;
```

Description

Use the VerticalAlignment property to control the position of the caption within the panel. Choose one of the following values.

Value	Description
taAlignBottom	The caption displays at the bottom of the panel.
taAlignTop	The caption displays at the top of the panel.
taVerticalCenter	The caption displays at the center of the panel.

Note: Use the Alignment (see page 807) property to control the horizontal position of the caption.

3.1.28 TCustomRadioGroup Class

TCustomRadioGroup is the base class for radio-group components.

Class Hierarchy

Pascal

```
TCustomRadioGroup = class(TCustomGroupBox);
```

C++

```
class TCustomRadioGroup : public TCustomGroupBox;
```

File

ExtCtrls

Description

Radio groups are collections of radio buttons in a single group box. TCustomRadioGroup is the class from which radio-group components—including TRadioGroup (see page 1406) and TDBRadioGroup—descend.

Radio buttons that are contained directly in the same control component are said to be "grouped." When the user checks a radio button, all other radio buttons in its group become unchecked. Hence, two radio buttons on a form can be checked at the same time only if they are placed in separate containers, such as group boxes.

See Also

TRadioGroup (see page 1406)

TDBRadioGroup

TRadioButton

3.1.28.1 TCustomRadioGroup Members

The following tables list the members exposed by TCustomRadioGroup.

Protected Methods

	Name	Description
	CanModify (see page 817)	Determines whether the user can select a different radio button in the group.
	Loaded (see page 818)	Initializes the radio group after it is loaded into memory.
	ReadState (see page 819)	Prepares the control for having its properties assigned values from a stream.

Protected Properties

	Name	Description
	Columns (see page 820)	Specifies number of columns in the radio group.
	ItemIndex (see page 820)	Indicates which radio button in the group is currently selected.
	Items (see page 821)	Lists the radio buttons in the radio group.

Public Methods

	Name	Description
	Create (see page 816)	Creates and initializes a TCustomRadioGroup (see page 815) instance.
	Destroy (see page 816)	Destroys the TCustomRadioGroup (see page 815) instance and the radio buttons it contains.
	FlipChildren (see page 817)	Prevents the default behavior of flipping the child radio buttons.
	GetChildren (see page 818)	Prevents the streaming system from loading and saving child controls in the usual fashion.

Public Properties

	Name	Description
	Buttons (see page 819)	Access individual TRadioButton objects.
	WordWrap (see page 822)	This is WordWrap, a member of class TCustomRadioGroup.

3.1.28.2 TCustomRadioGroup.Create Constructor

Creates and initializes a TCustomRadioGroup (see page 815) instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomRadioGroup(TComponent * AOwner);
```

Description

Call Create to instantiate a radio group at runtime. Radio group components added to forms at design time are created automatically.

AOwner is the component that is responsible for freeing the radio group instance. It becomes the value of the Owner property.

See Also

Owner

3.1.28.3 TCustomRadioGroup.Destroy Destructor

Destroys the TCustomRadioGroup (see page 815) instance and the radio buttons it contains.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomRadioGroup();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free checks that the radio group is not nil, and only then calls Destroy.

Destroy frees the memory for each item in the group, then calls the inherited destructor.

See Also

System::TObject::Free

3.1.28.4 TCustomRadioGroup Methods

The methods of the TCustomRadioGroup class are listed here.

Protected Methods

	Name	Description
	CanModify (see page 817)	Determines whether the user can select a different radio button in the group.
	Loaded (see page 818)	Initializes the radio group after it is loaded into memory.
	ReadState (see page 819)	Prepares the control for having its properties assigned values from a stream.

Public Methods

	Name	Description
	FlipChildren (see page 817)	Prevents the default behavior of flipping the child radio buttons.
	GetChildren (see page 818)	Prevents the streaming system from loading and saving child controls in the usual fashion.

3.1.28.4.1 TCustomRadioGroup.CanModify Method

Determines whether the user can select a different radio button in the group.

Pascal

```
function CanModify: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean CanModify();
```

Description

Event handlers call CanModify to verify that the user is allowed to select a different radio button in the group. As defined in TCustomRadioGroup (see page 815), this method always returns true; override it to return false in situations where the user should not be able to make changes.

See Also

CanModify

3.1.28.4.2 TCustomRadioGroup.FlipChildren Method

Prevents the default behavior of flipping the child radio buttons.

Pascal

```
procedure FlipChildren(AllLevels: Boolean); override;
```

C++

```
virtual __fastcall FlipChildren(Boolean AllLevels);
```

Description

FlipChildren overrides the inherited FlipChildren method to disable flipping the radio buttons.

To flip the children of a radio group, use the BiDiMode property.

See Also

BiDiMode

3.1.28.4.3 TCustomRadioGroup.GetChildren Method

Prevents the streaming system from loading and saving child controls in the usual fashion.

Pascal

```
procedure GetChildren(Proc: TGetChildProc; Root: TComponent); override;
```

C++

```
virtual __fastcall GetChildren(TGetChildProc Proc, TComponent * Root);
```

Description

GetChildren is called in the streaming sequence that loads and saves VCL components. Because radio groups load and save their buttons using the ReadState (see page 819) and WriteState methods, TCustomRadioGroup (see page 815) overrides TWinControl to disable the GetChildren method.

See Also

GetChildren

GetChildren

GetParentComponent

readstate (see page 819)

WriteState

3.1.28.4.4 TCustomRadioGroup.Loaded Method

Initializes the radio group after it is loaded into memory.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

Do not call Loaded. The component streaming system calls Loaded automatically after the radio group's form is loaded into memory so that it can complete any initializations that depend on other objects in the form.

Loaded overrides the inherited method to ensure that the buttons in the group are properly arranged.

See Also

Items (see page 821)

3.1.28.4.5 TCustomRadioGroup.ReadState Method

Prepares the control for having its properties assigned values from a stream.

Pascal

```
procedure ReadState(Reader: TReader); override;
```

C++

```
virtual __fastcall ReadState(TReader Reader);
```

Description

Override ReadState to change the preparations the control makes as it readies itself to have its property values assigned from a stream. For example, a control might destroy temporary internal data structures or objects before new instances are loaded from the stream. Be sure to include a call to the inherited method when overriding ReadState.

As implemented in TWinControl, ReadState disables control alignment until all the child controls have been read from the stream, calls the inherited ReadState method, and re-enables the alignment of all the controls. The method then builds the tab order list of controls and synchronizes its visibility with that of its parent control.

Parent

ReadState

3.1.28.5 TCustomRadioGroup Properties

The properties of the TCustomRadioGroup class are listed here.

Protected Properties

	Name	Description
	Columns (see page 820)	Specifies number of columns in the radio group.
	ItemIndex (see page 820)	Indicates which radio button in the group is currently selected.
	Items (see page 821)	Lists the radio buttons in the radio group.

Public Properties

	Name	Description
R	Buttons (see page 819)	Access individual TRadioButton objects.
	WordWrap (see page 822)	This is WordWrap, a member of class TCustomRadioGroup.

3.1.28.5.1 TCustomRadioGroup.Buttons Property

Access individual TRadioButton objects.

Pascal

```
property Buttons [Index: Integer]: TRadioButton;
```

C++

```
__property TRadioButton Buttons[int Index];
```

Description

Buttons provides direct access to the individual TRadioButton objects created by the control. Buttons is a read-only property. This means you can access individual TRadioButton objects, but you cannot add or delete TRadioButton objects. To modify the button list, change the Items (see page 821) property.

Index is the zero-origin button index. If Index is equal to or greater than the number of buttons, an error is raised.

See Also

Items (see page 821)

3.1.28.5.2 TCustomRadioGroup.Columns Property

Specifies number of columns in the radio group.

Pascal

```
property Columns: Integer;
```

C++

```
__property int Columns;
```

Description

Columns determines the number of columns in the radio group if Orientation is orVertical (the default), and the number of rows if Orientation is orHorizontal. Its value can range from 1 to 16. The default value is 1, which means that the radio buttons are arranged in a single line.

3.1.28.5.3 TCustomRadioGroup.ItemIndex Property

Indicates which radio button in the group is currently selected.

Pascal

```
property ItemIndex: Integer;
```

C++

```
__property int ItemIndex;
```

Description

ItemIndex holds the index of the selected radio button in the Items (see page 821) list. (The first button is 0.) The value of ItemIndex changes at runtime as the user selects radio buttons. If you want one of the buttons to appear selected when the application starts, assign that button to ItemIndex at design time; otherwise, leave ItemIndex set to the default value of -1, which means that no button is selected.

C++ Examples:

```
/*
This example uses a radio group box and a scroll bar on a
form. When the user selects one of the radio buttons, the
scroll bar changes orientation accordingly.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RadioGroup1->Items->Add("Vertical");
  RadioGroup1->Items->Add("Horizontal");
  RadioGroup1->ItemIndex = 2;
}

void __fastcall TForm1::RadioGroup1Click(TObject *Sender)
{
  if (RadioGroup1->Items->Strings[RadioGroup1->ItemIndex] == "Vertical")
    ScrollBar1->Kind = sbVertical;
  else if (RadioGroup1->Items->Strings[RadioGroup1->ItemIndex] == "Horizontal")
    ScrollBar1->Kind = sbHorizontal;
}
```

Delphi Examples:

```
{
This example uses a radio group box and a scroll bar on a
form. When the user selects one of the radio buttons, the
scroll bar changes orientation accordingly.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  RadioGroup1.Items.Add('Vertical');
  RadioGroup1.Items.Add('Horizontal');
  RadioGroup1.ItemIndex := 2;
end;

procedure TForm1.RadioGroup1Click(Sender: TObject);
begin
  if RadioGroup1.Items[RadioGroup1.ItemIndex] = 'Vertical' then
    ScrollBar1.Kind := sbVertical;
  if RadioGroup1.Items[RadioGroup1.ItemIndex] = 'Horizontal' then
    ScrollBar1.Kind := sbHorizontal;
end;
```

See Also

Items (see page 821)

3.1.28.5.4 TCustomRadioGroup.Items Property

Lists the radio buttons in the radio group.

Pascal

```
property Items: TStrings;
```

C++

```
__property TStrings Items;
```

Description

Items holds a TStrings object that lists the captions of the radio buttons in the group. In TCustomRadioGroup (see page 815) descendants, where this property is published, radio buttons can be added or removed by editing the Items list from the Object Inspector.

Note: A TRadioButton object is created automatically for each string in Items. You cannot directly add or remove TRadioButton objects, but you can access individual TButton objects through the Buttons (see page 819) property.

C++ Examples:

```
/*
This example uses a radio group box and a scroll bar on a
form. When the user selects one of the radio buttons, the
scroll bar changes orientation accordingly.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RadioGroup1->Items->Add("Vertical");
  RadioGroup1->Items->Add("Horizontal");
  RadioGroup1->ItemIndex = 2;
}

void __fastcall TForm1::RadioGroup1Click(TObject *Sender)
{
  if (RadioGroup1->Items->Strings[RadioGroup1->ItemIndex] == "Vertical")
```

```
    ScrollBar1->Kind = sbVertical;
  else if (RadioGroup1->Items->Strings[RadioGroup1->ItemIndex] == "Horizontal")
    ScrollBar1->Kind = sbHorizontal;
}
```

Delphi Examples:

```
{
This example uses a radio group box and a scroll bar on a
form. When the user selects one of the radio buttons, the
scroll bar changes orientation accordingly.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  RadioGroup1.Items.Add('Vertical');
  RadioGroup1.Items.Add('Horizontal');
  RadioGroup1.ItemIndex := 2;
end;

procedure TForm1.RadioGroup1Click(Sender: TObject);
begin
  if RadioGroup1.Items[RadioGroup1.ItemIndex] = 'Vertical' then
    ScrollBar1.Kind := sbVertical;
  if RadioGroup1.Items[RadioGroup1.ItemIndex] = 'Horizontal' then
    ScrollBar1.Kind := sbHorizontal;
end;
```

See Also

ItemIndex (see page 820)

TRadioButton

Buttons (see page 819)

3.1.28.5.5 TCustomRadioGroup.WordWrap Property

Pascal

```
property WordWrap: Boolean;
```

C++

```
__property Boolean WordWrap;
```

Description

This is WordWrap, a member of class TCustomRadioGroup.

3.1.29 TCustomTrayIcon Class

The base class for TTrayIcon (see page 1528).

Class Hierarchy

Pascal

```
[RootDesignerSerializerAttribute('', '', False)]
TCustomTrayIcon = class(TComponent);
```

C++

```
[RootDesignerSerializerAttribute('', '', False)]
class TCustomTrayIcon : public TComponent;
```

File

ExtCtrls

Description

TCustomTrayIcon is the base class for TTrayIcon (see page 1528), which places an icon in the system tray next to the clock.

3.1.29.1 TCustomTrayIcon Members

The following tables list the members exposed by TCustomTrayIcon.

Protected Methods

	Name	Description
	DoOnAnimate (see page 825)	This is DoOnAnimate, a member of class TCustomTrayIcon.
	GetAnimateInterval (see page 825)	This is GetAnimateInterval, a member of class TCustomTrayIcon.
	GetBalloonTimeout (see page 825)	This is GetBalloonTimeout, a member of class TCustomTrayIcon.
	Notification (see page 826)	Forwards notification messages to all owned components.
	SetAnimate (see page 827)	This is SetAnimate, a member of class TCustomTrayIcon.
	SetAnimateInterval (see page 827)	This is SetAnimateInterval, a member of class TCustomTrayIcon.
	SetBalloonHint (see page 827)	This is SetBalloonHint, a member of class TCustomTrayIcon.
	SetBalloonTimeout (see page 827)	This is SetBalloonTimeout, a member of class TCustomTrayIcon.
	SetBalloonTitle (see page 828)	This is SetBalloonTitle, a member of class TCustomTrayIcon.
	SetHint (see page 828)	This is SetHint, a member of class TCustomTrayIcon.
	SetIcon (see page 828)	This is SetIcon, a member of class TCustomTrayIcon.
	SetIconIndex (see page 828)	This is SetIconIndex, a member of class TCustomTrayIcon.
	SetIconList (see page 829)	This is SetIconList, a member of class TCustomTrayIcon.
	SetVisible (see page 829)	This is SetVisible, a member of class TCustomTrayIcon.
	WindowProc (see page 829)	This is WindowProc, a member of class TCustomTrayIcon.

Protected Properties

	Name	Description
	Data (see page 832)	This is Data, a member of class TCustomTrayIcon.

Public Events

	Name	Description
	OnAnimate (see page 834)	Occurs each time the icon changes when the tray icon is animating.
	OnBalloonClick (see page 834)	This is OnBalloonClick, a member of class TCustomTrayIcon.
	OnClick (see page 834)	Occurs when the user clicks the tray icon.
	OnDblClick (see page 834)	Occurs when the user double clicks the tray icon.
	OnMouseDown (see page 835)	Occurs when the user presses a mouse button while the mouse pointer is over a control.
	OnMouseMove (see page 835)	Occurs when the user moves the mouse pointer while the mouse pointer is over the tray icon.
	OnMouseUp (see page 835)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Public Methods

	Name	Description
	Create (see page 824)	Creates and initializes a TCustomTrayIcon (see page 822) instance.
	Destroy (see page 824)	Frees the memory associated with the TCustomTrayIcon (see page 822) object.

	Refresh (see page 826)	This is the overview for the Refresh method overload.
	SetDefaultIcon (see page 828)	Sets the tray icon to the default application icon.
	ShowBalloonHint (see page 829)	Displays the balloon hint.

Public Properties

	Name	Description
	Animate (see page 830)	Specifies whether the icon in the system tray is static or animated.
	AnimateInterval (see page 830)	Controls the length of time between image changes for the tray icon image.
	BalloonFlags (see page 831)	Specifies an icon for the balloon hint.
	BalloonHint (see page 831)	Specifies the text within a balloon hint.
	BalloonTimeout (see page 831)	Specifies the length of time that the balloon displays.
	BalloonTitle (see page 831)	Specifies the text that appears as the balloon title.
	Hint (see page 832)	Specifies the text that appears when the user moves the mouse over the control.
	Icon (see page 832)	Specifies the default icon shown in the system tray.
	IconIndex (see page 832)	This is an index into the Icons (see page 833) image list which is the icon currently being displayed in the system tray.
	Icons (see page 833)	Specifies the list of images to be displayed for the icon in the system tray.
	PopupMenu (see page 833)	Identifies the pop-up menu associated with the tray icon.
	Visible (see page 833)	Determines whether the icon appears in the system tray.

3.1.29.2 TCustomTrayIcon.Create Constructor

Creates and initializes a TCustomTrayIcon (see page 822) instance.

Pascal

```
constructor Create(Owner: TComponent); override;
```

C++

```
virtual __fastcall TCustomTrayIcon(TComponent * Owner);
```

Description

Creates and initializes a TCustomTrayIcon (see page 822) instance.

3.1.29.3 TCustomTrayIcon.Destroy Destructor

Frees the memory associated with the TCustomTrayIcon (see page 822) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomTrayIcon();
```

Description

Frees the memory associated with the TCustomTrayIcon (see page 822) object.

3.1.29.4 TCustomTrayIcon Methods

The methods of the TCustomTrayIcon class are listed here.

Protected Methods

	Name	Description
	DoOnAnimate (see page 825)	This is DoOnAnimate, a member of class TCustomTrayIcon.
	GetAnimateInterval (see page 825)	This is GetAnimateInterval, a member of class TCustomTrayIcon.
	GetBalloonTimeout (see page 825)	This is GetBalloonTimeout, a member of class TCustomTrayIcon.
	Notification (see page 826)	Forwards notification messages to all owned components.
	SetAnimate (see page 827)	This is SetAnimate, a member of class TCustomTrayIcon.
	SetAnimateInterval (see page 827)	This is SetAnimateInterval, a member of class TCustomTrayIcon.
	SetBalloonHint (see page 827)	This is SetBalloonHint, a member of class TCustomTrayIcon.
	SetBalloonTimeout (see page 827)	This is SetBalloonTimeout, a member of class TCustomTrayIcon.
	SetBalloonTitle (see page 828)	This is SetBalloonTitle, a member of class TCustomTrayIcon.
	SetHint (see page 828)	This is SetHint, a member of class TCustomTrayIcon.
	SetIcon (see page 828)	This is SetIcon, a member of class TCustomTrayIcon.
	SetIconIndex (see page 828)	This is SetIconIndex, a member of class TCustomTrayIcon.
	SetIconList (see page 829)	This is SetIconList, a member of class TCustomTrayIcon.
	SetVisible (see page 829)	This is SetVisible, a member of class TCustomTrayIcon.
	WindowProc (see page 829)	This is WindowProc, a member of class TCustomTrayIcon.

Public Methods

	Name	Description
	Refresh (see page 826)	This is the overview for the Refresh method overload.
	SetDefaultIcon (see page 828)	Sets the tray icon to the default application icon.
	ShowBalloonHint (see page 829)	Displays the balloon hint.

3.1.29.4.1 TCustomTrayIcon.DoOnAnimate Method

Pascal

```
procedure DoOnAnimate(Sender: TObject); virtual;
```

C++

```
virtual __fastcall DoOnAnimate(TObject * Sender);
```

Description

This is DoOnAnimate, a member of class TCustomTrayIcon.

3.1.29.4.2 TCustomTrayIcon.GetAnimateInterval Method

Pascal

```
function GetAnimateInterval: Cardinal;
```

C++

```
__fastcall unsigned GetAnimateInterval();
```

Description

This is GetAnimateInterval, a member of class TCustomTrayIcon.

3.1.29.4.3 TCustomTrayIcon.GetBalloonTimeout Method

Pascal

```
function GetBalloonTimeout: Integer;
```

C++

```
__fastcall int GetBalloonTimeout();
```

Description

This is GetBalloonTimeout, a member of class TCustomTrayIcon.

3.1.29.4.4 TCustomTrayIcon.Notification Method

Forwards notification messages to all owned components.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation. By default, components pass along the notification to their owned components, if any.

A component can, if needed, act on the notification that a component is being inserted or removed. For example, if a component has object fields or properties that contain references to other components, it can check the notifications of component removals and invalidate those references as needed.

Note: Notification is not called for components that are freed implicitly (because their Owner is freed).

See Also

FreeNotification

InsertComponent

RemoveComponent

Owner

3.1.29.4.5 Refresh Method

This is the overview for the Refresh method overload.

Overload List

	Name	Description
	TCustomTrayIcon.Refresh () (see page 826)	Repaints the tray icon on the screen.
	TCustomTrayIcon.Refresh (Integer) (see page 826)	Repaints the tray icon on the screen.

3.1.29.4.5.1 TCustomTrayIcon.Refresh Method ()

Repaints the tray icon on the screen.

Pascal

```
function Refresh(Message: Integer): Boolean; overload;
procedure Refresh; overload;
```

C++

```
__fastcall Boolean Refresh(int Message);
__fastcall Refresh();
```

Description

Repaints the tray icon on the screen.

3.1.29.4.6 TCustomTrayIcon.SetAnimate Method

Pascal

```
procedure SetAnimate(Value: Boolean);
```

C++

```
__fastcall SetAnimate(Boolean Value);
```

Description

This is SetAnimate, a member of class TCustomTrayIcon.

3.1.29.4.7 TCustomTrayIcon.SetAnimateInterval Method

Pascal

```
procedure SetAnimateInterval(Value: Cardinal);
```

C++

```
__fastcall SetAnimateInterval(unsigned Value);
```

Description

This is SetAnimateInterval, a member of class TCustomTrayIcon.

3.1.29.4.8 TCustomTrayIcon.SetBalloonHint Method

Pascal

```
procedure SetBalloonHint(const Value: string);
```

C++

```
__fastcall SetBalloonHint(const UnicodeString Value);
```

Description

This is SetBalloonHint, a member of class TCustomTrayIcon.

3.1.29.4.9 TCustomTrayIcon.SetBalloonTimeout Method

Pascal

```
procedure SetBalloonTimeout(Value: Integer);
```

C++

```
__fastcall SetBalloonTimeout(int Value);
```

Description

This is SetBalloonTimeout, a member of class TCustomTrayIcon.

3.1.29.4.10 TCustomTrayIcon.SetBalloonTitle Method

Pascal

```
procedure SetBalloonTitle(const Value: string);
```

C++

```
__fastcall SetBalloonTitle(const UnicodeString Value);
```

Description

This is SetBalloonTitle, a member of class TCustomTrayIcon.

3.1.29.4.11 TCustomTrayIcon.SetDefaultIcon Method

Sets the tray icon to the default application icon.

Pascal

```
procedure SetDefaultIcon;
```

C++

```
__fastcall SetDefaultIcon();
```

Description

This method sets the tray icon to the default application icon if the Icon (see page 832) property is unassigned. This method is generally not used.

3.1.29.4.12 TCustomTrayIcon.SetHint Method

Pascal

```
procedure SetHint(const Value: string);
```

C++

```
__fastcall SetHint(const UnicodeString Value);
```

Description

This is SetHint, a member of class TCustomTrayIcon.

3.1.29.4.13 TCustomTrayIcon.SetIcon Method

Pascal

```
procedure SetIcon(Value: TIcon);
```

C++

```
__fastcall SetIcon(TIcon Value);
```

Description

This is SetIcon, a member of class TCustomTrayIcon.

3.1.29.4.14 TCustomTrayIcon.SetIconIndex Method

Pascal

```
procedure SetIconIndex(Value: Integer); virtual;
```

C++

```
virtual __fastcall SetIconIndex(int Value);
```

Description

This is SetIconIndex, a member of class TCustomTrayIcon.

3.1.29.4.15 TCustomTrayIcon.SetIconList Method

Pascal

```
procedure SetIconList(Value: TImageList);
```

C++

```
__fastcall SetIconList(TImageList Value);
```

Description

This is SetIconList, a member of class TCustomTrayIcon.

3.1.29.4.16 TCustomTrayIcon.SetVisible Method

Pascal

```
procedure SetVisible(Value: Boolean); virtual;
```

C++

```
virtual __fastcall SetVisible(Boolean Value);
```

Description

This is SetVisible, a member of class TCustomTrayIcon.

3.1.29.4.17 TCustomTrayIcon.ShowBalloonHint Method

Displays the balloon hint.

Pascal

```
procedure ShowBalloonHint; virtual;
```

C++

```
virtual __fastcall ShowBalloonHint();
```

Description

Displays the balloon hint.

3.1.29.4.18 TCustomTrayIcon.WindowProc Method

Pascal

```
procedure WindowProc(var Message: TMessage); virtual;
```

C++

```
virtual __fastcall WindowProc(TMessage Message);
```

Description

This is WindowProc, a member of class TCustomTrayIcon.

3.1.29.5 TCustomTrayIcon Properties

The properties of the TCustomTrayIcon class are listed here.

Protected Properties

	Name	Description
	Data (see page 832)	This is Data, a member of class TCustomTrayIcon.

Public Properties

	Name	Description
	Animate (see page 830)	Specifies whether the icon in the system tray is static or animated.
	AnimateInterval (see page 830)	Controls the length of time between image changes for the tray icon image.
	BalloonFlags (see page 831)	Specifies an icon for the balloon hint.
	BalloonHint (see page 831)	Specifies the text within a balloon hint.
	BalloonTimeout (see page 831)	Specifies the length of time that the balloon displays.
	BalloonTitle (see page 831)	Specifies the text that appears as the balloon title.
	Hint (see page 832)	Specifies the text that appears when the user moves the mouse over the control.
	Icon (see page 832)	Specifies the default icon shown in the system tray.
	IconIndex (see page 832)	This is an index into the Icons (see page 833) image list which is the icon currently being displayed in the system tray.
	Icons (see page 833)	Specifies the list of images to be displayed for the icon in the system tray.
	PopupMenu (see page 833)	Identifies the pop-up menu associated with the tray icon.
	Visible (see page 833)	Determines whether the icon appears in the system tray.

3.1.29.5.1 TCustomTrayIcon.Animate Property

Specifies whether the icon in the system tray is static or animated.

Pascal

```
property Animate: Boolean;
```

C++

```
__property Boolean Animate;
```

Description

When set to True, the icon shown in the system tray displays, in sequence, the images in the image list specified by the Icons (see page 833) property. The images change only if the specified image list contains images. The images change on a rotating basis by the interval set by the AnimateInterval (see page 830) property. When set to False the animation stops.

3.1.29.5.2 TCustomTrayIcon.AnimateInterval Property

Controls the length of time between image changes for the tray icon image.

Pascal

```
property AnimateInterval: Cardinal;
```

C++

```
__property unsigned AnimateInterval;
```

Description

Use AnimateInterval to specify the length of time between image changes in the tray icon. The default interval is 1000 ms (1 second).

3.1.29.5.3 TCustomTrayIcon.BalloonFlags Property

Specifies an icon for the balloon hint.

Pascal

```
property BalloonFlags: TBalloonFlags;
```

C++

```
__property TBalloonFlags BalloonFlags;
```

Description

The following values specify an icon to be displayed in the balloon hint:

- bfNone
- bfInfo
- bfWarning
- bfError

3.1.29.5.4 TCustomTrayIcon.BalloonHint Property

Specifies the text within a balloon hint.

Pascal

```
property BalloonHint: string;
```

C++

```
__property UnicodeString BalloonHint;
```

Description

Use BalloonHint to specify the text string that appears when a balloon hint is shown.

3.1.29.5.5 TCustomTrayIcon.BalloonTimeout Property

Specifies the length of time that the balloon displays.

Pascal

```
property BalloonTimeout: Integer;
```

C++

```
__property int BalloonTimeout;
```

Description

Use BalloonTimeout to set the length of time that a balloon displays. By default, this value is set to 3000 ms (3 seconds).

3.1.29.5.6 TCustomTrayIcon.BalloonTitle Property

Specifies the text that appears as the balloon title.

Pascal

```
property BalloonTitle: string;
```

C++

```
__property UnicodeString BalloonTitle;
```

Description

Specifies the text that appears as the balloon title.

3.1.29.5.7 TCustomTrayIcon.Data Property

Pascal

```
property Data: TNotifyIconData;
```

C++

```
__property TNotifyIconData Data;
```

Description

This is Data, a member of class TCustomTrayIcon.

3.1.29.5.8 TCustomTrayIcon.Hint Property

Specifies the text that appears when the user moves the mouse over the control.

Pascal

```
property Hint: string;
```

C++

```
__property UnicodeString Hint;
```

Description

Specifies the text that appears when the user moves the mouse over the control.

3.1.29.5.9 TCustomTrayIcon.Icon Property

Specifies the default icon shown in the system tray.

Pascal

```
property Icon: TIcon;
```

C++

```
__property TIcon Icon;
```

Description

Use the Icon property to set the default icon to be shown in the system tray. If you do not specify a value, the application icon is used.

3.1.29.5.10 TCustomTrayIcon.IconIndex Property

This is an index into the Icons (see page 833) image list which is the icon currently being displayed in the system tray.

Pascal

```
property IconIndex: Integer;
```

C++

```
__property int IconIndex;
```

Description

This is an index into the Icons (see page 833) image list which is the icon currently being displayed in the system tray.

3.1.29.5.11 TCustomTrayIcon.Icons Property

Specifies the list of images to be displayed for the icon in the system tray.

Pascal

```
property Icons: TImageList;
```

C++

```
__property TImageList Icons;
```

Description

Use this property to specify the list of images used for the icon in the system tray. These images are displayed when the Animate (see page 830) property is set to True.

3.1.29.5.12 TCustomTrayIcon.PopupMenu Property

Identifies the pop-up menu associated with the tray icon.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Use PopupMenuOn to specify when the menu is displayed.

3.1.29.5.13 TCustomTrayIcon.Visible Property

Determines whether the icon appears in the system tray.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Determines whether the icon appears in the system tray.

3.1.29.6 TCustomTrayIcon Events

The events of the TCustomTrayIcon class are listed here.

Public Events

	Name	Description
	OnAnimate (see page 834)	Occurs each time the icon changes when the tray icon is animating.
	OnBalloonClick (see page 834)	This is OnBalloonClick, a member of class TCustomTrayIcon.

	OnClick (see page 834)	Occurs when the user clicks the tray icon.
	OnDblClick (see page 834)	Occurs when the user double clicks the tray icon.
	OnMouseDown (see page 835)	Occurs when the user presses a mouse button while the mouse pointer is over a control.
	OnMouseMove (see page 835)	Occurs when the user moves the mouse pointer while the mouse pointer is over the tray icon.
	OnMouseUp (see page 835)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

3.1.29.6.1 TCustomTrayIcon.OnAnimate Event

Occurs each time the icon changes when the tray icon is animating.

Pascal

```
property OnAnimate: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnAnimate;
```

Description

Occurs each time the icon changes when the tray icon is animating.

3.1.29.6.2 TCustomTrayIcon.OnBalloonClick Event

Pascal

```
property OnBalloonClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnBalloonClick;
```

Description

This is OnBalloonClick, a member of class TCustomTrayIcon.

3.1.29.6.3 TCustomTrayIcon.OnClick Event

Occurs when the user clicks the tray icon.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Occurs when the user clicks the tray icon.

3.1.29.6.4 TCustomTrayIcon.OnDblClick Event

Occurs when the user double clicks the tray icon.

Pascal

```
property OnDblClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDblClick;
```

Description

Occurs when the user double clicks the tray icon.

3.1.29.6.5 TCustomTrayIcon.OnMouseDown Event

Occurs when the user presses a mouse button while the mouse pointer is over a control.

Pascal

```
property OnMouseDown: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseDown;
```

Description

Occurs when the user presses a mouse button while the mouse pointer is over a control.

3.1.29.6.6 TCustomTrayIcon.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over the tray icon.

Pascal

```
property OnMouseMove: TMouseMoveEvent;
```

C++

```
__property TMouseMoveEvent OnMouseMove;
```

Description

Occurs when the user moves the mouse pointer while the mouse pointer is over the tray icon.

3.1.29.6.7 TCustomTrayIcon.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseUp;
```

Description

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

3.1.30 TEditButton Class

Button in a TButtonedEdit (see page 220).

Class Hierarchy

Pascal

```
TEditButton = class(TPersistent);
```

C++

```
class TEditButton : public TPersistent;
```

File

ExtCtrls

Description

TEditButton is a button in a TButtonedEdit (see page 220) control.

C++ Examples:

```
/*
This example shows how to use the TButtonedEdit class. This example
implements a component like "TButtonedEdit search" that's to be
found in the tool pallete window.
Entering the control will enable the right button, left button will
display a MessageDlg and the right button will clear the input text.
*/
__fastcall TForm4::TForm4(TComponent* Owner)
    : TForm(Owner)
{
    //declaring an instance
    btnEdit = new TButtonedEdit(this);

    //setting the parent so it will autodetele
    btnEdit->Parent = this;

    //positioning
    btnEdit->Left = 10;
    btnEdit->Top = 10;

    //creating a TImageList and using it for the button
    TImageList* imList = new TImageList(this);
    Graphics::TBitmap* bmap = new Graphics::TBitmap();
    bmap->LoadFromFile("..\\littleB_16.bmp");
    imList->Add(bmap,NULL);
    bmap->LoadFromFile("..\\little_logo_16.bmp");
    imList->Add(bmap,NULL);
    btnEdit->Images = imList;

    //selecting the image for the left button and enabling it
    btnEdit->LeftButton->Visible = true;
    btnEdit->LeftButton->Enabled = true;
    btnEdit->LeftButton->ImageIndex = 0;
    btnEdit->LeftButton->DisabledImageIndex = 0;
    btnEdit->LeftButton->HotImageIndex = 0;

    //selecting the image for the right button
    //this will be enabled when the content changes
    btnEdit->RightButton->Enabled = true;
    btnEdit->RightButton->ImageIndex = 1;
    btnEdit->RightButton->DisabledImageIndex = 1;
    btnEdit->RightButton->HotImageIndex = 1;

    //selecting action for the buttoned edit to take
    btnEdit->OnEnter = btnEditEnter;
    btnEdit->OnRightButtonClick = btnEditRightClick;
    btnEdit->OnLeftButtonClick = btnEditLeftClick;

    //default text in the edit
    btnEdit->Text = "Default";
```

```
    btnEdit->Constraints->MinHeight = 16;
    btnEdit->Height = 16;

    //finally displaying the button
    btnEdit->Show();

}
//---------------------------------------------------------------------------

void __fastcall TForm4::btnEditEnter(TObject* Sender){
   btnEdit->Text = "";
   btnEdit->RightButton->Visible = true;
}

void __fastcall TForm4::btnEditRightClick(TObject* Sender){
   //resetting to default state
   btnEdit->Text = "Default";
   btnEdit->RightButton->Visible = false;
}

void __fastcall TForm4::btnEditLeftClick(TObject* Sender){
   MessageDlg("Left button pressed with: " + btnEdit->Text,
             mtInformation, TMsgDlgButtons() << mbOK, 0);

}
```

Delphi Examples:

```
{
This example shows how to use the TButtonedEdit class. This example
implements a component like "TButtonedEdit search" that's to be
found in the tool pallete window.
Entering the control will enable the right button, left button will
display a MessageDlg and the right button will clear the input text.
}

TButtonedEdit (see page 220)

LeftButton (see page 685)

RightButton (see page 688)

3.1.30.1 TEditButton Members

The following tables list the members exposed by TEditButton.

Enumerations

	Name	Description
	TButtonPosition (see page 840)	TButtonPosition specifies the position of the button in a buttoned edit control.

Protected Methods

	Name	Description
	GetOwner (see page 841)	Returns the owner of an object.
	UpdateBounds (see page 842)	Updates the positon and size of the image in this TEditButton (see page 835) instance depending on themes and properties of this TEditButton (see page 835).

Protected Properties

	Name	Description
	EditControl (see page 846)	EditControl is a reference to the parent buttoned edit control that is the parent of this TEditButton (see page 835).
	Glyph (see page 849)	This is Glyph, a member of class TEditButton.
	Images (see page 856)	Retrieves the ImageList associated with the parent buttoned edit control.
	Position (see page 856)	This is Position, a member of class TEditButton.

Public Methods

	Name	Description
	Create (see page 839)	Allocates memory and constructs a safely initialized instance of a TEditButton (see page 835).
	Destroy (see page 840)	Destroys the TPersistent instance and frees its memory.

Published Properties

	Name	Description
	DisabledImageIndex (see page 842)	Determines which image is displayed when the button is diabled.
	DropDownMenu (see page 846)	Drop down menu for button.
	Enabled (see page 846)	Specifies whether the embedded button is enabled.
	HotImageIndex (see page 850)	Determines which image is displayed when the mouse is over the button.
	ImageIndex (see page 853)	Determines which image is displayed when the button in the unselected state.
	PressedImageIndex (see page 856)	Determines which image is displayed when the button is pressed.
	Visible (see page 857)	Indicates button visibility.

3.1.30.2 TEditButton.Create Constructor

Allocates memory and constructs a safely initialized instance of a TEditButton (see page 835).

Pascal

```
constructor Create(EditControl: TCustomButtonedEdit; APosition: TButtonPosition); virtual;
reintroduce;
```

C++

```
virtual __fastcall TEditButton(TCustomButtonedEdit EditControl, TButtonPosition APosition);
```

Description

Use Create to create an instance of the TEditButton (see page 835) class.

EditControl (see page 846) specifies the buttoned edit control that is to be the parent of this TEditButton (see page 835) instance.

APosition specifies whether this TEditButton (see page 835) instance is the LeftButton or the RightButton of the buttoned edit parent.

See Also

TButtonedEdit (see page 220)

LeftButton (see page 248)

RightButton (see page 261)

3.1.30.3 TEditButton.Destroy Destructor

Destroys the TPersistent instance and frees its memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TEditButton();
```

Description

Do not call Destroy directly. Call Free instead. Free checks that the object reference is not nil before calling Destroy.

See Also

System::TObject::Free

System::TObject::Destroy

3.1.30.4 TEditButton Enumerations

The enumerations of the TEditButton class are listed here.

Enumerations

	Name	Description
	TButtonPosition (see page 840)	TButtonPosition specifies the position of the button in a buttoned edit control.

3.1.30.4.1 ExtCtrls.TEditButton.TButtonPosition Enumeration

TButtonPosition specifies the position of the button in a buttoned edit control.

Pascal

```
TButtonPosition = (
  bpLeft,
  bpRight
);
```

C++

```
enum TButtonPosition {
```

```
    bpLeft,
    bpRight
};
```

File

ExtCtrls

Description

A TButtonedEdit (see page 220) has optional buttons on the left or on the right of it's edit field. These optional buttons are of type TEditButton (see page 835) and TButtonPosition is the enumeration that determines whether this TEditButton (see page 835) is on the left or the right. The following are possible values of TButtonPosition:

Value	Meaning
lpLeft	The button appears to the left of the edit field in a buttoned edit control.
lpRight	The button appears to the right of the edit field in a buttoned edit control.

3.1.30.5 TEditButton Methods

The methods of the TEditButton class are listed here.

Protected Methods

	Name	Description
	GetOwner (see page 841)	Returns the owner of an object.
	UpdateBounds (see page 842)	Updates the positon and size of the image in this TEditButton (see page 835) instance depending on themes and properties of this TEditButton (see page 835).

3.1.30.5.1 TEditButton.GetOwner Method

Returns the owner of an object.

Pascal

```
function GetOwner: TPersistent; override;
```

C++

```
virtual __fastcall TPersistent * GetOwner();
```

Description

GetOwner is used by the GetNamePath method to find the owner of a persistent object. GetNamePath and GetOwner are introduced in TPersistent so descendants such as collections can appear in the Object Inspector. As implemented in TPersistent, GetOwner returns nil (Delphi) or NULL (C++).

For TCollection, GetOwner returns the owner of the collection. For collection items, it returns the collection object into which the collection item has been inserted. For TComponent it is the value of the Owner property.

See Also

GetNamePath

TCollection

TComponent

Owner

3.1.30.5.2 TEditButton.UpdateBounds Method

Updates the positon and size of the image in this TEditButton (see page 835) instance depending on themes and properties of this TEditButton (see page 835).

Pascal

```
procedure UpdateBounds; dynamic;
```

C++

```
__fastcall UpdateBounds();
```

Description

Adjusts the position and size of the image in this buttoned edit control. This adjustment takes into account theming, and the dimensions, border style and beveling of the buttoned edit control in an effort to display as much of the image as possible. Height and width of this buttoned edit control are zeroed if the image list is not currently populated.

See Also

TButtonedEdit (see page 220)

BevelKind (see page 234)

BevelInner (see page 233)

BevelOuter (see page 234)

BevelEdges (see page 233)

BorderStyle (see page 235)

3.1.30.6 TEditButton Properties

The properties of the TEditButton class are listed here.

Protected Properties

	Name	Description
R	EditControl (see page 846)	EditControl is a reference to the parent buttoned edit control that is the parent of this TEditButton (see page 835).
R	Glyph (see page 849)	This is Glyph, a member of class TEditButton.
R	Images (see page 856)	Retrieves the ImageList associated with the parent buttoned edit control.
R	Position (see page 856)	This is Position, a member of class TEditButton.

Published Properties

	Name	Description
	DisabledImageIndex (see page 842)	Determines which image is displayed when the button is diabled.
	DropDownMenu (see page 846)	Drop down menu for button.
	Enabled (see page 846)	Specifies whether the embedded button is enabled.
	HotImageIndex (see page 850)	Determines which image is displayed when the mouse is over the button.
	ImageIndex (see page 853)	Determines which image is displayed when the button in the unselected state.
	PressedImageIndex (see page 856)	Determines which image is displayed when the button is pressed.
	Visible (see page 857)	Indicates button visibility.

3.1.30.6.1 TEditButton.DisabledImageIndex Property

Determines which image is displayed when the button is diabled.

Pascal

```
property DisabledImageIndex: TImageIndex;
```

C++

```
__property TImageIndex DisabledImageIndex;
```

Description

Set DisabledImageIndex to associate the button with one of the images in the Images (see page 856) property of the parent buttoned edit control. The selected image will be displayed when the button is in the disabled state.

C++ Examples:

```
/*
This example shows how to use the TButtonedEdit class. This example
implements a component like "TButtonedEdit search" that's to be
found in the tool pallete window.
Entering the control will enable the right button, left button will
display a MessageDlg and the right button will clear the input text.
*/
__fastcall TForm4::TForm4(TComponent* Owner)
    : TForm(Owner)
{
    //declaring an instance
    btnEdit = new TButtonedEdit(this);

    //setting the parent so it will autodetele
    btnEdit->Parent = this;

    //positioning
    btnEdit->Left = 10;
    btnEdit->Top = 10;

    //creating a TImageList and using it for the button
    TImageList* imList = new TImageList(this);
    Graphics::TBitmap* bmap = new Graphics::TBitmap();
    bmap->LoadFromFile("..\\littleB_16.bmp");
    imList->Add(bmap,NULL);
    bmap->LoadFromFile("..\\little_logo_16.bmp");
    imList->Add(bmap,NULL);
    btnEdit->Images = imList;

    //selecting the image for the left button and enabling it
    btnEdit->LeftButton->Visible = true;
    btnEdit->LeftButton->Enabled = true;
    btnEdit->LeftButton->ImageIndex = 0;
    btnEdit->LeftButton->DisabledImageIndex = 0;
    btnEdit->LeftButton->HotImageIndex = 0;

    //selecting the image for the right button
    //this will be enabled when the content changes
    btnEdit->RightButton->Enabled = true;
    btnEdit->RightButton->ImageIndex = 1;
    btnEdit->RightButton->DisabledImageIndex = 1;
    btnEdit->RightButton->HotImageIndex = 1;

    //selecting action for the buttoned edit to take
    btnEdit->OnEnter = btnEditEnter;
    btnEdit->OnRightButtonClick = btnEditRightClick;
    btnEdit->OnLeftButtonClick = btnEditLeftClick;

    //default text in the edit
    btnEdit->Text = "Default";

    btnEdit->Constraints->MinHeight = 16;
```

```
    btnEdit->Height = 16;

    //finally displaying the button
    btnEdit->Show();

}
//---------------------------------------------------------------------------

void __fastcall TForm4::btnEditEnter(TObject* Sender){
   btnEdit->Text = "";
   btnEdit->RightButton->Visible = true;
}

void __fastcall TForm4::btnEditRightClick(TObject* Sender){
   //resetting to default state
   btnEdit->Text = "Default";
   btnEdit->RightButton->Visible = false;
}

void __fastcall TForm4::btnEditLeftClick(TObject* Sender){
   MessageDlg("Left button pressed with: " + btnEdit->Text,
             mtInformation, TMsgDlgButtons() << mbOK, 0);

}
```

Delphi Examples:

```
{
This example shows how to use the TButtonedEdit class. This example
implements a component like "TButtonedEdit search" that's to be
found in the tool pallete window.

    //default text in the edit
    btnEdit.Text := 'Default';

    btnEdit.Constraints.MinHeight := 16;
    btnEdit.Height := 16;

    //finally displaying the button
    btnEdit.Show();

end;
```

See Also

TEditButton (see page 835)

Enabled (see page 846)

TButtonedEdit (see page 220)

Images (see page 244)

3.1.30.6.2 TEditButton.DropDownMenu Property

Drop down menu for button.

Pascal

```
property DropDownMenu: TPopupMenu;
```

C++

```
__property TPopupMenu DropDownMenu;
```

Description

DropDownMenu is a TPopupMenu (see page 4935) that is activated when the button is pressed.

See Also

TPopupMenu (see page 4935)

3.1.30.6.3 TEditButton.EditControl Property

EditControl is a reference to the parent buttoned edit control that is the parent of this TEditButton (see page 835).

Pascal

```
property EditControl: TCustomButtonedEdit;
```

C++

```
__property TCustomButtonedEdit EditControl;
```

Description

EditControl is a reference to the parent buttoned edit control that is the parent of this TEditButton (see page 835). This property is set when this instance of TButtonedEdit (see page 220) is created. Use edit control to access the properties of the buttoned edit control.

See Also

TEditButton (see page 835)

Create (see page 839)

TButtonedEdit (see page 220)

3.1.30.6.4 TEditButton.Enabled Property

Specifies whether the embedded button is enabled.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to enable or disable a embedded button. If Enabled is true, the button OnClick event handler is called when the user selects the item with the mouse. If Enabled is false, the embedded button appears dimmed and the user cannot select it.

However, calling the button OnClick event handler method works even when Enabled is false.

C++ Examples:

```
/*
This example shows how to use the TButtonedEdit class. This example
implements a component like "TButtonedEdit search" that's to be
found in the tool pallete window.

3.1.30.6.8 TEditButton.Images Property

Retrieves the ImageList associated with the parent buttoned edit control.

Pascal

```
property Images: TImageList;
```

C++

```
__property TImageList Images;
```

Description

Images is a read-only property that accesses the Images property of the parent buttoned edit control.

See Also

TImageList

Images (see page 682)

3.1.30.6.9 TEditButton.Position Property

Pascal

```
property Position: TButtonPosition;
```

C++

```
__property TButtonPosition Position;
```

Description

This is Position, a member of class TEditButton.

3.1.30.6.10 TEditButton.PressedImageIndex Property

Determines which image is displayed when the button is pressed.

Pascal

```
property PressedImageIndex: TImageIndex;
```

C++

```
__property TImageIndex PressedImageIndex;
```

Description

Set PressedImageIndex to associate the button with one of the images in the Images (see page 856) property of the parent buttoned edit control. The selected image will be displayed when the button is pressed.

See Also

TEditButton (see page 835)

3.1.30.6.11 TEditButton.Visible Property

Indicates button visibility.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Visible is true if the button is displayed and false otherwise.

See Also

Enabled (see page 846)

3.1.31 TFlowPanel Class

TFlowPanel implements a flow panel control in which components are placed in pre-defined locations.

Class Hierarchy

Pascal

```
TFlowPanel = class(TCustomFlowPanel);
```

C++

```
class TFlowPanel : public TCustomFlowPanel;
```

File

ExtCtrls

Description

Use TFlowPanel to put an empty flow panel on a form. The major difference between a traditional panel and a flow panel is the way in which controls are placed. With a traditional panel, you place a control (such as a button) in a specific location. You can freely move that control to any location within the panel using the mouse. In a flow panel, each control is placed in a specific location, regardless of where you place it with the mouse. The automatic location is controlled by the FlowStyle (see page 884) property. For example, using the default FlowStyle (see page 884) property of LeftRightTopBottom, the first control you add to the flow panel snaps to the top left corner. The second control that you add snaps next to the first control, and so on.

C++ Examples:

```
//
//This example demonstrates the use of Flow panel to automatically
//align a set of controls and the different methods that can be used for that.
//A Stack is used to control the order of destruction of buttons.
//
void __fastcall TForm2::btAButtonClick(TObject *Sender)
{
    TButton *thisButton;
    TButton *lastButton;
    String temp;

    /* Sender is a TButton, cast it */
    thisButton = dynamic_cast<TButton*>(Sender);

    if (m_Stack->Count() > 0)
    {
        /* If there are buttons in stack, peek it */
        lastButton = dynamic_cast<TButton*>(m_Stack->Peek());

        /* Change the captions of this button and the last one */
        temp = thisButton->Caption;
        thisButton->Caption = lastButton->Caption;
        lastButton->Caption = temp;
    }
}

void __fastcall TForm2::btAddButtonClick(TObject *Sender)
{
    /* Create a new button */
    TButton *button = new TButton(m_FlowPane);

    button->Parent = m_FlowPane;
    button->Caption = IntToStr(m_Stack->Count());
    button->OnClick = btAButtonClick;

    /* Push the button to the stack */
    m_Stack->Push(button);
}

void __fastcall TForm2::btReArrangeClick(TObject *Sender)
{
    /* Change the current flow style (rotate them) */
    TFlowStyle newFlowStyle = m_FlowPane->FlowStyle;

    if (newFlowStyle == fsBottomTopRightLeft)
        newFlowStyle = fsLeftRightTopBottom;
    else
        newFlowStyle = newFlowStyle + 1;

    m_FlowPane->FlowStyle = newFlowStyle;
}

void __fastcall TForm2::btRemoveButtonClick(TObject *Sender)
{
    TButton *button;

    if (m_Stack->Count() > 0)
    {
        /* if the stack is not empty, pop the last button */
        button = dynamic_cast<TButton*>(m_Stack->Pop());
        delete button;
    }
}

void __fastcall TForm2::FormCreate(TObject *Sender)
{
```

```
    /* Create a new TFlowPanel pane and align it to client */
    m_FlowPane = new TFlowPanel(this);
    m_FlowPane->Parent = this;
    m_FlowPane->Align = alClient;

3.1.31.1 TFlowPanel Members

The following tables list the members exposed by TFlowPanel.

Protected Methods

	Name	Description
	AdjustClientRect (see page 804)	Adjusts the ClientRect property for the idiosyncrasies of the window.
	AlignControls (see page 776)	Aligns any controls for which the control is the parent within a specified area of the control.
	CanAutoSize (see page 804)	Adjusts the way the panel responds to resize attempts.
	CreateParams (see page 805)	Initializes a window-creation parameter record passed in the Params parameter.
	Paint (see page 806)	Renders the image of the panel.
	SetParentBackground (see page 806)	This is SetParentBackground, a member of class TCustomPanel.

Public Methods

	Name	Description
	Create (see page 775)	Creates and initializes an instance of TCustomPanel.

	Create (see page 803)	Creates and initializes an instance of TCustomPanel (see page 802).
	Destroy (see page 775)	Destroys an instance of TCustomControl.
	GetChildren (see page 776)	Calls a specified method for each child of the control.
	GetControlIndex (see page 777)	This is GetControlIndex, a member of class TCustomFlowPanel.
	GetControlsAlignment (see page 805)	Returns the alignment of text in the panel.
	SetControlIndex (see page 777)	This is SetControlIndex, a member of class TCustomFlowPanel.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 903)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 904)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 905)	Occurs when an attempt is made to resize the control.
	OnClick (see page 905)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 907)	Adjust resize constraints.
	OnContextPopup (see page 907)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 908)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 908)	Occurs when another control is docked to the control.
	OnDockOver (see page 910)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 913)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 916)	Occurs when the user drags an object over a control.
	OnEndDock (see page 919)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 919)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 920)	Occurs when a control receives the input focus.
	OnExit (see page 923)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 925)	Returns the control's docking information.
	OnMouseActivate (see page 928)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 929)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 931)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 931)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 931)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 934)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnResize (see page 936)	Occurs immediately after the control is resized.
	OnStartDock (see page 937)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 937)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 938)	Occurs when the application tries to undock a control that is docked to the windowed control.

Published Properties

	Name	Description
	Align (see page 863)	Determines how the control aligns within its container (parent control).
	Alignment (see page 867)	Determines how the caption is aligned within the panel.
	Anchors (see page 867)	Specifies how the control is anchored to its parent.
	AutoSize (see page 868)	Specifies whether the control sizes itself automatically to accommodate its contents.
	AutoWrap (see page 868)	Specifies whether controls are automatically wrapped to fit on the flow panel.
	BevelEdges (see page 868)	Specifies which edges of the control are beveled.
	BevelInner (see page 869)	Determines the style of the inner bevel of a panel.
	BevelKind (see page 870)	Specifies the control's bevel style.
	BevelOuter (see page 870)	Determines the style of the outer bevel of a panel.

	BevelWidth (see page 871)	Determines the width, in pixels, of both the inner and outer bevels of a panel.
	BiDiMode (see page 872)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 873)	Determines the style of the line drawn around the perimeter of the panel control.
	BorderWidth (see page 873)	Specifies the distance, in pixels, between the outer and inner bevels.
	Caption (see page 874)	Specifies a text string that identifies the control to the user.
	Color (see page 877)	Specifies the background color of the control.
	Constraints (see page 878)	Specifies the size constraints for the control.
	Ctl3D (see page 878)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DockSite (see page 879)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 880)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 882)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 882)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 882)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 884)	Controls whether the control responds to mouse, keyboard, and timer events.
	FlowStyle (see page 884)	Specifies the starting point and direction for controls added to a flow panel.
	Font (see page 888)	Controls the attributes of text written on or in the control.
	FullRepaint (see page 889)	Determines how the panel repaints itself when it is resized.
	Locked (see page 889)	Determines whether a panel that is used as a toolbar is replaced by a toolbar supplied by an OLE server.
	Padding (see page 889)	Specifies the padding of a control.
	ParentBackground (see page 890)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 890)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 890)	Determines where a control looks for its color information.
	ParentCtl3D (see page 891)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 891)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 891)	Determines where a control looks for its font information.
	ParentShowHint (see page 892)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 893)	Identifies the pop-up menu associated with the control.
	ShowCaption (see page 898)	This is ShowCaption, a member of class TFlowPanel.
	ShowHint (see page 898)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 899)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 900)	Determines if the user can tab to a control.
	UseDockManager (see page 900)	Specifies whether the docking manager is used in drag-and-dock operations.
	VerticalAlignment (see page 901)	Sets the vertical position of the caption.
	Visible (see page 901)	Determines whether the component appears onscreen.

3.1.31.2 TFlowPanel Properties

The properties of the TFlowPanel class are listed here.

Published Properties

	Name	Description
	Align (see page 863)	Determines how the control aligns within its container (parent control).
	Alignment (see page 867)	Determines how the caption is aligned within the panel.
	Anchors (see page 867)	Specifies how the control is anchored to its parent.
	AutoSize (see page 868)	Specifies whether the control sizes itself automatically to accommodate its contents.
	AutoWrap (see page 868)	Specifies whether controls are automatically wrapped to fit on the flow panel.
	BevelEdges (see page 868)	Specifies which edges of the control are beveled.
	BevelInner (see page 869)	Determines the style of the inner bevel of a panel.

	BevelKind (see page 870)	Specifies the control's bevel style.
	BevelOuter (see page 870)	Determines the style of the outer bevel of a panel.
	BevelWidth (see page 871)	Determines the width, in pixels, of both the inner and outer bevels of a panel.
	BiDiMode (see page 872)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 873)	Determines the style of the line drawn around the perimeter of the panel control.
	BorderWidth (see page 873)	Specifies the distance, in pixels, between the outer and inner bevels.
	Caption (see page 874)	Specifies a text string that identifies the control to the user.
	Color (see page 877)	Specifies the background color of the control.
	Constraints (see page 878)	Specifies the size constraints for the control.
	Ctl3D (see page 878)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DockSite (see page 879)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 880)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 882)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 882)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 882)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 884)	Controls whether the control responds to mouse, keyboard, and timer events.
	FlowStyle (see page 884)	Specifies the starting point and direction for controls added to a flow panel.
	Font (see page 888)	Controls the attributes of text written on or in the control.
	FullRepaint (see page 889)	Determines how the panel repaints itself when it is resized.
	Locked (see page 889)	Determines whether a panel that is used as a toolbar is replaced by a toolbar supplied by an OLE server.
	Padding (see page 889)	Specifies the padding of a control.
	ParentBackground (see page 890)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 890)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 890)	Determines where a control looks for its color information.
	ParentCtl3D (see page 891)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 891)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 891)	Determines where a control looks for its font information.
	ParentShowHint (see page 892)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 893)	Identifies the pop-up menu associated with the control.
	ShowCaption (see page 898)	This is ShowCaption, a member of class TFlowPanel.
	ShowHint (see page 898)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 899)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 900)	Determines if the user can tab to a control.
	UseDockManager (see page 900)	Specifies whether the docking manager is used in drag-and-dock operations.
	VerticalAlignment (see page 901)	Sets the vertical position of the caption.
	Visible (see page 901)	Determines whether the component appears onscreen.

3.1.31.2.1 TFlowPanel.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it

continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
```

```
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
```

```
    Split.Left := Dirs.Left + Dirs.Width + 1;
    Split.Align := Dirs.Align; { give it the same alignment as the directory }
    { each pane must be at least one quarter of the form's width }
    Split.MinSize := Form1.ClientWidth div 4;
    { Finally, create the last pane – a file list box }
    Files := TFileListBox.Create(Form1);
    Files.Parent := Form1;
    Files.Align := alClient;
    Dirs.FileList := Files; { link the file list box to the directory list box }
  end;
  {
  Dynamically create a TProgressBar control and align it to
  the bottom of the form.
  }

  var

Parent

Anchors

3.1.31.2.2 TFlowPanel.Alignment Property

Determines how the caption is aligned within the panel.

Pascal

```
property Alignment: TAlignment;
```

C++

```
__property TAlignment Alignment;
```

Description

Use the Alignment property to specify if the caption of a panel appears on the left, right, or center of the panel. For example, to use a panel as a status bar that displays the TApplication. ::Hint property as the panel's Caption property, set Alignment to taLeftJustify to place the hint text on the left side of the panel.

Note: Use the VerticalAlignment property to control the vertical position of the caption.

See Also

Hint (see page 1976)

Caption

3.1.31.2.3 TFlowPanel.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the

length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Parent

Align

3.1.31.2.4 TFlowPanel.AutoSize Property

Specifies whether the control sizes itself automatically to accommodate its contents.

Pascal

```
property AutoSize;
```

C++

```
__property AutoSize;
```

Description

Use AutoSize to specify whether the control sizes itself automatically. When AutoSize is true, the control resizes automatically when its contents change.

By default, AutoSize is false.

See Also

Constraints

CanAutoSize

3.1.31.2.5 TFlowPanel.AutoWrap Property

Specifies whether controls are automatically wrapped to fit on the flow panel.

Pascal

```
property AutoWrap: Boolean;
```

C++

```
__property Boolean AutoWrap;
```

Description

If set to True, a new control is automatically placed in a location on the flow panel in which it is visible. If set to False, a new control continues in the same direction as the previous control, even if it would no longer be visible on the panel. You can increase the size of the panel to view controls that are not automatically wrapped to the next line or column.

3.1.31.2.6 TFlowPanel.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges;
```

C++

```
__property BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner

BevelOuter

BevelKind

3.1.31.2.7 TFlowPanel.BevelInner Property

Determines the style of the inner bevel of a panel.

Pascal

```
property BevelInner: TPanelBevel;
```

C++

```
__property TPanelBevel BevelInner;
```

Description

Use BevelInner to provide the panel with a three-dimensional beveled look. A panel component has two bevels, an outer bevel drawn next to the border of the control, and an inner bevel drawn inside the outer bevel, separated by the number of pixels specified in the BorderWidth property. The width of the bevels, if they are drawn, is the BevelWidth property.

C++ Examples:

```
/*
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
*/
void __fastcall TForm1::CreateStatusLineClick(TObject *Sender)
{
  Panel1->Align = alBottom;
  Panel1->BevelInner = bvLowered;
  Panel1->BevelOuter = bvRaised;
  Panel1->BorderWidth = 1;
  Panel1->BevelWidth = 1;
}
```

Delphi Examples:

```
{
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
}
procedure TForm1.CreateStatusLineClick(Sender: TObject);
begin
  with Panel1 do
  begin
    Align := alBottom;
    BevelInner := bvLowered;
```

```
    BevelOuter := bvRaised;
    BorderWidth := 1;
    BevelWidth := 1;
  end;
end;
```

BevelWidth (see page 809)

BorderWidth (see page 811)

3.1.31.2.8 TFlowPanel.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind;
```

C++

```
__property BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

3.1.31.2.9 TFlowPanel.BevelOuter Property

Determines the style of the outer bevel of a panel.

Pascal

```
property BevelOuter: TPanelBevel;
```

C++

```
__property TPanelBevel BevelOuter;
```

Description

Use BevelOuter to provide the panel with a three-dimensional beveled look. A panel component has two bevels, an outer bevel drawn next to the border of the control, and an inner bevel drawn inside the outer bevel, separated by the number of pixels specified in the BorderWidth property. The width of the outer bevel is specified in the BevelWidth property in pixels.

C++ Examples:

```
/*
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
```

```
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
*/
void __fastcall TForm1::CreateStatusLineClick(TObject *Sender)
{
  Panel1->Align = alBottom;
  Panel1->BevelInner = bvLowered;
  Panel1->BevelOuter = bvRaised;
  Panel1->BorderWidth = 1;
  Panel1->BevelWidth = 1;
}
```

Delphi Examples:

```
{
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
}
procedure TForm1.CreateStatusLineClick(Sender: TObject);
begin
  with Panel1 do
  begin
    Align := alBottom;
    BevelInner := bvLowered;
    BevelOuter := bvRaised;
    BorderWidth := 1;
    BevelWidth := 1;
  end;
end;
```

See Also

BevelInner (see page 807)

BevelWidth (see page 809)

BorderWidth (see page 811)

3.1.31.2.10 TFlowPanel.BevelWidth Property

Determines the width, in pixels, of both the inner and outer bevels of a panel.

Pascal

```
property BevelWidth: TBevelWidth;
```

C++

```
__property TBevelWidth BevelWidth;
```

Description

Use BevelWidth to specify how wide the inner or outer bevel should be. Do not confuse BevelWidth, which is the width of the bevels, with BorderWidth, which is the space between the bevels.

If both the BevelInner and BevelOuter properties are bvNone, BevelWidth has no effect. To remove both bevels, set the BevelInner and BevelOuter properties to bvNone, rather than setting the BevelWidth to 0, as this involves less overhead when painting.

C++ Examples:

```
/*
```

```
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
*/
void __fastcall TForm1::CreateStatusLineClick(TObject *Sender)
{
  Panel1->Align = alBottom;
  Panel1->BevelInner = bvLowered;
  Panel1->BevelOuter = bvRaised;
  Panel1->BorderWidth = 1;
  Panel1->BevelWidth = 1;
}
```

Delphi Examples:

```
{
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
}
procedure TForm1.CreateStatusLineClick(Sender: TObject);
begin
  with Panel1 do
  begin
    Align := alBottom;
    BevelInner := bvLowered;
    BevelOuter := bvRaised;
    BorderWidth := 1;
    BevelWidth := 1;
  end;
end;
```

See Also

BevelInner (see page 807)

BevelOuter (see page 808)

BorderWidth (see page 811)

3.1.31.2.11 TFlowPanel.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency,

ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

3.1.31.2.12 TFlowPanel.BorderStyle Property

Determines the style of the line drawn around the perimeter of the panel control.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Use BorderStyle to specify whether the panel has a single line drawn around it. These are the possible values:

Value	Meaning
bsNone	No visible border
bsSingle	Single-line border

Do not confuse the line drawn around the panel with the BorderWidth of the panel. The BorderWidth of the panel is the distance between the outer and inner bevels.

See Also

BorderWidth (see page 811)

3.1.31.2.13 TFlowPanel.BorderWidth Property

Specifies the distance, in pixels, between the outer and inner bevels.

Pascal

```
property BorderWidth: TBorderWidth;
```

C++

```
__property TBorderWidth BorderWidth;
```

Description

Use BorderWidth to specify how wide the border around the panel should be. A value of 0 (zero) means no border should appear.

The border of a panel is the area between the outer and inner bevels. It is visible only if the inner bevel is raised or lowered, but affects the inset of the caption within the panel even if BevelInner is bvNone. If the Alignment property is not taCenter, the Caption will be aligned to the inner edge of the border. This edge is BorderWidth pixels in from the outer bevel if BevelInner is bvNone. It is the inner edge of the inner bevel otherwise.

Do not confuse the border of the panel with line drawn around the panel itself. The line around the panel is specified by the BorderStyle property.

C++ Examples:

```
/*
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
*/
void __fastcall TForm1::CreateStatusLineClick(TObject *Sender)
{
  Panel1->Align = alBottom;
  Panel1->BevelInner = bvLowered;
  Panel1->BevelOuter = bvRaised;
  Panel1->BorderWidth = 1;
  Panel1->BevelWidth = 1;
}
```

Delphi Examples:

```
{
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
}
procedure TForm1.CreateStatusLineClick(Sender: TObject);
begin
  with Panel1 do
  begin
    Align := alBottom;
    BevelInner := bvLowered;
    BevelOuter := bvRaised;
    BorderWidth := 1;
    BevelWidth := 1;
  end;
end;
```

BevelOuter (see page 808)

BorderStyle (see page 810)

Caption

3.1.31.2.14 TFlowPanel.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption;
```

C++

```
__property Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of

character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long to be the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>
#include <memory>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);  // The owner (toolBar) will clean this up.
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this); // The owner (this) will clean this up.
  myToolBar->Parent = this;
//  TStringList *captions = new TStringList();
  std::auto_ptr<TStringList> captions(new TStringList());
```

```
  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions.get());
//  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long to be the caption of this label';
end;
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
        Caption := ButtonCaptions[I];
        if (ButtonCaptions[I] = '|') then
          Style := tbsSeparator
        else
          Style := tbsButton;
      end;
    end;
end;
```

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  ToolBar1 := TToolBar.Create(Self);
  ToolBar1.Parent := Self;
  AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
  ToolBar1.ShowCaptions := True;
  ToolBar1.Height := 40;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  I: Integer;
begin
  for I := ToolBar1.ButtonCount - 1 downto 0 do
    ToolBar1.Buttons[I].Free;
  ToolBar1.Free;
end;
```

3.1.31.2.15 TFlowPanel.Color Property

Specifies the background color of the control.

Pascal

```
property Color;
```

C++

```
__property Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
```

```
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

ParentColor

3.1.31.2.16 TFlowPanel.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints;
```

C++

```
__property Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

OnCanResize

3.1.31.2.17 TFlowPanel.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D;
```

C++

```
__property Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

3.1.31.2.18 TFlowPanel.DockSite Property

Specifies whether the control can be the target of drag-and-dock operations.

Pascal

```
property DockSite;
```

C++

```
__property DockSite;
```

Description

Set DockSite to true to allow other controls to be docked to this windowed control.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/
void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
      TWinControl *NewTarget, bool &Allow)
{
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if (Client->ClassNameIs("TDockableForm"))
    dynamic_cast<TDockableForm *>(Client)->DockSite = True;
  if ((DockClientCount == 2) && (NewTarget != this))        // Self?
    PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
}
procedure TConjoinDockHost.FormUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
```

```
    // Only 2 dock clients means the host must be destroyed and
    // the remaining window undocked to its old position and size.
    // Recall that OnUnDock gets called before the undocking
    // actually occurs.
    if Client is TDockableForm then
      TDockableForm(Client).DockSite := True;
    if (DockClientCount = 2) and (NewTarget <> Self) then
      PostMessage(Self.Handle, WM_CLOSE, 0, 0);
    UpdateCaption(Client);
  end;
```

3.1.31.2.19 TFlowPanel.DoubleBuffered Property

Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

Pascal

```
property DoubleBuffered;
```

C++

```
__property DoubleBuffered;
```

Description

When DoubleBuffered is false, the windowed control paints itself directly to the window. When DoubleBuffered is true, the windowed control paints itself to an in-memory bitmap that is then used to paint the window. Double buffering reduces the amount of flicker when the control repaints, but is more memory intensive.

When a windowed control is a dock site and has an associated dock manager, it must be double-buffered.

Note: Some controls, such as TRichEdit, can't paint themselves into a bitmap. For such controls, DoubleBuffered must be set to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
```

```
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code requires a list box and three labels, each with a
different font and color.  The DragMode property for each of
the labels is dmAutomatic.  The user can select a label and
drag it to a list box and drop it. When the label is dropped,
the items in the list box assume the color and font of the
dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

DragKind

DragMode

3.1.31.2.21 TFlowPanel.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind;
```

C++

```
__property DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor

DragMode

3.1.31.2.22 TFlowPanel.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode;
```

C++

```
__property DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != dynamic_cast<TObject *>(TreeView1) || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == dynamic_cast<TObject *>(TreeView1));
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property must be set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);

3.1.31.2.23 TFlowPanel.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled;
```

C++

```
__property Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

3.1.31.2.24 TFlowPanel.FlowStyle Property

Specifies the starting point and direction for controls added to a flow panel.

Pascal

```
property FlowStyle: TFlowStyle;
```

C++

```
__property TFlowStyle FlowStyle;
```

Description

Use FlowStyle to set the starting position for the first control added to a flow panel, as well as the subsequent position for additional controls.

Flow Style	Description
BottomTopLeftRight	The first control is at the bottom left corner of the panel. Subsequent controls are added from bottom to top and then from left to right.
BottomTopRightLeft	The first control is at the bottom right corner of the panel. Subsequent controls are added from bottom to top and then from right to left.
LeftRightBottomTop	The first control is at the bottom left corner of the panel. Subsequent controls are added from left to right and then from bottom to top.
LeftRightTopBottom	The first control is at the top left corner of the panel. Subsequent controls are added from left to right and then from top to bottom. This is the default setting.
RightLeftBottomTop	The first control is at the bottom right corner of the panel. Subsequent controls are added from right to left and then from bottom to top.
RightLeftTopBottom	The first control is at the top right corner of the panel. Subsequent controls are added from right to left and then from top to bottom.
TopBottomLeftRight	The first control is at the top left corner of the panel. Subsequent controls are added from top to bottom and then from left to right.
TopBottomRightLeft	The first control is at the top right corner of the panel. Subsequent controls are added from top to bottom and then from right to left.

C++ Examples:

```
//
//This example demonstrates the use of Flow panel to automatically
//align a set of controls and the different methods that can be used for that.
//A Stack is used to control the order of destruction of buttons.
//
void __fastcall TForm2::btAButtonClick(TObject *Sender)
{
    TButton *thisButton;
    TButton *lastButton;
    String temp;

    /* Sender is a TButton, cast it */
    thisButton = dynamic_cast<TButton*>(Sender);

    if (m_Stack->Count() > 0)
    {
        /* If there are buttons in stack, peek it */
        lastButton = dynamic_cast<TButton*>(m_Stack->Peek());

        /* Change the captions of this button and the last one */
        temp = thisButton->Caption;
        thisButton->Caption = lastButton->Caption;
        lastButton->Caption = temp;
    }
}

void __fastcall TForm2::btAddButtonClick(TObject *Sender)
{
    /* Create a new button */
    TButton *button = new TButton(m_FlowPane);

    button->Parent = m_FlowPane;
    button->Caption = IntToStr(m_Stack->Count());
    button->OnClick = btAButtonClick;

    /* Push the button to the stack */
    m_Stack->Push(button);
}
```

```
void __fastcall TForm2::btReArrangeClick(TObject *Sender)
{
    /* Change the current flow style (rotate them) */
    TFlowStyle newFlowStyle = m_FlowPane->FlowStyle;

    if (newFlowStyle == fsBottomTopRightLeft)
        newFlowStyle = fsLeftRightTopBottom;
    else
        newFlowStyle = newFlowStyle + 1;

    m_FlowPane->FlowStyle = newFlowStyle;
}

void __fastcall TForm2::btRemoveButtonClick(TObject *Sender)
{
    TButton *button;

    if (m_Stack->Count() > 0)
    {
        /* if the stack is not empty, pop the last button */
        button = dynamic_cast<TButton*>(m_Stack->Pop());
        delete button;
    }
}

void __fastcall TForm2::FormCreate(TObject *Sender)
{
    /* Create a new TFlowPanel pane and align it to client */
    m_FlowPane = new TFlowPanel(this);
    m_FlowPane->Parent = this;
    m_FlowPane->Align = alClient;

    /* Set the initial flowing style */
    m_FlowPane->FlowStyle = fsLeftRightTopBottom;

    /* Create the button stack */
    m_Stack = new TObjectStack();
}

void __fastcall TForm2::FormDestroy(TObject *Sender)
{
    /* Destroy the stack also */
    delete m_Stack;
}
```

Delphi Examples:

```
{
This example demonstrates the use of Flow panel to automatically
align a set of controls and the different methods that can be used for that.
A Stack is used to control the order of destruction of buttons.
}
procedure TForm2.btAButtonClick(Sender: TObject);
var
  ThisButton : TButton;
  LastButton : TButton;
  Temp       : String;
begin
  { Sender is a TButton, cast it }
  ThisButton := Sender as TButton;

  if FStack.Count > 0 then
  begin
    { If there are buttons in stack, peek it }
    LastButton := FStack.Peek() as TButton;
```

```
    { Change the captions of this button and the last one }
    Temp := ThisButton.Caption;
    ThisButton.Caption := LastButton.Caption;
    LastButton.Caption := Temp;
  end;
end;

procedure TForm2.btAddButtonClick(Sender: TObject);
var
  Button : TButton;
begin
  { Create a new button }
  Button := TButton.Create(FFlowPane);
  Button.Parent := FFlowPane;
  Button.Caption := IntToStr(FStack.Count);
  Button.OnClick := btAButtonClick;

  { Push the button to the stack }
  FStack.Push(Button);
end;

procedure TForm2.btReArrangeClick(Sender: TObject);
var
  NewFlowStyle : TFlowStyle;
begin
  { Chnage the flow order (rotate) }
  NewFlowStyle := FFlowPane.FlowStyle;

  if NewFlowStyle = fsBottomTopRightLeft then
     NewFlowStyle := fsLeftRightTopBottom
  else
    Inc(NewFlowStyle);

  FFlowPane.FlowStyle := NewFlowStyle;
end;

procedure TForm2.btRemoveButtonClick(Sender: TObject);
var
  Button : TButton;
begin
  if FStack.Count > 0 then
  begin
    { if the stack is not empty, pop the last button }
    Button := FStack.Pop() as TButton;
    Button.Free();
  end;
end;

procedure TForm2.FormCreate(Sender: TObject);
begin
  { Create a new TFlowPanel pane and align it to client }
  FFlowPane := TFlowPanel.Create(Self);
  FFlowPane.Parent := Self;
  FFlowPane.Align := alClient;

  { Set the initial flowing style }
  FFlowPane.FlowStyle := fsLeftRightTopBottom;

  { Create the button stack }
  FStack := TObjectStack.Create();
end;

procedure TForm2.FormDestroy(Sender: TObject);
begin
  { Destroy the stack also }
  FStack.Free();
```

```
end;
```

3.1.31.2.25 TFlowPanel.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font;
```

C++

```
__property Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

3.1.31.2.26 TFlowPanel.FullRepaint Property

Determines how the panel repaints itself when it is resized.

Pascal

```
property FullRepaint: Boolean;
```

C++

```
__property Boolean FullRepaint;
```

Description

FullRepaint controls how the panel responds when it is resized. When FullRepaint is true, the entire panel, including the beveled border repaints when the size changes. When FullRepaint is false, only the area inside the beveled border repaints.

See Also

Invalidate

3.1.31.2.27 TFlowPanel.Locked Property

Determines whether a panel that is used as a toolbar is replaced by a toolbar supplied by an OLE server.

Pascal

```
property Locked: Boolean;
```

C++

```
__property Boolean Locked;
```

Description

Set the Locked property to false when the panel is used as a toolbar by a TOleContainer component. Any panels aligned to a TOleContainer are assumed to be replaceable toolbars unless the Locked property is true. Prevent the panel from being replaced by an OLE server's toolbar by setting the panel's Locked property to true.

Note: An OLE application's toolbars must be in panels aligned to a side of the form (that is, their Align properties must be set to alTop, alBottom, alLeft, or alRight).

See Also

Align

TOleContainer (see page 5969)

3.1.31.2.28 TFlowPanel.Padding Property

Specifies the padding of a control.

Pascal

```
property Padding;
```

C++

```
__property Padding;
```

Description

Use Padding to specify the padding of a control. This value is an instance of the class TPadding.

See Also

TPadding

3.1.31.2.29 TFlowPanel.ParentBackground Property

Determines whether control uses parent's theme background.

Pascal

```
property ParentBackground;
```

C++

```
__property ParentBackground;
```

Description

If ParentBackground is true, the control uses the parent's theme background to draw its own background. ParentBackground has no effect unless XP themes are enabled.

3.1.31.2.30 TFlowPanel.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode;
```

C++

```
__property ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent

BiDiMode

3.1.31.2.31 TFlowPanel.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor;
```

C++

```
__property ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

ParentShowHint

3.1.31.2.32 TFlowPanel.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D;
```

C++

```
__property ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D

3.1.31.2.33 TFlowPanel.ParentDoubleBuffered Property

ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.

Pascal

```
property ParentDoubleBuffered;
```

C++

```
__property ParentDoubleBuffered;
```

Description

ParentDoubleBuffered is a boolean indicating that the DoubleBuffered property of this component is overridden by the value of the parent's DoubleBuffered property.

3.1.31.2.34 TFlowPanel.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont;
```

C++

```
__property ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

Parent

ParentColor

ParentShowHint

3.1.31.2.35 TFlowPanel.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint;
```

C++

```
__property ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

3.1.31.2.36 TFlowPanel.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu;
```

C++

```
__property PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->CutToClipboard();
    else
      MessageBeep(0);
  }
```

```
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      (dynamic_cast<TEdit *>(pComponent))->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    // The owner (PopupMenu1) will cleanup this menu item.
    TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
    int index = PopupMenu1->Items->Count;
    PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
    NewItem->Caption = "Menu Item " + IntToStr(index);
    NewItem->Tag = index;
    NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
    TNotifyEvent();
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
```

```
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        // The owner (PopupMenu1) will cleanup this menu item.
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
```

```
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

OnContextPopup

3.1.31.2.37 TFlowPanel.ShowCaption Property

Pascal

```
property ShowCaption: Boolean;
```

C++

```
__property Boolean ShowCaption;
```

Description

This is ShowCaption, a member of class TFlowPanel.

3.1.31.2.38 TFlowPanel.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint;
```

C++

```
__property ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
```

```
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

3.1.31.2.39 TFlowPanel.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder;
```

C++

```
__property TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl

TabStop

3.1.31.2.40 TFlowPanel.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop;
```

C++

```
__property TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder

3.1.31.2.41 TFlowPanel.UseDockManager Property

Specifies whether the docking manager is used in drag-and-dock operations.

Pascal

```
property UseDockManager;
```

C++

```
__property UseDockManager;
```

Description

Use UseDockManager to get or set whether a docking manager is used in drag-and-dock operations.

The docking manager handles the positioning of docked controls and any painting of docking zones around those controls. If you do not use a docking manager, docked controls are aligned to the windowed control based on the closest edge to where they are released. When you do not use a docking manager, there is no region for a user to grab to automatically undock a docked control.

DockManager

3.1.31.2.42 TFlowPanel.VerticalAlignment Property

Sets the vertical position of the caption.

Pascal

```
property VerticalAlignment: TVerticalAlignment;
```

C++

```
__property TVerticalAlignment VerticalAlignment;
```

Description

Use the VerticalAlignment property to control the position of the caption within the panel. Choose one of the following values.

Value	Description
taAlignBottom	The caption displays at the bottom of the panel.
taAlignTop	The caption displays at the top of the panel.
taVerticalCenter	The caption displays at the center of the panel.

Note: Use the Alignment property to control the horizontal position of the caption.

See Also

Caption

3.1.31.2.43 TFlowPanel.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible;
```

C++

```
__property Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}
```

```
void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;

3.1.31.3 TFlowPanel Events

The events of the TFlowPanel class are listed here.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 903)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 904)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 905)	Occurs when an attempt is made to resize the control.
	OnClick (see page 905)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 907)	Adjust resize constraints.
	OnContextPopup (see page 907)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 908)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 908)	Occurs when another control is docked to the control.
	OnDockOver (see page 910)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 913)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 916)	Occurs when the user drags an object over a control.
	OnEndDock (see page 919)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 919)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 920)	Occurs when a control receives the input focus.
	OnExit (see page 923)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 925)	Returns the control's docking information.
	OnMouseActivate (see page 928)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 929)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 931)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 931)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 931)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 934)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnResize (see page 936)	Occurs immediately after the control is resized.
	OnStartDock (see page 937)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 937)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 938)	Occurs when the application tries to undock a control that is docked to the windowed control.

3.1.31.3.1 TFlowPanel.OnAlignInsertBefore Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignInsertBefore;
```

C++

```
__property OnAlignInsertBefore;
```

Description

OnAlignInsertBefore occurs for each pair of child controls with an Align property of **alCustom**.

It can determine the order in which custom-aligned child controls are placed. OnAlignInsertBefore returns true if **C2** should be presented before **C1**, and false otherwise. It holds a TAlignInsertBeforeEvent type.

CustomAlignInsertBefore triggers the OnAlignInsertBefore event. If this event is defined, CustomAlignInsertBefore returns the value returned by OnAlignInsertBefore. Defining this event allows users to define the order of control alignment without overriding CustomAlignInsertBefore.

CustomAlignInsertBefore

Align

TAlignInsertBeforeEvent

3.1.31.3.2 TFlowPanel.OnAlignPosition Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignPosition;
```

C++

```
__property OnAlignPosition;
```

Description

OnAlignPosition occurs when child controls with an Align property of **alCustom** are aligned.

CustomAlignPosition triggers the OnAlignPosition event. If this event is defined, CustomAlignPosition uses the alignment parameters it obtains from OnAlignPosition. Defining this event allows users to set the alignment parameters without overriding CustomAlignPosition. It holds a TAlignPositionEvent type.

These are the parameters:

Parameter	Meaning
NewLeft | NewTop | NewWidth | NewHeight	Location and size of child control, as determined by container's size and the Anchors TControl_Anchors constraints for the control. OnAlignPosition can modify these values to reposition the control.
AlignRect	The client area in which the control is aligned. OnAlignPosition can modify this value.
AlignInfo	Alignment information in a TAlignInfo.
As implemented in TWinControl, OnAlignPosition does nothing.

3.1.31.3.3 TFlowPanel.OnCanResize Event

Occurs when an attempt is made to resize the control.

Pascal

```
property OnCanResize;
```

C++

```
__property OnCanResize;
```

Description

Use OnCanResize to adjust the way a control is resized. If necessary, change the new width and height of the control in the OnCanResize event handler. The OnCanResize event handler also allows applications to indicate that the entire resize should be aborted.

If there is no OnCanResize event handler, or if the OnCanResize event handler indicates that the resize attempt can proceed, the OnCanResize event is followed immediately by an OnConstrainedResize event.

OnConstrainedResize

SetBounds

OnResize

3.1.31.3.4 TFlowPanel.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick;
```

C++

```
__property OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this); // The owner will clean this up.
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this); // The owner will clean this up.
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
```

```
          Left := Random(PageControl1.ActivePage.ClientWidth - Width);
          Top := Random(PageControl1.ActivePage.ClientHeight - Height);
        end;
      end;
      PageControl1Change(Sender);
  end;
```

3.1.31.3.5 TFlowPanel.OnConstrainedResize Event

Adjust resize constraints.

Pascal

```
property OnConstrainedResize;
```

C++

```
__property OnConstrainedResize;
```

Description

Use OnConstrainedResize to adjust a control's constraints when an attempt is made to resize it. Upon entry to the OnConstrainedResize event handler, the parameters of the event handler are set to the corresponding properties of the control's Constraints object. The event handler can adjust those values before they are applied to the new height and width that is being applied to the control. (The CanAutoSize method or an OnCanResize event handler may already have adjusted this new height and width).

On exit from the OnConstrainedResize event handler, the constraints are applied to the attempted new height and width. Once the constraints are applied, the control's height and width are changed. After the control's height and width change, an OnResize event occurs to allow any final adjustments or responses.

Note: The OnConstrainedResize handler is called immediately after the OnCanResize handler.

3.1.31.3.6 TFlowPanel.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup;
```

C++

```
__property OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

3.1.31.3.7 TFlowPanel.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick;
```

C++

```
__property OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

OnClick

Responding to User Actions at Runtime

3.1.31.3.8 TFlowPanel.OnDockDrop Event

Occurs when another control is docked to the control.

Pascal

```
property OnDockDrop;
```

C++

```
__property OnDockDrop;
```

Description

Write code in the OnDockDrop event to perform actions when another control is docked on the control.

OnDockDrop can only occur if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
```

```
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;
```

DockSite

OnDockOver

3.1.31.3.9 TFlowPanel.OnDockOver Event

Occurs when another control is dragged over the control.

Pascal

```
property OnDockOver;
```

C++

```
__property OnDockOver;
```

Description

Write code in the OnDockOver event to indicate whether a dockable control that is dragged over the windowed control can be accepted as a dock client. OnDockOver occurs after the TDragDockObject has been initialized by an OnGetSiteInfo event.

OnDockOver occurs only if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
```

```
      ShowMessage(L"GetSiteInfo CanDock went bad!");
    }
  }
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;

3.1.31.3.10 TFlowPanel.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop;
```

C++

```
__property OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
*/
void __fastcall TForm1::FormDragDrop(TObject *Sender, TObject *Source, int X, int Y)

{
  reinterpret_cast<TForm1 *>(Source)->Left = X;
  reinterpret_cast<TForm1 *>(Source)->Top = Y;
}

void __fastcall TForm1::FormDragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = Source->ClassNameIs("TLabel");
}

void __fastcall TForm1::Panel1DragOver(TObject *Sender, TObject *Source, int X, int Y,
          TDragState State, bool &Accept)
{
  Accept = false;
  if ((Source->ClassNameIs("TLabel")) && (State == dsDragEnter))
    dynamic_cast<TLabel *>(Source)->EndDrag(false);
}
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
```

```
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = dynamic_cast<TListBox *>(Sender);
    DestList->Font = (dynamic_cast<TLabel *>(Source))->Font;
    DestList->Color = (dynamic_cast<TLabel *>(Source))->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

3.1.31.3.11 TFlowPanel.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver;
```

C++

```
__property OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.

3.1.31.3.13 TFlowPanel.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag;
```

C++

```
__property OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
```

```
    AnsiString S = (dynamic_cast<TLabel *>(Sender))->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;

DragKind

3.1.31.3.14 TFlowPanel.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter;
```

C++

```
__property OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter

event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

Using a Single Navigator for Multiple Datasets

3.1.31.3.15 TFlowPanel.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit;
```

C++

```
__property OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
```

```
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses three mask edit components on a form,
where the third mask edit box is set to be read only.
When the application runs, it initializes the mask edit boxes
to contain the empty string, to use the Courier font and to
use a particular mask, corresponding to IP address coding convetions.
The mask edit boxes display the IP address, the subnet mask
and the subnet address correspondingly. When the user exits the
subnet mask edit box, the subnet address is automatically calculated
using bit-wise AND operations and displayed in the third mask edit box.
An additional test is made to assure that the values in the IP address
and in the subnet mask are in the interval from 0 to 255,
as this validation test cannot be accomplished
using the edit mask property alone.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  { initialize the maskedit boxes to contain the empty string }
  MaskEdit1.Text := '';
  MaskEdit2.Text := '';
  MaskEdit3.Text := '';

  { use the Courier font in the maskedit boxes }
  MaskEdit1.Font.Name := 'Courier';
  MaskEdit2.Font.Name := 'Courier';
  MaskEdit3.Font.Name := 'Courier';

  {
  initialize the mask of each maskedit box
  according to IP address coding conventions
  }
  MaskEdit1.EditMask := '!099.099.099.099;1; ';
  MaskEdit2.EditMask := '!099.099.099.099;1; ';
  MaskEdit3.EditMask := '!099.099.099.099;1; ';

  MaskEdit2.OnExit := MaskEdit2Exit;
end;

procedure TForm1.MaskEdit2Exit(Sender: TObject);
var
  net1, net2, host1, host2,
  netmask1, netmask2, hostmask1, hostmask2,
  sub_net1, sub_net2, sub_host1, sub_host2: Integer;

  IP, mask: String;

begin
  // extract the net and host address from the IP
  IP := MaskEdit1.Text;
  net1 := StrToInt(TrimRight(Copy(IP, 0, 3)));
  net2 := StrToInt(TrimRight(Copy(IP, 5, 3)));
  host1 := StrToInt(TrimRight(Copy(IP, 9, 3)));
  host2 := StrToInt(TrimRight(Copy(IP, 13, 3)));

  // a range test that you cannot validate through edit masks
  if ((net1 < 0) Or (net1 > 255) Or
      (net2 < 0) Or (net2 > 255) Or
      (host1 < 0) Or (host1 > 255) Or
      (host2 < 0) Or (host2 > 255)) then
    raise EArgumentException.Create('Not a valid IP address.');

  // extract the net and host mask from the subnet mask
```

```
    mask := MaskEdit2.Text;
    netmask1 := StrToInt(TrimRight(Copy(mask, 0, 3)));
    netmask2 := StrToInt(TrimRight(Copy(mask, 5, 3)));
    hostmask1 := StrToInt(TrimRight(Copy(mask, 9, 3)));
    hostmask2 := StrToInt(TrimRight(Copy(mask, 13, 3)));

    // a range test that you cannot validate through edit masks
    if ((netmask1 < 0) Or (netmask1 > 255) Or
        (netmask2 < 0) Or (netmask2 > 255) Or
        (hostmask1 < 0) Or (hostmask1 > 255) Or
        (hostmask2 < 0) Or (hostmask2 > 255)) then
      raise EArgumentException.Create('Not a valid subnet mask.');

    // compute the subnet address using bit-wise AND
    sub_net1 := net1 And netmask1;
    sub_net2 := net2 And netmask2;
    sub_host1 := host1 And hostmask1;
    sub_host2 := host2 And hostmask2;

    // display the subnet address
    MaskEdit3.Text :=
      IntToStr(sub_net1) + '.' + IntToStr(sub_net2) + '.' +
      IntToStr(sub_host1) + '.' + IntToStr(sub_host2);
  end;
  {
  This example uses an edit box and a memo control on a form.
  When either the edit box or the memo is the active control,
  it is colored yellow. When the active control becomes
  inactive, the color of the control returns to the Windows
  system color for a window.  These event handlers could also
  be shared.
  }
  procedure TForm1.Edit1Enter(Sender: TObject);
  begin
    Edit1.Color := clYellow;
  end;

  procedure TForm1.Edit1Exit(Sender: TObject);
  begin
    Edit1.Color := clWindow;
  end;

  procedure TForm1.Memo1Enter(Sender: TObject);
  begin
    Memo1.Color := clYellow;
  end;

  procedure TForm1.Memo1Exit(Sender: TObject);
  begin
    Memo1.Color := clWindow;
  end;

3.1.31.3.16 TFlowPanel.OnGetSiteInfo Event

Returns the control's docking information.

Pascal

```
  property OnGetSiteInfo;
```

C++

```
__property OnGetSiteInfo;
```

Description

Write code in the OnGetSiteInfo event handler to initialize a TDragDockObject with information about where a dragged object can be docked, if at all. OnGetSiteInfo occurs before the OnDockOver event.

OnGetSiteInfo occurs only if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage(L"GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;

OnDockOver

TDragDockObject

3.1.31.3.17 TFlowPanel.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate;
```

C++

```
__property OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

MouseCapture

3.1.31.3.18 TFlowPanel.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown;
```

C++

```
__property OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
```

```
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

3.1.31.3.19 TFlowPanel.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter;
```

C++

```
__property OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

3.1.31.3.20 TFlowPanel.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave;
```

C++

```
__property OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

3.1.31.3.21 TFlowPanel.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove;
```

C++

```
__property OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

3.1.31.3.23 TFlowPanel.OnResize Event

Occurs immediately after the control is resized.

Pascal

```
property OnResize;
```

C++

```
__property OnResize;
```

Description

Use OnResize to make any final adjustments after a control is resized.

To modify the way a control responds when an attempt is made to resize it, use OnCanResize or OnConstrainedResize.

Note: Some controls call this event handler when the control is first created.

C++ Examples:

```
/*
The following code keeps the right edge on Button1 against
the right edge of Form1 when Form1 is resized.
*/
void __fastcall TForm1::FormResize(TObject *Sender)
{
  Button1->Left = Form1->ClientWidth - Button1->Width;
}
```

Delphi Examples:

```
{
The following code keeps the right edge on Button1 against
the right edge of Form1 when Form1 is resized.
}
procedure TForm1.FormResize(Sender: TObject);
begin
  Button1.Left := Form1.ClientWidth-Button1.Width;
end;
```

OnConstrainedResize

3.1.31.3.24 TFlowPanel.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock;
```

C++

```
__property OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

OnDragOver

OnDockDrop

3.1.31.3.25 TFlowPanel.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag;
```

C++

```
__property OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

OnDragDrop

3.1.31.3.26 TFlowPanel.OnUnDock Event

Occurs when the application tries to undock a control that is docked to the windowed control.

Pascal

```
property OnUnDock;
```

C++

```
__property OnUnDock;
```

Description

Write an OnUnDock event handler to adjust the windowed control when a dock client is undocked. The OnUnDock event handler can make any necessary adjustments, or it can block the undock attempt by setting the Allow parameter to false.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/

3.1.32 TGridPanel Class

TGridPanel implements a grid panel control in which each component is placed within a cell on a grid.

Class Hierarchy

Pascal

```
TGridPanel = class(TCustomGridPanel);
```

C++

```
class TGridPanel : public TCustomGridPanel;
```

File

ExtCtrls

Description

Use TGridPanel to put an empty grid panel on a form. The major difference between a traditional panel and a grid panel is the way in which controls are placed. With a traditional panel, you place a control (such as a button) in a specific location. You can freely move that control to any location within the panel using the mouse. In a grid panel, you specify the number of rows and columns on the panel, then each component is placed into the next available cell in the grid, regardless of where you place it with the mouse. If each grid contains a control and you add more controls, the location for the new controls is determined by the ExpandStyle (see page 968) property. For example, using the default ExpandStyle (see page 968) property of AddRows, a new row is added to the grid, and each cell in the row can contain a new control.

TPanel (see page 1326)

3.1.32.1 TGridPanel Members

The following tables list the members exposed by TGridPanel.

Protected Methods

	Name	Description
	AdjustClientRect (see page 804)	Adjusts the ClientRect property for the idiosyncrasies of the window.
	AlignControls (see page 784)	Aligns any controls for which the control is the parent within a specified area of the control.
	AutoAddColumn (see page 785)	This is AutoAddColumn, a member of class TCustomGridPanel.
	AutoAddRow (see page 785)	This is AutoAddRow, a member of class TCustomGridPanel.
	CanAutoSize (see page 804)	Adjusts the way the panel responds to resize attempts.
	CellIndexToCell (see page 785)	This is CellIndexToCell, a member of class TCustomGridPanel.
	CellToCellIndex (see page 785)	This is CellToCellIndex, a member of class TCustomGridPanel.
	CreateParams (see page 805)	Initializes a window-creation parameter record passed in the Params parameter.
	Loaded (see page 786)	Initializes the control after it is loaded from a stream.
	Paint (see page 787)	Renders the image of the panel.
	Paint (see page 806)	Renders the image of the panel.
	RemoveEmptyAutoAddColumns (see page 787)	This is RemoveEmptyAutoAddColumns, a member of class TCustomGridPanel.
	RemoveEmptyAutoAddRows (see page 787)	This is RemoveEmptyAutoAddRows, a member of class TCustomGridPanel.

	SetParentBackground (see page 806)	This is SetParentBackground, a member of class TCustomPanel.
	UpdateControlOriginalParentSize (see page 788)	This is UpdateControlOriginalParentSize, a member of class TCustomGridPanel.

Public Methods

	Name	Description
	Create (see page 783)	Creates and initializes an instance of TCustomPanel.
	Create (see page 803)	Creates and initializes an instance of TCustomPanel (see page 802).
	Destroy (see page 783)	Destroys an instance of TCustomControl.
	GetChildren (see page 785)	Calls a specified method for each child of the control.
	GetControlsAlignment (see page 805)	Returns the alignment of text in the panel.
	IsColumnEmpty (see page 786)	This is IsColumnEmpty, a member of class TCustomGridPanel.
	IsRowEmpty (see page 786)	This is IsRowEmpty, a member of class TCustomGridPanel.

Public Properties

	Name	Description
	CellCount (see page 788)	This is CellCount, a member of class TCustomGridPanel.
	CellRect (see page 788)	Returns the screen coordinates of a cell in the grid.
	CellSize (see page 789)	This is CellSize, a member of class TCustomGridPanel.
	ColumnSpanIndex (see page 789)	This is ColumnSpanIndex, a member of class TCustomGridPanel.
	DockManager (see page 960)	Specifies the control's docking manager interface.
	RowSpanIndex (see page 790)	This is RowSpanIndex, a member of class TCustomGridPanel.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 984)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 984)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 985)	Occurs when an attempt is made to resize the control.
	OnClick (see page 986)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 987)	Adjust resize constraints.
	OnContextPopup (see page 988)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 989)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 989)	Occurs when another control is docked to the control.
	OnDockOver (see page 991)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 993)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 996)	Occurs when the user drags an object over a control.
	OnEndDock (see page 999)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 1000)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 1001)	Occurs when a control receives the input focus.
	OnExit (see page 1003)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 1006)	Returns the control's docking information.
	OnMouseActivate (see page 1008)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 1009)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 1011)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 1011)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 1012)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 1014)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnResize (see page 1016)	Occurs immediately after the control is resized.
	OnStartDock (see page 1017)	Occurs when the user begins to drag a control with a DragKind of dkDock.

	OnStartDrag (see page 1018)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 1018)	Occurs when the application tries to undock a control that is docked to the windowed control.

Published Properties

	Name	Description
	Align (see page 945)	Determines how the control aligns within its container (parent control).
	Alignment (see page 948)	Determines how the caption is aligned within the panel.
	Anchors (see page 949)	Specifies how the control is anchored to its parent.
	BevelEdges (see page 949)	Specifies which edges of the control are beveled.
	BevelInner (see page 950)	Determines the style of the inner bevel of a panel.
	BevelKind (see page 951)	Specifies the control's bevel style.
	BevelOuter (see page 951)	Determines the style of the outer bevel of a panel.
	BevelWidth (see page 952)	Determines the width, in pixels, of both the inner and outer bevels of a panel.
	BiDiMode (see page 953)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 954)	Determines the style of the line drawn around the perimeter of the panel control.
	BorderWidth (see page 954)	Specifies the distance, in pixels, between the outer and inner bevels.
	Caption (see page 955)	Specifies a text string that identifies the control to the user.
	Color (see page 958)	Specifies the background color of the control.
	ColumnCollection (see page 959)	Sets the number and size of the columns on the grid panel.
	Constraints (see page 959)	Specifies the size constraints for the control.
	ControlCollection (see page 959)	This is ControlCollection, a member of class TGridPanel.
	Ctl3D (see page 960)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DockSite (see page 962)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 963)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 965)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 965)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 966)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 967)	Controls whether the control responds to mouse, keyboard, and timer events.
	ExpandStyle (see page 968)	Specifies whether rows or columns are added to a filled grid panel to accommodate additional controls.
	Font (see page 968)	Controls the attributes of text written on or in the control.
	FullRepaint (see page 969)	Determines how the panel repaints itself when it is resized.
	Locked (see page 969)	Determines whether a panel that is used as a toolbar is replaced by a toolbar supplied by an OLE server.
	Padding (see page 970)	Specifies the padding of a control.
	ParentBackground (see page 970)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 970)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 971)	Determines where a control looks for its color information.
	ParentCtl3D (see page 971)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 972)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 972)	Determines where a control looks for its font information.
	ParentShowHint (see page 972)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 973)	Identifies the pop-up menu associated with the control.
	RowCollection (see page 978)	Sets the number and size of the rows on the grid panel.
	ShowCaption (see page 978)	This is ShowCaption, a member of class TGridPanel.
	ShowHint (see page 978)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 980)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 980)	Determines if the user can tab to a control.
	UseDockManager (see page 981)	Specifies whether the docking manager is used in drag-and-dock operations.

	VerticalAlignment (see page 981)	Sets the vertical position of the caption.
	Visible (see page 982)	Determines whether the component appears onscreen.

3.1.32.2 TGridPanel Properties

The properties of the TGridPanel class are listed here.

Public Properties

	Name	Description
	DockManager (see page 960)	Specifies the control's docking manager interface.

Published Properties

	Name	Description
	Align (see page 945)	Determines how the control aligns within its container (parent control).
	Alignment (see page 948)	Determines how the caption is aligned within the panel.
	Anchors (see page 949)	Specifies how the control is anchored to its parent.
	BevelEdges (see page 949)	Specifies which edges of the control are beveled.
	BevelInner (see page 950)	Determines the style of the inner bevel of a panel.
	BevelKind (see page 951)	Specifies the control's bevel style.
	BevelOuter (see page 951)	Determines the style of the outer bevel of a panel.
	BevelWidth (see page 952)	Determines the width, in pixels, of both the inner and outer bevels of a panel.
	BiDiMode (see page 953)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 954)	Determines the style of the line drawn around the perimeter of the panel control.
	BorderWidth (see page 954)	Specifies the distance, in pixels, between the outer and inner bevels.
	Caption (see page 955)	Specifies a text string that identifies the control to the user.
	Color (see page 958)	Specifies the background color of the control.
	ColumnCollection (see page 959)	Sets the number and size of the columns on the grid panel.
	Constraints (see page 959)	Specifies the size constraints for the control.
	ControlCollection (see page 959)	This is ControlCollection, a member of class TGridPanel.
	Ctl3D (see page 960)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DockSite (see page 962)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 963)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DragCursor (see page 965)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 965)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 966)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 967)	Controls whether the control responds to mouse, keyboard, and timer events.
	ExpandStyle (see page 968)	Specifies whether rows or columns are added to a filled grid panel to accommodate additional controls.
	Font (see page 968)	Controls the attributes of text written on or in the control.
	FullRepaint (see page 969)	Determines how the panel repaints itself when it is resized.
	Locked (see page 969)	Determines whether a panel that is used as a toolbar is replaced by a toolbar supplied by an OLE server.
	Padding (see page 970)	Specifies the padding of a control.
	ParentBackground (see page 970)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 970)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 971)	Determines where a control looks for its color information.
	ParentCtl3D (see page 971)	Determines where a component looks to determine if it should appear three dimensional.
	ParentDoubleBuffered (see page 972)	ParentDoubleBuffered defers the DoubleBuffered property of this component to the value of the parent's DoubleBuffered property.
	ParentFont (see page 972)	Determines where a control looks for its font information.
	ParentShowHint (see page 972)	Determines where a control looks to find out if its Help Hint should be shown.

	PopupMenu (see page 973)	Identifies the pop-up menu associated with the control.
	RowCollection (see page 978)	Sets the number and size of the rows on the grid panel.
	ShowCaption (see page 978)	This is ShowCaption, a member of class TGridPanel.
	ShowHint (see page 978)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 980)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 980)	Determines if the user can tab to a control.
	UseDockManager (see page 981)	Specifies whether the docking manager is used in drag-and-dock operations.
	VerticalAlignment (see page 981)	Sets the vertical position of the caption.
	Visible (see page 982)	Determines whether the component appears onscreen.

3.1.32.2.1 TGridPanel.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align;
```

C++

```
__property Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1); // These objects will all be cleaned up by the owner
```

```
(Form1).
  TFileListBox* pflb = new TFileListBox(Form1); // The parent (Form1) will clean up these
objects.
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);  // The owner will clean this up.
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);  // The owner will clean this up.
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this); // The owner (this) will clean this up.
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this); // The owner (this) will clean this up.
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
```

```
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}

Anchors

3.1.32.2.2 TGridPanel.Alignment Property

Determines how the caption is aligned within the panel.

Pascal

```
property Alignment: TAlignment;
```

C++

```
__property TAlignment Alignment;
```

Description

Use the Alignment property to specify if the caption of a panel appears on the left, right, or center of the panel. For example, to use a panel as a status bar that displays the TApplication. ::Hint property as the panel's Caption property, set Alignment to taLeftJustify to place the hint text on the left side of the panel.

Note: Use the VerticalAlignment property to control the vertical position of the caption.

Hint (see page 1976)

Caption

3.1.32.2.3 TGridPanel.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors;
```

C++

```
__property Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

Align

3.1.32.2.4 TGridPanel.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges;
```

C++

```
__property BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner

BevelOuter

BevelKind

3.1.32.2.5 TGridPanel.BevelInner Property

Determines the style of the inner bevel of a panel.

Pascal

```
property BevelInner: TPanelBevel;
```

C++

```
__property TPanelBevel BevelInner;
```

Description

Use BevelInner to provide the panel with a three-dimensional beveled look. A panel component has two bevels, an outer bevel drawn next to the border of the control, and an inner bevel drawn inside the outer bevel, separated by the number of pixels specified in the BorderWidth property. The width of the bevels, if they are drawn, is the BevelWidth property.

C++ Examples:

```
/*
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
*/
void __fastcall TForm1::CreateStatusLineClick(TObject *Sender)
{
  Panel1->Align = alBottom;
  Panel1->BevelInner = bvLowered;
  Panel1->BevelOuter = bvRaised;
  Panel1->BorderWidth = 1;
  Panel1->BevelWidth = 1;
}
```

Delphi Examples:

```
{
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
}
procedure TForm1.CreateStatusLineClick(Sender: TObject);
begin
  with Panel1 do
  begin
    Align := alBottom;
    BevelInner := bvLowered;
    BevelOuter := bvRaised;
    BorderWidth := 1;
    BevelWidth := 1;
  end;
end;
```

See Also

BevelOuter (see page 808)

BevelWidth (see page 809)

BorderWidth (see page 811)

3.1.32.2.6 TGridPanel.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind;
```

C++

```
__property BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

3.1.32.2.7 TGridPanel.BevelOuter Property

Determines the style of the outer bevel of a panel.

Pascal

```
property BevelOuter: TPanelBevel;
```

C++

```
__property TPanelBevel BevelOuter;
```

Description

Use BevelOuter to provide the panel with a three-dimensional beveled look. A panel component has two bevels, an outer bevel drawn next to the border of the control, and an inner bevel drawn inside the outer bevel, separated by the number of pixels specified in the BorderWidth property. The width of the outer bevel is specified in the BevelWidth property in pixels.

C++ Examples:

```
/*
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
*/
void __fastcall TForm1::CreateStatusLineClick(TObject *Sender)
{
  Panel1->Align = alBottom;
  Panel1->BevelInner = bvLowered;
  Panel1->BevelOuter = bvRaised;
  Panel1->BorderWidth = 1;
  Panel1->BevelWidth = 1;
}
```

Delphi Examples:

```
{
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
}
procedure TForm1.CreateStatusLineClick(Sender: TObject);
begin
  with Panel1 do
  begin
    Align := alBottom;
    BevelInner := bvLowered;
    BevelOuter := bvRaised;
    BorderWidth := 1;
    BevelWidth := 1;
  end;
end;
```

See Also

BevelInner (see page 807)

BevelWidth (see page 809)

BorderWidth (see page 811)

3.1.32.2.8 TGridPanel.BevelWidth Property

Determines the width, in pixels, of both the inner and outer bevels of a panel.

Pascal

```
property BevelWidth: TBevelWidth;
```

C++

```
__property TBevelWidth BevelWidth;
```

Description

Use BevelWidth to specify how wide the inner or outer bevel should be. Do not confuse BevelWidth, which is the width of the bevels, with BorderWidth, which is the space between the bevels.

If both the BevelInner and BevelOuter properties are bvNone, BevelWidth has no effect. To remove both bevels, set the BevelInner and BevelOuter properties to bvNone, rather than setting the BevelWidth to 0, as this involves less overhead when painting.

C++ Examples:

```
/*
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
*/
void __fastcall TForm1::CreateStatusLineClick(TObject *Sender)
{
  Panel1->Align = alBottom;
  Panel1->BevelInner = bvLowered;
  Panel1->BevelOuter = bvRaised;
```

```
  Panel1->BorderWidth = 1;
  Panel1->BevelWidth = 1;
}
```

Delphi Examples:

```
{
This example uses a panel component and a button named
CreateStatusLine on a form. The code moves the panel to the
bottom of the form when the user clicks the button and gives
the panel the appearance of a status line by changing the
value of the BevelInner, BevelOuter, BevelWidth, and
BorderWidth properties.
}
procedure TForm1.CreateStatusLineClick(Sender: TObject);
begin
  with Panel1 do
  begin
    Align := alBottom;
    BevelInner := bvLowered;
    BevelOuter := bvRaised;
    BorderWidth := 1;
    BevelWidth := 1;
  end;
end;
```

See Also

BevelInner (see page 807)

BevelOuter (see page 808)

BorderWidth (see page 811)

3.1.32.2.9 TGridPanel.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode;
```

C++

```
__property BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

3.1.32.2.10 TGridPanel.BorderStyle Property

Determines the style of the line drawn around the perimeter of the panel control.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Use BorderStyle to specify whether the panel has a single line drawn around it. These are the possible values:

Value	Meaning
bsNone	No visible border
